MySQL 5.5 Reference Manual: Including MySQL Cluster NDB 7.2 Reference Guide

Abstract

This is the MySQL™ Reference Manual. It documents MySQL 5.5 through 5.5.40, as well as MySQL Cluster releases based on version 7.2 of NDBCLUSTER through 5.5.38-ndb-7.2.18.

MySQL 5.5 features. This manual describes features that are not included in every edition of MySQL 5.5; such features may not be included in the edition of MySQL 5.5 licensed to you. If you have any questions about the features included in your edition of MySQL 5.5, refer to your MySQL 5.5 license agreement or contact your Oracle sales representative.

For notes detailing the changes in each release, see the MySQL 5.5 Release Notes.

For legal information, see the Legal Notices.

Preface and Legal Notices ........................................................................................................ xxv
1 General Information ............................................................................................................. 1
  1.1 About This Manual ........................................................................................................ 2
  1.2 Typographical and Syntax Conventions .................................................................... 3
  1.3 Overview of the MySQL Database Management System ........................................... 5
    1.3.1 What is MySQL? .................................................................................................. 5
    1.3.2 The Main Features of MySQL ........................................................................... 6
    1.3.3 History of MySQL ............................................................................................... 9
  1.4 What Is New in MySQL 5.5 .......................................................................................... 9
    1.4.1 Scalability Improvements ................................................................................... 14
    1.4.2 InnoDB I/O Subsystem Changes ....................................................................... 15
    1.4.3 Diagnostic and Monitoring Capabilities ............................................................ 15
    1.4.4 Enhanced Solaris Support .................................................................................. 16
  1.5 MySQL Development History ....................................................................................... 17
  1.6 MySQL Information Sources ......................................................................................... 17
    1.6.1 MySQL Mailing Lists .......................................................................................... 17
    1.6.2 MySQL Community Support at the MySQL Forums ......................................... 20
    1.6.3 MySQL Community Support on Internet Relay Chat (IRC) ............................. 20
    1.6.4 MySQL Enterprise .............................................................................................. 21
  1.7 How to Report Bugs or Problems .................................................................................. 21
  1.8 MySQL Standards Compliance ...................................................................................... 25
    1.8.1 MySQL Extensions to Standard SQL .................................................................. 27
    1.8.2 MySQL Differences from Standard SQL .............................................................. 30
    1.8.3 How MySQL Deals with Constraints .................................................................. 34
  1.9 Credits ........................................................................................................................... 38
    1.9.1 Contributors to MySQL ..................................................................................... 38
    1.9.2 Documenters and translators ............................................................................. 42
    1.9.3 Packages that support MySQL .......................................................................... 44
    1.9.4 Tools that were used to create MySQL ............................................................... 44
    1.9.5 Supporters of MySQL ......................................................................................... 45
2 Installing and Upgrading MySQL ......................................................................................... 47
  2.1 General Installation Guidance ....................................................................................... 49
    2.1.1 Operating Systems Supported by MySQL Community Server ......................... 50
    2.1.2 Choosing Which MySQL Distribution to Install ................................................ 50
    2.1.3 How to Get MySQL ............................................................................................. 53
    2.1.4 Verifying Package Integrity Using MD5 Checksums or GnuPG .......................... 53
    2.1.5 Installation Layouts ............................................................................................... 63
    2.1.6 Compiler-Specific Build Characteristics ............................................................... 63
  2.2 Installing MySQL on Unix/Linux Using Generic Binaries ............................................. 63
  2.3 Installing MySQL on Microsoft Windows ........................................................................ 66
    2.3.1 MySQL Installation Layout on Microsoft Windows .............................................. 68
    2.3.2 Choosing An Installation Package ....................................................................... 68
    2.3.3 Installing MySQL on Microsoft Windows Using MySQL Installer .................. 69
    2.3.4 MySQL Notifier for Microsoft Windows ............................................................... 87
    2.3.5 Installing MySQL on Microsoft Windows Using an MSI Package .................... 98
    2.3.6 MySQL Server Instance Configuration Wizard .................................................. 105
    2.3.7 Installing MySQL on Microsoft Windows Using a noinstall Zip Archive .......... 120
    2.3.8 Troubleshooting a Microsoft Windows MySQL Server Installation ................ 128
    2.3.9 Upgrading MySQL on Windows ......................................................................... 129
    2.3.10 Windows Postinstallation Procedures ................................................................. 131
  2.4 Installing MySQL on Mac OS X ...................................................................................... 132
MySQL 5.5 Reference Manual

2.4.1 General Notes on Installing MySQL on Mac OS X .................................................. 133
2.4.2 Installing MySQL on Mac OS X Using Native Packages .................................. 134
2.4.3 Installing the MySQL Startup Item ................................................................. 137
2.4.4 Installing and Using the MySQL Preference Pane ........................................... 141
2.4.5 Using the Bundled MySQL on Mac OS X Server ............................................. 143
2.5 Installing MySQL on Linux ................................................................. 144
  2.5.1 Installing MySQL on Linux Using RPM Packages .......................................... 144
  2.5.2 Installing MySQL on Linux Using Debian Packages ................................... 149
  2.5.3 Installing MySQL on Linux Using Native Package Managers ......................... 150
2.6 Installing MySQL Using Unbreakable Linux Network (ULN) ................................. 154
2.7 Installing MySQL on Solaris and OpenSolaris ..................................................... 154
  2.7.1 Installing MySQL on Solaris Using a Solaris PKG .......................................... 155
  2.7.2 Installing MySQL on OpenSolaris Using IPS ................................................. 156
2.8 Installing MySQL on FreeBSD ................................................................................. 157
2.9 Installing MySQL from Source ............................................................................. 158
  2.9.1 MySQL Layout for Source Installation ........................................................... 160
  2.9.2 Installing MySQL Using a Standard Source Distribution ................................ 160
  2.9.3 Installing MySQL Using a Development Source Tree ................................... 164
  2.9.4 MySQL Source-Configuration Options .......................................................... 166
  2.9.5 Dealing with Problems Compiling MySQL ..................................................... 177
  2.9.6 MySQL Configuration and Third-Party Tools ................................................. 179
  2.9.7 MySQL Layout for Source Installation ........................................................... 160
  2.9.8 Installing MySQL Using a Development Source Tree ................................... 164
  2.9.9 MySQL Source-Configuration Options .......................................................... 166
  2.9.10 Dealing with Problems Compiling MySQL .................................................... 177
  2.9.11 MySQL Configuration and Third-Party Tools ................................................. 179
2.10 Postinstallation Setup and Testing ....................................................................... 179
  2.10.1 Postinstallation Procedures for Unix-like Systems ........................................ 180
  2.10.2 Securing the Initial MySQL Accounts ......................................................... 191
2.11 Upgrading or Downgrading MySQL ...................................................................... 195
  2.11.1 Upgrading MySQL ......................................................................................... 195
  2.11.2 Downgrading MySQL ..................................................................................... 207
  2.11.3 Checking Whether Tables or Indexes Must Be Rebuilt .................................. 210
  2.11.4 Rebuilding orRepairing Tables or Indexes ....................................................... 212
  2.11.5 Copying MySQL Databases to Another Machine ........................................... 213
2.12 Environment Variables ....................................................................................... 214
2.13 Perl Installation Notes ......................................................................................... 215
  2.13.1 Installing Perl on Unix ..................................................................................... 216
  2.13.2 Installing ActiveState Perl on Windows .......................................................... 217
  2.13.3 Problems Using the Perl DBI/DBD Interface .................................................. 217
3 Tutorial .................................................................................................................. 219
  3.1 Connecting to and Disconnecting from the Server ............................................... 219
  3.2 Entering Queries .................................................................................................. 220
  3.3 Creating and Using a Database ............................................................................. 224
    3.3.1 Creating and Selecting a Database ................................................................. 225
    3.3.2 Creating a Table .............................................................................................. 225
    3.3.3 Loading Data into a Table ............................................................................... 227
    3.3.4 Retrieving Information from a Table ............................................................... 228
  3.4 Getting Information About Databases and Tables ................................................ 242
  3.5 Using mysql in Batch Mode ................................................................................ 243
  3.6 Examples of Common Queries ............................................................................. 244
    3.6.1 The Maximum Value for a Column ................................................................. 245
    3.6.2 The Row Holding the Maximum of a Certain Column ................................... 245
    3.6.3 Maximum of Column per Group ................................................................... 246
    3.6.4 The Rows Holding the Group-wise Maximum of a Certain Column ............... 246
    3.6.5 Using User-Defined Variables ...................................................................... 247
    3.6.6 Using Foreign Keys .......................................................................................... 247
    3.6.7 Searching on Two Keys .................................................................................... 249
    3.6.8 Calculating Visits Per Day .............................................................................. 249
MySQL 5.5 Reference Manual

3.6.9 Using AUTO_INCREMENT ......................................................... 250
3.7 Using MySQL with Apache ....................................................... 252
4 MySQL Programs ........................................................................ 253
  4.1 Overview of MySQL Programs .................................................. 254
  4.2 Using MySQL Programs .......................................................... 258
    4.2.1 Invoking MySQL Programs ................................................ 258
    4.2.2 Connecting to the MySQL Server ........................................ 259
    4.2.3 Specifying Program Options .............................................. 263
    4.2.4 Using Options on the Command Line ................................... 264
    4.2.5 Program Option Modifiers ................................................ 265
    4.2.6 Using Option Files .......................................................... 266
    4.2.7 Command-Line Options that Affect Option-File Handling ....... 270
    4.2.8 Using Options to Set Program Variables .............................. 271
    4.2.9 Option Defaults, Options Expecting Values, and the = Sign ...... 272
    4.2.10 Setting Environment Variables ......................................... 276
  4.3 MySQL Server and Server-Startup Programs .............................. 277
    4.3.1 mysqld — The MySQL Server ............................................ 277
    4.3.2 mysqld_safe — MySQL Server Startup Script ...................... 277
    4.3.3 mysql.server — MySQL Server Startup Script .................... 282
    4.3.4 mysqld_multi — Manage Multiple MySQL Servers ............... 283
  4.4 MySQL Installation-Related Programs .................................... 288
    4.4.1 comp_err — Compile MySQL Error Message File .................. 288
    4.4.2 mysqlbug — Generate Bug Report ...................................... 289
    4.4.3 mysql_install_db — Initialize MySQL Data Directory .......... 289
    4.4.4 mysql_plugin — Configure MySQL Server Plugins ............... 291
    4.4.5 mysql_secure_installation — Improve MySQL Installation Security ... 293
    4.4.6 mysql_tzinfo_to_sql — Load the Time Zone Tables .............. 294
    4.4.7 mysql_upgrade — Check and Upgrade MySQL Tables .......... 295
  4.5 MySQL Client Programs ....................................................... 299
    4.5.1 mysql — The MySQL Command-Line Tool ............................. 299
    4.5.2 mysqladmin — Client for Administering a MySQL Server ....... 322
    4.5.3 mysqlcheck — A Table Maintenance Program ....................... 330
    4.5.4 mysqldump — A Database Backup Program ......................... 337
    4.5.5 mysqlimport — A Data Import Program ............................... 356
    4.5.6 mysqlshow — Display Database, Table, and Column Information ... 362
    4.5.7 mysqlslap — Load Emulation Client .................................... 366
  4.6 MySQL Administrative and Utility Programs ............................ 375
    4.6.1 innochecksum — Offline InnoDB File Checksum Utility .......... 375
    4.6.2 myisam_ftdump — Display Full-Text Index information ............ 375
    4.6.3 myisamchk — MyISAM Table-Maintenance Utility .................... 377
    4.6.4 myisamlog — Display MyISAM Log File Contents .................... 394
    4.6.5 myisampack — Generate Compressed, Read-Only MyISAM Tables ... 395
    4.6.6 myisamkeys — Client for Checking Access Privileges ............... 401
    4.6.7 mysqlbinlog — Utility for Processing Binary Log Files .......... 404
    4.6.8 mysqldumpslow — Summarize Slow Query Log Files ............... 420
    4.6.9 mysqlhotcopy — A Database Backup Program ......................... 422
    4.6.10 mysql_convert_table_format — Convert Tables to Use a Given Storage Engine .......................................................... 425
    4.6.11 mysql_find_rows — Extract SQL Statements from Files ............ 426
    4.6.12 mysql_fix_extensions — Normalize Table File Name Extensions .......... 427
    4.6.13 mysql_setpermission — Interactively Set Permissions in Grant Tables ... 427
    4.6.14 mysql_waitpid — Kill Process and Wait for Its Termination .... 428
    4.6.15 mysql_zap — Kill Processes That Match a Pattern ................ 428
  4.7 MySQL Program Development Utilities ................................... 429
12.16 Functions and Modifiers for Use with GROUP BY Clauses .............................................. 1288
  12.16.1 GROUP BY (Aggregate) Functions .................................................................................. 1288
  12.16.2 GROUP BY Modifiers ....................................................................................................... 1292
  12.16.3 MySQL Extensions to GROUP BY ................................................................................... 1295
12.17 Spatial Analysis Functions ..................................................................................................... 1296
  12.17.1 Spatial Function Reference ............................................................................................... 1297
  12.17.2 Functions That Create Geometry Values from WKT Values ....................................... 1299
  12.17.3 Functions That Create Geometry Values from WKB Values ....................................... 1299
  12.17.4 MySQL-Specific Functions That Create Geometry Values .......................................... 1300
  12.17.5 Geometry Format Conversion Functions ........................................................................ 1301
  12.17.6 Geometry Property Functions ........................................................................................ 1301
  12.17.7 Spatial Operator Functions .............................................................................................. 1308
  12.17.8 Functions That Test Spatial Relations Between Geometry Objects .............................. 1308
12.18 Precision Math ......................................................................................................................... 1311
  12.18.1 Types of Numeric Values ................................................................................................. 1311
  12.18.2 DECIMAL Data Type Characteristics ............................................................................. 1312
  12.18.3 Expression Handling ...................................................................................................... 1313
  12.18.4 Rounding Behavior ........................................................................................................ 1314
  12.18.5 Precision Math Examples ............................................................................................... 1315
13 SQL Statement Syntax ................................................................................................................ 1321
  13.1 Data Definition Statements ................................................................................................... 1322
    13.1.1 ALTER DATABASE Syntax ............................................................................................... 1322
    13.1.2 ALTER EVENT Syntax .................................................................................................. 1323
    13.1.3 ALTER LOGFILE GROUP Syntax .................................................................................. 1325
    13.1.4 ALTER FUNCTION Syntax ............................................................................................. 1326
    13.1.5 ALTER PROCEDURE Syntax .......................................................................................... 1327
    13.1.6 ALTER SERVER Syntax ................................................................................................. 1327
    13.1.7 ALTER TABLE Syntax .................................................................................................... 1327
    13.1.8 ALTER TABLESPACE Syntax ........................................................................................ 1348
    13.1.9 ALTER VIEW Syntax ...................................................................................................... 1349
    13.1.10 CREATE DATABASE Syntax ......................................................................................... 1349
    13.1.11 CREATE EVENT Syntax ............................................................................................... 1350
    13.1.12 CREATE FUNCTION Syntax .......................................................................................... 1355
    13.1.13 CREATE INDEX Syntax ................................................................................................. 1355
    13.1.14 CREATE LOGFILE GROUP Syntax ............................................................................. 1358
    13.1.15 CREATE PROCEDURE and CREATE FUNCTION Syntax ............................................. 1360
    13.1.16 CREATE SERVER Syntax .............................................................................................. 1365
    13.1.17 CREATE TABLE Syntax ................................................................................................ 1366
    13.1.18 CREATE TABLESPACE Syntax ...................................................................................... 1396
    13.1.19 CREATE TRIGGER Syntax ............................................................................................ 1398
    13.1.20 CREATE VIEW Syntax .................................................................................................. 1400
    13.1.21 DROP DATABASE Syntax .............................................................................................. 1404
    13.1.22 DROP EVENT Syntax .................................................................................................. 1405

    13.1.33 TRUNCATE TABLE Syntax ............................................................................................ 1409
14.12 InnoDB Row Storage and Row Formats .................................................. 1703
14.12.1 Overview of InnoDB Row Storage .................................................. 1704
14.12.2 Specifying the Row Format for a Table ........................................ 1704
14.12.3 DYNAMIC and COMPRESSED Row Formats .................................. 1704
14.12.4 COMPACT and REDUNDANT Row Formats .................................. 1705
14.13 InnoDB Disk I/O and File Space Management .................................. 1705
  14.13.1 InnoDB Disk I/O ........................................................................ 1706
  14.13.2 File Space Management .............................................................. 1706
  14.13.3 InnoDB Checkpoints ................................................................ 1707
  14.13.4 Defragmenting a Table ............................................................... 1708
  14.13.5 Reclaiming Disk Space with TRUNCATE TABLE .................... 1708
14.14 InnoDB Fast Index Creation ............................................................... 1709
  14.14.1 Overview of Fast Index Creation ............................................. 1709
  14.14.2 Examples of Fast Index Creation ............................................. 1709
  14.14.3 Implementation Details of Fast Index Creation ....................... 1710
  14.14.4 Concurrency Considerations for Fast Index Creation .......... 1710
  14.14.6 Limitations of Fast Index Creation ....................................... 1711
14.15 InnoDB Startup Options and System Variables .................................. 1712
  14.15.1 Changes to InnoDB Startup Options and System Variables .... 1749
14.16 InnoDB Performance ......................................................................... 1751
  14.16.1 Overview of InnoDB Performance ........................................... 1751
  14.16.2 InnoDB Buffer Pool Configuration .......................................... 1752
  14.16.3 InnoDB Mutex and Read/Write Lock Implementation ................ 1755
  14.16.4 Configuring the Memory Allocator for InnoDB ....................... 1756
  14.16.5 Configuring InnoDB Change Buffering ..................................... 1757
  14.16.6 Configuring Thread Concurrency for InnoDB ......................... 1758
  14.16.7 Configuring the Number of Background InnoDB I/O Threads .... 1759
  14.16.8 Group Commit ...................................................................... 1760
  14.16.9 Configuring the InnoDB Master Thread I/O Rate .................... 1760
  14.16.10 Using the PAUSE Instruction in InnoDB Spin Loops ............ 1761
  14.16.11 Configuring Spin Lock Polling ............................................. 1761
  14.16.12 InnoDB Integration with MySQL Performance Schema ........ 1761
  14.16.13 Better Scalability with Multiple Rollback Segments ............ 1762
  14.16.14 Configuring InnoDB Purge Scheduling ................................ 1763
  14.16.15 Configuring Optimizer Statistics Parameters ...................... 1763
  14.16.16 Estimating ANALYZE TABLE Complexity for InnoDB Tables .... 1764
14.17 InnoDB INFORMATION_SCHEMA Tables ............................................. 1764
  14.17.1 Information Schema Tables about Compression ..................... 1764
  14.17.2 Information Schema Tables about Transactions .................. 1766
  14.17.3 Special Locking Considerations for InnoDB INFORMATION_SCHEMA Tables .... 1771
14.18 InnoDB Monitors ............................................................................. 1772
  14.18.1 InnoDB Monitor Types ......................................................... 1772
  14.18.2 Enabling InnoDB Monitors .................................................... 1773
  14.18.3 InnoDB Standard Monitor and Lock Monitor Output ............ 1774
  14.18.4 InnoDB Tablespace Monitor Output ...................................... 1779
  14.18.5 InnoDB Table Monitor Output ............................................. 1781
14.19 InnoDB Backup and Recovery ........................................................... 1783
  14.19.1 The InnoDB Recovery Process ............................................. 1785
14.20 InnoDB and MySQL Replication ........................................................ 1786
14.21 InnoDB Troubleshooting ................................................................ 1788
  14.21.1 Troubleshooting InnoDB I/O Problems ................................. 1788
  14.21.2 Starting InnoDB on a Corrupted Database .......................... 1789
  14.21.3 Troubleshooting InnoDB Data Dictionary Operations .......... 1790
18.5.5 Management of MySQL Cluster

18.5.1 Summary of MySQL Cluster Start Phases
18.5.2 Commands in the MySQL Cluster Management Client
18.5.3 Online Backup of MySQL Cluster
18.5.4 MySQL Server Usage for MySQL Cluster
18.5.5 Performing a Rolling Restart of a MySQL Cluster
18.5.6 Event Reports Generated in MySQL Cluster
18.5.7 MySQL Cluster Log Messages
18.5.8 MySQL Cluster Single User Mode
18.5.9 Quick Reference: MySQL Cluster SQL Statements
18.5.10 The ndbinfo MySQL Cluster Information Database
18.5.11 MySQL Cluster Security Issues
18.5.12 MySQL Cluster Disk Data Tables
18.5.13 Adding MySQL Cluster Data Nodes Online
18.5.14 Distributed MySQL Privileges for MySQL Cluster
18.5.15 NDB API Statistics Counters and Variables

18.6 MySQL Cluster Replication

18.6.1 MySQL Cluster Replication: Abbreviations and Symbols
18.6.2 General Requirements for MySQL Cluster Replication
18.6.3 Known Issues in MySQL Cluster Replication
18.6.4 MySQL Cluster Replication Schema and Tables
18.6.5 Preparing the MySQL Cluster for Replication
18.6.6 Starting MySQL Cluster Replication (Single Replication Channel)
18.6.7 Using Two Replication Channels for MySQL Cluster Replication
18.6.8 Implementing Failover with MySQL Cluster Replication
18.6.9 MySQL Cluster Backups With MySQL Cluster Replication
18.6.10 MySQL Cluster Replication: Multi-Master and Circular Replication
18.6.11 MySQL Cluster Replication Conflict Resolution

18.7 MySQL Cluster Release Notes

19 Partitioning

19.1 Overview of Partitioning in MySQL
19.2 Partitioning Types
20 Stored Programs and Views

20.1 Defining Stored Programs .................................................. 2608

20.2 Using Stored Routines (Procedures and Functions) ..................... 2609
  20.2.1 Stored Routine Syntax ................................................. 2610
  20.2.2 Stored Routines and MySQL Privileges .............................. 2610
  20.2.3 Stored Routine Metadata ............................................ 2611
  20.2.4 Stored Procedures, Functions, Triggers, and LAST_INSERT_ID () .. 2611

20.3 Using Triggers .............................................................. 2611
  20.3.1 Trigger Syntax and Examples ....................................... 2612
  20.3.2 Trigger Metadata ..................................................... 2616

20.4 Using the Event Scheduler ................................................ 2616
  20.4.1 Event Scheduler Overview .......................................... 2616
  20.4.2 Event Scheduler Configuration .................................... 2617
  20.4.3 Event Syntax .......................................................... 2619
  20.4.4 Event Metadata ...................................................... 2620
  20.4.5 Event Scheduler Status ............................................. 2621
  20.4.6 The Event Scheduler and MySQL Privileges ....................... 2621

20.5 Using Views ............................................................... 2624
  20.5.1 View Syntax .......................................................... 2624
  20.5.2 View Processing Algorithms ....................................... 2625
  20.5.3 Updatable and Insertable Views .................................... 2626
  20.5.4 View Metadata ........................................................ 2628

20.6 Access Control for Stored Programs and Views .......................... 2629

20.7 Binary Logging of Stored Programs ..................................... 2630

21 INFORMATION_SCHEMA Tables .............................................. 2637

21.1 The INFORMATION_SCHEMA CHARACTER_SETS Table .................... 2640

21.2 The INFORMATION_SCHEMA COLLATIONS Table .......................... 2641

21.3 The INFORMATION_SCHEMA COLLATION_CHARACTER_SET_APPLICABILITY Table .................. 2641

21.4 The INFORMATION_SCHEMA COLUMNS Table ............................. 2641

21.5 The INFORMATION_SCHEMA COLUMN_PRIVILEGES Table .............. 2642

21.6 The INFORMATION_SCHEMA ENGINES Table ............................. 2643

21.7 The INFORMATION_SCHEMA EVENTS Table ................................ 2644

21.8 The INFORMATION_SCHEMA GLOBAL_STATUS and SESSION_STATUS Tables .................. 2647

21.9 The INFORMATION_SCHEMA GLOBAL_VARIABLES and SESSION_VARIABLES Tables .................. 2647

21.10 The INFORMATION_SCHEMA KEY_COLUMN_USAGE Table .................. 2648

21.11 The INFORMATION_SCHEMA PARAMETERS Table .......................... 2649
22 MySQL Performance Schema .................................................. 2690
  22.1 Performance Schema Quick Start ........................................ 2690
  22.2 Performance Schema Configuration ...................................... 2696
    22.2.1 Performance Schema Build Configuration .......................... 2696
    22.2.2 Performance Schema Startup Configuration ......................... 2697
    22.2.3 Performance Schema Runtime Configuration ......................... 2698
  22.3 Performance Schema Queries ............................................. 2705
  22.4 Performance Schema Instrument Naming Conventions ................... 2706
  22.5 Performance Schema Status Monitoring .................................. 2707
  22.6 Performance Schema General Table Characteristics .................... 2710
  22.7 Performance Schema Table Descriptions ................................ 2711
    22.7.1 Performance Schema Table Index .................................... 2711
    22.7.2 Performance Schema Setup Tables ................................... 2712
    22.7.3 Performance Schema Instance Tables ................................ 2714
    22.7.4 Performance Schema Wait Event Tables .............................. 2717
    22.7.5 Performance Schema Summary Tables ................................ 2720
    22.7.6 Performance Schema Miscellaneous Tables ......................... 2723
  22.8 Performance Schema Option and Variable Reference ..................... 2725
  22.9 Performance Schema System Variables ................................... 2726
  22.10 Performance Schema Status Variables ................................... 2732

21 INNODB
  21.1 INFORMATION_SCHEMA PARTITIONS Table ................................ 2650
  21.2 INFORMATION_SCHEMA PLUGINS Table .................................... 2653
  21.3 INFORMATION_SCHEMA PROCESSLIST Table ................................ 2654
  21.4 INFORMATION_SCHEMA PROFILING Table .................................. 2655
  21.5 INFORMATION_SCHEMA REFERENTIAL_CONSTRAINTS Table .................. 2656
  21.6 INFORMATION_SCHEMA ROUTINES Table ................................... 2656
  21.7 INFORMATION_SCHEMA SCHEMATA Table ................................... 2658
  21.8 INFORMATION_SCHEMA_SCHEMA_PRIVILEGES Table .......................... 2658
  21.9 INFORMATION_SCHEMA STATISTICS Table .................................. 2659
  21.10 INFORMATION_SCHEMA TABLES Table ..................................... 2660
  21.11 INFORMATION_SCHEMA TABLESPACES Table ................................ 2661
  21.12 INFORMATION_SCHEMA TABLE_CONSTRAINTS Table ........................ 2661
  21.13 INFORMATION_SCHEMA TABLE_PRIVILEGES Table .......................... 2662

Preface and Legal Notices

This is the Reference Manual for the MySQL Database System, version 5.5, through release 5.5.40. Differences between minor versions of MySQL 5.5 are noted in the present text with reference to release numbers (5.5.x). For license information, see the Legal Notices. This product may contain third-party code. For license information on third-party code, see Appendix E, Licenses for Third-Party Components.

This manual is not intended for use with older versions of the MySQL software due to the many functional and other differences between MySQL 5.5 and previous versions. If you are using an earlier release of the MySQL software, please refer to the appropriate manual. For example, MySQL 5.1 Reference Manual covers the 5.1 series of MySQL software releases.

If you are using MySQL 5.6, please refer to the MySQL 5.6 Reference Manual.

This software and related documentation are provided under a license agreement containing restrictions on use and disclosure and are protected by intellectual property laws. Except as expressly permitted in your license agreement or allowed by law, you may not use, copy, reproduce, translate, broadcast, modify, license, transmit, distribute, exhibit, perform, publish, or display any part, in any form, or by any means. Reverse engineering, disassembly, or decompilation of this software, unless required by law for interoperability, is prohibited.

The information contained herein is subject to change without notice and is not warranted to be error-free. If you find any errors, please report them to us in writing.

If this software or related documentation is delivered to the U.S. Government or anyone licensing it on behalf of the U.S. Government, the following notice is applicable:

U.S. GOVERNMENT RIGHTS Programs, software, databases, and related documentation and technical data delivered to U.S. Government customers are "commercial computer software" or "commercial technical data" pursuant to the applicable Federal Acquisition Regulation and agency-specific supplemental regulations. As such, the use, duplication, disclosure, modification, and adaptation shall be subject to the restrictions and license terms set forth in the applicable Government contract, and, to the extent applicable by the terms of the Government contract, the additional rights set forth in FAR 52.227-19, Commercial Computer Software License (December 2007). Oracle USA, Inc., 500 Oracle Parkway, Redwood City, CA 94065.

This software is developed for general use in a variety of information management applications. It is not developed or intended for use in any inherently dangerous applications, including applications which may create a risk of personal injury. If you use this software in dangerous applications, then you shall be responsible to take all appropriate fail-safe, backup, redundancy, and other measures to ensure the safe use of this software. Oracle Corporation and its affiliates disclaim any liability for any damages caused by use of this software in dangerous applications.

Oracle is a registered trademark of Oracle Corporation and/or its affiliates. MySQL is a trademark of Oracle Corporation and/or its affiliates, and shall not be used without Oracle's express written authorization. Other names may be trademarks of their respective owners.

This software and documentation may provide access to or information on content, products, and services from third parties. Oracle Corporation and its affiliates are not responsible for and expressly disclaim all warranties of any kind with respect to third-party content, products, and services. Oracle Corporation and
its affiliates will not be responsible for any loss, costs, or damages incurred due to your access to or use of third-party content, products, or services.

This document in any form, software or printed matter, contains proprietary information that is the exclusive property of Oracle. Your access to and use of this material is subject to the terms and conditions of your Oracle Software License and Service Agreement, which has been executed and with which you agree to comply. This document and information contained herein may not be disclosed, copied, reproduced, or distributed to anyone outside Oracle without prior written consent of Oracle or as specifically provided below. This document is not part of your license agreement nor can it be incorporated into any contractual agreement with Oracle or its subsidiaries or affiliates.

This documentation is NOT distributed under a GPL license. Use of this documentation is subject to the following terms:

You may create a printed copy of this documentation solely for your own personal use. Conversion to other formats is allowed as long as the actual content is not altered or edited in any way. You shall not publish or distribute this documentation in any form or on any media, except if you distribute the documentation in a manner similar to how Oracle disseminates it (that is, electronically for download on a Web site with the software) or on a CD-ROM or similar medium, provided however that the documentation is disseminated together with the software on the same medium. Any other use, such as any dissemination of printed copies or use of this documentation, in whole or in part, in another publication, requires the prior written consent from an authorized representative of Oracle. Oracle and/or its affiliates reserve any and all rights to this documentation not expressly granted above.

For more information on the terms of this license, or for details on how the MySQL documentation is built and produced, please visit MySQL Contact & Questions.

For additional licensing information, including licenses for third-party libraries used by MySQL products, see Preface and Legal Notices.

For help with using MySQL, please visit either the MySQL Forums or MySQL Mailing Lists where you can discuss your issues with other MySQL users.

For additional documentation on MySQL products, including translations of the documentation into other languages, and downloadable versions in variety of formats, including HTML and PDF formats, see the MySQL Documentation Library.

  1.6.4 MySQL Enterprise .......................................................... 21
1.7 How to Report Bugs or Problems ............................................. 21
1.8 MySQL Standards Compliance ............................................... 25
  1.8.1 MySQL Extensions to Standard SQL ................................... 27
  1.8.2 MySQL Differences from Standard SQL ............................... 30
  1.8.3 How MySQL Deals with Constraints ................................... 34
1.9 Credits ................................................................................. 38
  1.9.1 Contributors to MySQL ..................................................... 38
  1.9.2 Documenters and translators ............................................. 42
  1.9.3 Packages that support MySQL .......................................... 44
  1.9.4 Tools that were used to create MySQL ................................. 44
  1.9.5 Supporters of MySQL ....................................................... 45

The MySQL™ software delivers a very fast, multi-threaded, multi-user, and robust SQL (Structured Query Language) database server. MySQL Server is intended for mission-critical, heavy-load production systems as well as for embedding into mass-deployed software. Oracle is a registered trademark of Oracle Corporation and/or its affiliates. MySQL is a trademark of Oracle Corporation and/or its affiliates, and shall not be used by Customer without Oracle’s express written authorization. Other names may be trademarks of their respective owners.

The MySQL software is Dual Licensed. Users can choose to use the MySQL software as an Open Source product under the terms of the GNU General Public License (http://www.fsf.org/licenses/) or can purchase a standard commercial license from Oracle. See http://www.mysql.com/company/legal/licensing/ for more information on our licensing policies.

The following list describes some sections of particular interest in this manual:

• For a discussion of MySQL Database Server capabilities, see Section 1.3.2, “The Main Features of MySQL”.

• For an overview of new MySQL features, see Section 1.4, “What Is New in MySQL 5.5”. For information about the changes in each version, see the Release Notes.
1.1 About This Manual

This is the Reference Manual for the MySQL Database System, version 5.5, through release 5.5.40. Differences between minor versions of MySQL 5.5 are noted in the present text with reference to release numbers (5.5.x). For license information, see the Legal Notices. This product may contain third-party code. For license information on third-party code, see Appendix E, Licenses for Third-Party Components.

This manual is not intended for use with older versions of the MySQL software due to the many functional and other differences between MySQL 5.5 and previous versions. If you are using an earlier release of the MySQL software, please refer to the appropriate manual. For example, MySQL 5.1 Reference Manual covers the 5.1 series of MySQL software releases.

If you are using MySQL 5.6, please refer to the MySQL 5.6 Reference Manual.

Because this manual serves as a reference, it does not provide general instruction on SQL or relational database concepts. It also does not teach you how to use your operating system or command-line interpreter.

The MySQL Database Software is under constant development, and the Reference Manual is updated frequently as well. The most recent version of the manual is available online in searchable form at http://dev.mysql.com/doc/. Other formats also are available there, including HTML, PDF, and EPUB versions.

The Reference Manual source files are written in DocBook XML format. The HTML version and other formats are produced automatically, primarily using the DocBook XSL stylesheets. For information about DocBook, see http://docbook.org/

If you have questions about using MySQL, you can ask them using our mailing lists or forums. See Section 1.6.1, “MySQL Mailing Lists”, and Section 1.6.2, “MySQL Community Support at the MySQL
Forums”. If you have suggestions concerning additions or corrections to the manual itself, please send them to the http://www.mysql.com/company/contact/.

This manual was originally written by David Axmark and Michael “Monty” Widenius. It is maintained by the MySQL Documentation Team, consisting of Paul DuBois, Stefan Hinz, Philip Olson, Daniel Price, Daniel So, Edward Gilmore, and Jon Stephens.

1.2 Typographical and Syntax Conventions

This manual uses certain typographical conventions:

- **Text in this style** is used for SQL statements; database, table, and column names; program listings and source code; and environment variables. Example: “To reload the grant tables, use the `FLUSH PRIVILEGES` statement.”

- **Text in this style** indicates input that you type in examples.

- **Text in this style** indicates the names of executable programs and scripts, examples being `mysql` (the MySQL command-line client program) and `mysqld` (the MySQL server executable).

- **Text in this style** is used for variable input for which you should substitute a value of your own choosing.

- **Text in this style** is used for emphasis.

- **Text in this style** is used in table headings and to convey especially strong emphasis.

- **Text in this style** is used to indicate a program option that affects how the program is executed, or that supplies information that is needed for the program to function in a certain way. Example: “The `--host` option (short form `-h`) tells the `mysql` client program the hostname or IP address of the MySQL server that it should connect to”.

- File names and directory names are written like this: “The global `my.cnf` file is located in the `/etc` directory.”

- Character sequences are written like this: “To specify a wildcard, use the ‘%’ character.”

When commands are shown that are meant to be executed from within a particular program, the prompt shown preceding the command indicates which command to use. For example, `shell>` indicates a command that you execute from your login shell, `root-shell>` is similar but should be executed as `root`, and `mysql>` indicates a statement that you execute from the `mysql` client program:

```
shell> type a shell command here
root-shell> type a shell command as root here
mysql> type a mysql statement here
```

In some areas different systems may be distinguished from each other to show that commands should be executed in two different environments. For example, while working with replication the commands might be prefixed with `master` and `slave`:

```
master> type a mysql command on the replication master here
slave> type a mysql command on the replication slave here
```

The “shell” is your command interpreter. On Unix, this is typically a program such as `sh`, `csh`, or `bash`. On Windows, the equivalent program is `command.com` or `cmd.exe`, typically run in a console window.
When you enter a command or statement shown in an example, do not type the prompt shown in the example.

Database, table, and column names must often be substituted into statements. To indicate that such substitution is necessary, this manual uses `db_name`, `tbl_name`, and `col_name`. For example, you might see a statement like this:

```
mysql> SELECT col_name FROM db_name.tbl_name;
```

This means that if you were to enter a similar statement, you would supply your own database, table, and column names, perhaps like this:

```
mysql> SELECT author_name FROM biblio_db.author_list;
```

SQL keywords are not case sensitive and may be written in any lettercase. This manual uses uppercase.

In syntax descriptions, square brackets ("["] and "]") indicate optional words or clauses. For example, in the following statement, `IF EXISTS` is optional:

```sql
DROP TABLE [IF EXISTS] tbl_name
```

When a syntax element consists of a number of alternatives, the alternatives are separated by vertical bars ("|"). When one member from a set of choices may be chosen, the alternatives are listed within square brackets ("[" and "]"):

```sql
TRIM([[BOTH | LEADING | TRAILING] [remstr] FROM] str)
```

When one member from a set of choices must be chosen, the alternatives are listed within braces ("{" and "}"):

```sql
{DESCRIBE | DESC} tbl_name [col_name | wild]
```

An ellipsis (... ) indicates the omission of a section of a statement, typically to provide a shorter version of more complex syntax. For example, `SELECT ... INTO OUTFILE` is shorthand for the form of `SELECT` statement that has an `INTO OUTFILE` clause following other parts of the statement.

An ellipsis can also indicate that the preceding syntax element of a statement may be repeated. In the following example, multiple `reset_option` values may be given, with each of those after the first preceded by commas:

```sql
RESET reset_option [,reset_option] ...
```

Commands for setting shell variables are shown using Bourne shell syntax. For example, the sequence to set the `CC` environment variable and run the `configure` command looks like this in Bourne shell syntax:

```
shell> CC=gcc ./configure
```

If you are using `csh` or `tcsh`, you must issue commands somewhat differently:
1.3 Overview of the MySQL Database Management System

1.3.1 What is MySQL?

MySQL, the most popular Open Source SQL database management system, is developed, distributed, and supported by Oracle Corporation.

The MySQL Web site (http://www.mysql.com/) provides the latest information about MySQL software.

- MySQL is a database management system.
  
  A database is a structured collection of data. It may be anything from a simple shopping list to a picture gallery or the vast amounts of information in a corporate network. To add, access, and process data stored in a computer database, you need a database management system such as MySQL Server. Since computers are very good at handling large amounts of data, database management systems play a central role in computing, as standalone utilities, or as parts of other applications.

- MySQL databases are relational.
  
  A relational database stores data in separate tables rather than putting all the data in one big storeroom. The database structures are organized into physical files optimized for speed. The logical model, with objects such as databases, tables, views, rows, and columns, offers a flexible programming environment. You set up rules governing the relationships between different data fields, such as one-to-one, one-to-many, unique, required or optional, and “pointers” between different tables. The database enforces these rules, so that with a well-designed database, your application never sees inconsistent, duplicate, orphan, out-of-date, or missing data.

  The SQL part of “MySQL” stands for “Structured Query Language”. SQL is the most common standardized language used to access databases. Depending on your programming environment, you might enter SQL directly (for example, to generate reports), embed SQL statements into code written in another language, or use a language-specific API that hides the SQL syntax.

  SQL is defined by the ANSI/ISO SQL Standard. The SQL standard has been evolving since 1986 and several versions exist. In this manual, “SQL-92” refers to the standard released in 1992, “SQL:1999” refers to the standard released in 1999, and “SQL:2003” refers to the current version of the standard. We use the phrase “the SQL standard” to mean the current version of the SQL Standard at any time.

- MySQL software is Open Source.

  Open Source means that it is possible for anyone to use and modify the software. Anybody can download the MySQL software from the Internet and use it without paying anything. If you wish, you may study the source code and change it to suit your needs. The MySQL software uses the GPL (GNU General Public License), http://www.fsf.org/licenses/, to define what you may and may not do with the software in different situations. If you feel uncomfortable with the GPL or need to embed MySQL code into a commercial application, you can buy a commercially licensed version from us. See the MySQL Licensing Overview for more information (http://www.mysql.com/company/legal/licensing/).

- The MySQL Database Server is very fast, reliable, scalable, and easy to use.

  If that is what you are looking for, you should give it a try. MySQL Server can run comfortably on a desktop or laptop, alongside your other applications, web servers, and so on, requiring little or no attention. If you dedicate an entire machine to MySQL, you can adjust the settings to take advantage
of all the memory, CPU power, and I/O capacity available. MySQL can also scale up to clusters of machines, networked together.

You can find a performance comparison of MySQL Server with other database managers on our benchmark page. See Section 8.12.2, “The MySQL Benchmark Suite”.

MySQL Server was originally developed to handle large databases much faster than existing solutions and has been successfully used in highly demanding production environments for several years. Although under constant development, MySQL Server today offers a rich and useful set of functions. Its connectivity, speed, and security make MySQL Server highly suited for accessing databases on the Internet.

• MySQL Server works in client/server or embedded systems.

The MySQL Database Software is a client/server system that consists of a multi-threaded SQL server that supports different backends, several different client programs and libraries, administrative tools, and a wide range of application programming interfaces (APIs).

We also provide MySQL Server as an embedded multi-threaded library that you can link into your application to get a smaller, faster, easier-to-manage standalone product.

• A large amount of contributed MySQL software is available.

MySQL Server has a practical set of features developed in close cooperation with our users. It is very likely that your favorite application or language supports the MySQL Database Server.

The official way to pronounce “MySQL” is “My Ess Que Ell” (not “my sequel”), but we do not mind if you pronounce it as “my sequel” or in some other localized way.

1.3.2 The Main Features of MySQL

This section describes some of the important characteristics of the MySQL Database Software. See also Section 1.5, “MySQL Development History”. In most respects, the roadmap applies to all versions of MySQL. For information about features as they are introduced into MySQL on a series-specific basis, see the “In a Nutshell” section of the appropriate Manual:

• MySQL 5.6: MySQL 5.6 in a Nutshell
• MySQL 5.5: MySQL 5.5 in a Nutshell
• MySQL 5.1: MySQL 5.1 in a Nutshell
• MySQL 5.0: MySQL 5.0 in a Nutshell

Internals and Portability

• Written in C and C++.
• Tested with a broad range of different compilers.
• Works on many different platforms. See http://www.mysql.com/support/supportedplatforms/database.html.
• For portability, uses CMake in MySQL 5.5 and up. Previous series use GNU Automake, Autoconf, and Libtool.
The Main Features of MySQL

- Tested with Purify (a commercial memory leakage detector) as well as with Valgrind, a GPL tool (http://developer.kde.org/~seward/).
- Uses multi-layered server design with independent modules.
- Designed to be fully multi-threaded using kernel threads, to easily use multiple CPUs if they are available.
- Provides transactional and nontransactional storage engines.
- Uses very fast B-tree disk tables (MyISAM) with index compression.
- Designed to make it relatively easy to add other storage engines. This is useful if you want to provide an SQL interface for an in-house database.
- Uses a very fast thread-based memory allocation system.
- Executes very fast joins using an optimized nested-loop join.
- Implements in-memory hash tables, which are used as temporary tables.
- Implements SQL functions using a highly optimized class library that should be as fast as possible. Usually there is no memory allocation at all after query initialization.
- Provides the server as a separate program for use in a client/server networked environment, and as a library that can be embedded (linked) into standalone applications. Such applications can be used in isolation or in environments where no network is available.

Data Types

- Many data types: signed/unsigned integers 1, 2, 3, 4, and 8 bytes long, FLOAT, DOUBLE, CHAR, VARCHAR, BINARY, VARBINARY, TEXT, BLOB, DATE, TIME, DATETIME, TIMESTAMP, YEAR, SET, ENUM, and OpenGIS spatial types. See Chapter 11, Data Types.
- Fixed-length and variable-length string types.

Statements and Functions

- Full operator and function support in the SELECT list and WHERE clause of queries. For example:

```sql
mysql> SELECT CONCAT(first_name, ' ', last_name) FROM citizen WHERE income/dependents > 10000 AND age > 30;
```

- Full support for SQL GROUP BY and ORDER BY clauses. Support for group functions (COUNT(), AVG(), STD(), SUM(), MAX(), MIN(), and GROUP_CONCAT()).
- Support for LEFT OUTER JOIN and RIGHT OUTER JOIN with both standard SQL and ODBC syntax.
- Support for aliases on tables and columns as required by standard SQL.
- Support for DELETE, INSERT, REPLACE, and UPDATE to return the number of rows that were changed (affected), or to return the number of rows matched instead by setting a flag when connecting to the server.
- Support for MySQL-specific SHOW statements that retrieve information about databases, storage engines, tables, and indexes. MySQL 5.0 adds support for the INFORMATION_SCHEMA database, implemented according to standard SQL.
The Main Features of MySQL

- An `EXPLAIN` statement to show how the optimizer resolves a query.
- Independence of function names from table or column names. For example, `ABS` is a valid column name. The only restriction is that for a function call, no spaces are permitted between the function name and the "()" that follows it. See Section 9.3, “Reserved Words”.
- You can refer to tables from different databases in the same statement.

Security

- A privilege and password system that is very flexible and secure, and that enables host-based verification.
- Password security by encryption of all password traffic when you connect to a server.

Scalability and Limits

- Support for large databases. We use MySQL Server with databases that contain 50 million records. We also know of users who use MySQL Server with 200,000 tables and about 5,000,000,000 rows.
- Support for up to 64 indexes per table (32 before MySQL 4.1.2). Each index may consist of 1 to 16 columns or parts of columns. The maximum index width is 767 bytes for `InnoDB` tables, or 1000 for `MyISAM`; before MySQL 4.1.2, the limit is 500 bytes. An index may use a prefix of a column for `CHAR`, `VARCHAR`, `BLOB`, or `TEXT` column types.

Connectivity

- Clients can connect to MySQL Server using several protocols:
  - Clients can connect using TCP/IP sockets on any platform.
  - On Windows systems in the NT family (NT, 2000, XP, 2003, or Vista), clients can connect using named pipes if the server is started with the `--enable-named-pipe` option. In MySQL 4.1 and higher, Windows servers also support shared-memory connections if started with the `--shared-memory` option. Clients can connect through shared memory by using the `--protocol=memory` option.
  - On Unix systems, clients can connect using Unix domain socket files.
  - MySQL client programs can be written in many languages. A client library written in C is available for clients written in C or C++, or for any language that provides C bindings.
  - APIs for C, C++, Eiffel, Java, Perl, PHP, Python, Ruby, and Tcl are available, enabling MySQL clients to be written in many languages. See Chapter 23, Connectors and APIs.
  - The Connector/ODBC (MyODBC) interface provides MySQL support for client programs that use ODBC (Open Database Connectivity) connections. For example, you can use MS Access to connect to your MySQL server. Clients can be run on Windows or Unix. Connector/ODBC source is available. All ODBC 2.5 functions are supported, as are many others. See MySQL Connector/ODBC Developer Guide.
  - The Connector/J interface provides MySQL support for Java client programs that use JDBC connections. Clients can be run on Windows or Unix. Connector/J source is available. See MySQL Connector/J Developer Guide.
  - MySQL Connector/Net enables developers to easily create .NET applications that require secure, high-performance data connectivity with MySQL. It implements the required ADO.NET interfaces and
integrates into ADO.NET aware tools. Developers can build applications using their choice of .NET languages. MySQL Connector/Net is a fully managed ADO.NET driver written in 100% pure C#. See MySQL Connector/Net Developer Guide.

Localization

- The server can provide error messages to clients in many languages. See Section 10.2, “Setting the Error Message Language”.

- Full support for several different character sets, including latin1 (cp1252), german, big5, ujis, and more. For example, the Scandinavian characters “å”, “ä” and “ö” are permitted in table and column names. Unicode support is available as of MySQL 4.1.

- All data is saved in the chosen character set.

- Sorting and comparisons are done according to the chosen character set and collation (using latin1 and Swedish collation by default). It is possible to change this when the MySQL server is started. To see an example of very advanced sorting, look at the Czech sorting code. MySQL Server supports many different character sets that can be specified at compile time and runtime.

- As of MySQL 4.1, the server time zone can be changed dynamically, and individual clients can specify their own time zone. Section 10.6, “MySQL Server Time Zone Support”.

Clients and Tools

- MySQL includes several client and utility programs. These include both command-line programs such as mysqldump and mysqladmin, and graphical programs such as MySQL Workbench.

- MySQL Server has built-in support for SQL statements to check, optimize, and repair tables. These statements are available from the command line through the mysqlcheck client. MySQL also includes myisamchk, a very fast command-line utility for performing these operations on MyISAM tables. See Chapter 4, MySQL Programs.

- MySQL programs can be invoked with the --help or -? option to obtain online assistance.

1.3.3 History of MySQL

We started out with the intention of using the mSQL database system to connect to our tables using our own fast low-level (ISAM) routines. However, after some testing, we came to the conclusion that mSQL was not fast enough or flexible enough for our needs. This resulted in a new SQL interface to our database but with almost the same API interface as mSQL. This API was designed to enable third-party code that was written for use with mSQL to be ported easily for use with MySQL.

MySQL is named after co-founder Monty Widenius's daughter, My.

The name of the MySQL Dolphin (our logo) is “Sakila,” which was chosen from a huge list of names suggested by users in our “Name the Dolphin” contest. The winning name was submitted by Ambrose Twebaze, an Open Source software developer from Swaziland, Africa. According to Ambrose, the feminine name Sakila has its roots in SiSwati, the local language of Swaziland. Sakila is also the name of a town in Arusha, Tanzania, near Ambrose's country of origin, Uganda.

1.4 What Is New in MySQL 5.5

This section summarizes what has been added to, deprecated in, and removed from MySQL 5.5.
Added Features

The following features have been added to MySQL 5.5:

- **MySQL Enterprise Thread Pool.** The default thread-handling model in MySQL Server executes statements using one thread per client connection. As more clients connect to the server and execute statements, overall performance degrades. As of MySQL 5.5.16, MySQL Enterprise Edition distributions include a thread pool plugin that provides an alternative thread-handling model designed to reduce overhead and improve performance. The plugin implements a thread pool that increases server performance by efficiently managing statement execution threads for large numbers of client connections. For more information, see Section 8.11.6, “The Thread Pool Plugin”.

- **MySQL Enterprise Audit.** MySQL Enterprise Edition now includes MySQL Enterprise Audit, implemented using a server plugin named `audit_log`. MySQL Enterprise Audit uses the open MySQL Audit API to enable standard, policy-based monitoring and logging of connection and query activity executed on specific MySQL servers. Designed to meet the Oracle audit specification, MySQL Enterprise Audit provides an out of box, easy to use auditing and compliance solution for applications that are governed by both internal and external regulatory guidelines. When installed, the audit plugin enables MySQL Server to produce a log file containing an audit record of server activity. The log contents include when clients connect and disconnect, and what actions they perform while connected, such as which databases and tables they access. For more information, see Section 6.3.11, “MySQL Enterprise Audit Log Plugin”.

- **Pluggable authentication.** MySQL authentication supports two new capabilities, pluggable authentication and proxy users. With pluggable authentication, the server can use plugins to authenticate incoming client connections, and clients can load an authentication plugin that interacts properly with the corresponding server plugin. This capability enables clients to connect to the MySQL server with credentials that are appropriate for authentication methods other than the built-in MySQL authentication based on native MySQL passwords stored in the `mysql.user` table. For example, plugins can be created to use external authentication methods such as LDAP, Kerberos, PAM, or Windows login IDs. Proxy user capability enables a client who connects and authenticates as one user to be treated, for purposes of access control while connected, as having the privileges of a different user. In effect, one user impersonates another. Proxy capability depends on pluggable authentication because it is based on having an authentication plugin return to the server the user name that the connecting user impersonates. See Section 6.3.6, “Pluggable Authentication”, and Section 6.3.8, “Proxy Users”.

As of MySQL 5.5.16, commercial distributions of MySQL include two plugins that enable MySQL Server to use external authentication methods to authenticate MySQL users:

- PAM (Pluggable Authentication Modules) enables a system to access various kinds of authentication methods through a standard interface. A PAM authentication plugin enables MySQL Server to use PAM to authenticate MySQL users.

- Distributions of MySQL for Windows include an authentication plugin that enables MySQL Server to use native Windows services to authenticate client connections. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password.

These authentication plugins enable MySQL Server to accept connections from users defined outside the MySQL grant tables. They also support the MySQL proxy-user capability. Each plugin can return to MySQL a user name different from the login user, which means that the plugin can return the MySQL user that defines the privileges the externally authenticated user should have.

For more information, see Section 6.3.7.3, “The PAM Authentication Plugin”, and Section 6.3.7.4, “The Windows Native Authentication Plugin”.
• **Multi-core scalability.** Scalability on multi-core CPUs is improved. The trend in hardware development now is toward more cores rather than continued increases in CPU clock speeds, which renders “wait until CPUs get faster” a nonviable means of improving database performance. Instead, it is necessary to make better use of multiple cores to maximally exploit the processing cycles they make available. MySQL 5.5 takes advantage of features of SMP systems and tries to eliminate bottlenecks in MySQL architecture that hinder full use of multiple cores. The focus has been on InnoDB, especially locking and memory management. See Section 1.4.1, “Scalability Improvements”.

• **InnoDB I/O subsystem.** InnoDB I/O subsystem changes enable more effective use of available I/O capacity. See Section 1.4.2, “InnoDB I/O Subsystem Changes”.

• **Diagnostic improvements.** There is better access to execution and performance information. Diagnostic improvements include Performance Schema (a feature for monitoring MySQL Server execution at a low level), DTrace probes, expanded SHOW ENGINE INNODB STATUS output, Debug Sync, and a new status variable. See Section 1.4.3, “Diagnostic and Monitoring Capabilities”.

• **Solaris.** Several modifications improve operation of MySQL Server on Solaris. See Section 1.4.4, “Enhanced Solaris Support”.

• **Default storage engine.** The default storage engine for new tables is InnoDB rather than MyISAM. See Section 14.1.2, “InnoDB as the Default MySQL Storage Engine”.

• **MySQL Cluster.** MySQL Cluster is released as a separate product, with new development for version 7.2 of the NDB storage engine being based on MySQL 5.5. Clustering support is not available in mainline MySQL Server 5.5 releases. For more information about MySQL Cluster NDB 7.2, see Chapter 18, MySQL Cluster NDB 7.2.

MySQL Cluster releases are identified by a 3-part NDB version number. Currently, MySQL Cluster NDB 7.1 is the most recent GA release series. MySQL Cluster NDB 6.3 and MySQL Cluster NDB 7.0 are also still available. These versions of MySQL Cluster are based on MySQL Server 5.1 and documented in the MySQL 5.1 Manual. See MySQL Cluster NDB 6.1 - 7.1.

• **Semisynchronous replication.** A commit performed on the master side blocks before returning to the session that performed the transaction until at least one slave acknowledges that it has received and logged the events for the transaction. Semisynchronous replication is implemented through an optional plugin component. See Section 17.3.8, “Semisynchronous Replication”.

• **Unicode.** Support for supplementary Unicode characters; that is, characters outside the Basic Multilingual Plane (BMP). These new Unicode character sets include supplementary characters: utf16, utf32, and utf8mb4. See Section 10.1.10, “Unicode Support”.

• **Partitioning.** Enhancements to table partitioning:

  • Two new types of user-defined partitioning are supported: RANGE COLUMNS partitioning is an extension to RANGE partitioning; LIST COLUMNS partitioning is an extension to LIST partitioning. Each of these extensions provides two enhancements to MySQL partitioning capabilities:

    • It is possible to define partitioning ranges or lists based on DATE, DATETIME, or string values (such as CHAR or VARCHAR).

    You can also define ranges or lists based on multiple column values when partitioning tables by RANGE COLUMNS or LIST COLUMNS, respectively. Such a range or list may refer to up to 16 columns.

    • For tables defined using these partitioning types, partition pruning can now optimize queries with WHERE conditions that use multiple comparisons between (different) column values and constants, such as a = 10 AND b > 5 or a < "2005-11-25" AND b = 10 AND c = 50.
See Section 19.2.1, “RANGE Partitioning”, and Section 19.2.2, “LIST Partitioning”.

- It is now possible to delete all rows from one or more partitions of a partitioned table using the ALTER TABLE ... TRUNCATE PARTITION statement. Executing the statement deletes rows without affecting the structure of the table. The partitions named in the TRUNCATE PARTITION clause do not have to be contiguous.

- Key caches are now supported for indexes on partitioned MyISAM tables, using the CACHE INDEX and LOAD INDEX INTO CACHE statements. In addition, a key cache can be defined for and loaded with indexes from an entire partitioned table, or for one or more partitions. In the latter case, the partitions are not required to be contiguous.

- The new TO_SECONDS() function converts a date or datetime expression to a number of seconds since the year 0. This is a general-purpose function, but is useful for partitioning. You may use it in partitioning expressions, and partition pruning is supported for tables defined using such expressions.

- SIGNAL and RESIGNAL. Support for the SQL standard SIGNAL and RESIGNAL statements. See Section 13.6.7, “Condition Handling”.

- Metadata locking. The server now prevents DDL statements from compromising transaction serializibility by using a new class of locks called metadata locks. See Section 8.10.4, “Metadata Locking”.

- IPv6 support. MySQL Server can accept TCP/IP connections from clients connecting over IPv6. See Section 5.1.9, “IPv6 Support”.

- XML. Enhancements to XML functionality, including a new LOAD XML INFILE statement. See Section 13.2.7, “LOAD XML Syntax”.

- Build configuration. MySQL releases are now built using CMake rather than the GNU autotools. Accordingly, the instructions for installing MySQL from source have been updated to discuss how to build MySQL using CMake. See Section 2.9, “Installing MySQL from Source”.

The build process is now similar enough on all platforms, including Windows, that there are no longer sections dedicated to notes for specific platforms.

### Deprecated Features

The following features are deprecated in MySQL 5.5 and may be or will be removed in a future series. Where alternatives are shown, applications should be updated to use them.

- Relying on implicit GROUP BY sorting in MySQL 5.5 is deprecated. To achieve a specific sort order of grouped results, it is preferable to use an explicit ORDER BY clause. GROUP BY sorting is a MySQL extension that may change in a future release; for example, to make it possible for the optimizer to order groupings in whatever manner it deems most efficient and to avoid the sorting overhead.

- The YEAR(2) data type. YEAR(2) columns in existing tables are treated as before, but YEAR(2) in new or altered tables are converted to YEAR(4). For more information, see Section 11.3.4, “YEAR(2) Limitations and Migrating to YEAR(4)”.

The SHOW AUTHORS and SHOW CONTRIBUTORS statements.

- The --ignore-builtin-innodb server option. It does nothing and has no effect.

- The --language server option. Use the lc_messages_dir and lc_messages system variables instead.
- The `ALWAYS` value for the `--base64-output` option for `mysqlbinlog`.
- The `--config-file` option for `mysqld_multi`. Use `--defaults-extra-file` instead.
- Use of unambiguous option prefixes. If an unambiguous prefix is given, a warning occurs to provide feedback. Option prefixes are no longer supported in MySQL 5.7; only full options are accepted.
- The `engine_condition_pushdown` system variable. Use the `engine_condition_pushdown` flag of the `optimizer_switch` variable instead.
- The `timed_mutexes` system variable. It does nothing and has no effect.
- The `storage_engine` system variable. Use `default_storage_engine` instead.
- Use of the data directory as the location for `my.cnf`.

**Removed Features**

The following constructs are obsolete and have been removed in MySQL 5.5. Where alternatives are shown, applications should be updated to use them.

- The `language` system variable (use `lc_messages_dir` and `lc_messages`).
- The `log_bin_trust_routine_creators` system variable (use `log_bin_trust_function_creators`).
- The `myisam_max_extra_sort_file_size` system variable.
- The `record_buffer` system variable (use `read_buffer_size`).
- The `sql_log_update` system variable.
- The `Innodb_buffer_pool_read_ahead_rnd` and `Innodb_buffer_pool_read_ahead_seq` status variables (use `Innodb_buffer_pool_read_ahead` and `Innodb_buffer_pool_read_ahead_evicted`).
- The `table_lock_wait_timeout` system variable.
- The `table_type` system variable (use `default_storage_engine`).
- The `FRAC_SECOND` modifier for the `TIMESTAMPADD()` function (use `MICROSECOND`).
- The `TYPE` table option to specify the storage engine for `CREATE TABLE` or `ALTER TABLE` (use `ENGINE`).
- The `SHOW TABLE TYPES` SQL statement (use `SHOW ENGINES`).
- The `SHOW INNODB STATUS` and `SHOW MUTEX STATUS` SQL statements (use `SHOW ENGINE INNODB STATUS` and `SHOW ENGINE INNODB MUTEX`).
- The `SHOW PLUGIN` SQL statement (use `SHOW PLUGINS`).
- The `LOAD TABLE ... FROM MASTER` and `LOAD DATA FROM MASTER` SQL statements (use `mysqldump` or `mysqlhotcopy` to dump tables and `mysql` to reload dump files).
- The `BACKUP TABLE` and `RESTORE TABLE` SQL statements (use `mysqldump` or `mysqlhotcopy` to dump tables and `mysql` to reload dump files).
- `TIMESTAMP(N)` data type: The ability to specify a display width of `N` (use without `N`).
Scalability Improvements

- The `--default-character-set` and `--default-collation` server options (use `--character-set-server` and `--collation-server`).

- The `--default-table-type` server option (use `--default-storage-engine`).

- The `--delay-key-write-for-all-tables` server option (use `--delay-key-write=ALL`).

- The `--enable-locking` and `--skip-locking` server options (use `--external-locking` and `--skip-external-locking`).

- The `--log-bin-trust-routine-creators` server option (use `--log-bin-trust-function-creators`).

- The `--log-long-format` server option.

- The `--log-update` server option.

- The `--master-xxx` server options to set replication parameters (use the `CHANGE MASTER TO` statement instead): `--master-host`, `--master-user`, `--master-password`, `--master-port`, `--master-connect-retry`, `--master-ssl`, `--master-ssl-ca`, `--master-ssl-capath`, `--master-ssl-cert`, `--master-ssl-cipher`, `--master-ssl-key`.

- The `--safe-show-database` server option.

- The `--skip-symlink` and `--use-symbolic-links` server options (use `--skip-symbolic-links` and `--symbolic-links`).

- The `--sql-bin-update-same` server option.

- The `--warnings` server option (use `--log-warnings`).

- The `--no-named-commands` option for `mysql` (use `--skip-named-commands`).

- The `--no-pager` option for `mysql` (use `--skip-pager`).

- The `--no-tee` option for `mysql` (use `--skip-tee`).

- The `--position` option for `mysqlbinlog` (use `--start-position`).

- The `--all` option for `mysqldump` (use `--create-options`).

- The `--first-slave` option for `mysqldump` (use `--lock-all-tables`).

- The `--config-file` option for `mysqld_multi` (use `--defaults-extra-file`).

- The `--set-variable=var_name=value` and `-O var_name=value` general-purpose options for setting program variables (use `--var_name=value`).

- The `--with-pstack` option for `configure` and the `--enable-pstack` option for `mysqld`.

### 1.4.1 Scalability Improvements

MySQL 5.5 modifications improve performance on SMP systems to increase scalability on multi-core systems. The changes affect InnoDB locking and memory management.

MySQL 5.5 incorporates changes in InnoDB that improve the performance of RW-locks by using atomic CPU instructions (on platforms where they are available), rather than less scalable mutexes. It is also possible for InnoDB memory allocation to be disabled and replaced by the normal `malloc` library, or by a different library that implements `malloc` such as `tcmalloc` on Linux or `mtmalloc` on Solaris.
The reimplementation of RW-locks requires atomic instructions. A status variable, Innodb_have_atomic_builtins, shows whether the server was built with atomic instructions.

1.4.2 InnoDB I/O Subsystem Changes

MySQL 5.5 changes to the InnoDB I/O subsystem enable more effective use of available I/O capacity. The changes also provide more control over configuration of the I/O subsystem.

Background I/O Threads

InnoDB uses background threads to perform I/O for several kinds of activities, two of which are prefetching disk blocks and flushing dirty pages. Previously, InnoDB used only one thread each to perform these activities, but that can underutilize server capacity. MySQL 5.5 enables use of multiple background read and write threads, making it possible to read and write pages faster.

The patch makes the number of background I/O threads configurable using system variables:
innodb_read_io_threads controls the number of threads to use for read prefetch requests.
innodb_write_io_threads controls the number of threads to use for writing dirty pages from the buffer cache to disk. The default for both variables is 4.

The ability to increase the number of I/O threads can benefit systems that use multiple disks for InnoDB. However, the type of I/O being done should be considered. On systems that use buffered writes rather than direct writes, increasing the write thread count higher than 1 might yield little benefit because writes will be quick already.

Adjustable I/O Rate

Previously, the number of input/output operations per second (IOPS) that InnoDB will perform was a compile-time parameter. The rate was chosen to prevent background I/O from exhausting server capacity and the compiled-in value of 100 reflected an assumption that the server can perform 100 IOPS. However, many modern systems can exceed this, so the value is low and unnecessarily restricts I/O utilization.

MySQL 5.5 exposes this I/O rate parameter as a system variable, innodb_io_capacity. This variable can be set at server startup, which enables higher values to be selected for systems capable of higher I/O rates. Having a higher I/O rate can help the server handle a higher rate of row changes because it may be able to increase dirty-page flushing, deleted-row removal, and application of changes to the insert buffer. The default value of innodb_io_capacity is 200. In general, you can increase the value as a function of the number of drives used for InnoDB I/O.

The ability to raise the I/O limit should be especially beneficial on platforms that support many IOPS. For example, systems that use multiple disks or solid-state disks for InnoDB are likely to benefit from the ability to control this parameter.

1.4.3 Diagnostic and Monitoring Capabilities

MySQL 5.5 provides improved access to execution and performance information. Diagnostic improvements include Performance Schema, Dtrace probes, expanded SHOW ENGINE INNODB STATUS output, Debug Sync, and a new status variable.

Performance Schema

Performance Schema is a feature for monitoring MySQL Server execution at a low level. See Chapter 22, MySQL Performance Schema.

DTrace Support
Enhanced Solaris Support

The DTrace probes work on Solaris, Mac OS X, and FreeBSD. For information on using DTrace in MySQL, see Section 5.4, “Tracing mysqld Using DTrace”.

**Enhanced SHOW ENGINE INNODB STATUS Output**

The output from `SHOW ENGINE INNODB STATUS` includes more information due to changes made for InnoDB Plugin. A description of revisions to statement output follows.

A new **BACKGROUND THREAD** section has `srv_master_thread` lines that show work done by the main background thread.

---

**BACKGROUND THREAD**

---

`srv_master_thread` loops: 53 1_second, 44 sleeps, 5 10_second, 7 background, 7 flush
`srv_master_thread` log flush and writes: 48

The **SEMAPHORES** section includes a line to show the number of spinlock rounds per OS wait for a mutex.

---

**SEMAPHORES**

...

Spin rounds per wait: 0.00 mutex, 20.00 RW-shared, 0.00 RW-excl

**Debug Sync**

The Debug Sync facility provides synchronization points for debugging, see MySQL Internals: Test Synchronization.

**New Status Variable**

The `Innodb_have_atomic_builtins` status variable provides information about availability of atomic instructions; see Section 1.4.1, “Scalability Improvements”.

### 1.4.4 Enhanced Solaris Support

MySQL 5.5 incorporates several modifications for improved operation of MySQL Server on Solaris:

- DTrace support for execution monitoring. See Section 1.4.3, “Diagnostic and Monitoring Capabilities”.

- Atomic instructions, which are needed for the improvements to RW-locking described in Section 1.4.1, “Scalability Improvements”. Atomic instructions are now supported for Sun Studio on SPARC and x86 platforms. This extends their previous availability (supported for gcc 4.1 and up on all platforms).

- The SMP improvements described in Section 1.4.1, “Scalability Improvements”, were originally intended for x86 platforms. In MySQL 5.5, these also work on SPARC platforms. Also, Solaris optimizations have been implemented.

- Large page support is enhanced for recent SPARC platforms. Standard use of large pages in MySQL attempts to use the largest size supported, up to 4MB. Under Solaris, a “super large pages” feature enables uses of pages up to 256MB. This feature can be enabled or disabled by using the `--super-large-pages` or `--skip-super-large-pages` option.

- Inline handling for InnoDB and processor instruction prefetching support, previously not enabled for builds created using Sun Studio, now are supported for that build environment.
1.5 MySQL Development History

This section describes the general MySQL development history, provides an overview about features that have been implemented in previous series and that are new in MySQL 5.5, the release series covered in this manual. The maturity level this release series is general availability. Information about maturity levels can be found in Section 2.1.2.1, “Choosing Which Version of MySQL to Install”.

Before upgrading from one release series to the next, please see the notes in Section 2.11.1, “Upgrading MySQL”.

The most requested features and the versions in which they were implemented are summarized in the following table.

<table>
<thead>
<tr>
<th>Feature</th>
<th>MySQL Series</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unions</td>
<td>4.0</td>
</tr>
<tr>
<td>Subqueries</td>
<td>4.1</td>
</tr>
<tr>
<td>R-trees</td>
<td>4.1 (for the MyISAM storage engine)</td>
</tr>
<tr>
<td>Stored procedures and functions</td>
<td>5.0</td>
</tr>
<tr>
<td>Views</td>
<td>5.0</td>
</tr>
<tr>
<td>Cursors</td>
<td>5.0</td>
</tr>
<tr>
<td>XA transactions</td>
<td>5.0</td>
</tr>
<tr>
<td>Triggers</td>
<td>5.0 and 5.1</td>
</tr>
<tr>
<td>Event scheduler</td>
<td>5.1</td>
</tr>
<tr>
<td>Partitioning</td>
<td>5.1</td>
</tr>
<tr>
<td>Pluggable storage engine API</td>
<td>5.1</td>
</tr>
<tr>
<td>Plugin API</td>
<td>5.1</td>
</tr>
<tr>
<td>InnoDB Plugin</td>
<td>5.1</td>
</tr>
<tr>
<td>Row-based replication</td>
<td>5.1</td>
</tr>
<tr>
<td>Server log tables</td>
<td>5.1</td>
</tr>
<tr>
<td>Scalability and performance improvements</td>
<td>5.1 (with InnoDB Plugin)</td>
</tr>
<tr>
<td>DTrace support</td>
<td>5.5</td>
</tr>
<tr>
<td>InnoDB as default storage engine</td>
<td>5.5</td>
</tr>
<tr>
<td>Semisynchronous replication</td>
<td>5.5</td>
</tr>
<tr>
<td>SIGNAL/RESIGNAL support in stored routines</td>
<td>5.5</td>
</tr>
<tr>
<td>Performance Schema</td>
<td>5.5</td>
</tr>
<tr>
<td>Supplementary Unicode characters</td>
<td>5.5</td>
</tr>
</tbody>
</table>

1.6 MySQL Information Sources

This section lists sources of additional information that you may find helpful, such as the MySQL mailing lists and user forums, and Internet Relay Chat.

1.6.1 MySQL Mailing Lists
This section introduces the MySQL mailing lists and provides guidelines as to how the lists should be used. When you subscribe to a mailing list, you receive all postings to the list as email messages. You can also send your own questions and answers to the list.

To subscribe to or unsubscribe from any of the mailing lists described in this section, visit http://lists.mysql.com/. For most of them, you can select the regular version of the list where you get individual messages, or a digest version where you get one large message per day.

Please do not send messages about subscribing or unsubscribing to any of the mailing lists, because such messages are distributed automatically to thousands of other users.

Your local site may have many subscribers to a MySQL mailing list. If so, the site may have a local mailing list, so that messages sent from lists.mysql.com to your site are propagated to the local list. In such cases, please contact your system administrator to be added to or dropped from the local MySQL list.

To have traffic for a mailing list go to a separate mailbox in your mail program, set up a filter based on the message headers. You can use either the List-ID: or Delivered-To: headers to identify list messages.

The MySQL mailing lists are as follows:

- **announce**
  The list for announcements of new versions of MySQL and related programs. This is a low-volume list to which all MySQL users should subscribe.

- **mysql**
  The main list for general MySQL discussion. Please note that some topics are better discussed on the more-specialized lists. If you post to the wrong list, you may not get an answer.

- **bugs**
  The list for people who want to stay informed about issues reported since the last release of MySQL or who want to be actively involved in the process of bug hunting and fixing. See Section 1.7, “How to Report Bugs or Problems”.

- **internals**
  The list for people who work on the MySQL code. This is also the forum for discussions on MySQL development and for posting patches.

- **mysqldoc**
  The list for people who work on the MySQL documentation.

- **benchmarks**
  The list for anyone interested in performance issues. Discussions concentrate on database performance (not limited to MySQL), but also include broader categories such as performance of the kernel, file system, disk system, and so on.

- **packagers**
  The list for discussions on packaging and distributing MySQL. This is the forum used by distribution maintainers to exchange ideas on packaging MySQL and on ensuring that MySQL looks and feels as similar as possible on all supported platforms and operating systems.
- **java**
  The list for discussions about the MySQL server and Java. It is mostly used to discuss JDBC drivers such as MySQL Connector/J.

- **win32**
  The list for all topics concerning the MySQL software on Microsoft operating systems, such as Windows 9x, Me, NT, 2000, XP, and 2003.

- **myodbc**
  The list for all topics concerning connecting to the MySQL server with ODBC.

- **gui-tools**
  The list for all topics concerning MySQL graphical user interface tools such as MySQL Workbench.

- **cluster**
  The list for discussion of MySQL Cluster.

- **dotnet**
  The list for discussion of the MySQL server and the .NET platform. It is mostly related to MySQL Connector/Net.

- **plusplus**
  The list for all topics concerning programming with the C++ API for MySQL.

- **perl**
  The list for all topics concerning Perl support for MySQL with DBD::mysql.

If you're unable to get an answer to your questions from a MySQL mailing list or forum, one option is to purchase support from Oracle. This puts you in direct contact with MySQL developers.

The following MySQL mailing lists are in languages other than English. These lists are not operated by Oracle.

- **<mysql-france-subscribe@yahoogroups.com>**
  A French mailing list.

- **<list@tinc.net>**
  A Korean mailing list. To subscribe, email subscribe mysql your@email.address to this list.

- **<mysql-de-request@lists.4t2.com>**
  A German mailing list. To subscribe, email subscribe mysql-de your@email.address to this list. You can find information about this mailing list at http://www.4t2.com/mysql/.

- **<mysql-br-request@listas.linkway.com.br>**
  A Portuguese mailing list. To subscribe, email subscribe mysql-br your@email.address to this list.
1.6.1 Guidelines for Using the Mailing Lists

Please do not post mail messages from your browser with HTML mode turned on. Many users do not read mail with a browser.

When you answer a question sent to a mailing list, if you consider your answer to have broad interest, you may want to post it to the list instead of replying directly to the individual who asked. Try to make your answer general enough that people other than the original poster may benefit from it. When you post to the list, please make sure that your answer is not a duplication of a previous answer.

Try to summarize the essential part of the question in your reply. Do not feel obliged to quote the entire original message.

When answers are sent to you individually and not to the mailing list, it is considered good etiquette to summarize the answers and send the summary to the mailing list so that others may have the benefit of responses you received that helped you solve your problem.

1.6.2 MySQL Community Support at the MySQL Forums

The forums at [http://forums.mysql.com](http://forums.mysql.com) are an important community resource. Many forums are available, grouped into these general categories:

- Migration
- MySQL Usage
- MySQL Connectors
- Programming Languages
- Tools
- 3rd-Party Applications
- Storage Engines
- MySQL Technology
- SQL Standards
- Business

1.6.3 MySQL Community Support on Internet Relay Chat (IRC)

In addition to the various MySQL mailing lists and forums, you can find experienced community people on Internet Relay Chat (IRC). These are the best networks/channels currently known to us:

**freenode** (see [http://www.freenode.net/](http://www.freenode.net/) for servers)

- #mysql is primarily for MySQL questions, but other database and general SQL questions are welcome. Questions about PHP, Perl, or C in combination with MySQL are also common.

If you are looking for IRC client software to connect to an IRC network, take a look at [xChat](http://www.xchat.org/). X-Chat (GPL licensed) is available for Unix as well as for Windows platforms (a free Windows build of X-Chat is available at [http://www.silverex.org/download/](http://www.silverex.org/download/)).
1.6.4 MySQL Enterprise

Oracle offers technical support in the form of MySQL Enterprise. For organizations that rely on the MySQL DBMS for business-critical production applications, MySQL Enterprise is a commercial subscription offering which includes:

- MySQL Enterprise Server
- MySQL Enterprise Monitor
- Monthly Rapid Updates and Quarterly Service Packs
- MySQL Knowledge Base
- 24x7 Technical and Consultative Support

MySQL Enterprise is available in multiple tiers, giving you the flexibility to choose the level of service that best matches your needs. For more information, see MySQL Enterprise.

1.7 How to Report Bugs or Problems

Before posting a bug report about a problem, please try to verify that it is a bug and that it has not been reported already:

- Start by searching the MySQL online manual at http://dev.mysql.com/doc/. We try to keep the manual up to date by updating it frequently with solutions to newly found problems. In addition, the release notes accompanying the manual can be particularly useful since it is quite possible that a newer version contains a solution to your problem. The release notes are available at the location just given for the manual.

- If you get a parse error for an SQL statement, please check your syntax closely. If you cannot find something wrong with it, it is extremely likely that your current version of MySQL Server doesn't support the syntax you are using. If you are using the current version and the manual doesn't cover the syntax that you are using, MySQL Server doesn't support your statement.

If the manual covers the syntax you are using, but you have an older version of MySQL Server, you should check the MySQL change history to see when the syntax was implemented. In this case, you have the option of upgrading to a newer version of MySQL Server.

- For solutions to some common problems, see Section B.5, “Problems and Common Errors”.

- Search the bugs database at http://bugs.mysql.com/ to see whether the bug has been reported and fixed.

- Search the MySQL mailing list archives at http://lists.mysql.com/. See Section 1.6.1, “MySQL Mailing Lists”.

- You can also use http://www.mysql.com/search/ to search all the Web pages (including the manual) that are located at the MySQL Web site.

If you cannot find an answer in the manual, the bugs database, or the mailing list archives, check with your local MySQL expert. If you still cannot find an answer to your question, please use the following guidelines for reporting the bug.

The normal way to report bugs is to visit http://bugs.mysql.com/, which is the address for our bugs database. This database is public and can be browsed and searched by anyone. If you log in to the system, you can enter new reports.
How to Report Bugs or Problems

Bugs posted in the bugs database at http://bugs.mysql.com/ that are corrected for a given release are noted in the release notes.

If you find a sensitive security bug in MySQL Server, please let us know immediately by sending an email message to <secalert_us@oracle.com>. Exception: Support customers should report all problems, including security bugs, to Oracle Support at http://support.oracle.com/.

To discuss problems with other users, you can use one of the MySQL mailing lists. Section 1.6.1, “MySQL Mailing Lists”.

Writing a good bug report takes patience, but doing it right the first time saves time both for us and for yourself. A good bug report, containing a full test case for the bug, makes it very likely that we will fix the bug in the next release. This section helps you write your report correctly so that you do not waste your time doing things that may not help us much or at all. Please read this section carefully and make sure that all the information described here is included in your report.

Preferably, you should test the problem using the latest production or development version of MySQL Server before posting. Anyone should be able to repeat the bug by just using mysql test <script_file> on your test case or by running the shell or Perl script that you include in the bug report. Any bug that we are able to repeat has a high chance of being fixed in the next MySQL release.

It is most helpful when a good description of the problem is included in the bug report. That is, give a good example of everything you did that led to the problem and describe, in exact detail, the problem itself. The best reports are those that include a full example showing how to reproduce the bug or problem. See Section 24.4, “Debugging and Porting MySQL”.

Remember that it is possible for us to respond to a report containing too much information, but not to one containing too little. People often omit facts because they think they know the cause of a problem and assume that some details do not matter. A good principle to follow is that if you are in doubt about stating something, state it. It is faster and less troublesome to write a couple more lines in your report than to wait longer for the answer if we must ask you to provide information that was missing from the initial report.

The most common errors made in bug reports are (a) not including the version number of the MySQL distribution that you use, and (b) not fully describing the platform on which the MySQL server is installed (including the platform type and version number). These are highly relevant pieces of information, and in 99 cases out of 100, the bug report is useless without them. Very often we get questions like, “Why doesn't this work for me?” Then we find that the feature requested wasn't implemented in that MySQL version, or that a bug described in a report has been fixed in newer MySQL versions. Errors often are platform-dependent. In such cases, it is next to impossible for us to fix anything without knowing the operating system and the version number of the platform.

If you compiled MySQL from source, remember also to provide information about your compiler if it is related to the problem. Often people find bugs in compilers and think the problem is MySQL-related. Most compilers are under development all the time and become better version by version. To determine whether your problem depends on your compiler, we need to know what compiler you used. Note that every compiling problem should be regarded as a bug and reported accordingly.

If a program produces an error message, it is very important to include the message in your report. If we try to search for something from the archives, it is better that the error message reported exactly matches the one that the program produces. (Even the lettercase should be observed.) It is best to copy and paste the entire error message into your report. You should never try to reproduce the message from memory.

If you have a problem with Connector/ODBC (MyODBC), please try to generate a trace file and send it with your report. See How to Report Connector/ODBC Problems or Bugs.
If your report includes long query output lines from test cases that you run with the `mysql` command-line tool, you can make the output more readable by using the `--vertical` option or the `\G` statement terminator. The `EXPLAIN SELECT` example later in this section demonstrates the use of `\G`.

Please include the following information in your report:

- The version number of the MySQL distribution you are using (for example, MySQL 5.0.19). You can find out which version you are running by executing `mysqladmin version`. The `mysqladmin` program can be found in the `bin` directory under your MySQL installation directory.

- The manufacturer and model of the machine on which you experience the problem.

- The operating system name and version. If you work with Windows, you can usually get the name and version number by double-clicking your My Computer icon and pulling down the “Help/About Windows” menu. For most Unix-like operating systems, you can get this information by executing the command `uname -a`.

- Sometimes the amount of memory (real and virtual) is relevant. If in doubt, include these values.

- If you are using a source distribution of the MySQL software, include the name and version number of the compiler that you used. If you have a binary distribution, include the distribution name.

- If the problem occurs during compilation, include the exact error messages and also a few lines of context around the offending code in the file where the error occurs.

- If `mysqld` died, you should also report the statement that crashed `mysqld`. You can usually get this information by running `mysqld` with query logging enabled, and then looking in the log after `mysqld` crashes. See Section 24.4, “Debugging and Porting MySQL”.

- If a database table is related to the problem, include the output from the `SHOW CREATE TABLE db_name.tbl_name` statement in the bug report. This is a very easy way to get the definition of any table in a database. The information helps us create a situation matching the one that you have experienced.

- The SQL mode in effect when the problem occurred can be significant, so please report the value of the `sql_mode` system variable. For stored procedure, stored function, and trigger objects, the relevant `sql_mode` value is the one in effect when the object was created. For a stored procedure or function, the `SHOW CREATE PROCEDURE` or `SHOW CREATE FUNCTION` statement shows the relevant SQL mode, or you can query `INFORMATION_SCHEMA` for the information:

```sql
SELECT ROUTINE_SCHEMA, ROUTINE_NAME, SQL_MODE
FROM INFORMATION_SCHEMA.ROUTINES;
```

For triggers, you can use this statement:

```sql
SELECT EVENT_OBJECT_SCHEMA, EVENT_OBJECT_TABLE, TRIGGER_NAME, SQL_MODE
FROM INFORMATION_SCHEMA.TRIGGERS;
```

- For performance-related bugs or problems with `SELECT` statements, you should always include the output of `EXPLAIN SELECT ...`, and at least the number of rows that the `SELECT` statement produces. You should also include the output from `SHOW CREATE TABLE tbl_name` for each table that is involved. The more information you provide about your situation, the more likely it is that someone can help you.

The following is an example of a very good bug report. The statements are run using the `mysql` command-line tool. Note the use of the `\G` statement terminator for statements that would otherwise provide very long output lines that are difficult to read.
How to Report Bugs or Problems

- If a bug or problem occurs while running mysqld, try to provide an input script that reproduces the anomaly. This script should include any necessary source files. The more closely the script can reproduce your situation, the better. If you can make a reproducible test case, you should upload it to be attached to the bug report.

If you cannot provide a script, you should at least include the output from mysqladmin variables extended-status processlist in your report to provide some information on how your system is performing.

- If you cannot produce a test case with only a few rows, or if the test table is too big to be included in the bug report (more than 10 rows), you should dump your tables using mysqldump and create a README file that describes your problem. Create a compressed archive of your files using tar and gzip or zip. After you initiate a bug report for our bugs database at http://bugs.mysql.com/, click the Files tab in the bug report for instructions on uploading the archive to the bugs database.

- If you believe that the MySQL server produces a strange result from a statement, include not only the result, but also your opinion of what the result should be, and an explanation describing the basis for your opinion.

- When you provide an example of the problem, it is better to use the table names, variable names, and so forth that exist in your actual situation than to come up with new names. The problem could be related to the name of a table or variable. These cases are rare, perhaps, but it is better to be safe than sorry. After all, it should be easier for you to provide an example that uses your actual situation, and it is by all means better for us. If you have data that you do not want to be visible to others in the bug report, you can upload it using the Files tab as previously described. If the information is really top secret and you do not want to show it even to us, go ahead and provide an example using other names, but please regard this as the last choice.

- Include all the options given to the relevant programs, if possible. For example, indicate the options that you use when you start the mysqld server, as well as the options that you use to run any MySQL client programs. The options to programs such as mysqld and mysql, and to the configure script, are often key to resolving problems and are very relevant. It is never a bad idea to include them. If your problem involves a program written in a language such as Perl or PHP, please include the language processor’s version number, as well as the version for any modules that the program uses. For example, if you have a Perl script that uses the DBI and DBD::mysql modules, include the version numbers for Perl, DBI, and DBD::mysql.

- If your question is related to the privilege system, please include the output of mysqlaccess, the output of mysqladmin reload, and all the error messages you get when trying to connect. When you test your privileges, you should first run mysqlaccess. After this, execute mysqladmin reload version and try to connect with the program that gives you trouble. mysqlaccess can be found in the bin directory under your MySQL installation directory.

- If you have a patch for a bug, do include it. But do not assume that the patch is all we need, or that we can use it, if you do not provide some necessary information such as test cases showing the bug that
your patch fixes. We might find problems with your patch or we might not understand it at all. If so, we cannot use it.

If we cannot verify the exact purpose of the patch, we will not use it. Test cases help us here. Show that the patch handles all the situations that may occur. If we find a borderline case (even a rare one) where the patch will not work, it may be useless.

- Guesses about what the bug is, why it occurs, or what it depends on are usually wrong. Even the MySQL team cannot guess such things without first using a debugger to determine the real cause of a bug.

- Indicate in your bug report that you have checked the reference manual and mail archive so that others know you have tried to solve the problem yourself.

- If your data appears corrupt or you get errors when you access a particular table, first check your tables with `CHECK TABLE`. If that statement reports any errors:
  
  - The InnoDB crash recovery mechanism handles cleanup when the server is restarted after being killed, so in typical operation there is no need to “repair” tables. If you encounter an error with InnoDB tables, restart the server and see whether the problem persists, or whether the error affected only cached data in memory. If data is corrupted on disk, consider restarting with the `innodb_force_recovery` option enabled so that you can dump the affected tables.

  - For non-transactional tables, try to repair them with `REPAIR TABLE` or with `myisamchk`. See Chapter 5, *MySQL Server Administration*.

  If you are running Windows, please verify the value of `lower_case_table_names` using the `SHOW VARIABLES LIKE 'lower_case_table_names'` statement. This variable affects how the server handles lettercase of database and table names. Its effect for a given value should be as described in Section 9.2.2, “Identifier Case Sensitivity”.

  - If you often get corrupted tables, you should try to find out when and why this happens. In this case, the error log in the MySQL data directory may contain some information about what happened. (This is the file with the .err suffix in the name.) See Section 5.2.2, “The Error Log”. Please include any relevant information from this file in your bug report. Normally `mysqld` should never crash a table if nothing killed it in the middle of an update. If you can find the cause of `mysqld` dying, it is much easier for us to provide you with a fix for the problem. See Section B.5.1, “How to Determine What Is Causing a Problem”.

  - If possible, download and install the most recent version of MySQL Server and check whether it solves your problem. All versions of the MySQL software thoroughly tested and should work without problems. We believe in making everything as backward-compatible as possible, and you should be able to switch MySQL versions without difficulty. See Section 2.1.2, “Choosing Which MySQL Distribution to Install”.

### 1.8 MySQL Standards Compliance

This section describes how MySQL relates to the ANSI/ISO SQL standards. MySQL Server has many extensions to the SQL standard, and here you can find out what they are and how to use them. You can also find information about functionality missing from MySQL Server, and how to work around some of the differences.

The SQL standard has been evolving since 1986 and several versions exist. In this manual, “SQL-92” refers to the standard released in 1992, “SQL:1999” refers to the standard released in 1999, “SQL:2003” refers to the standard released in 2003, and “SQL:2008” refers to the most recent version of the standard, released in 2008. We use the phrase “the SQL standard” or “standard SQL” to mean the current version of the SQL Standard at any time.
One of our main goals with the product is to continue to work toward compliance with the SQL standard, but without sacrificing speed or reliability. We are not afraid to add extensions to SQL or support for non-SQL features if this greatly increases the usability of MySQL Server for a large segment of our user base. The \texttt{HANDLER} interface is an example of this strategy. See Section 13.2.4, "HANDLER Syntax".

We continue to support transactional and nontransactional databases to satisfy both mission-critical 24/7 usage and heavy Web or logging usage.

MySQL Server was originally designed to work with medium-sized databases (10-100 million rows, or about 100MB per table) on small computer systems. Today MySQL Server handles terabyte-sized databases, but the code can also be compiled in a reduced version suitable for hand-held and embedded devices. The compact design of the MySQL server makes development in both directions possible without any conflicts in the source tree.

Currently, we are not targeting real-time support, although MySQL replication capabilities offer significant functionality.

MySQL supports ODBC levels 0 to 3.51.

MySQL supports high-availability database clustering using the \texttt{NDBCLUSTER} storage engine. See Chapter 18, \textit{MySQL Cluster NDB 7.2}.

We are implementing XML functionality beginning in MySQL 5.1, which supports most of the W3C XPath standard. See Section 12.11, "XML Functions".

### Selecting SQL Modes

The MySQL server can operate in different SQL modes, and can apply these modes differently for different clients, depending on the value of the \texttt{sql_mode} system variable. DBAs can set the global SQL mode to match site server operating requirements, and each application can set its session SQL mode to its own requirements.

Modes affect the SQL syntax MySQL supports and the data validation checks it performs. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers.

For more information on setting the SQL mode, see Section 5.1.7, "Server SQL Modes".

### Running MySQL in ANSI Mode

To run MySQL Server in ANSI mode, start \texttt{mysqld} with the \texttt{--ansi} option. Running the server in ANSI mode is the same as starting it with the following options:

\begin{verbatim}
--transaction-isolation=SERIALIZABLE --sql-mode=ANSI
\end{verbatim}

To achieve the same effect at runtime, execute these two statements:

\begin{verbatim}
SET GLOBAL TRANSACTION ISOLATION LEVEL SERIALIZABLE;
SET GLOBAL sql_mode = 'ANSI';
\end{verbatim}

You can see that setting the \texttt{sql_mode} system variable to \texttt{'ANSI'} enables all SQL mode options that are relevant for ANSI mode as follows:

\begin{verbatim}
mysql> SET GLOBAL sql_mode='ANSI';
m attends SELECT 8@global.sql_mode;
-> 'REAL_AS_FLOAT,PIPES_AS_CONCAT,ANSI_QUOTES,IGNORE_SPACE,ANSI'
\end{verbatim}
MySQL Extensions to Standard SQL

Running the server in ANSI mode with `--ansi` is not quite the same as setting the SQL mode to 'ANSI' because the `--ansi` option also sets the transaction isolation level.

See Section 5.1.3, “Server Command Options”.

1.8.1 MySQL Extensions to Standard SQL

MySQL Server supports some extensions that you probably won’t find in other SQL DBMSs. Be warned that if you use them, your code won’t be portable to other SQL servers. In some cases, you can write code that includes MySQL extensions, but is still portable, by using comments of the following form:

```sql
/*! MySQL-specific code */
```

In this case, MySQL Server parses and executes the code within the comment as it would any other SQL statement, but other SQL servers will ignore the extensions. For example, MySQL Server recognizes the `STRAIGHT_JOIN` keyword in the following statement, but other servers will not:

```sql
SELECT /*! STRAIGHT_JOIN */ col1 FROM table1,table2 WHERE ...
```

If you add a version number after the “!” character, the syntax within the comment is executed only if the MySQL version is greater than or equal to the specified version number. The `TEMPORARY` keyword in the following comment is executed only by servers from MySQL 3.23.02 or higher:

```sql
CREATE /*!32302 TEMPORARY */ TABLE t (a INT);
```

The following descriptions list MySQL extensions, organized by category:

- **Organization of data on disk**
  
  MySQL Server maps each database to a directory under the MySQL data directory, and maps tables within a database to file names in the database directory. This has a few implications:

  - Database and table names are case sensitive in MySQL Server on operating systems that have case-sensitive file names (such as most Unix systems). See Section 9.2.2, “Identifier Case Sensitivity”.

  - You can use standard system commands to back up, rename, move, delete, and copy tables that are managed by the MyISAM storage engine. For example, it is possible to rename a MyISAM table by renaming the `.MYD`, `.MYI`, and `.frm` files to which the table corresponds. (Nevertheless, it is preferable to use `RENAME TABLE` or `ALTER TABLE ... RENAME` and let the server rename the files.)

- **General language syntax**

  - By default, strings can be enclosed by either "" or ' ', not just by "". (If the ANSI_QUOTES SQL mode is enabled, strings can be enclosed only by "" and the server interprets strings enclosed by "" as identifiers.)

  - "\" is the escape character in strings.

  - In SQL statements, you can access tables from different databases with the `db_name.tbl_name` syntax. Some SQL servers provide the same functionality but call this User space. MySQL Server doesn't support tablespaces such as used in statements like this: `CREATE TABLE ralph.my_table ... IN my_tablespace`.

- **SQL statement syntax**
• The **ANALYZE TABLE**, **CHECK TABLE**, **OPTIMIZE TABLE**, and **REPAIR TABLE** statements.

• The **CREATE DATABASE**, **DROP DATABASE**, and **ALTER DATABASE** statements. See Section 13.1.10, "CREATE DATABASE Syntax", Section 13.1.21, "DROP DATABASE Syntax", and Section 13.1.1, "ALTER DATABASE Syntax".

• The **DO** statement.

• **EXPLAIN SELECT** to obtain a description of how tables are processed by the query optimizer.

• The **FLUSH** and **RESET** statements.

• The **SET** statement. See Section 13.7.4, "SET Syntax".

• The **SHOW** statement. See Section 13.7.5, "SHOW Syntax". The information produced by many of the MySQL-specific **SHOW** statements can be obtained in more standard fashion by using **SELECT** to query **INFORMATION_SCHEMA**. See Chapter 21, **INFORMATION_SCHEMA Tables**.

• Use of **LOAD DATA INFILE**. In many cases, this syntax is compatible with Oracle’s **LOAD DATA INFILE**. See Section 13.2.6, "LOAD DATA INFILE Syntax".

• Use of **RENAME TABLE**. See Section 13.1.32, "RENAME TABLE Syntax".

• Use of **REPLACE** instead of **DELETE** plus **INSERT**. See Section 13.2.8, "REPLACE Syntax".

• Use of **CHANGE col_name**, **DROP col_name**, or **DROP INDEX**, **IGNORE** or **RENAME** in **ALTER TABLE** statements. Use of multiple **ADD**, **ALTER**, **DROP**, or **CHANGE** clauses in an **ALTER TABLE** statement. See Section 13.1.7, "ALTER TABLE Syntax".

• Use of index names, indexes on a prefix of a column, and use of **INDEX** or **KEY** in **CREATE TABLE** statements. See Section 13.1.17, "CREATE TABLE Syntax".

• Use of **TEMPORARY** or **IF NOT EXISTS** with **CREATE TABLE**.

• Use of **IF EXISTS** with **DROP TABLE** and **DROP DATABASE**.

• The capability of dropping multiple tables with a single **DROP TABLE** statement.

• The **ORDER BY** and **LIMIT** clauses of the **UPDATE** and **DELETE** statements.

• **INSERT INTO tbl_name SET col_name = ...** syntax.

• The **DELAYED** clause of the **INSERT** and **REPLACE** statements.

• The **LOW_PRIORITY** clause of the **INSERT, REPLACE, DELETE, and UPDATE** statements.

• Use of **INTO OUTFILE** or **INTO DUMPFILE** in **SELECT** statements. See Section 13.2.9, "SELECT Syntax".

• Options such as **STRAIGHT_JOIN** or **SQL_SMALL_RESULT** in **SELECT** statements.

• You don’t need to name all selected columns in the **GROUP BY** clause. This gives better performance for some very specific, but quite normal queries. See Section 12.16, “Functions and Modifiers for Use with **GROUP BY** Clauses”.

• You can specify **ASC** and **DESC** with **GROUP BY**, not just with **ORDER BY**.
MySQL Extensions to Standard SQL

- The ability to set variables in a statement with the := assignment operator. See Section 9.4, “User-Defined Variables”.

- Data types
  - The MEDIUMINT, SET, and ENUM data types, and the various BLOB and TEXT data types.
  - The AUTO_INCREMENT, BINARY, NULL, UNSIGNED, and ZEROFILL data type attributes.

- Functions and operators
  - To make it easier for users who migrate from other SQL environments, MySQL Server supports aliases for many functions. For example, all string functions support both standard SQL syntax and ODBC syntax.
  - MySQL Server understands the || and && operators to mean logical OR and AND, as in the C programming language. In MySQL Server, || and OR are synonyms, as are && and AND. Because of this nice syntax, MySQL Server doesn’t support the standard SQL || operator for string concatenation; use CONCAT() instead. Because CONCAT() takes any number of arguments, it is easy to convert use of the || operator to MySQL Server.
  - The COUNT(DISTINCT value_list) where value_list has more than one element.
  - String comparisons are case-insensitive by default, with sort ordering determined by the collation of the current character set, which is latin1 (cp1252 West European) by default. If you don’t like this, you should declare your columns with the BINARY attribute or use the BINARY cast, which causes comparisons to be done using the underlying character code values rather than a lexical ordering.
  - The % operator is a synonym for MOD(). That is, $N \% M$ is equivalent to $\text{MOD}(N, M)$. % is supported for C programmers and for compatibility with PostgreSQL.
  - The =, <>, <=, >=, >, <=>, AND, OR, or LIKE operators may be used in expressions in the output column list (to the left of the FROM) in SELECT statements. For example:

    ```sql
    mysql> SELECT col1=1 AND col2=2 FROM my_table;
    ```

  - The LAST_INSERT_ID() function returns the most recent AUTO_INCREMENT value. See Section 12.14, “Information Functions”.

  - LIKE is permitted on numeric values.

  - The REGEXP and NOT REGEXP extended regular expression operators.

  - CONCAT() or CHAR() with one argument or more than two arguments. (In MySQL Server, these functions can take a variable number of arguments.)

  - The BIT_COUNT(), CASE, ELT(), FROM_DAYS(), FORMAT(), IF(), PASSWORD(), ENCRYPT(), MD5(), ENCODE(), DECODE(), PERIOD_ADD(), PERIOD_DIFF(), TO_DAYS(), and WEEKDAY() functions.

  - Use of TRIM() to trim substrings. Standard SQL supports removal of single characters only.

  - The GROUP BY functions STD(), BIT_OR(), BIT_AND(), BIT_XOR(), and GROUP_CONCAT(). See Section 12.16, “Functions and Modifiers for Use with GROUP BY Clauses”.
1.8.2 MySQL Differences from Standard SQL

We try to make MySQL Server follow the ANSI SQL standard and the ODBC SQL standard, but MySQL Server performs operations differently in some cases:

- There are several differences between the MySQL and standard SQL privilege systems. For example, in MySQL, privileges for a table are not automatically revoked when you delete a table. You must explicitly issue a `REVOKE` statement to revoke privileges for a table. For more information, see Section 13.7.1.5, "REVOKE Syntax".

- The `CAST()` function does not support cast to `REAL` or `BIGINT`. See Section 12.10, “Cast Functions and Operators”.

1.8.2.1 SELECT INTO TABLE Differences

MySQL Server doesn’t support the `SELECT ... INTO TABLE` Sybase SQL extension. Instead, MySQL Server supports the `INSERT INTO ... SELECT` standard SQL syntax, which is basically the same thing. See Section 13.2.5.1, “INSERT ... SELECT Syntax”. For example:

```sql
INSERT INTO tbl_temp2 (fld_id)
SELECT tbl_temp1.fld_order_id
FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

Alternatively, you can use `SELECT ... INTO OUTFILE` or `CREATE TABLE ... SELECT`.

You can use `SELECT ... INTO` with user-defined variables. The same syntax can also be used inside stored routines using cursors and local variables. See Section 13.2.9.1, “SELECT ... INTO Syntax”.

1.8.2.2 UPDATE Differences

If you access a column from the table to be updated in an expression, `UPDATE` uses the current value of the column. The second assignment in the following statement sets `col2` to the current (updated) `col1` value, not the original `col1` value. The result is that `col1` and `col2` have the same value. This behavior differs from standard SQL.

```sql
UPDATE t1 SET col1 = col1 + 1, col2 = col1;
```

1.8.2.3 Transaction and Atomic Operation Differences

MySQL Server (version 3.23-max and all versions 4.0 and above) supports transactions with the InnoDB transactional storage engine. InnoDB provides full ACID compliance. See Chapter 15, Alternative Storage Engines. For information about InnoDB differences from standard SQL with regard to treatment of transaction errors, see Section 14.21.4, “InnoDB Error Handling”.

The other nontransactional storage engines in MySQL Server (such as MyISAM) follow a different paradigm for data integrity called “atomic operations.” In transactional terms, MyISAM tables effectively always operate in `autocommit = 1` mode. Atomic operations often offer comparable integrity with higher performance.

Because MySQL Server supports both paradigms, you can decide whether your applications are best served by the speed of atomic operations or the use of transactional features. This choice can be made on a per-table basis.

As noted, the tradeoff for transactional versus nontransactional storage engines lies mostly in performance. Transactional tables have significantly higher memory and disk space requirements, and more CPU overhead. On the other hand, transactional storage engines such as InnoDB also offer many significant
features. MySQL Server’s modular design enables the concurrent use of different storage engines to suit different requirements and deliver optimum performance in all situations.

Workarounds for Reliability with Non-Transactional Tables

But how do you use the features of MySQL Server to maintain integrity even with the nontransactional MyISAM tables, and how do these features compare with the transactional storage engines?

• If your applications are written in a way that is dependent on being able to call ROLLBACK rather than COMMIT in critical situations, transactions are more convenient. Transactions also ensure that unfinished updates or corrupting activities are not committed to the database; the server is given the opportunity to do an automatic rollback and your database is saved.

If you use nontransactional tables, you must resolve potential problems at the application level by including simple checks before updates and by running simple scripts that check the databases for inconsistencies and automatically repair or warn if such an inconsistency occurs. You can normally fix tables perfectly with no data integrity loss just by using the MySQL log or even adding one extra log.

• More often than not, critical transactional updates can be rewritten to be atomic. Generally speaking, all integrity problems that transactions solve can be done with LOCK TABLES or atomic updates, ensuring that there are no automatic aborts from the server, which is a common problem with transactional database systems.

• To be safe with MySQL Server, regardless of what kinds of tables you use, make regular backups and have binary logging turned on. It is always good to have backups, regardless of which database system you use.

The transactional paradigm has its advantages and disadvantages. Many users and application developers depend on the ease with which they can code around problems where an abort appears to be necessary, or is necessary. However, even if you are new to the atomic operations paradigm, or more familiar with transactions, do consider the speed benefit that nontransactional tables can offer on the order of three to five times the speed of the fastest and most optimally tuned transactional tables.

In situations where integrity is of highest importance, MySQL Server offers transaction-level reliability and integrity even for nontransactional tables. If you lock tables with LOCK TABLES, all updates stall until integrity checks are made. If you obtain a READ LOCAL lock (as opposed to a write lock) for a table that enables concurrent inserts at the end of the table, reads are permitted, as are inserts by other clients. The newly inserted records are not be seen by the client that has the read lock until it releases the lock. With INSERT DELAYED, you can write inserts that go into a local queue until the locks are released, without having the client wait for the insert to complete. See Section 8.10.3, “Concurrent Inserts”, and Section 13.2.5.2, “INSERT DELAYED Syntax”.

“Atomic,” in the sense that we mean it, is nothing magical. It only means that you can be sure that while each specific update is running, no other user can interfere with it, and there can never be an automatic rollback (which can happen with transactional tables if you are not very careful). MySQL Server also guarantees that there are no dirty reads.

Following are some techniques for working with nontransactional tables:

• Loops that need transactions normally can be coded with the help of LOCK TABLES, and you don't need cursors to update records on the fly.

• To avoid using ROLLBACK, you can employ the following strategy:
  1. Use LOCK TABLES to lock all the tables you want to access.
  2. Test the conditions that must be true before performing the update.
3. Update if the conditions are satisfied.
4. Use `UNLOCK TABLES` to release your locks.

**Note**

This solution does not handle the situation when someone kills the threads in the middle of an update. In that case, all locks are released but some of the updates may not have been executed.

- You can also use functions to update records in a single operation, using the following techniques:
  - Modify columns relative to their current value. This makes the update correct even if another client has changed the column values in the meantime.
  - Update only those columns that actually have changed. This is a good database practice in general.
  - When managing unique identifiers, you can avoid statements such as `LOCK TABLES` or `ROLLBACK` by using an `AUTO_INCREMENT` column and either the `LAST_INSERT_ID()` SQL function or the `mysql_insert_id()` C API function. See Section 12.14, “Information Functions”, and Section 23.8.7.37, “mysql_insert_id()”.

For situations that require row-level locking, use InnoDB tables. Otherwise, with MyISAM tables, you can use a flag column in the table and do something like the following:

```sql
UPDATE tbl_name SET row_flag=1 WHERE id=ID;
```

MySQL returns 1 for the number of affected rows if the row was found and `row_flag` wasn’t 1 in the original row. You can think of this as though MySQL Server changed the preceding statement to:

```sql
UPDATE tbl_name SET row_flag=1 WHERE id=ID AND row_flag <> 1;
```

### 1.8.2.4 Foreign Key Differences

The InnoDB storage engine supports checking of foreign key constraints, including `CASCADE`, `ON DELETE`, and `ON UPDATE`. See Section 14.9.6, “InnoDB and FOREIGN KEY Constraints”.

For storage engines other than InnoDB, MySQL Server parses the `FOREIGN KEY` syntax in `CREATE TABLE` statements, but does not use or store it. This information is also present in `mysqldump`, and can be retrieved using Connector/ODBC. You can see which tables have foreign key constraints by checking the `INFORMATION_SCHEMA.TABLE_CONSTRAINTS` table in the `INFORMATION_SCHEMA` information database. You can obtain more detailed information about foreign keys from the `INFORMATION_SCHEMA.REFERENTIAL_CONSTRAINTS` table.

Foreign key enforcement offers several benefits to database developers:

- Assuming proper design of the relationships, foreign key constraints make it more difficult for a programmer to introduce an inconsistency into the database.
- Centralized checking of constraints by the database server makes it unnecessary to perform these checks on the application side. This eliminates the possibility that different applications may not all check the constraints in the same way.
- Using cascading updates and deletes can simplify the application code.
- Properly designed foreign key rules aid in documenting relationships between tables.
Foreign keys in SQL are used to check and enforce referential integrity, not to join tables. If you want to get results from multiple tables from a `SELECT` statement, you do this by performing a join between them:

```sql
SELECT * FROM t1 INNER JOIN t2 ON t1.id = t2.id;
```

See Section 13.2.9.2, “`JOIN` Syntax”, and Section 3.6.6, “Using Foreign Keys”.

The `FOREIGN KEY` syntax without `ON DELETE` ... is often used by ODBC applications to produce automatic `WHERE` clauses.

### 1.8.2.5 '--' as the Start of a Comment

Standard SQL uses the C syntax `/* this is a comment */` for comments, and MySQL Server supports this syntax as well. MySQL also support extensions to this syntax that enable MySQL-specific SQL to be embedded in the comment, as described in Section 9.6, “Comment Syntax”.

Standard SQL uses “--” as a start-comment sequence. MySQL Server uses “#” as the start comment character. MySQL Server 3.23.3 and up also supports a variant of the “--” comment style. That is, the “--” start-comment sequence must be followed by a space (or by a control character such as a newline). The space is required to prevent problems with automatically generated SQL queries that use constructs such as the following, where we automatically insert the value of the payment for `payment`:

```sql
UPDATE account SET credit = credit - payment
```

Consider about what happens if `payment` has a negative value such as `-1`:

```sql
UPDATE account SET credit = credit -- 1
```

`credit--1` is a valid expression in SQL, but “--” is interpreted as the start of a comment, part of the expression is discarded. The result is a statement that has a completely different meaning than intended:

```sql
UPDATE account SET credit = credit
```

The statement produces no change in value at all. This illustrates that permitting comments to start with “--” can have serious consequences.

Using our implementation requires a space following the “--” for it to be recognized as a start-comment sequence in MySQL Server 3.23.3 and newer. Therefore, `credit--1` is safe to use.

Another safe feature is that the `mysql` command-line client ignores lines that start with “--”.

The following information is relevant only if you are running a MySQL version earlier than 3.23.3:

If you have an SQL script in a text file that contains “--” comments, you should use the `replace` utility as follows to convert the comments to use “#” characters before executing the script:

```bash
shell> replace " -- " " # " < text-file-with-funny-comments.sql \ | mysql db_name
```

That is safer than executing the script in the usual way:

```bash
shell> mysql db_name < text-file-with-funny-comments.sql
```

You can also edit the script file “in place” to change the “--” comments to “#” comments:
1.8.3 How MySQL Deals with Constraints

MySQL enables you to work both with transactional tables that permit rollback and with nontransactional tables that do not. Because of this, constraint handling is a bit different in MySQL than in other DBMSs. We must handle the case when you have inserted or updated a lot of rows in a nontransactional table for which changes cannot be rolled back when an error occurs.

The basic philosophy is that MySQL Server tries to produce an error for anything that it can detect while parsing a statement to be executed, and tries to recover from any errors that occur while executing the statement. We do this in most cases, but not yet for all.

The options MySQL has when an error occurs are to stop the statement in the middle or to recover as well as possible from the problem and continue. By default, the server follows the latter course. This means, for example, that the server may coerce invalid values to the closest valid values.

Several SQL mode options are available to provide greater control over handling of bad data values and whether to continue statement execution or abort when errors occur. Using these options, you can configure MySQL Server to act in a more traditional fashion that is like other DBMSs that reject improper input. The SQL mode can be set globally at server startup to affect all clients. Individual clients can set the SQL mode at runtime, which enables each client to select the behavior most appropriate for its requirements. See Section 5.1.7, "Server SQL Modes".

The following sections describe how MySQL Server handles different types of constraints.

1.8.3.1 PRIMARY KEY and UNIQUE Index Constraints

Normally, errors occur for data-change statements (such as INSERT or UPDATE) that would violate primary-key, unique-key, or foreign-key constraints. If you are using a transactional storage engine such as InnoDB, MySQL automatically rolls back the statement. If you are using a nontransactional storage engine, MySQL stops processing the statement at the row for which the error occurred and leaves any remaining rows unprocessed.

MySQL supports an IGNORE keyword for INSERT, UPDATE, and so forth. If you use it, MySQL ignores primary-key or unique-key violations and continues processing with the next row. See the section for the statement that you are using (Section 13.2.5, "INSERT Syntax", Section 13.2.11, "UPDATE Syntax", and so forth).

You can get information about the number of rows actually inserted or updated with the mysql_info() C API function. You can also use the SHOW WARNINGS statement. See Section 23.8.7.35, "mysql_info()"), and Section 13.7.5.41, "SHOW WARNINGS Syntax".

Currently, only InnoDB tables support foreign keys. See Section 14.9.6, "InnoDB and FOREIGN KEY Constraints".

1.8.3.2 FOREIGN KEY Constraints

Foreign keys let you cross-reference related data across tables, and foreign key constraints help keep this spread-out data consistent.
MySQL supports **ON UPDATE** and **ON DELETE** foreign key references in **CREATE TABLE** and **ALTER TABLE** statements. The available referential actions are **RESTRICT** (the default), **CASCADE**, **SET NULL**, and **NO ACTION**.

**SET DEFAULT** is also supported by the MySQL Server but is currently rejected as invalid by **InnoDB**. Since MySQL does not support deferred constraint checking, **NO ACTION** is treated as **RESTRICT**. For the exact syntax supported by MySQL for foreign keys, see Section 13.1.17.2, “Using **FOREIGN KEY** Constraints”.

**MATCH FULL**, **MATCH PARTIAL**, and **MATCH SIMPLE** are allowed, but their use should be avoided, as they cause the MySQL Server to ignore any **ON DELETE** or **ON UPDATE** clause used in the same statement. **MATCH options do not have any other effect in MySQL, which in effect enforces MATCH SIMPLE semantics full-time.**

MySQL requires that foreign key columns be indexed; if you create a table with a foreign key constraint but no index on a given column, an index is created.

You can obtain information about foreign keys from the **INFORMATION_SCHEMA.KEY_COLUMN_USAGE** table. An example of a query against this table is shown here:

```sql
mysql> SELECT TABLE_SCHEMA, TABLE_NAME, COLUMN_NAME, CONSTRAINT_NAME
    > FROM INFORMATION_SCHEMA.KEY_COLUMN_USAGE
    > WHERE REFERENCED_TABLE_SCHEMA IS NOT NULL;
```

<table>
<thead>
<tr>
<th>TABLE_SCHEMA</th>
<th>TABLE_NAME</th>
<th>COLUMN_NAME</th>
<th>CONSTRAINT_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>fk1</td>
<td>myuser</td>
<td>myuser_id</td>
<td>f</td>
</tr>
<tr>
<td>fk1</td>
<td>product_order</td>
<td>customer_id</td>
<td>f2</td>
</tr>
<tr>
<td>fk1</td>
<td>product_order</td>
<td>product_id</td>
<td>f1</td>
</tr>
</tbody>
</table>

3 rows in set (0.01 sec)

Information about foreign keys on **InnoDB** tables can also be found in the **INNODB_SYS_FOREIGN** and **INNODB_SYS_FOREIGN_COLS** tables, in the **INFORMATION_SCHEMA** database.

Currently, only **InnoDB** tables support foreign keys. See Section 14.9.6, “**InnoDB** and **FOREIGN KEY** Constraints”, for information specific to foreign key support in **InnoDB**.

**Deviations from SQL Standards**

MySQL's implementation of foreign keys differs from the SQL standard in the following key respects:

- If there are several rows in the parent table that have the same referenced key value, **InnoDB** acts in foreign key checks as if the other parent rows with the same key value do not exist. For example, if you have defined a **RESTRICT** type constraint, and there is a child row with several parent rows, **InnoDB** does not permit the deletion of any of those parent rows.

  **InnoDB** performs cascading operations through a depth-first algorithm, based on records in the indexes corresponding to the foreign key constraints.

- A **FOREIGN KEY** constraint that references a non-**UNIQUE** key is not standard SQL but rather an **InnoDB** extension.

- If **ON UPDATE CASCADE** or **ON UPDATE SET NULL** recurses to update the **same table** it has previously updated during the same cascade, it acts like **RESTRICT**. This means that you cannot use self-referential **ON UPDATE CASCADE** or **ON UPDATE SET NULL** operations. This is to prevent infinite loops resulting from cascaded updates. A self-referential **ON DELETE SET NULL**, on the other hand, is possible, as is a self-referential **ON DELETE CASCADE**. Cascading operations may not be nested more than 15 levels deep.
How MySQL Deals with Constraints

• In an SQL statement that inserts, deletes, or updates many rows, foreign key constraints (like unique constraints) are checked row-by-row. When performing foreign key checks, InnoDB sets shared row-level locks on child or parent records that it must examine. MySQL checks foreign key constraints immediately; the check is not deferred to transaction commit. According to the SQL standard, the default behavior should be deferred checking. That is, constraints are only checked after the entire SQL statement has been processed. This means that it is not possible to delete a row that refers to itself using a foreign key.

For information how InnoDB foreign keys differ from the SQL standard, see Section 14.9.6, “InnoDB and FOREIGN KEY Constraints”.

1.8.3.3 Constraints on Invalid Data

By default, MySQL is forgiving of invalid or improper data values and coerces them to valid values for data entry. However, you can enable strict SQL mode to select more traditional treatment of bad values such that the server rejects them and aborts the statement in which they occur. See Section 5.1.7, “Server SQL Modes”.

This section describes the default (forgiving) behavior of MySQL, as well as the strict SQL mode and how it differs.

If you are not using strict mode, then whenever you insert an “incorrect” value into a column, such as a NULL into a NOT NULL column or a too-large numeric value into a numeric column, MySQL sets the column to the “best possible value” instead of producing an error: The following rules describe in more detail how this works:

• If you try to store an out of range value into a numeric column, MySQL Server instead stores zero, the smallest possible value, or the largest possible value, whichever is closest to the invalid value.

• For strings, MySQL stores either the empty string or as much of the string as can be stored in the column.

• If you try to store a string that does not start with a number into a numeric column, MySQL Server stores 0.

• Invalid values for ENUM and SET columns are handled as described in Section 1.8.3.4, “ENUM and SET Constraints”.

• MySQL permits you to store certain incorrect date values into DATE and DATETIME columns (such as ‘2000-02-31’ or ‘2000-02-00’). In this case, when an application that has not enabled strict SQL mode, it up to the application to validate the dates before storing them. If MySQL can store a date value and retrieve exactly the same value, MySQL stores it as given. If the date is totally wrong (outside the server's ability to store it), the special “zero” date value '0000-00-00' is stored in the column instead.

• If you try to store NULL into a column that doesn't take NULL values, an error occurs for single-row INSERT statements. For multiple-row INSERT statements or for INSERT INTO ... SELECT statements, MySQL Server stores the implicit default value for the column data type. In general, this is 0 for numeric types, the empty string ("") for string types, and the “zero” value for date and time types. Implicit default values are discussed in Section 11.6, “Data Type Default Values”.

• If an INSERT statement specifies no value for a column, MySQL inserts its default value if the column definition includes an explicit DEFAULT clause. If the definition has no such DEFAULT clause, MySQL inserts the implicit default value for the column data type.

The reason for using the preceding rules in nonstrict mode is that we can't check these conditions until the statement has begun executing. We can't just roll back if we encounter a problem after updating a few
rows, because the storage engine may not support rollback. The option of terminating the statement is not that good; in this case, the update would be “half done,” which is probably the worst possible scenario. In this case, it is better to “do the best you can” and then continue as if nothing happened.

In MySQL 5.0.2 and up, you can select stricter treatment of input values by using the `STRICT_TRANS_TABLES` or `STRICT_ALL_TABLES` SQL modes:

```
SET sql_mode = 'STRICT_TRANS_TABLES';
SET sql_mode = 'STRICT_ALL_TABLES';
```

`STRICT_TRANS_TABLES` enables strict mode for transactional storage engines, and also to some extent for nontransactional engines. It works like this:

- For transactional storage engines, bad data values occurring anywhere in a statement cause the statement to abort and roll back.

- For nontransactional storage engines, a statement aborts if the error occurs in the first row to be inserted or updated. (When the error occurs in the first row, the statement can be aborted to leave the table unchanged, just as for a transactional table.) Errors in rows after the first do not abort the statement, because the table has already been changed by the first row. Instead, bad data values are adjusted and result in warnings rather than errors. In other words, with `STRICT_TRANS_TABLES`, a wrong value causes MySQL to roll back all updates done so far, if that can be done without changing the table. But once the table has been changed, further errors result in adjustments and warnings.

For even stricter checking, enable `STRICT_ALL_TABLES`. This is the same as `STRICT_TRANS_TABLES` except that for nontransactional storage engines, errors abort the statement even for bad data in rows following the first row. This means that if an error occurs partway through a multiple-row insert or update for a nontransactional table, a partial update results. Earlier rows are inserted or updated, but those from the point of the error on are not. To avoid this for nontransactional tables, either use single-row statements or else use `STRICT_TRANS_TABLES` if conversion warnings rather than errors are acceptable. To avoid problems in the first place, do not use MySQL to check column content. It is safest (and often faster) to let the application ensure that it passes only valid values to the database.

With either of the strict mode options, you can cause errors to be treated as warnings by using `INSERT IGNORE` or `UPDATE IGNORE` rather than `INSERT` or `UPDATE` without `IGNORE`.

### 1.8.3.4 `ENUM` and `SET` Constraints

`ENUM` and `SET` columns provide an efficient way to define columns that can contain only a given set of values. See Section 11.4.4, “The `ENUM` Type”, and Section 11.4.5, “The `SET` Type”. However, before MySQL 5.0.2, `ENUM` and `SET` columns do not provide true constraints on entry of invalid data:

- `ENUM` columns always have a default value. If you specify no default value, then it is `NULL` for columns that can have `NULL`, otherwise it is the first enumeration value in the column definition.

- If you insert an incorrect value into an `ENUM` column or if you force a value into an `ENUM` column with `IGNORE`, it is set to the reserved enumeration value of `0`, which is displayed as an empty string in string context.

- If you insert an incorrect value into a `SET` column, the incorrect value is ignored. For example, if the column can contain the values `'a'`, `'b'`, and `'c'`, an attempt to assign `'a, x, b, y'` results in a value of `'a, b'`.

As of MySQL 5.0.2, you can configure the server to use strict SQL mode. See Section 5.1.7, “Server SQL Modes”. With strict mode enabled, the definition of a `ENUM` or `SET` column does act as a constraint on values entered into the column. An error occurs for values that do not satisfy these conditions:
• An **ENUM** value must be one of those listed in the column definition, or the internal numeric equivalent thereof. The value cannot be the error value (that is, 0 or the empty string). For a column defined as `ENUM('a','b','c')`, values such as `' '`, `'d'`, or `'ax'` are invalid and are rejected.

• A **SET** value must be the empty string or a value consisting only of the values listed in the column definition separated by commas. For a column defined as `SET('a','b','c')`, values such as `'d'` or `'a,b,c,d'` are invalid and are rejected.

Errors for invalid values can be suppressed in strict mode if you use **INSERT IGNORE** or **UPDATE IGNORE**. In this case, a warning is generated rather than an error. For **ENUM**, the value is inserted as the error member (0). For **SET**, the value is inserted as given except that any invalid substrings are deleted. For example, `'a,x,b,y'` results in a value of `'a,b'`.

### 1.9 Credits

The following sections list developers, contributors, and supporters that have helped to make MySQL what it is today.

#### 1.9.1 Contributors to MySQL

Although Oracle Corporation and/or its affiliates own all copyrights in the MySQL server and the MySQL manual, we wish to recognize those who have made contributions of one kind or another to the MySQL distribution. Contributors are listed here, in somewhat random order:

• **Gianmassimo Vigazzola** `<qwerg@mbox.vol.it>` or `<qwerg@tin.it>`
  
  The initial port to Win32/NT.

• **Per Eric Olsson**
  
  For constructive criticism and real testing of the dynamic record format.

• **Irena Pancirov** `<irena@mail.yacc.it>`
  
  Win32 port with Borland compiler. `mysqlshutdown.exe` and `mysqlwatch.exe`.

• **David J. Hughes**
  
  For the effort to make a shareware SQL database. At TcX, the predecessor of MySQL AB, we started with mSQL, but found that it couldn't satisfy our purposes so instead we wrote an SQL interface to our application builder Unireg. `mysqladmin` and `mysql` client are programs that were largely influenced by their mSQL counterparts. We have put a lot of effort into making the MySQL syntax a superset of mSQL. Many of the API's ideas are borrowed from mSQL to make it easy to port free mSQL programs to the MySQL API. The MySQL software doesn't contain any code from mSQL. Two files in the distribution (`client/insert_test.c` and `client/select_test.c`) are based on the corresponding (noncopyrighted) files in the mSQL distribution, but are modified as examples showing the changes necessary to convert code from mSQL to MySQL Server. (mSQL is copyrighted David J. Hughes.)

• **Patrick Lynch**
  
  For helping us acquire http://www.mysql.com/.

• **Fred Lindberg**
  
  For setting up qmail to handle the MySQL mailing list and for the incredible help we got in managing the MySQL mailing lists.
Contributors to MySQL

- Igor Romanenko <igor@frog.kiev.ua>
  mysqldump (previously msqldump, but ported and enhanced by Monty).
- Yuri Dario
  For keeping up and extending the MySQL OS/2 port.
- Tim Bunce
  Author of mysqlhotcopy.
- Zarko Mocnik <zarko.mocnik@dem.si>
  Sorting for Slovenian language.
- "TAMITO" <tommy@valley.ne.jp>
  The _MB character set macros and the ujis and sjis character sets.
- Joshua Chamas <joshua@chamas.com>
  Base for concurrent insert, extended date syntax, debugging on NT, and answering on the MySQL mailing list.
- Yves Carlier <Yves.Carlier@rug.ac.be>
  mysqlaccess, a program to show the access rights for a user.
- Rhys Jones <rhys@wales.com> (And GWE Technologies Limited)
  For one of the early JDBC drivers.
- Dr Xiaokun Kelvin ZHU <X.Zhu@brad.ac.uk>
  Further development of one of the early JDBC drivers and other MySQL-related Java tools.
- James Cooper <pixel@organic.com>
  For setting up a searchable mailing list archive at his site.
- Rick Mehalick <Rick_Mehalick@i-o.com>
  For xmysql, a graphical X client for MySQL Server.
- Doug Sisk <sisk@wix.com>
  For providing RPM packages of MySQL for Red Hat Linux.
- Diemand Alexander V. <axeld@vial.ethz.ch>
  For providing RPM packages of MySQL for Red Hat Linux-Alpha.
- Antoni Pamies Olive <toni@readysoft.es>
  For providing RPM versions of a lot of MySQL clients for Intel and SPARC.
- Jay Bloodworth <jay@pathways.sde.state.sc.us>
  For providing RPM versions for MySQL 3.21.
• David Sacerdote <davids@secnet.com>
  Ideas for secure checking of DNS host names.
• Wei-Jou Chen <jou@nematic.ieo.nctu.edu.tw>
  Some support for Chinese(BIG5) characters.
• Wei He <hewei@mail.ied.ac.cn>
  A lot of functionality for the Chinese(GBK) character set.
• Jan Pazdziora <adelton@fi.muni.cz>
  Czech sorting order.
• Zeev Suraski <bourbon@netvision.net.il>
  `FROM_UNIXTIME()` time formatting, `ENCRYPT()` functions, and `bison` advisor. Active mailing list member.
• Luuk de Boer <luuk@wxs.nl>
  Ported (and extended) the benchmark suite to `DBI/DBD`. Have been of great help with `crash-me` and running benchmarks. Some new date functions. The `mysql_setpermission` script.
• Alexis Mikhailov <root@medinf.chuvashia.su>
  User-defined functions (UDFs); `CREATE FUNCTION` and `DROP FUNCTION`.
• Andreas F. Bobak <bobak@relog.ch>
  The `AGGREGATE` extension to user-defined functions.
• Ross Wakelin <R.Wakelin@march.co.uk>
  Help to set up InstallShield for MySQL-Win32.
• Jethro Wright III <jetman@li.net>
  The `libmysql.dll` library.
• James Pereria <jpereira@iafrica.com>
  Mysqlmanager, a Win32 GUI tool for administering MySQL Servers.
• Curt Sampson <cjs@portal.ca>
  Porting of MIT-pthreads to NetBSD/Alpha and NetBSD 1.3/i386.
• Martin Ramsch <m.ramsch@computer.org>
  Examples in the MySQL Tutorial.
• Steve Harvey
  For making `mysqlaccess` more secure.
• Konark IA-64 Centre of Persistent Systems Private Limited
Contributors to MySQL

Help with the Win64 port of the MySQL server.

• Albert Chin-A-Young.
  Configure updates for Tru64, large file support and better TCP wrappers support.

• John Birrell
  Emulation of `pthread_mutex()` for OS/2.

• Benjamin Pflugmann
  Extended `MERGE` tables to handle `INSERTS`. Active member on the MySQL mailing lists.

• Jocelyn Fournier
  Excellent spotting and reporting innumerable bugs (especially in the MySQL 4.1 subquery code).

• Marc Liyanage
  Maintaining the Mac OS X packages and providing invaluable feedback on how to create Mac OS X packages.

• Robert Rutherford
  Providing invaluable information and feedback about the QNX port.

• Previous developers of NDB Cluster
  Lots of people were involved in various ways summer students, master thesis students, employees. In total more than 100 people so too many to mention here. Notable name is Ataullah Dabaghi who up until 1999 contributed around a third of the code base. A special thanks also to developers of the AXE system which provided much of the architectural foundations for NDB Cluster with blocks, signals and crash tracing functionality. Also credit should be given to those who believed in the ideas enough to allocate of their budgets for its development from 1992 to present time.

• Google Inc.
  We wish to recognize Google Inc. for contributions to the MySQL distribution: Mark Callaghan's SMP Performance patches and other patches.

Other contributors, bugfinders, and testers: James H. Thompson, Maurizio Menghini, Wojciech Tryc, Luca Berra, Zarko Mocnik, Wim Bonis, Elmar Haneke, <jehamby@lightside>, <psmith@BayNetworks.com>, <duane@connect.com.au>, Ted Deppner <ted@psyber.com>, Mike Simons, Jaakko Hyvatti.

And lots of bug report/patches from the folks on the mailing list.

A big tribute goes to those that help us answer questions on the MySQL mailing lists:

• Daniel Koch <dkoch@amcity.com>
  Irix setup.

• Luuk de Boer <luuk@wxs.nl>
  Benchmark questions.
• Tim Sailer <tps@users.buoy.com>  
**DBD::mysql** questions.

• Boyd Lynn Gerber <gerberb@zenez.com>  
SCO-related questions.

• Richard Mehalick <RM186061@shellus.com>  
xmysql-related questions and basic installation questions.

• Zeev Suraski <bourbon@netvision.net.il>  
Apache module configuration questions (log & auth), PHP-related questions, SQL syntax-related questions and other general questions.

• Francesc Guasch <frankie@citel.upc.es>  
General questions.

• Jonathan J Smith <jsmith@wtp.net>  
Questions pertaining to OS-specifcs with Linux, SQL syntax, and other things that might need some work.

• David Sklar <sklar@student.net>  
Using MySQL from PHP and Perl.

• Alistair MacDonald <A.MacDonald@uel.ac.uk>  
Is flexible and can handle Linux and perhaps HP-UX.

• John Lyon <jlyon@imag.net>  
Questions about installing MySQL on Linux systems, using either .rpm files or compiling from source.

• Lorvid Ltd. <lorvid@WOLFENET.com>  
Simple billing/license/support/copyright issues.

• Patrick Sherrill <patrick@coconet.com>  
ODBC and VisualC++ interface questions.

• Randy Harmon <rjharmon@uptimecomputers.com>  
**DBD**, Linux, some SQL syntax questions.

### 1.9.2 Documenters and translators

The following people have helped us with writing the MySQL documentation and translating the documentation or error messages in MySQL.

• Paul DuBois  
Ongoing help with making this manual correct and understandable. That includes rewriting Monty’s and David’s attempts at English into English as other people know it.
• Kim Aldale
  Helped to rewrite Monty’s and David’s early attempts at English into English.

• Michael J. Miller Jr. <mke@terrapin.turbolift.com>
  For the first MySQL manual. And a lot of spelling/language fixes for the FAQ (that turned into the MySQL manual a long time ago).

• Yan Cailin
  First translator of the MySQL Reference Manual into simplified Chinese in early 2000 on which the Big5 and HK coded versions were based.

• Jay Flaherty <fty@mediapulse.com>
  Big parts of the Perl DBI/DBD section in the manual.

• Paul Southworth <pauls@etext.org>, Ray Loyzaga <yar@cs.su.oz.au>

• Therrien Gilbert <gilbert@ican.net>, Jean-Marc Pouyot <jmp@scalaire.fr>
  French error messages.

• Petr Snajdr, <snajdr@pvt.net>
  Czech error messages.

• Jaroslaw Lewandowski <jotel@itnet.com.pl>
  Polish error messages.

• Miguel Angel Fernandez Roiz
  Spanish error messages.

• Roy-Magne Mo <rmo@www.hivolda.no>
  Norwegian error messages and testing of MySQL 3.21.xx.

• Timur I. Bakeyev <root@timur.tatarstan.ru>
  Russian error messages.

• <brenno@dewinter.com> & Filippo Grassilli <phil@hyppo.com>
  Italian error messages.

• Dirk Munzinger <dirk@trinity.saar.de>
  German error messages.

• Billik Stefan <billik@sun.uniag.sk>
  Slovak error messages.

• Stefan Saroiu <tzoompy@cs.washington.edu>
Romanian error messages.
• Peter Feher
  Hungarian error messages.
• Roberto M. Serqueira
  Portuguese error messages.
• Carsten H. Pedersen
  Danish error messages.
• Arjen Lentz
  Dutch error messages, completing earlier partial translation (also work on consistency and spelling).

### 1.9.3 Packages that support MySQL

The following is a list of creators/maintainers of some of the most important API/packages/applications that a lot of people use with MySQL.

We cannot list every possible package here because the list would then be way too hard to maintain. For other packages, please refer to the software portal at [http://solutions.mysql.com/software/](http://solutions.mysql.com/software/).

• Tim Bunce, Alligator Descartes
  For the DBD (Perl) interface.
• Andreas Koenig <a.koenig@mind.de>
  For the Perl interface for MySQL Server.
• Jochen Wiedmann <wiedmann@neckar-alb.de>
  For maintaining the Perl DBD::mysql module.
• Eugene Chan <eugene@acenet.com.sg>
  For porting PHP for MySQL Server.
• Georg Richter
  MySQL 4.1 testing and bug hunting. New PHP 5.0 mysqli extension (API) for use with MySQL 4.1 and up.
• Giovanni Maruzzelli <maruzz@matrice.it>
  For porting iODBC (Unix ODBC).
• Xavier Leroy <Xavier.Leroy@inria.fr>
  The author of LinuxThreads (used by the MySQL Server on Linux).

### 1.9.4 Tools that were used to create MySQL

The following is a list of some of the tools we have used to create MySQL. We use this to express our thanks to those that has created them as without these we could not have made MySQL what it is today.
• Free Software Foundation

From whom we got an excellent compiler (gcc), an excellent debugger (gdb and the libc library (from which we have borrowed strto.c to get some code working in Linux).

• Free Software Foundation & The XEmacs development team

For a really great editor/environment.

• Julian Seward

Author of valgrind, an excellent memory checker tool that has helped us find a lot of otherwise hard to find bugs in MySQL.

• Dorothea Lütkehaus and Andreas Zeller

For DDD (The Data Display Debugger) which is an excellent graphical front end to gdb).

1.9.5 Supporters of MySQL

Although Oracle Corporation and/or its affiliates own all copyrights in the MySQL server and the MySQL manual, we wish to recognize the following companies, which helped us finance the development of the MySQL server, such as by paying us for developing a new feature or giving us hardware for development of the MySQL server.

• VA Linux / Andover.net

Funded replication.

• NuSphere

Editing of the MySQL manual.

• Stork Design studio

• Intel

Contributed to development on Windows and Linux platforms.

• Compaq

Contributed to Development on Linux/Alpha.

• SWSoft

Development on the embedded mysqld version.

• FutureQuest

The --skip-show-database option.
# Chapter 2 Installing and Upgrading MySQL

## Table of Contents

2.1 General Installation Guidance ........................................................................................................... 49  
  2.1.1 Operating Systems Supported by MySQL Community Server ..................................................... 50  
  2.1.2 Choosing Which MySQL Distribution to Install .............................................................................. 50  
  2.1.3 How to Get MySQL ........................................................................................................................ 53  
  2.1.4 Verifying Package Integrity Using MD5 Checksums or GnuPG .................................................... 53  
  2.1.5 Installation Layouts .......................................................................................................................... 63  
  2.1.6 Compiler-Specific Build Characteristics ......................................................................................... 63  
2.2 Installing MySQL on Unix/Linux Using Generic Binaries ................................................................. 63  
2.3 Installing MySQL on Microsoft Windows .......................................................................................... 66  
  2.3.1 MySQL Installation Layout on Microsoft Windows ....................................................................... 68  
  2.3.2 Choosing An Installation Package .................................................................................................. 68  
  2.3.3 Installing MySQL on Microsoft Windows Using MySQL Installer ............................................ 69  
  2.3.4 MySQL Notifier for Microsoft Windows ......................................................................................... 87  
  2.3.5 Installing MySQL on Microsoft Windows Using an MSI Package ............................................. 98  
  2.3.6 MySQL Server Instance Configuration Wizard ............................................................................ 105  
  2.3.7 Installing MySQL on Microsoft Windows Using a noinstall Zip Archive ................................ 120  
  2.3.8 Troubleshooting a Microsoft Windows MySQL Server Installation .......................................... 128  
  2.3.9 Upgrading MySQL on Windows .................................................................................................... 129  
  2.3.10 Windows Postinstallation Procedures ......................................................................................... 131  
2.4 Installing MySQL on Mac OS X ...................................................................................................... 132  
  2.4.1 General Notes on Installing MySQL on Mac OS X ................................................................. 133  
  2.4.2 Installing MySQL on Mac OS X Using Native Packages ......................................................... 134  
  2.4.3 Installing the MySQL Startup Item ......................................................................................... 137  
  2.4.4 Installing and Using the MySQL Preference Pane ................................................................. 141  
  2.4.5 Using the Bundled MySQL on Mac OS X Server ....................................................................... 143  
2.5 Installing MySQL on Linux .............................................................................................................. 144  
  2.5.1 Installing MySQL on Linux Using RPM Packages .................................................................. 144  
  2.5.2 Installing MySQL on Linux Using Debian Packages .................................................................. 149  
  2.5.3 Installing MySQL on Linux Using Native Package Managers ............................................... 150  
2.6 Installing MySQL Using Unbreakable Linux Network (ULN) ......................................................... 154  
2.7 Installing MySQL on Solaris and OpenSolaris ............................................................................... 154  
  2.7.1 Installing MySQL on Solaris Using a Solaris PKG ................................................................... 155  
  2.7.2 Installing MySQL on OpenSolaris Using IPS ............................................................................ 156  
2.8 Installing MySQL on FreeBSD ........................................................................................................ 157  
2.9 Installing MySQL from Source ....................................................................................................... 158  
  2.9.1 MySQL Layout for Source Installation ......................................................................................... 160  
  2.9.2 Installing MySQL Using a Standard Source Distribution ......................................................... 160  
  2.9.3 Installing MySQL Using a Development Source Tree .............................................................. 164  
  2.9.4 MySQL Source-Configuration Options ....................................................................................... 166  
  2.9.5 Dealing with Problems Compiling MySQL .................................................................................. 177  
  2.9.6 MySQL Configuration and Third-Party Tools .......................................................................... 179  
2.10 Postinstallation Setup and Testing ................................................................................................. 179  
  2.10.1 Postinstallation Procedures for Unix-like Systems ................................................................. 180  
  2.10.2 Securing the Initial MySQL Accounts ...................................................................................... 191  
2.11 Upgrading or Downgrading MySQL ............................................................................................... 195  
  2.11.1 Upgrading MySQL ....................................................................................................................... 195  
  2.11.2 Downgrading MySQL .................................................................................................................. 207
This chapter describes how to obtain and install MySQL. A summary of the procedure follows and later sections provide the details. If you plan to upgrade an existing version of MySQL to a newer version rather than install MySQL for the first time, see Section 2.11.1, “Upgrading MySQL”, for information about upgrade procedures and about issues that you should consider before upgrading.

If you are interested in migrating to MySQL from another database system, you may wish to read Section A.8, “MySQL 5.5 FAQ: Migration”, which contains answers to some common questions concerning migration issues.

If you are migrating from MySQL Enterprise Edition to MySQL Community Server, see Section 2.11.2.2, “Downgrading from MySQL Enterprise Edition to MySQL Community Server”.

Installation of MySQL generally follows the steps outlined here:

1. **Determine whether MySQL runs and is supported on your platform.**

   Please note that not all platforms are equally suitable for running MySQL, and that not all platforms on which MySQL is known to run are officially supported by Oracle Corporation:

2. **Choose which distribution to install.**

   Several versions of MySQL are available, and most are available in several distribution formats. You can choose from pre-packaged distributions containing binary (precompiled) programs or source code. When in doubt, use a binary distribution. We also provide public access to our current source tree for those who want to see our most recent developments and help us test new code. To determine which version and type of distribution you should use, see Section 2.1.2, “Choosing Which MySQL Distribution to Install”.

3. **Download the distribution that you want to install.**

   For instructions, see Section 2.1.3, “How to Get MySQL”. To verify the integrity of the distribution, use the instructions in Section 2.1.4, “Verifying Package Integrity Using MD5 Checksums or GnuPG”.

4. **Install the distribution.**

   To install MySQL from a binary distribution, use the instructions in Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”.

   To install MySQL from a source distribution or from the current development source tree, use the instructions in Section 2.9, “Installing MySQL from Source”.

5. **Perform any necessary postinstallation setup.**

   After installing MySQL, see Section 2.10, “Postinstallation Setup and Testing” for information about making sure the MySQL server is working properly. Also refer to the information provided in Section 2.10.2, “Securing the Initial MySQL Accounts”. This section describes how to secure the initial
MySQL user accounts, which have no passwords until you assign passwords. The section applies whether you install MySQL using a binary or source distribution.

6. If you want to run the MySQL benchmark scripts, Perl support for MySQL must be available. See Section 2.13, “Perl Installation Notes”.

Instructions for installing MySQL on different platforms and environments is available on a platform by platform basis:

- **Unix, Linux, FreeBSD**

  For instructions on installing MySQL on most Linux and Unix platforms using a generic binary (for example, a `.tar.gz` package), see Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”.

  For information on building MySQL entirely from the source code distributions or the source code repositories, see Section 2.9, “Installing MySQL from Source”.

  For specific platform help on installation, configuration, and building from source see the corresponding platform section:

  - Linux, including notes on distribution specific methods, see Section 2.5, “Installing MySQL on Linux”.
  - Solaris and OpenSolaris, including PKG and IPS formats, see Section 2.7, “Installing MySQL on Solaris and OpenSolaris”.
  - IBM AIX, see Section 2.7, “Installing MySQL on Solaris and OpenSolaris”.
  - FreeBSD, see Section 2.8, “Installing MySQL on FreeBSD”.

- **Microsoft Windows**

  For instructions on installing MySQL on Microsoft Windows, using either a Zipped binary or an MSI package, see Section 2.3, “Installing MySQL on Microsoft Windows”.

  For information on using the MySQL Server Instance Config Wizard, see Section 2.3.6, “MySQL Server Instance Configuration Wizard”.

  For details and instructions on building MySQL from source code using Microsoft Visual Studio, see Section 2.9, “Installing MySQL from Source”.

- **Mac OS X**

  For installation on Mac OS X, including using both the binary package and native PKG formats, see Section 2.4, “Installing MySQL on Mac OS X”.

  For information on making use of the MySQL Startup Item to automatically start and stop MySQL, see Section 2.4.3, “Installing the MySQL Startup Item”.

  For information on the MySQL Preference Pane, see Section 2.4.4, “Installing and Using the MySQL Preference Pane”.

### 2.1 General Installation Guidance

The immediately following sections contain the information necessary to choose, download, and verify your distribution. The instructions in later sections of the chapter describe how to install the distribution that you choose. For binary distributions, see the instructions at Section 2.2, “Installing MySQL on Unix/Linux Using
2.1 Operating Systems Supported by MySQL Community Server

MySQL is available on a number of operating systems and platforms. For information about those platforms that are officially supported, see http://www.mysql.com/support/supportedplatforms/database.html on the MySQL Web site.

2.1.1 Operating Systems Supported by MySQL Community Server

MySQL is available on a number of operating systems and platforms. For information about those platforms that are officially supported, see http://www.mysql.com/support/supportedplatforms/database.html on the MySQL Web site.

2.1.2 Choosing Which MySQL Distribution to Install

When preparing to install MySQL, you should decide which version to use. MySQL development occurs in several release series, and you can pick the one that best fits your needs. After deciding which version to install, you can choose a distribution format. Releases are available in binary or source format.

2.1.2.1 Choosing Which Version of MySQL to Install

The first decision to make is whether you want to use a production (stable) release or a development release. In the MySQL development process, multiple release series co-exist, each at a different stage of maturity.

Production Releases

- MySQL 5.6: Latest General Availability (Production) release
- MySQL 5.5: Previous General Availability (Production) release
- MySQL 5.1: Older General Availability (Production) release
- MySQL 5.0: Older Production release nearing the end of the product lifecycle

MySQL 4.1, 4.0, and 3.23 are old releases that are no longer supported.

See http://www.mysql.com/about/legal/lifecycle/ for information about support policies and schedules.

Normally, if you are beginning to use MySQL for the first time or trying to port it to some system for which there is no binary distribution, use the most recent General Availability series listed in the preceding descriptions. All MySQL releases, even those from development series, are checked with the MySQL benchmarks and an extensive test suite before being issued.

If you are running an older system and want to upgrade, but do not want to take the chance of having a nonseamless upgrade, you should upgrade to the latest version in the same release series you are using (where only the last part of the version number is newer than yours). We have tried to fix only fatal bugs and make only small, relatively “safe” changes to that version.

If you want to use new features not present in the production release series, you can use a version from a development series. Be aware that development releases are not as stable as production releases.

We do not use a complete code freeze because this prevents us from making bugfixes and other fixes that must be done. We may add small things that should not affect anything that currently works in a production release. Naturally, relevant bugfixes from an earlier series propagate to later series.

If you want to use the very latest sources containing all current patches and bugfixes, you can use one of our source code repositories (see Section 2.9.3, “Installing MySQL Using a Development Source Tree”). These are not “releases” as such, but are available as previews of the code on which future releases are to be based.

The naming scheme in MySQL 5.5 uses release names that consist of three numbers and a suffix; for example, mysql-5.5.6-m3. The numbers within the release name are interpreted as follows:
Choosing Which MySQL Distribution to Install

- The first number (5) is the major version and describes the file format. All MySQL 5 releases have the same file format.

- The second number (5) is the release level. Taken together, the major version and release level constitute the release series number.

- The third number (6) is the version number within the release series. This is incremented for each new release. Usually you want the latest version for the series you have chosen.

For each minor update, the last number in the version string is incremented. When there are major new features or minor incompatibilities with previous versions, the second number in the version string is incremented. When the file format changes, the first number is increased.

Release names also include a suffix that indicates the stability level of the release. Releases within a series progress through a set of suffixes to indicate how the stability level improves. The possible suffixes are:

- \texttt{mN} (for example, \texttt{m1}, \texttt{m2}, \texttt{m3}, ...) indicate a milestone number. MySQL development uses a milestone model, in which each milestone proceeds through a small number of versions with a tight focus on a small subset of thoroughly tested features. Following the releases for one milestone, development proceeds with another small number of releases that focuses on the next small set of features, also thoroughly tested. Features within milestone releases may be considered to be of pre-production quality.

- \texttt{rc} indicates a Release Candidate. Release candidates are believed to be stable, having passed all of MySQL’s internal testing, and with all known fatal runtime bugs fixed. However, the release has not been in widespread use long enough to know for sure that all bugs have been identified. Only minor fixes are added.

- If there is no suffix, it indicates that the release is a General Availability (GA) or Production release. GA releases are stable, having successfully passed through all earlier release stages and are believed to be reliable, free of serious bugs, and suitable for use in production systems. Only critical bugfixes are applied to the release.

All releases of MySQL are run through our standard tests and benchmarks to ensure that they are relatively safe to use. Because the standard tests are extended over time to check for all previously found bugs, the test suite keeps getting better.

All releases have been tested at least with these tools:

- \textbf{An internal test suite.} The \texttt{mysql-test} directory contains an extensive set of test cases. We run these tests for every server binary. See Section 24.1.2, “The MySQL Test Suite”, for more information about this test suite.

- \textbf{The MySQL benchmark suite.} This suite runs a range of common queries. It is also a test to determine whether the latest batch of optimizations actually made the code faster. See Section 8.12.2, “The MySQL Benchmark Suite”.

We also perform additional integration and nonfunctional testing of the latest MySQL version in our internal production environment. Integration testing is done with different connectors, storage engines, replication modes, backup, partitioning, stored programs, and so forth in various combinations. Additional nonfunctional testing is done in areas of performance, concurrency, stress, high volume, upgrade and downgrade.

\subsection*{2.1.2.2 Choosing a Distribution Format}

After choosing which version of MySQL to install, you should decide whether to use a binary distribution or a source distribution. In most cases, you should probably use a binary distribution, if one exists for your platform. Binary distributions are available in native format for many platforms, such as RPM packages.
Choosing Which MySQL Distribution to Install

for Linux, DMG packages for Mac OS X, and PKG packages for Solaris. Distributions are also available in more generic formats such as Zip archives or compressed tar files.

Reasons to choose a binary distribution include the following:

• Binary distributions generally are easier to install than source distributions.

• To satisfy different user requirements, we provide several servers in binary distributions. mysqld is an optimized server that is a smaller, faster binary. mysqld-debug is compiled with debugging support.

  Each of these servers is compiled from the same source distribution, though with different configuration options. All native MySQL clients can connect to servers from either MySQL version.

Under some circumstances, you may be better off installing MySQL from a source distribution:

• You want to install MySQL at some explicit location. The standard binary distributions are ready to run at any installation location, but you might require even more flexibility to place MySQL components where you want.

• You want to configure mysqld to ensure that features are available that might not be included in the standard binary distributions. Here is a list of the most common extra options that you may want to use to ensure feature availability:

  • -DWITH_LIBWRAP=1 for TCP wrappers support.
  • -DWITH_ZLIB={system|bundled} for features that depend on compression
  • -DWITH_DEBUG=1 for debugging support

  For additional information, see Section 2.9.4, “MySQL Source-Configuration Options”.

• You want to configure mysqld without some features that are included in the standard binary distributions. For example, distributions normally are compiled with support for all character sets. If you want a smaller MySQL server, you can recompile it with support for only the character sets you need.

• You want to use the latest sources from one of the Bazaar repositories to have access to all current bugfixes. For example, if you have found a bug and reported it to the MySQL development team, the bugfix is committed to the source repository and you can access it there. The bugfix does not appear in a release until a release actually is issued.

• You want to read (or modify) the C and C++ code that makes up MySQL. For this purpose, you should get a source distribution, because the source code is always the ultimate manual.

• Source distributions contain more tests and examples than binary distributions.

2.1.2.3 How and When Updates Are Released

MySQL is evolving quite rapidly and we want to share new developments with other MySQL users. We try to produce a new release whenever we have new and useful features that others also seem to have a need for.

We also try to help users who request features that are easy to implement. We take note of what our licensed users want, and we especially take note of what our support customers want and try to help them in this regard.

No one is required to download a new release. The Release Notes help you determine whether the new release has something you really want.

We use the following policy when updating MySQL:
• Enterprise Server releases are meant to appear every 18 months, supplemented by quarterly service packs and monthly rapid updates. Community Server releases are meant to appear 2 to 3 times per year.

• Releases are issued within each series. For each release, the last number in the version is one more than the previous release within the same series.

• Binary distributions for some platforms are made by us for major releases. Other people may make binary distributions for other systems, but probably less frequently.

• We make fixes available as soon as we have identified and corrected small or noncritical but annoying bugs. The fixes are available in source form immediately from our public Bazaar repositories, and are included in the next release.

• If by any chance a security vulnerability or critical bug is found in a release, our policy is to fix it in a new release as soon as possible. (We would like other companies to do this, too!)

2.1.3 How to Get MySQL

Check our downloads page at http://dev.mysql.com/downloads/ for information about the current version of MySQL and for downloading instructions. For a complete up-to-date list of MySQL download mirror sites, see http://dev.mysql.com/downloads/mirrors.html. You can also find information there about becoming a MySQL mirror site and how to report a bad or out-of-date mirror.

To obtain the latest development source, see Section 2.9.3, “Installing MySQL Using a Development Source Tree”.

2.1.4 Verifying Package Integrity Using MD5 Checksums or GnuPG

After you have downloaded the MySQL package that suits your needs and before you attempt to install it, you should make sure that it is intact and has not been tampered with. There are three means of integrity checking:

• MD5 checksums

• Cryptographic signatures using GnuPG, the GNU Privacy Guard

• For RPM packages, the built-in RPM integrity verification mechanism

The following sections describe how to use these methods.

If you notice that the MD5 checksum or GPG signatures do not match, first try to download the respective package one more time, perhaps from another mirror site.

2.1.4.1 Verifying the MD5 Checksum

After you have downloaded a MySQL package, you should make sure that its MD5 checksum matches the one provided on the MySQL download pages. Each package has an individual checksum that you can verify against the package that you downloaded. The correct MD5 checksum is listed on the downloads page for each MySQL product, and you will compare it against the MD5 checksum of the file (product) that you download.

Each operating system and setup offers its own version of tools for checking the MD5 checksum. Typically the command is named md5sum, or it may be named md5, and some operating systems do not ship it at all. On Linux, it is part of the GNU Text Utilities package, which is available for a wide range of platforms. You can also download the source code from http://www.gnu.org/software/textutils/. If you have OpenSSL installed, you can use the command openssl md5 package_name instead. A Windows implementation of the md5 command line utility is available from http://www.fourmilab.ch/md5/. winMd5Sum is a graphical...
Verifying Package Integrity Using MD5 Checksums or GnuPG

MD5 checking tool that can be obtained from http://www.nullriver.com/index/products/winmd5sum. Our Microsoft Windows examples will assume the name `md5.exe`.

Linux and Microsoft Windows examples:

```
shell> md5sum mysql-standard-5.5.40-linux-i686.tar.gz
aaab65abbec64d5e907dcd41b8699945  mysql-standard-5.5.40-linux-i686.tar.gz
```

```
shell> md5.exe mysql-installer-community-5.5.40.msi
aaab65abbec64d5e907dcd41b8699945  mysql-installer-community-5.5.40.msi
```

You should verify that the resulting checksum (the string of hexadecimal digits) matches the one displayed on the download page immediately below the respective package.

**Note**

Make sure to verify the checksum of the *archive file* (for example, the `.zip`, `.tar.gz`, or `.msi` file) and not of the files that are contained inside of the archive. In other words, verify the file before extracting its contents.

2.1.4.2 Signature Checking Using GnuPG

Another method of verifying the integrity and authenticity of a package is to use cryptographic signatures. This is more reliable than using MD5 checksums, but requires more work.

We sign MySQL downloadable packages with GnuPG (GNU Privacy Guard). GnuPG is an Open Source alternative to the well-known Pretty Good Privacy (PGP) by Phil Zimmermann. See http://www.gnupg.org/ for more information about GnuPG and how to obtain and install it on your system. Most Linux distributions ship with GnuPG installed by default. For more information about GnuPG, see http://www.openpgp.org/.

To verify the signature for a specific package, you first need to obtain a copy of our public GPG build key, which you can download from http://pgp.mit.edu/. The key that you want to obtain is named `mysql-build@oss.oracle.com`. Alternatively, you can cut and paste the key directly from the following text:

```
-----BEGIN PGP PUBLIC KEY BLOCK-----
Version: GnuPG v1.4.9 (SunOS)

-----END PGP PUBLIC KEY BLOCK-----
```
Verifying Package Integrity Using MD5 Checksums or GnuPG

To import the build key into your personal public GPG keyring, use `gpg --import`. For example, if you have saved the key in a file named `mysql_pubkey.asc`, the import command looks like this:

```
shell> gpg --import mysql_pubkey.asc
```

```
gpg: key 5072E1F5: public key "MySQL Release Engineering <mysql-build@oss.oracle.com>" imported
gpg: Total number processed: 1
gpg: imported: 1
```

You can also download the key from the public keys server using the public key id, `5072E1F5`:

```
shell> gpg --recv-keys 5072E1F5
```

```
gpg: requesting key 5072E1F5 from hkp server keys.gnupg.net
gpg: key 5072E1F5: "MySQL Release Engineering <mysql-build@oss.oracle.com>"
1 new user ID
gpg: key 5072E1F5: "MySQL Release Engineering <mysql-build@oss.oracle.com>"
53 new signatures
gpg: no ultimately trusted keys found
gpg: Total number processed: 1
```

If you want to import the key into your RPM configuration to validate RPM install packages, you should be able to import the key directly:

```
shell> rpm --import mysql_pubkey.asc
```

If you experience problems or require RPM specific information, see Section 2.1.4.4, "Signature Checking Using RPM".

After you have downloaded and imported the public build key, download your desired MySQL package and the corresponding signature, which also is available from the download page. The signature file has the same name as the distribution file with an `.asc` extension, as shown by the examples in the following table.

### Table 2.1 MySQL Package and Signature Files for Source files

<table>
<thead>
<tr>
<th>File Type</th>
<th>File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Distribution file</td>
<td>mysql-standard-5.5.40-linux-i686.tar.gz</td>
</tr>
<tr>
<td>Signature file</td>
<td>mysql-standard-5.5.40-linux-i686.tar.gz.asc</td>
</tr>
</tbody>
</table>

Make sure that both files are stored in the same directory and then run the following command to verify the signature for the distribution file:

```
shell> gpg --verify package_name.asc
```

If the downloaded package is valid, you will see a “Good signature” similar to:

```
shell> gpg --verify mysql-standard-5.5.40-linux-i686.tar.gz.asc
```

```
gpg: Signature made Tue 01 Feb 2011 02:38:30 AM CST using DSA key ID 5072E1F5
```

56
Verifying Package Integrity Using MD5 Checksums or GnuPG

The **Good signature** message indicates that the file signature is valid, when compared to the signature listed on our site. But you might also see warnings, like so:

```
shell> gpg --verify mysql-standard-5.5.40-linux-i686.tar.gz.asc
gpg: Signature made Wed 23 Jan 2013 02:25:45 AM PST using DSA key ID 5072E1F5
gpg: checking the trustdb
gpg: no ultimately trusted keys found
gpg: Good signature from "MySQL Release Engineering <mysql-build@oss.oracle.com>"
Warning: This key is not certified with a trusted signature!
Primary key fingerprint: A4A9 4068 76FC BD3C 4567  70C8 8C71 8D3B 5072 E1F5
```

That is normal, as they depend on your setup and configuration. Here are explanations for these warnings:

- **gpg: no ultimately trusted keys found**: This means that the specific key is not "ultimately trusted" by you or your web of trust, which is okay for the purposes of verifying file signatures.

- **WARNING: This key is not certified with a trusted signature! There is no indication that the signature belongs to the owner.**

  This refers to your level of trust in your belief that you possess our real public key. This is a personal decision. Ideally, a MySQL developer would hand you the key in person, but more commonly, you downloaded it. Was the download tampered with? Probably not, but this decision is up to you. Setting up a web of trust is one method for trusting them.

See the GPG documentation for more information on how to work with public keys.

### 2.1.4.3 Signature Checking Using Gpg4win for Windows

The **Section 2.1.4.2, “Signature Checking Using GnuPG”** section describes how to verify MySQL downloads using GPG. That guide also applies to Microsoft Windows, but another option is to use a GUI tool like Gpg4win. You may use a different tool but our examples are based on Gpg4win, and utilize its bundled Kleopatra GUI.

Download and install Gpg4win, and then load Kleopatra. The dialog should look similar to:
Verifying Package Integrity Using MD5 Checksums or GnuPG

Figure 2.1 Initial screen after loading Kleopatra

Next, add the MySQL Release Engineering certificate. Do this by clicking File, Lookup Certificates on Server. Type "Mysql Release Engineering" into the search box and press Search.

Figure 2.2 Finding the MySQL Release Engineering certificate

Select the "MySQL Release Engineering" certificate. The Fingerprint and Key-ID must be "5072E1F5", or choose Details... to confirm the certificate is valid. Now, import it by clicking Import. An import dialog will be displayed, choose Okay, and this certificate will now be listed under the Imported Certificates tab.
Next, configure the trust level for our certificate. Select our certificate, then from the main menu select **Certificates, Change Owner Trust...**. We suggest choosing **I believe checks are very accurate** for our certificate, as otherwise you might not be able to verify our signature. Select **I believe checks are very accurate** and then press **OK**.

**Figure 2.3 Changing the Trust level**

![Image of Kleopatra Trust Level Selection](image)

Next, verify the downloaded MySQL package file. This requires files for both the packaged file, and the signature. The signature file must have the same name as the packaged file but with an appended `.asc` extension, as shown by the example in the following table. The signature is linked to on the downloads page for each MySQL product. You must create the `.asc` file with this signature.

**Table 2.2 MySQL Package and Signature Files for MySQL Installer for Microsoft Windows**

<table>
<thead>
<tr>
<th>File Type</th>
<th>File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Distribution file</td>
<td>mysql-installer-community-5.5.40.msi</td>
</tr>
<tr>
<td>Signature file</td>
<td>mysql-installer-community-5.5.40.msi.asc</td>
</tr>
</tbody>
</table>

Make sure that both files are stored in the same directory and then run the following command to verify the signature for the distribution file. Either drag and drop the signature (.asc) file into Kleopatra, or load the dialog from **File, Decrypt/Verify Files...**, and then choose either the `.msi` or `.asc` file.
Click Decrypt/Verify to check the file. The two most common results will look like the following, and although the yellow warning looks problematic, the following means that the file check passed with success. You may now run this installer.
Figure 2.5 The Decrypt/Verify Results: Good

Seeing a red "The signature is bad" error means the file is invalid. Do not execute the MSI file if you see this error.
Figure 2.6 The Decrypt/Verify Results: Bad

The Section 2.1.4.2, “Signature Checking Using GnuPG” section explains why you probably don’t see a green Good signature result.

2.1.4.4 Signature Checking Using RPM

For RPM packages, there is no separate signature. RPM packages have a built-in GPG signature and MD5 checksum. You can verify a package by running the following command:

```
shell> rpm --checksig package_name.rpm
```

Example:

```
shell> rpm --checksig MySQL-server-5.5.40-0.glibc23.i386.rpm
MySQL-server-5.5.40-0.glibc23.i386.rpm: md5 gpg OK
```

Note

If you are using RPM 4.1 and it complains about (GPG) NOT OK (MISSING KEYS: GPG#5072e1f5), even though you have imported the MySQL public build
key into your own GPG keyring, you need to import the key into the RPM keyring first. RPM 4.1 no longer uses your personal GPG keyring (or GPG itself). Rather, RPM maintains a separate keyring because it is a system-wide application and a user's GPG public keyring is a user-specific file. To import the MySQL public key into the RPM keyring, first obtain the key, then use `rpm --import` to import the key. For example:

```bash
shell> gpg --export -a 5072e1f5 > 5072e1f5.asc
shell> rpm --import 5072e1f5.asc
```

Alternatively, `rpm` also supports loading the key directly from a URL, and you can use this manual page:

```bash
```

If you need to obtain the MySQL public key, see Section 2.1.4.2, "Signature Checking Using GnuPG".

## 2.1.5 Installation Layouts

The installation layout differs for different installation types (for example, native packages, binary tarballs, and source tarballs), which can lead to confusion when managing different systems or using different installation sources. The individual layouts are given in the corresponding installation type or platform chapter, as described following. Note that the layout of installations from vendors other than Oracle may differ from these layouts.

- Section 2.3.1, “MySQL Installation Layout on Microsoft Windows”
- Section 2.9.1, “MySQL Layout for Source Installation”
- Table 2.3, “MySQL Installation Layout for Generic Unix/Linux Binary Package”
- Table 2.12, “MySQL Installation Layout for Linux RPM Packages”
- Table 2.9, “MySQL Installation Layout on Mac OS X”

## 2.1.6 Compiler-Specific Build Characteristics

In some cases, the compiler used to build MySQL affects the features available for use. The notes in this section apply for binary distributions provided by Oracle Corporation or that you compile yourself from source.

### icc (Intel C++ Compiler) Builds

A server built with `icc` has these characteristics:

- SSL support is not included.

## 2.2 Installing MySQL on Unix/Linux Using Generic Binaries

Oracle provides a set of binary distributions of MySQL. These include binary distributions in the form of compressed `tar` files (files with a `.tar.gz` extension) for a number of platforms, as well as binaries in platform-specific package formats for selected platforms.

This section covers the installation of MySQL from a compressed `tar` file binary distribution. For other platform-specific package formats, see the other platform-specific sections. For example, for Windows distributions, see Section 2.3, “Installing MySQL on Microsoft Windows”. 
To obtain MySQL, see Section 2.1.3, “How to Get MySQL”.

MySQL compressed tar file binary distributions have names of the form `mysql-VERSION-OS.tar.gz`, where `VERSION` is a number (for example, 5.5.40), and `OS` indicates the type of operating system for which the distribution is intended (for example, `pc-linux-i686` or `winx64`).

To install MySQL from a compressed tar file binary distribution, your system must have GNU `gunzip` to uncompress the distribution and a reasonable `tar` to unpack it. If your `tar` program supports the `z` option, it can both uncompress and unpack the file.

GNU `tar` is known to work. The standard `tar` provided with some operating systems is not able to unpack the long file names in the MySQL distribution. You should download and install GNU `tar`, or if available, use a preinstalled version of GNU `tar`. Usually this is available as `gnutar`, `gtar`, or as `tar` within a GNU or Free Software directory, such as `/usr/sfw/bin` or `/usr/local/bin`. GNU `tar` is available from [http://www.gnu.org/software/tar/](http://www.gnu.org/software/tar/).

**Warning**

If you have previously installed MySQL using your operating system native package management system, such as `yum` or `apt-get`, you may experience problems installing using a native binary. Make sure your previous MySQL previous installation has been removed entirely (using your package management system), and that any additional files, such as old versions of your data files, have also been removed. You should also check the existence of configuration files such as `/etc/my.cnf` or the `/etc/mysql` directory have been deleted.

If you run into problems and need to file a bug report, please use the instructions in Section 1.7, “How to Report Bugs or Problems”.

On Unix, to install a compressed tar file binary distribution, unpack it at the installation location you choose (typically `/usr/local/mysql`). This creates the directories shown in the following table.

**Table 2.3 MySQL Installation Layout for Generic Unix/Linux Binary Package**

<table>
<thead>
<tr>
<th>Directory</th>
<th>Contents of Directory</th>
</tr>
</thead>
<tbody>
<tr>
<td>bin</td>
<td>Client programs and the <code>mysqld</code> server</td>
</tr>
<tr>
<td>data</td>
<td>Log files, databases</td>
</tr>
<tr>
<td>docs</td>
<td>Manual in Info format</td>
</tr>
<tr>
<td>man</td>
<td>Unix manual pages</td>
</tr>
<tr>
<td>include</td>
<td>Include (header) files</td>
</tr>
<tr>
<td>lib</td>
<td>Libraries</td>
</tr>
<tr>
<td>scripts</td>
<td><code>mysql_install_db</code></td>
</tr>
<tr>
<td>share</td>
<td>Miscellaneous support files, including error messages, sample configuration files, SQL for database installation</td>
</tr>
<tr>
<td>sql-bench</td>
<td>Benchmarks</td>
</tr>
</tbody>
</table>

Debug versions of the `mysqld` binary are available as `mysqld-debug`. To compile your own debug version of MySQL from a source distribution, use the appropriate configuration options to enable debugging support. For more information on compiling from source, see Section 2.9, “Installing MySQL from Source”.

To install and use a MySQL binary distribution, the basic command sequence looks like this:
Create a *mysql* User and Group

The following commands add the *mysql* group and the *mysql* user. You might want to call the user and group something else instead of *mysql*. If so, substitute the appropriate name in the following instructions.

```shell
shell> groupadd mysql
shell> useradd -r -g mysql mysql
```

**Note**

Because the user is required only for ownership purposes, not login purposes, the `useradd` command uses the `-r` option to create a user that does not have login permissions to your server host. Omit this option to permit logins for the user (or if your `useradd` does not support the option).

Obtain and Unpack the Distribution

Pick the directory under which you want to unpack the distribution and change location into it. The example here unpacks the distribution under `/usr/local`. The instructions, therefore, assume that you have permission to create files and directories in `/usr/local`. If that directory is protected, you must perform the installation as `root`.

```shell
shell> cd /usr/local
```

Obtain a distribution file using the instructions in Section 2.1.3, “How to Get MySQL”. For a given release, binary distributions for all platforms are built from the same MySQL source distribution.
Perform Postinstallation Setup

Unpack the distribution, which creates the installation directory. Then create a symbolic link to that directory. `tar` can uncompress and unpack the distribution if it has `z` option support:

```
shell> tar zxf /path/to/mysql-VERSION-OS.tar.gz
shell> ln -s full-path-to-mysql-VERSION-OS mysql
```

The `tar` command creates a directory named `mysql-VERSION-OS`. The `ln` command makes a symbolic link to that directory. This enables you to refer more easily to the installation directory as `/usr/local/mysql`.

If your `tar` does not have `z` option support, use `gunzip` to unpack the distribution and `tar` to unpack it. Replace the preceding `tar` command with the following alternative command to uncompress and extract the distribution:

```
shell> gunzip < /path/to/mysql-VERSION-OS.tar.gz | tar xvf -
```

Perform Postinstallation Setup

The remainder of the installation process involves setting up the configuration file, creating the core databases, and starting the MySQL server. For next steps, see Section 2.10, “Postinstallation Setup and Testing”.

Note

The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.10.2, “Securing the Initial MySQL Accounts”.

2.3 Installing MySQL on Microsoft Windows

MySQL is available for Microsoft Windows, for both 32-bit and 64-bit versions. For supported Windows platform information, see [http://www.mysql.com/support/supportedplatforms/database.html](http://www.mysql.com/support/supportedplatforms/database.html).

It is possible to run MySQL as a standard application or as a Windows service. By using a service, you can monitor and control the operation of the server through the standard Windows service management tools. For more information, see Section 2.3.7.7, “Starting MySQL as a Windows Service”.

Generally, you should install MySQL on Windows using an account that has administrator rights. Otherwise, you may encounter problems with certain operations such as editing the `PATH` environment variable or accessing the Service Control Manager. Once installed, MySQL does not need to be executed using a user with Administrator privileges.

For a list of limitations on the use of MySQL on the Windows platform, see Section D.10.6, “Windows Platform Limitations”.

In addition to the MySQL Server package, you may need or want additional components to use MySQL with your application or development environment. These include, but are not limited to:

- To connect to the MySQL server using ODBC, you must have a Connector/ODBC driver. For more information, including installation and configuration instructions, see [MySQL Connector/ODBC Developer Guide](http://www.mysql.com/support/odbc/).

- To use MySQL server with .NET applications, you must have the Connector/Net driver. For more information, including installation and configuration instructions, see [MySQL Connector/Net Developer Guide](http://www.mysql.com/support/net/).

MySQL for Windows is available in several distribution formats, detailed below. Generally speaking, you should use MySQL Installer. It contains more features and MySQL products than the older MSI, is simpler to use than the ZIP file, and you need no additional tools to get MySQL up and running. MySQL Installer automatically installs MySQL Server and additional MySQL products, creates an options file, starts the server, and enables you to create default user accounts. For more information on choosing a package, see Section 2.3.2, “Choosing An Installation Package”.

- Binary installer distributions. There are two different installable distributions that come packaged as a Microsoft Windows Installer (MSI) package that you can install manually or automatically on your systems. The preferred MySQL Installer package includes MySQL Server and additional MySQL products including MySQL Workbench, MySQL Notifier, and MySQL for Excel. MySQL Installer can also be used to upgrade these products in the future. The older MSI package contains all the files you need to install and configure MySQL server, but no additional components.

  For instructions on installing MySQL using MySQL Installer, see Section 2.3.3, “Installing MySQL on Microsoft Windows Using MySQL Installer”.

- The standard binary distribution (packaged as a Zip file) contains all of the necessary files that you unpack into your chosen location. This package contains all of the files in the full Windows MSI Installer package, but does not include an installation program.

  For instructions on installing MySQL using the Zip file, see Section 2.3.7, “Installing MySQL on Microsoft Windows Using a noinstall Zip Archive”.

- The source distribution format contains all the code and support files for building the executables using the Visual Studio compiler system.

  For instructions on building MySQL from source on Windows, see Section 2.9, “Installing MySQL from Source”.

MySQL on Windows considerations:

- **Large Table Support**

  If you need tables with a size larger than 4GB, install MySQL on an NTFS or newer file system. Do not forget to use \texttt{MAX\_ROWS} and \texttt{AVG\_ROW\_LENGTH} when you create tables. See Section 13.1.17, “\texttt{CREATE TABLE} Syntax”.

- **MySQL and Virus Checking Software**

  Virus-scanning software such as Norton/Symantec Anti-Virus on directories containing MySQL data and temporary tables can cause issues, both in terms of the performance of MySQL and the virus-scanning software misidentifying the contents of the files as containing spam. This is due to the fingerprinting mechanism used by the virus-scanning software, and the way in which MySQL rapidly updates different files, which may be identified as a potential security risk.

  After installing MySQL Server, it is recommended that you disable virus scanning on the main directory (\texttt{datadir}) used to store your MySQL table data. There is usually a system built into the virus-scanning software to enable specific directories to be ignored.

  In addition, by default, MySQL creates temporary files in the standard Windows temporary directory. To prevent the temporary files also being scanned, configure a separate temporary directory for MySQL temporary files and add this directory to the virus scanning exclusion list. To do this, add a
configuration option for the tmpdir parameter to your my.ini configuration file. For more information, see Section 2.3.7.2, "Creating an Option File".

### 2.3.1 MySQL Installation Layout on Microsoft Windows

For MySQL 5.5 on Windows, the default installation directory is `C:\Program Files\MySQL\MySQL Server 5.5`. Some Windows users prefer to install in `C:\mysql`, the directory that formerly was used as the default. However, the layout of the subdirectories remains the same.

All of the files are located within this parent directory, using the structure shown in the following table.

<table>
<thead>
<tr>
<th>Directory</th>
<th>Contents of Directory</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>bin</code></td>
<td>Client programs and the mysqld server</td>
<td></td>
</tr>
<tr>
<td><code>%ALLUSERSPROFILE%\MySQL\MySQL Server 5.5\</code></td>
<td>Log files, databases (Windows XP, Windows Server 2003)</td>
<td>The Windows system variable %ALLUSERSPROFILE% defaults to <code>C:\Documents and Settings\All Users\Application Data</code></td>
</tr>
<tr>
<td><code>%PROGRAMDATA%\MySQL\MySQL Server 5.5\</code></td>
<td>Log files, databases (Vista, Windows 7, Windows Server 2008, and newer)</td>
<td>The Windows system variable %PROGRAMDATA% defaults to <code>C:\ProgramData</code></td>
</tr>
<tr>
<td><code>examples</code></td>
<td>Example programs and scripts</td>
<td></td>
</tr>
<tr>
<td><code>include</code></td>
<td>Include (header) files</td>
<td></td>
</tr>
<tr>
<td><code>lib</code></td>
<td>Libraries</td>
<td></td>
</tr>
<tr>
<td><code>scripts</code></td>
<td>Utility scripts</td>
<td></td>
</tr>
<tr>
<td><code>share</code></td>

</table>

If you install MySQL using a Windows MSI package, this package creates and sets up the data directory that the installed server will use, but as of MySQL 5.5.5, it also creates a pristine “template” data directory named `data` under the installation directory. This directory can be useful when the machine will be used to run multiple instances of MySQL: After an installation has been performed using an MSI package, the template data directory can be copied to set up additional MySQL instances. See Section 5.3, "Running Multiple MySQL Instances on One Machine".

### 2.3.2 Choosing An Installation Package

For MySQL 5.5, there are installation package formats to choose from when installing MySQL on Windows:

- **MySQL Installer**: This package has a file name similar to `mysql-installer-community-5.5.40.0.msi` or `mysql-installer-commercial-5.5.40.0.msi`, and utilizes MSIs
to automatically install MySQL server and other products. It will download and apply updates to itself, and for each of the installed products. It also configures the additional non-server products.

The installed products are configurable, and this includes: documentation with samples and examples, connectors (such as C, C++, J, NET, and ODBC), MySQL Workbench, MySQL Notifier for Microsoft Windows, MySQL for Excel, and the MySQL Server with its components.

MySQL Installer will run on all Windows platforms that are supported by MySQL (see http://www.mysql.com/support/supportedplatforms/database.html).

**Note**

Because MySQL Installer is not a native component of Microsoft Windows and depends on .NET, it will not work on minimal installation options like the "Server Core" version of Windows Server 2008.

For instructions on installing MySQL using MySQL Installer, see Section 2.3.3, “Installing MySQL on Microsoft Windows Using MySQL Installer”.

- **The Complete Package**: This package has a file name similar to `mysql-5.5.40-win32.msi` and contains all files needed for a complete Windows installation, including the Configuration Wizard. This package includes optional components such as the embedded server and benchmark suite.

- **The Noinstall Archive**: This package has a file name similar to `mysql-5.5.40-win32.zip` and contains all the files found in the Complete install package, with the exception of the Configuration Wizard. This package does not include an automated installer, and must be manually installed and configured.

MySQL Installer is recommended for most users. Both MySQL Installer and the alternative "Complete distribution" versions are available as `.msi` files for use with installations on Windows. The Noinstall distribution is packaged as a Zip archive. To use a Zip archive, you must have a tool that can unpack `.zip` files.

Your choice of install package affects the installation process you must follow. If you choose to install using MySQL Installer, see Section 2.3.3, “Installing MySQL on Microsoft Windows Using MySQL Installer”. If you choose to install a standard MSI package, see Section 2.3.5, “Installing MySQL on Microsoft Windows Using an MSI Package”. If you choose to install a Noinstall archive, see Section 2.3.7, “Installing MySQL on Microsoft Windows Using a noinstall Zip Archive”.

### 2.3.3 Installing MySQL on Microsoft Windows Using MySQL Installer

MySQL Installer is an application that simplifies the installation and updating process for a wide range of MySQL products, including MySQL Notifier for Microsoft Windows, MySQL Workbench, and MySQL for Excel. From this central application, you can see which MySQL products are already installed, configure them, and update or remove them if necessary. The installer can also install plugins, documentation, tutorials, and example databases. The MySQL Installer is only available for Microsoft Windows, and includes both a GUI and command-line interface.

**Installer package types**

- **Full**: Bundles all of the MySQL products (including MySQL Server). The file size is over 160MB, and its name has the form `mysql-installer-community-VERSION.N.msi` where `VERSION` is the MySQL Server version number such as 5.6 and `N` is the package number, which begins at 0.

- **Web**: Only contains the Installer and configuration files, and it only downloads the MySQL products you choose to install. The size of this file is about 2MB; the name of the file has the form `mysql-
Installing MySQL on Microsoft Windows Using MySQL Installer

installer-community-web-VERSION.N.msi where VERSION is the MySQL Server version number such as 5.6 and N is the package number, which begins at 0.

Installer editions

- **Commercial edition**: Downloadable at either My Oracle Support (MOS) or https://edelivery.oracle.com/. It installs the commercial version of all MySQL products, including Workbench SE. It also integrates with your MOS account, so enter in your MOS credentials to automatically receive updates for your commercial MySQL products.

For notes detailing the changes in each release of MySQL Installer, see MySQL Installer Release Notes.

MySQL Installer is compatible with pre-existing installations, and adds them to its list of installed components. While the MySQL Installer is bundled with a specific version of MySQL Server, a single MySQL Installer instance can install and manage multiple MySQL Server versions. For example, a single MySQL Installer instance can install versions 5.1, 5.5, and 5.6. It can also manage either commercial or community editions of the MySQL Server.

Note
A single host can not have both community and commercial editions of MySQL Server installed. For example, if you want both MySQL Server 5.5 and 5.6 installed on a single host, then both must be the same commercial or community edition.

MySQL Installer handles the initial configuration and setup of the applications. For example:

1. It will create MySQL Server connections in MySQL Workbench.

2. It creates the configuration file (my.ini) that is used to configure the MySQL Server. The values written to this file are influenced by choices you make during the installation process.

3. It imports example databases.

4. It creates MySQL Server user accounts with configurable permissions based on general roles, such as DB Administrator, DB Designer, and Backup Admin. It optionally creates a Windows user named MysqlSys with limited privileges, which would then run the MySQL Server.

   This feature is only available during the initial installation of the MySQL Server, and not during future updates. User accounts may also be added with MySQL Workbench.

5. If the "Advanced Configuration" option is checked, then the **Logging Options** are also configured. This includes defining file paths for the error log, general log, slow query log (including the configuration of seconds it requires to execute a query), and the binary log.

MySQL Installer can optionally check for updated components and download them for you automatically.

### 2.3.3.1 MySQL Installer GUI

After installation of the GUI version, the installer will have add its own Start Menu item under MySQL.

Note
Files that are generated by MySQL Installer grant full permissions to the user that executes MySQL Installer, including my.ini. This does not apply to files
and directories for specific products such as the MySQL Server data directory in `ProgramData`, that is owned by `SYSTEM`.

After the installer itself has been installed and started, the following screen is displayed:

**Figure 2.7 MySQL Installer - Welcome Screen**

There are three main options:

1. **Install MySQL Products** - The Installation Wizard.
2. **About MySQL** - Learn about MySQL products and features.
3. **Resources** - Information to help install and configure MySQL.

To **Install MySQL Products** after executing MySQL Installer for the first time, you must accept the license agreement before proceeding with the installation process.
Figure 2.8 MySQL Installer - License Agreement

If you are connected to the Internet, then the Installer will search for the latest MySQL components and add them to the installation bundle. Click Connect to the Internet to complete this step, or otherwise check the Skip checkbox and then Continue.
Figure 2.9 MySQL Installer - Find latest products

If you chose "Connect to the Internet," the next page will show the progress of MySQL Installer's search for available updates. When the search is complete (or if you opted to skip the search), you will be taken to the **Choose Setup Type** page:
Determine the option most compatible with your preferences by reading the Setup Type Description descriptions.

The Installation and Data paths are also defined here, and a caution flag will notify you if the data path you define already exists.

After you select a setup type, the MySQL Installer will check your system for the necessary external requirements and download then install missing components onto your system.
Figure 2.11 MySQL Installer - Check Requirements

The next window lists the MySQL products that are scheduled to be installed:
As components are installed, you'll see their status change from "to be installed" to "install success."
After all components are installed, the next step involves configuring the products. The **Configuration Overview** window displays the progress and then loads a configuration window if it is required.
The ideal MySQL Server configuration depends on your intended use, as explained in the next window. Choose the description that most closely applies to your machine.

You may enable TCP/IP Networking here as otherwise only localhost connections are allowed.

Checking the “Advanced Configuration” option provides additional **Logging Options** to configure. This includes defining file paths for the error log, general log, slow query log (including the configuration of seconds it requires to execute a query), and the binary log.
Next, choose your account information. Defining a root password is required, whereas it's optional to create additional users. There are several different predefined user roles that each have different permission levels. For example, a "DB Admin" will have more privileges than a "DB Designer."
Figure 2.16 MySQL Installer - MySQL Server Configuration: User accounts

Note

If the MySQL Server is already installed, then the current Root Password will also be needed.

Next, configure the Windows Service Details. This includes the service name, how the MySQL Server should be loaded at startup, and how the Windows Service for MySQL Server will be run.
Figure 2.17 MySQL Installer - MySQL Server Configuration: Windows service details

Note

When configuring Run Windows Services as ... using a Custom User, the custom user must have privileges to log on to Windows as a service. And the Next button will be disabled until this user is given these user rights.

On Microsoft Windows 7, this is configured by loading the Start Menu, Control Panel, Administrative Tools, Local Security Policy, Local Policies, User Rights Assignment, then Log On As A Service. Choose Add User or Group here to add the custom user, and then OK, OK to save.

The final configuration step is available if the Advanced Configuration option was checked, and it includes configuration options related to log file names:
After the MySQL Installer configuration process is completed, you may save the installation log, and then load MySQL Workbench if the **Start MySQL Workbench after Setup** option is checked:
You can now open MySQL Installer from the Microsoft Windows Start menu under the MySQL group, which will load the MySQL Installer Maintenance Screen. This is used to add, update, and remove features.
Figure 2.20 MySQL Installer - Maintenance Screen

Note

An Update Screen screen is shown if MySQL Installer is used on a machine with older products installed, as opposed to the Maintenance Screen shown above. However, the functionality remains the same.

Add/Modify Products and Features will list all installed and available MySQL products.
The installation is now complete. MySQL Server should be running, and most MySQL products installed and available for use.

See also the MySQL Workbench documentation (http://dev.mysql.com/doc/workbench/en/).

2.3.3.2 MySQL Installer Console

MySQLInstallerConsole provides functionality similar to the GUI version of MySQL Installer, but from the command-line. It is installed when MySQL Installer is initially executed, and then available within the MySQL Installer directory. Typically that is in C:\Program Files (x86)\MySQL\MySQL Installer\, and the console must be executed with administrative privileges.

To use, invoke the Command Prompt with administrative privileges by choosing Start, Accessories, then right-click on Command Prompt and choose Run as administrator. And from the command-line, optionally change the directory to where MySQLInstallerConsole is located:

C:\> cd "C:\Program Files (x86)\MySQL\MySQL Installer"

MySQLInstallerConsole supports the following options, which are specified on the command line:

• --help, -h, or -?
Displays a help message with usage examples, and then exits.

```
C:\> MySQLInstallerConsole --help
```

- **--updates** (or **-u**)  
  Checks for new products before any further action is taken. Disabled by default.

- **--nowait**  
  Skips the final pause when the program finishes. Otherwise, a "Press Enter to continue." dialogue is generated. It is used in conjunction with other options.

- **--catalog=catalog_name** (or **-c**)  
  Sets the default catalog. Use **--list** to view a list of available catalogs.

- **--type=installation_type** (or **-t**)  
  Sets the installation type.
  The possible values for **installation_type** are: developer, server, client, full, and custom.

- **--action=action_name**  
  The action being performed.
  The possible values are: install, remove, upgrade, list, and status.

  - **install**: Installs a product or products, as defined by **--products**
  
  - **upgrade**: Upgrades a product or products, as defined by **--products**.
  
  - **remove**: Removes a product or products, as defined by **--products**.
  
  - **list**: Lists the product manifest, both installed and available products.
  
  - **status**: Shows the status after another action is performed.

- **--product=product_name[:feature1],[feature2],...** (or **-p**)  
  Set the feature list of a product. Use **--list** to view available products, or pass in **--product=*** (an asterisk) to install all available products.

- **--config=product_name:passwd=root_password[,parameter1=value], [parameter2=value],...**  
  The configuration parameters for the most recently listed products.

- **--user=product_name:name=username,host:hostname,role=rolename,password=password** or  
  **--user=product_name:name=username,host:hostname,role=rolename,tokens=tokens**  
  Creates a new user.
Requires: name, host, role, and the password or tokens. Tokens are separated by pipe ("|") characters.

2.3.4 MySQL Notifier for Microsoft Windows

The MySQL Notifier for Microsoft Windows is a tool that enables you to monitor and adjust the status of your local and remote MySQL Server instances through an indicator that resides in the system tray. The MySQL Notifier for Microsoft Windows also gives quick access to several MySQL GUI tools (such as MySQL Workbench) through its context menu.

The MySQL Notifier for Microsoft Windows is installed by MySQL Installer, and (by default) will start-up when Microsoft Windows is started.

Note

To install, download and execute the MySQL Installer, be sure the MySQL Notifier for Microsoft Windows product is selected, then proceed with the installation. See the MySQL Installer manual for additional details.

For notes detailing the changes in each release of MySQL Notifier for Microsoft Windows, see the MySQL Notifier Release Notes.

Visit the MySQL Notifier forum for additional MySQL Notifier for Microsoft Windows help and support.

Features include:

• Start, Stop, and Restart instances of the MySQL Server.

• Automatically detects (and adds) new MySQL Server services. These are listed under Manage Monitored Items, and may also be configured.

• The Tray icon changes, depending on the status. It's green if all monitored MySQL Server instances are running, or red if at least one service is stopped. The Update MySQL Notifier tray icon based on service status option, which dictates this behavior, is enabled by default for each service.

• Links to other applications like MySQL Workbench, MySQL Installer, and the MySQL Utilities. For example, choosing Configure Instance will load the MySQL Workbench Server Administration window for that particular instance.

• If MySQL Workbench is also installed, then the Configure Instance and SQL Editor options are available for local (but not remote) MySQL instances.

• Monitoring of both local and remote MySQL instances.

Note

Remote monitoring is available since MySQL Notifier for Microsoft Windows 1.1.0.

The MySQL Notifier for Microsoft Windows resides in the system tray and provides visual status information for your MySQL Server instances. A green icon is displayed at the top left corner of the tray icon if the current MySQL Server is running, or a red icon if the service is stopped.

The MySQL Notifier for Microsoft Windows automatically adds discovered MySQL Services on the local machine, and each service is saved and configurable. By default, the Automatically add new services whose name contains option is enabled and set to mysql. Related Notifications Options include being
MySQL Notifier for Microsoft Windows

notified when new services are either discovered or experience status changes, and are also enabled by default. And uninstalling a service will also remove the service from the MySQL Notifier for Microsoft Windows.

Note

The **Automatically add new services whose name contains** option default changed from ".*mysqld.*" to "mysql" in Notifier 1.1.0.

Clicking the system tray icon will reveal several options, as seen in the screenshots below:

The Service Instance menu is the main MySQL Notifier for Microsoft Windows window, and enables you to Stop, Start, and Restart the MySQL Server.

**Figure 2.22 MySQL Notifier for Microsoft Windows Service Instance menu**

The **Actions** menu includes several links to external applications (if they are installed), and a **Refresh Status** option to manually refresh the status of all monitored services (in both local and remote computers) and MySQL instances.

Note

The main menu will not show the **Actions** menu when there are no services being monitored by MySQL Notifier for Microsoft Windows.

Note

The **Refresh Status** feature is available since MySQL Notifier for Microsoft Windows 1.1.0.

**Figure 2.23 MySQL Notifier for Microsoft Windows Actions menu**
The **Actions, Options** menu configures MySQL Notifier for Microsoft Windows and includes options to:

- **Use colorful status icons**: Enables a colorful style of icons for the tray of the MySQL Notifier for Microsoft Windows.

- **Run at Windows Startup**: Allows the application to be loaded when Microsoft Windows starts.

- **Automatically Check For Updates Every # Weeks**: Checks for a new version of MySQL Notifier for Microsoft Windows, and runs this check every # weeks.

- **Automatically add new services whose name contains**: The text used to filter services and add them automatically to the monitored list of the local computer running MySQL Notifier, and on remote computers already monitoring Windows services, monitored services, and also filters the list of the Microsoft Windows services for the **Add New Service** dialog.

  Prior to version 1.1.0, this option was named "Automatically add new services that match this pattern."

- **Notify me when a service is automatically added**: Will display a balloon notification from the taskbar when a newly discovered service is added to the monitored services list.

- **Notify me when a service changes status**: Will display a balloon notification from the taskbar when a monitored service changes its status.

**Figure 2.24 MySQL Notifier for Microsoft Windows Options menu**

The **Actions, Manage Monitored Items** menu enables you to configure the monitored services and MySQL instances. First, with the **Services** tab open:
Figure 2.25 MySQL Notifier for Microsoft Windows Manage Services menu

The **Instances** tab is similar:
Figure 2.26 MySQL Notifier for Microsoft Windows Manage Instances menu

Adding a service or instance (after clicking Add in the Manage Monitored Items window) enables you to select a running Microsoft Windows service or instance connection, and configure MySQL Notifier for Microsoft Windows to monitor it. Add a new service or instance by clicking service name from the list, then OK to accept. Multiple services and instances may be selected.
Figure 2.27 MySQL Notifier for Microsoft Windows Adding new services

And instances:
2.3.4.1 Remote monitoring set up and installation instructions

The MySQL Notifier for Microsoft Windows uses Windows Management Instrumentation (WMI) to manage and monitor services in remote computers running Windows XP or later. This guide explains how it works, and how to set up your system to monitor remote MySQL instances.

In order to configure WMI, it is important to understand that the underlying Distributed Component Object Model (DCOM) architecture is doing the WMI work. Specifically, MySQL Notifier for Microsoft Windows is using asynchronous notification queries on remote Microsoft Windows hosts as .NET events. These events send an asynchronous callback to the computer running the MySQL Notifier for Microsoft Windows so it knows when a service status has changed on the remote computer. Asynchronous notifications offer the best performance compared to semisynchronous notifications or synchronous notifications that use timers.
Asynchronous notifications requires the remote computer to send a callback to the client computer (thus opening a reverse connection), so the Windows Firewall and DCOM settings must be properly configured for the communication to function properly.

**Figure 2.29 MySQL Notifier for Microsoft Windows Distributed Component Object Model (DCOM)**

Most of the common errors thrown by asynchronous WMI notifications are related to Windows Firewall blocking the communication, or to DCOM / WMI settings not being set up properly. For a list of common errors with solutions, see [Common Errors](#).

The following steps are required to make WMI function. These steps are divided between two machines. A single host computer that runs MySQL Notifier for Microsoft Windows (Computer A), and multiple remote machines that are being monitored (Computer B).

**Computer running MySQL Notifier for Microsoft Windows (Computer A)**

1. Allow for remote administration by either editing the Group Policy Editor, or using NETSH:

   Using the **Group Policy Editor**:
   a. Click **Start**, click **Run**, type **GPEDIT.MSC**, and then click **OK**.
   b. Under the **Local Computer Policy** heading, double-click **Computer Configuration**.
   c. Double-click **Administrative Templates**, then **Network, Network Connections**, and then **Windows Firewall**.
   d. If the computer is in the domain, then double-click **Domain Profile**; otherwise, double-click **Standard Profile**.
   e. Click **Windows Firewall: Allow inbound remote administration exception**.
   f. On the Action menu either select **Edit**, or double-click the selection from the previous step.
   g. Check the **Enabled** radio button, and then click **OK**.

   Using the **NETSH** command:
   a. Open a command prompt window with Administrative rights (you can right-click the Command Prompt icon and click **Run as Administrator**).
   b. Execute the following command:

      ```bash
      NETSH firewall set service RemoteAdmin enable
      ```

2. Open the DCOM port TCP 135:
a. Open a command prompt window with Administrative rights (you can right-click the Command Prompt icon and click Run as Administrator).

b. Execute the following command:

```
NETSH firewall add portopening protocol=tcp port=135 name=DCOM_TCP135
```

3. Add the client application which contains the sink for the callback (MySqlNotifier.exe) to the Windows Firewall Exceptions List (use either the Windows Firewall configuration or NETSH):

Using the Windows Firewall configuration:

a. In the Control Panel, double-click Windows Firewall.

b. In the Windows Firewall window's left panel, click Allow a program or feature through Windows Firewall.

c. In the Allowed Programs window, click Change Settings.

d. If MySqlNotifier.exe is in the Allowed programs and features list, make sure it is checked for the type of networks the computer connects to (Private, Public or both).

e. If MySqlNotifier.exe is not in the list, click Allow another program....

f. In the Add a Program window, select the MySqlNotifier.exe if it exists in the Programs list, otherwise click Browse... and go to the directory where MySqlNotifier.exe was installed to select it, then click Add.

g. Make sure MySqlNotifier.exe is checked for the type of networks the computer connects to (Private, Public or both).

Using the NETSH command:

a. Open a command prompt window with Administrative rights (you can right-click the Command Prompt icon and click Run as Administrator).

b. Execute the following command, where you change "[YOUR_INSTALL_DIRECTORY]":

```
NETSH firewall add allowedprogram program=[YOUR_INSTALL_DIRECTORY]\MySqlNotifier.exe name=MySqlNotifier
```

4. If Computer B is either a member of WORKGROUP or is in a different domain that is untrusted by Computer A, then the callback connection (Connection 2) is created as an Anonymous connection. To grant Anonymous connections DCOM Remote Access permissions:

a. Click Start, click Run, type DCOMCNFG, and then click OK.

b. In the Component Services dialog box, expand Component Services, expand Computers, and then right-click My Computer and click Properties.

c. In the My Computer Properties dialog box, click the COM Security tab.

d. Under Access Permissions, click Edit Limits.
In the Access Permission dialog box, select **ANONYMOUS LOGON name** in the Group or user names box. In the Allow column under Permissions for User, select **Remote Access**, and then click OK.

**Monitored Remote Computer (Computer B)**

If the user account that is logged into the computer running the MySQL Notifier for Microsoft Windows (Computer A) is a local administrator on the remote computer (Computer B), such that the same account is an administrator on Computer B, you can skip to the “Allow for remote administration” step.

Setting DCOM security to allow a non-administrator user to access a computer remotely:

1. Grant “DCOM remote launch” and activation permissions for a user or group:
   a. Click **Start**, click **Run**, type **DCOMCNFG**, and then click OK.
   b. In the Component Services dialog box, expand Component Services, expand Computers, and then right-click **My Computer** and click **Properties**.
   c. In the My Computer Properties dialog box, click the **COM Security** tab.
   d. Under Access Permissions, click **Edit Limits**.
   e. In the **Launch Permission** dialog box, follow these steps if your name or your group does not appear in the Groups or user names list:
      i. In the **Launch Permission** dialog box, click **Add**.
      ii. In the Select Users, Computers, or Groups dialog box, add your name and the group in the “Enter the object names to select” box, and then click OK.
   f. In the **Launch Permission** dialog box, select your user and group in the Group or user names box. In the Allow column under Permissions for User, select **Remote Launch**, select **Remote Activation**, and then click OK.

Grant DCOM remote access permissions:

a. Click **Start**, click **Run**, type **DCOMCNFG**, and then click OK.

b. In the Component Services dialog box, expand Component Services, expand Computers, and then right-click **My Computer** and click **Properties**.

c. In the My Computer Properties dialog box, click the **COM Security** tab.

d. Under Access Permissions, click **Edit Limits**.

e. In the Access Permission dialog box, select **ANONYMOUS LOGON name** in the Group or user names box. In the Allow column under Permissions for User, select **Remote Access**, and then click OK.

2. Allowing non-administrator users access to a specific WMI namespace:
   a. In the Control Panel, double-click **Administrative Tools**.
   b. In the Administrative Tools window, double-click **Computer Management**.
c. In the Computer Management window, expand the Services and Applications tree and double-click the WMI Control.

d. Right-click the WMI Control icon and select Properties.

e. In the WMI Control Properties window, click the Security tab.

f. In the Security tab, select the namespace and click Security.

g. Locate the appropriate account and check Remote Enable in the Permissions list.

3. Allow for remote administration by either editing the Group Policy Editor or using NETSH:

Using the Group Policy Editor:

a. Click Start, click Run, type GPEDIT.MSC, and then click OK.

c. Double-click Administrative Templates, then Network, Network Connections, and then Windows Firewall.

d. If the computer is in the domain, then double-click Domain Profile; otherwise, double-click Standard Profile.

e. Click Windows Firewall: Allow inbound remote administration exception.

f. On the Action menu either select Edit, or double-click the selection from the previous step.

g. Check the Enabled radio button, and then click OK.

Using the NETSH command:

a. Open a command prompt window with Administrative rights (you can right-click the Command Prompt icon and click Run as Administrator).

b. Execute the following command:

```
NETSH firewall set service RemoteAdmin enable
``` 

4. Now, be sure the user you are logging in with uses the Name value and not the Full Name value:

a. In the Control Panel, double-click Administrative Tools.

b. In the Administrative Tools window, double-click Computer Management.

c. In the Computer Management window, expand the System Tools then Local Users and Groups.

d. Click the Users node, and on the right side panel locate your user and make sure it uses the Name value to connect, and not the Full Name value.

5. If the remote computer is running on Windows XP Professional, make sure that remote logins are not being forcefully changed to the guest account user (also known as ForceGuest), which is enabled by default on computers that are not attached to a domain.

a. Click Start, click Run, type SECPOL.MSC, and then click OK.
b. Under the **Local Policies** node, double-click **Security Options**.

c. Select **Network Access: Sharing and security model for local accounts** and save.

**Common Errors**

- **0x80070005**

  DCOM Security was not configured properly (see Computer B, the **Setting DCOM security**... step).

  The remote computer (Computer B) is a member of WORKGROUP or is in a domain that is untrusted by the client computer (Computer A) (see Computer A, the **Grant Anonymous connections DCOM Remote Access permissions** step).

- **0x8007000E**

  The remote computer (Computer B) is a member of WORKGROUP or is in a domain that is untrusted by the client computer (Computer A) (see Computer A, the **Grant Anonymous connections DCOM Remote Access permissions** step).

- **0x80041003**

  Access to the remote WMI namespace was not configured properly (see Computer B, the **Allowing non-administrator users access to a specific WMI namespace** step).

- **0x800706BA**

  The DCOM port is not open on the client computers (Computer A) firewall. See the **Open the DCOM port TCP 135** step for Computer A.

  The remote computer (Computer B) is inaccessible because its network location is set to Public. Make sure you can access it through the Windows Explorer.

### 2.3.5 Installing MySQL on Microsoft Windows Using an MSI Package

The MSI package is designed to install and configure MySQL in such a way that you can immediately get started using MySQL.

The MySQL Installation Wizard and MySQL Configuration Wizard are available in the Complete install package, which is recommended for most standard MySQL installations. Exceptions include users who need to install multiple instances of MySQL on a single server host and advanced users who want complete control of server configuration.

- For information on installing using the GUI MSI installer process, see [Section 2.3.5.1, “Using the MySQL Installation Wizard”](#).

- For information on installing using the command line using the MSI package, see [Section 2.3.5.2, “Automating MySQL Installation on Microsoft Windows Using the MSI Package”](#).

- If you have previously installed MySQL using the MSI package and want to remove MySQL, see [Section 2.3.5.3, “Removing MySQL When Installed from the MSI Package”](#).

The workflow sequence for using the installer is shown in the figure below:
Microsoft Windows XP and later include a firewall which specifically blocks ports. If you plan on using MySQL through a network port then you should open and create an exception for this port before performing the installation. To check and if necessary add an exception to the firewall settings:

1. First ensure that you are logged in as an Administrator or a user with Administrator privileges.
2. Go to the Control Panel, and double click the Windows Firewall icon.
3. Choose the Allow a program through Windows Firewall option and click the Add port button.
4. Enter MySQL into the Name text box and 3306 (or the port of your choice) into the Port number text box.
5. Also ensure that the **TCP** protocol radio button is selected.

6. If you wish, you can also limit access to the MySQL server by choosing the **Change scope** button.

7. Confirm your choices by clicking the **OK** button.

Additionally, when running the MySQL Installation Wizard on Windows Vista or newer, ensure that you are logged in as a user with administrative rights.

**Note**

When using Windows Vista or newer, you may want to disable User Account Control (UAC) before performing the installation. If you do not do so, then MySQL may be identified as a security risk, which will mean that you need to enable MySQL. You can disable the security checking by following these instructions:

1. Open **Control Panel**.
2. Under the **User Accounts and Family Safety**, select **Add or remove user accounts**.
3. Click the **Got to the main User Accounts page** link.
4. Click on **Turn User Account Control on or off**. You may be prompted to provide permission to change this setting. Click **Continue**.
5. Deselect or uncheck the check box next to **Use User Account Control (UAC) to help protect your computer**. Click **OK** to save the setting.

You will need to restart to complete the process. Click **Restart Now** to reboot the machine and apply the changes. You can then follow the instructions below for installing Windows.

### 2.3.5.1 Using the MySQL Installation Wizard

MySQL Installation Wizard is an installer for the MySQL server that uses the latest installer technologies for Microsoft Windows. The MySQL Installation Wizard, in combination with the MySQL Configuration Wizard, enables a user to install and configure a MySQL server that is ready for use immediately after installation.

The MySQL Installation Wizard is the standard installer for all MySQL server distributions, version 4.1.5 and higher. Users of previous versions of MySQL need to shut down and remove their existing MySQL installations manually before installing MySQL with the MySQL Installation Wizard. See [Upgrading MySQL with the Installation Wizard](#), for more information on upgrading from a previous version.

Microsoft has included an improved version of their Microsoft Windows Installer (MSI) in the recent versions of Windows. MSI has become the de-facto standard for application installations on Windows 2000, Windows XP, and Windows Server 2003. The MySQL Installation Wizard makes use of this technology to provide a smoother and more flexible installation process.

The Microsoft Windows Installer Engine was updated with the release of Windows XP; those using a previous version of Windows can reference [this Microsoft Knowledge Base article](#) for information on upgrading to the latest version of the Windows Installer Engine.
In addition, Microsoft has introduced the WiX (Windows Installer XML) toolkit recently. This is the first highly acknowledged Open Source project from Microsoft. We have switched to WiX because it is an Open Source project and it enables us to handle the complete Windows installation process in a flexible manner using scripts.

Improving the MySQL Installation Wizard depends on the support and feedback of users like you. If you find that the MySQL Installation Wizard is lacking some feature important to you, or if you discover a bug, please report it in our bugs database using the instructions given in Section 1.7, “How to Report Bugs or Problems”.

**Downloading and Starting the MySQL Installation Wizard**

The MySQL installation packages can be downloaded from http://dev.mysql.com/downloads/. If the package you download is contained within a Zip archive, you need to extract the archive first.

**Note**

If you are installing on Windows Vista or newer, it is best to open a network port before beginning the installation. To do this, first ensure that you are logged in as an Administrator, go to the Control Panel, and double-click the Windows Firewall icon. Choose the Allow a program through Windows Firewall option and click the Add port button. Enter MySQL into the Name text box and 3306 (or the port of your choice) into the Port number text box. Also ensure that the TCP protocol radio button is selected. If you wish, you can also limit access to the MySQL server by choosing the Change scope button. Confirm your choices by clicking the OK button. If you do not open a port prior to installation, you cannot configure the MySQL server immediately after installation. Additionally, when running the MySQL Installation Wizard on Windows Vista or newer, ensure that you are logged in as a user with administrative rights.

The process for starting the wizard depends on the contents of the installation package you download. If there is a setup.exe file present, double-click it to start the installation process. If there is an .msi file present, double-click it to start the installation process.

**Choosing an Install Type**

There are three installation types available: **Typical**, **Complete**, and **Custom**.

The **Typical** installation type installs the MySQL server, the mysql command-line client, and the command-line utilities. The command-line clients and utilities include mysqldump, myisamchk, and several other tools to help you manage the MySQL server.

The **Complete** installation type installs all components included in the installation package. The full installation package includes components such as the embedded server library, the benchmark suite, support scripts, and documentation.

The **Custom** installation type gives you complete control over which packages you wish to install and the installation path that is used. See The Custom Install Dialog, for more information on performing a custom install.

If you choose the **Typical** or **Complete** installation types and click the **Next** button, you advance to the confirmation screen to verify your choices and begin the installation. If you choose the **Custom** installation type and click the **Next** button, you advance to the custom installation dialog, described in The Custom Install Dialog.
The Custom Install Dialog

If you wish to change the installation path or the specific components that are installed by the MySQL Installation Wizard, choose the Custom installation type.

A tree view on the left side of the custom install dialog lists all available components. Components that are not installed have a red X icon; components that are installed have a gray icon. To change whether a component is installed, click that component's icon and choose a new option from the drop-down list that appears.

You can change the default installation path by clicking the Change... button to the right of the displayed installation path.

After choosing your installation components and installation path, click the Next button to advance to the confirmation dialog.

The Confirmation Dialog

Once you choose an installation type and optionally choose your installation components, you advance to the confirmation dialog. Your installation type and installation path are displayed for you to review.

To install MySQL if you are satisfied with your settings, click the Install button. To change your settings, click the Back button. To exit the MySQL Installation Wizard without installing MySQL, click the Cancel button.

The final screen of the installer provides a summary of the installation and gives you the option to launch the MySQL Configuration Wizard, which you can use to create a configuration file, install the MySQL service, and configure security settings.

Changes Made by MySQL Installation Wizard

Once you click the Install button, the MySQL Installation Wizard begins the installation process and makes certain changes to your system which are described in the sections that follow.

Changes to the Registry

The MySQL Installation Wizard creates one Windows registry key in a typical install situation, located in HKEY_LOCAL_MACHINE\SOFTWARE\MySQL AB.

The MySQL Installation Wizard creates a key named after the major version of the server that is being installed, such as MySQL Server 5.5. It contains two string values, Location and Version. The Location string contains the path to the installation directory. In a default installation it contains C:\Program Files\MySQL\MySQL Server 5.5\. The Version string contains the release number. For example, for an installation of MySQL Server 5.5.40, the key contains a value of 5.5.40.

These registry keys are used to help external tools identify the installed location of the MySQL server, preventing a complete scan of the hard-disk to determine the installation path of the MySQL server. The registry keys are not required to run the server, and if you install MySQL using the noinstall Zip archive, the registry keys are not created.

Changes to the Start Menu

The MySQL Installation Wizard creates a new entry in the Windows Start menu under a common MySQL menu heading named after the major version of MySQL that you have installed. For example, if you install MySQL 5.5, the MySQL Installation Wizard creates a MySQL Server 5.5 section in the Start menu.

The following entries are created within the new Start menu section:
• MySQL Command-Line Client: This is a shortcut to the `mysql` command-line client and is configured to connect as the `root` user. The shortcut prompts for a `root` user password when you connect.

• MySQL Server Instance Config Wizard: This is a shortcut to the MySQL Configuration Wizard. Use this shortcut to configure a newly installed server, or to reconfigure an existing server.

• MySQL Documentation: This is a link to the MySQL server documentation that is stored locally in the MySQL server installation directory.

Changes to the File System

The MySQL Installation Wizard by default installs the MySQL 5.5 server to `C:\Program Files\MySQL\MySQL Server 5.5`, where `Program Files` is the default location for applications in your system, and `5.5` is the major version of your MySQL server. This is the recommended location for the MySQL server, replacing the former default location `C:\mysql`.

By default, all MySQL applications are stored in a common directory at `C:\Program Files\MySQL`, where `Program Files` is the default location for applications in your Windows installation. A typical MySQL installation on a developer machine might look like this:

```
C:\Program Files\MySQL\MySQL Server 5.5
C:\Program Files\MySQL\MySQL Workbench 5.1 OSS
```

This approach makes it easier to manage and maintain all MySQL applications installed on a particular system.

The default location of the data directory is the `AppData` directory configured for the user that installed the MySQL application.

Upgrading MySQL with the Installation Wizard

The MySQL Installation Wizard can perform server upgrades automatically using the upgrade capabilities of MSI. That means you do not need to remove a previous installation manually before installing a new release. The installer automatically shuts down and removes the previous MySQL service before installing the new version.

Automatic upgrades are available only when upgrading between installations that have the same major and minor version numbers. For example, you can upgrade automatically from MySQL 5.5.5 to MySQL 5.5.6, but not from MySQL 5.1 to MySQL 5.5.

See Section 2.3.9, “Upgrading MySQL on Windows”.

2.3.5.2 Automating MySQL Installation on Microsoft Windows Using the MSI Package

The Microsoft Installer (MSI) supports a both a `quiet` and a `passive` mode that can be used to install MySQL automatically without requiring intervention. You can use this either in scripts to automatically install MySQL or through a terminal connection such as Telnet where you do not have access to the standard Windows user interface. The MSI packages can also be used in combination with Microsoft's Group Policy system (part of Windows Server 2003 and Windows Server 2008) to install MySQL across multiple machines.

To install MySQL from one of the MSI packages automatically from the command line (or within a script), you need to use the `msiexec.exe` tool. For example, to perform a quiet installation (which shows no dialog boxes or progress):

```
shell> msiexec /i mysql-5.5.40.msi /quiet
```
Installing MySQL on Microsoft Windows Using an MSI Package

The `/i` indicates that you want to perform an installation. The `/quiet` option indicates that you want no interactive elements.

To provide a dialog box showing the progress during installation, and the dialog boxes providing information on the installation and registration of MySQL, use `/passive` mode instead of `/quiet`:

```
shell> msiexec /i mysql-5.5.40.msi /passive
```

Regardless of the mode of the installation, installing the package in this manner performs a “Typical” installation, and installs the default components into the standard location.

You can also use this method to uninstall MySQL by using the `/uninstall` or `/x` options:

```
shell> msiexec /x mysql-5.5.40.msi /uninstall
```

To install MySQL and configure a MySQL instance from the command line, see Section 2.3.6.13, “MySQL Server Instance Config Wizard: Creating an Instance from the Command Line”.

For information on using MSI packages to install software automatically using Group Policy, see How to use Group Policy to remotely install software in Windows Server 2003.

### 2.3.5.3 Removing MySQL When Installed from the MSI Package

To uninstall a MySQL where you have used the MSI packages, you must use the Add/Remove Programs tool within Control Panel. To do this:

1. Right-click the start menu and choose Control Panel.
2. If the Control Panel is set to category mode (you will see Pick a category at the top of the Control Panel window), double-click Add or Remove Programs. If the Control is set to classic mode, double-click the Add or Remove Programs icon.
3. Find MySQL in the list of installed software. MySQL Server is installed against major version numbers (MySQL 5.1, MySQL 5.5, etc.). Select the version that you want to remove and click Remove.
4. You will be prompted to confirm the removal. Click Yes to remove MySQL.

When MySQL is removed using this method, only the installed components are removed. Any database information (including the tables and data), import or export files, log files, and binary logs produced during execution are kept in their configured location.

If you try to install MySQL again the information will be retained and you will be prompted to enter the password configured with the original installation.

If you want to delete MySQL completely:

- Delete the associated data directory. On Windows XP and Windows Server 2003, the default data directory is the configured AppData directory, which is `C:\Documents and Settings\All Users \Application Data\MySQL` by default.
- On Windows 7 and Windows Server 2008, the default data directory location is `C:\ProgramData \Mysql`.

![Note]

The `C:\ProgramData` directory is hidden by default. You must change your folder options to view the hidden file. Choose Organize, Folder and search options, Show hidden folders.
2.3.6 MySQL Server Instance Configuration Wizard

The MySQL Server Instance Configuration Wizard helps automate the process of configuring your server. It creates a custom MySQL configuration file (my.ini or my.cnf) by asking you a series of questions and then applying your responses to a template to generate the configuration file that is tuned to your installation.

The MySQL Server Instance Configuration Wizard is included with the MySQL 5.5 server. The MySQL Server Instance Configuration Wizard is only available for Windows.

2.3.6.1 Starting the MySQL Server Instance Configuration Wizard

The MySQL Server Instance Configuration Wizard is normally started as part of the installation process. You should only need to run the MySQL Server Instance Configuration Wizard again when you need to change the configuration parameters of your server.

If you chose not to open a port prior to installing MySQL on Windows Vista or newer, you can choose to use the MySQL Server Configuration Wizard after installation. However, you must open a port in the Windows Firewall. To do this see the instructions given in Downloading and Starting the MySQL Installation Wizard. Rather than opening a port, you also have the option of adding MySQL as a program that bypasses the Windows Firewall. One or the other option is sufficient—you need not do both. Additionally, when running the MySQL Server Configuration Wizard on Windows Vista or newer, ensure that you are logged in as a user with administrative rights.
You can launch the MySQL Configuration Wizard by clicking the MySQL Server Instance Config Wizard entry in the MySQL section of the Windows Start menu.

Alternatively, you can navigate to the bin directory of your MySQL installation and launch the MySQLInstanceConfig.exe file directly.

The MySQL Server Instance Configuration Wizard places the my.ini file in the installation directory for the MySQL server. This helps associate configuration files with particular server instances.

To ensure that the MySQL server knows where to look for the my.ini file, an argument similar to this is passed to the MySQL server as part of the service installation:

```
--defaults-file="C:\Program Files\MySQL\MySQL Server 5.5\my.ini"
```

Here, C:\Program Files\MySQL\MySQL Server 5.5 is replaced with the installation path to the MySQL Server. The --defaults-file option instructs the MySQL server to read the specified file for configuration options when it starts.

Apart from making changes to the my.ini file by running the MySQL Server Instance Configuration Wizard again, you can modify it by opening it with a text editor and making any necessary changes. You can also modify the server configuration with the http://www.mysql.com/products/administrator/ utility. For more information about server configuration, see Section 5.1.3, “Server Command Options”.

MySQL clients and utilities such as the mysql and mysqldump command-line clients are not able to locate the my.ini file located in the server installation directory. To configure the client and utility applications, create a new my.ini file in the Windows installation directory (for example, C:\WINDOWS).

Under Windows Server 2003, Windows Server 2000, Windows XP, and Windows Vista, MySQL Server Instance Configuration Wizard will configure MySQL to work as a Windows service. To start and stop MySQL you use the Services application that is supplied as part of the Windows Administrator Tools.

### 2.3.6.2 Choosing a Maintenance Option

If the MySQL Server Instance Configuration Wizard detects an existing configuration file, you have the option of either reconfiguring your existing server, or removing the server instance by deleting the configuration file and stopping and removing the MySQL service.

To reconfigure an existing server, choose the Re-configure Instance option and click the Next button. Any existing configuration file is not overwritten, but renamed (within the same directory) using a timestamp (Windows) or sequential number (Linux). To remove the existing server instance, choose the Remove Instance option and click the Next button.

If you choose the Remove Instance option, you advance to a confirmation window. Click the Execute button. The MySQL Server Configuration Wizard stops and removes the MySQL service, and then deletes the configuration file. The server installation and its data folder are not removed.

If you choose the Re-configure Instance option, you advance to the Configuration Type dialog where you can choose the type of installation that you wish to configure.

### 2.3.6.3 Choosing a Configuration Type

When you start the MySQL Server Instance Configuration Wizard for a new MySQL installation, or choose the Re-configure Instance option for an existing installation, you advance to the Configuration Type dialog.
There are two configuration types available: Detailed Configuration and Standard Configuration. The Standard Configuration option is intended for new users who want to get started with MySQL quickly without having to make many decisions about server configuration. The Detailed Configuration option is intended for advanced users who want more fine-grained control over server configuration.

If you are new to MySQL and need a server configured as a single-user developer machine, the Standard Configuration should suit your needs. Choosing the Standard Configuration option causes the MySQL Configuration Wizard to set all configuration options automatically with the exception of Service Options and Security Options.

The Standard Configuration sets options that may be incompatible with systems where there are existing MySQL installations. If you have an existing MySQL installation on your system in addition to the installation you wish to configure, the Detailed Configuration option is recommended.

To complete the Standard Configuration, please refer to the sections on Service Options and Security Options in Section 2.3.6.10, “The Service Options Dialog”, and Section 2.3.6.11, “The Security Options Dialog”, respectively.

2.3.6.4 The Server Type Dialog

There are three different server types available to choose from. The server type that you choose affects the decisions that the MySQL Server Instance Configuration Wizard makes with regard to memory, disk, and processor usage.
• Developer Machine: Choose this option for a typical desktop workstation where MySQL is intended only for personal use. It is assumed that many other desktop applications are running. The MySQL server is configured to use minimal system resources.

• Server Machine: Choose this option for a server machine where the MySQL server is running alongside other server applications such as FTP, email, and Web servers. The MySQL server is configured to use a moderate portion of the system resources.

• Dedicated MySQL Server Machine: Choose this option for a server machine that is intended to run only the MySQL server. It is assumed that no other applications are running. The MySQL server is configured to use all available system resources.

Note

By selecting one of the preconfigured configurations, the values and settings of various options in your `my.cnf` or `my.ini` will be altered accordingly. The default values and options as described in the reference manual may therefore be different to the options and values that were created during the execution of the configuration wizard.
2.3.6.5 The Database Usage Dialog

The Database Usage dialog enables you to indicate the storage engines that you expect to use when creating MySQL tables. The option you choose determines whether the InnoDB storage engine is available and what percentage of the server resources are available to InnoDB.

- Multifunctional Database: This option enables both the InnoDB and MyISAM storage engines and divides resources evenly between the two. This option is recommended for users who use both storage engines on a regular basis.

- Transactional Database Only: This option enables both the InnoDB and MyISAM storage engines, but dedicates most server resources to the InnoDB storage engine. This option is recommended for users who use InnoDB almost exclusively and make only minimal use of MyISAM.

- Non-Transactional Database Only: This option disables the InnoDB storage engine completely and dedicates all server resources to the MyISAM storage engine. This option is recommended for users who do not use InnoDB.

The Configuration Wizard uses a template to generate the server configuration file. The Database Usage dialog sets one of the following option strings:

- Multifunctional Database: MIXED
- Transactional Database Only: INNODB
- Non-Transactional Database Only: MYISAM
When these options are processed through the default template (my-template.ini) the result is:

Multifunctional Database:
default-storage-engine=InnoDB
_myisam_pct=50

Transactional Database Only:
default-storage-engine=InnoDB
_myisam_pct=5

Non-Transactional Database Only:
default-storage-engine=MyISAM
_myisam_pct=100
skip-innodb

The _myisam_pct value is used to calculate the percentage of resources dedicated to MyISAM. The remaining resources are allocated to InnoDB.

2.3.6.6 The InnoDB Tablespace Dialog

Some users may want to locate the InnoDB tablespace files in a different location than the MySQL server data directory. Placing the tablespace files in a separate location can be desirable if your system has a higher capacity or higher performance storage device available, such as a RAID storage system.
To change the default location for the InnoDB tablespace files, choose a new drive from the drop-down list of drive letters and choose a new path from the drop-down list of paths. To create a custom path, click the ... button.

If you are modifying the configuration of an existing server, you must click the Modify button before you change the path. In this situation you must move the existing tablespace files to the new location manually before starting the server.

2.3.6.7 The Concurrent Connections Dialog

To prevent the server from running out of resources, it is important to limit the number of concurrent connections to the MySQL server that can be established. The Concurrent Connections dialog enables you to choose the expected usage of your server, and sets the limit for concurrent connections accordingly. It is also possible to set the concurrent connection limit manually.

- Decision Support (DSS)/OLAP: Choose this option if your server does not require a large number of concurrent connections. The maximum number of connections is set at 100, with an average of 20 concurrent connections assumed.

- Online Transaction Processing (OLTP): Choose this option if your server requires a large number of concurrent connections. The maximum number of connections is set at 500.

- Manual Setting: Choose this option to set the maximum number of concurrent connections to the server manually. Choose the number of concurrent connections from the drop-down box provided, or enter the maximum number of connections into the drop-down box if the number you desire is not listed.
2.3.6.8 The Networking and Strict Mode Options Dialog

Use the Networking Options dialog to enable or disable TCP/IP networking and to configure the port number that is used to connect to the MySQL server.

TCP/IP networking is enabled by default. To disable TCP/IP networking, uncheck the box next to the Enable TCP/IP Networking option.

Port 3306 is used by default. To change the port used to access MySQL, choose a new port number from the drop-down box or type a new port number directly into the drop-down box. If the port number you choose is in use, you are prompted to confirm your choice of port number.

Set the Server SQL Mode to either enable or disable strict mode. Enabling strict mode (default) makes MySQL behave more like other database management systems. If you run applications that rely on MySQL's old “forgiving” behavior, make sure to either adapt those applications or to disable strict mode. For more information about strict mode, see Section 5.1.7, “Server SQL Modes”.

2.3.6.9 The Character Set Dialog

The MySQL server supports multiple character sets and it is possible to set a default server character set that is applied to all tables, columns, and databases unless overridden. Use the Character Set dialog to change the default character set of the MySQL server.
MySQL Server Instance Configuration Wizard

Configure the MySQL Server 5.0 server instance.

Please select the default character set.

- **Standard Character Set**: Choose this option if you want to use `latin1` as the default server character set. `latin1` is used for English and many Western European languages.

- **Best Support For Multilingualism**: Choose this option if you want to use `utf8` as the default server character set. This is a Unicode character set that can store characters from many different languages.

- **Manual Selected Default Character Set / Collation**: Choose this option if you want to pick the server’s default character set manually. Choose the desired character set from the provided drop-down list.

2.3.6.10 The Service Options Dialog

On Windows platforms, the MySQL server can be installed as a Windows service. When installed this way, the MySQL server can be started automatically during system startup, and even restarted automatically by Windows in the event of a service failure.

The MySQL Server Instance Configuration Wizard installs the MySQL server as a service by default, using the service name `MySQL`. If you do not wish to install the service, uncheck the box next to the Install As Windows Service option. You can change the service name by picking a new service name from the drop-down box provided or by entering a new service name into the drop-down box.

**Note**

Service names can include any legal character except forward (`/`) or backward (`\`) slashes, and must be less than 256 characters long.
Warning

If you are installing multiple versions of MySQL onto the same machine, you must choose a different service name for each version that you install. If you do not choose a different service for each installed version then the service manager information will be inconsistent and this will cause problems when you try to uninstall a previous version.

If you have already installed multiple versions using the same service name, you must manually edit the contents of the HKEY_LOCAL_MACHINE\SYSTEM \CurrentControlSet\Services parameters within the Windows registry to update the association of the service name with the correct server version.

Typically, when installing multiple versions you create a service name based on the version information. For example, you might install MySQL 5.x as mysql5, or specific versions such as MySQL 5.5.0 as mysql50500.

To install the MySQL server as a service but not have it started automatically at startup, uncheck the box next to the Launch the MySQL Server Automatically option.

2.3.6.11 The Security Options Dialog

The content of the security options portion of the MySQL Server Instance Configuration Wizard will depend on whether this is a new installation, or modifying an existing installation.

- Setting the root password for a new installation

*It is strongly recommended that you set a root password for your MySQL server*, and the MySQL Server Instance Config Wizard requires by default that you do so. If you do not wish to set a root password, uncheck the box next to the Modify Security Settings option.
• To set the root password, enter the desired password into both the New root password and Confirm boxes.

**Setting the root password for an existing installation**

If you are modifying the configuration of an existing configuration, or you are installing an upgrade and the MySQL Server Instance Configuration Wizard has detected an existing MySQL system, then you must enter the existing password for root before changing the configuration information.
If you want to change the current root password, enter the desired new password into both the New root password and Confirm boxes.

To permit root logins from across the network, check the box next to the Enable root access from remote machines option. This decreases the security of your root account.

To create an anonymous user account, check the box next to the Create An Anonymous Account option. Creating an anonymous account can decrease server security and cause login and permission difficulties. For this reason, it is not recommended.

2.3.6.12 The Confirmation Dialog

The final dialog in the MySQL Server Instance Configuration Wizard is the Confirmation Dialog. To start the configuration process, click the Execute button. To return to a previous dialog, click the Back button. To exit the MySQL Server Instance Configuration Wizard without configuring the server, click the Cancel button.
After you click the **Execute** button, the MySQL Server Instance Configuration Wizard performs a series of tasks and displays the progress onscreen as the tasks are performed.

The MySQL Server Instance Configuration Wizard first determines configuration file options based on your choices using a template prepared by MySQL developers and engineers. This template is named `my-template.ini` and is located in your server installation directory.

The MySQL Configuration Wizard then writes these options to the corresponding configuration file.

If you chose to create a service for the MySQL server, the MySQL Server Instance Configuration Wizard creates and starts the service. If you are reconfiguring an existing service, the MySQL Server Instance Configuration Wizard restarts the service to apply your configuration changes.

If you chose to set a **root** password, the MySQL Configuration Wizard connects to the server, sets your new **root** password, and applies any other security settings you may have selected.

After the MySQL Server Instance Configuration Wizard has completed its tasks, it displays a summary. Click the **Finish** button to exit the MySQL Server Configuration Wizard.

2.3.6.13 MySQL Server Instance Config Wizard: Creating an Instance from the Command Line

In addition to using the GUI interface to the MySQL Server Instance Config Wizard, you can also create instances automatically from the command line.
To use the MySQL Server Instance Config Wizard on the command line, you need to use the MySQLInstanceConfig.exe command that is installed with MySQL in the bin directory within the installation directory. MySQLInstanceConfig.exe takes a number of command-line arguments that set the properties that would normally be selected through the GUI interface, and then creates a new configuration file (my.ini) by combining these selections with a template configuration file to produce the working configuration file.

The main command line options are provided in the table below. Some of the options are required, while some options are optional.

Table 2.5 MySQL Server Instance Config Wizard Command Line Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required Parameters</td>
<td></td>
</tr>
<tr>
<td>-nPRODUCTNAME</td>
<td>The name of the instance when installed</td>
</tr>
<tr>
<td>-pPATH</td>
<td>Path of the base directory for installation. This is equivalent to the directory when using the basedir configuration parameter</td>
</tr>
<tr>
<td>-vVERSION</td>
<td>The version tag to use for this installation</td>
</tr>
<tr>
<td>Action to Perform</td>
<td></td>
</tr>
<tr>
<td>-i</td>
<td>Install an instance</td>
</tr>
<tr>
<td>-r</td>
<td>Remove an instance</td>
</tr>
<tr>
<td>-s</td>
<td>Stop an existing instance</td>
</tr>
<tr>
<td>-q</td>
<td>Perform the operation quietly</td>
</tr>
<tr>
<td>-lFILENAME</td>
<td>Sae the installation progress in a logfile</td>
</tr>
<tr>
<td>Config File to Use</td>
<td></td>
</tr>
<tr>
<td>-tFILENAME</td>
<td>Path to the template config file that will be used to generate the installed configuration file</td>
</tr>
<tr>
<td>-cFILENAME</td>
<td>Path to a config file to be generated</td>
</tr>
</tbody>
</table>

The -t and -c options work together to set the configuration parameters for a new instance. The -t option specifies the template configuration file to use as the basic configuration, which are then merged with the configuration parameters generated by the MySQL Server Instance Config Wizard into the configuration file specified by the -c option.

A sample template file, my-template.ini is provided in the toplevel MySQL installation directory. The file contains elements are replaced automatically by the MySQL Server Instance Config Wizard during configuration.

If you specify a configuration file that already exists, the existing configuration file will be saved in the file with the original, with the date and time added. For example, the mysql.ini will be copied to mysql2009-10-27 1646.ini.bak.

The parameters that you can specify on the command line are listed in the table below.

Table 2.6 MySQL Server Instance Config Wizard Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ServiceName=$</td>
<td>Specify the name of the service to be created</td>
</tr>
<tr>
<td>AddBinToPath={yes</td>
<td>no}</td>
</tr>
</tbody>
</table>
### Parameter | Description
--- | ---
ServerType={DEVELOPMENT | SERVER | DEDICATED} | Specify the server type. For more information, see Section 2.3.6.4, “The Server Type Dialog”
DatabaseType={MIXED | INNODB | MYISAM} | Specify the default database type. For more information, see Section 2.3.6.5, “The Database Usage Dialog”
ConnectionUsage={DSS | OLTP} | Specify the type of connection support, this automates the setting for the number of concurrent connections (see the ConnectionCount parameter). For more information, see Section 2.3.6.7, “The Concurrent Connections Dialog”
ConnectionCount=# | Specify the number of concurrent connections to support. For more information, see Section 2.3.6.4, “The Server Type Dialog”
SkipNetworking={yes | no} | Specify whether network support should be supported. Specifying yes disables network access altogether
Port=# | Specify the network port number to use for network connections. For more information, see Section 2.3.6.8, “The Networking and Strict Mode Options Dialog”
StrictMode={yes | no} | Specify whether to use the strict SQL mode. For more information, see Section 2.3.6.8, “The Networking and Strict Mode Options Dialog”
Charset=$ | Specify the default character set. For more information, see Section 2.3.6.9, “The Character Set Dialog”
RootPassword=$ | Specify the root password
RootCurrentPassword=$ | Specify the current root password then stopping or reconfiguring an existing service

**Note**

When specifying options on the command line, you can enclose the entire command-line option and the value you are specifying using double quotation marks. This enables you to use spaces in the options. For example, "-cC:\mysql.ini".

The following command installs a MySQL Server 5.5 instance from the directory C:\Program Files\MySQL\MySQL Server 5.5 using the service name MySQL55 and setting the root password to 1234.

```
shell> MySQLInstanceConfig.exe -i -q "-lC:\mysql_install_log.txt" »
    "-nMySQL Server 5.5" "-pC:\Program Files\MySQL\MySQL Server 5.5 -v5.5.40 »
    "-tmy-template.ini" "-cC:\mytest.ini" ServerType=DEVELOPMENT DatabaseType=MIXED »
    ConnectionUsage=DSS Port=3311 ServiceName=MySQL55 RootPassword=1234
```

In the above example, a log file will be generated in mysql_install_log.txt containing the information about the instance creation process. The log file generated by the above example is shown below:

```
Welcome to the MySQL Server Instance Configuration Wizard 1.0.16.0
Date: 2009-10-27 17:07:21
Installing service ...
Product Name: MySQL Server 5.5
Version: 5.5.40
Installation Path: C:\Program Files\MySQL\MySQL Server 5.5
```
Creating configuration file C:\mytest.ini using template my-template.ini.
Options:
  DEVELOPMENT
  MIXED
  DSS
  STRICTMODE

Variables:
  port: 3311
  default-character-set: latin1
  basedir: "C:/Program Files/MySQL/MySQL Server 5.5/"
  datadir: "C:/Program Files/MySQL/MySQL Server 5.5/Data/"

Creating Windows service entry.
Service name: "MySQL55"
Parameters: "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysqld" --defaults-file="C:\mytest.ini" MySQL55. Windows service MySQL55 installed.

When using the command line, the return values in the following table indicate an error performing the specified option.

### Table 2.7 Return Value from MySQL Server Instance Config Wizard

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>Configuration template file cannot be found</td>

</table>

You can perform an installation of MySQL automatically using the MSI package. For more information, see Section 2.3.5.2, “Automating MySQL Installation on Microsoft Windows Using the MSI Package”.

### 2.3.7 Installing MySQL on Microsoft Windows Using a noinstall Zip Archive

Users who are installing from the noinstall package can use the instructions in this section to manually install MySQL. The process for installing MySQL from a Zip archive is as follows:

1. Extract the archive to the desired install directory
2. Create an option file
3. Choose a MySQL server type
4. Start the MySQL server
5. Secure the default user accounts

This process is described in the sections that follow.

#### 2.3.7.1 Extracting the Install Archive

To install MySQL manually, do the following:
1. If you are upgrading from a previous version please refer to Section 2.3.9, “Upgrading MySQL on Windows”, before beginning the upgrade process.

2. Make sure that you are logged in as a user with administrator privileges.

3. Choose an installation location. Traditionally, the MySQL server is installed in C:\mysql. The MySQL Installation Wizard instalils MySQL under C:\Program Files\MySQL. If you do not install MySQL at C:\mysql, you must specify the path to the install directory during startup or in an option file. See Section 2.3.7.2, “Creating an Option File”.

4. Extract the install archive to the chosen installation location using your preferred Zip archive tool. Some tools may extract the archive to a folder within your chosen installation location. If this occurs, you can move the contents of the subfolder into the chosen installation location.

2.3.7.2 Creating an Option File

If you need to specify startup options when you run the server, you can indicate them on the command line or place them in an option file. For options that are used every time the server starts, you may find it most convenient to use an option file to specify your MySQL configuration. This is particularly true under the following circumstances:

- The installation or data directory locations are different from the default locations (C:\Program Files \MySQL\MySQL Server 5.5 and C:\Program Files\MySQL\MySQL Server 5.5\data).
- You need to tune the server settings, such as memory, cache, or InnoDB configuration information.

When the MySQL server starts on Windows, it looks for option files in several locations, such as the Windows directory, C:\, and the MySQL installation directory (for the full list of locations, see Section 4.2.6, “Using Option Files”). The Windows directory typically is named something like C:\WINDOWS. You can determine its exact location from the value of the WINDIR environment variable using the following command:

```cmd
C:\> echo %WINDIR%
```

MySQL looks for options in each location first in the my.ini file, and then in the my.cnf file. However, to avoid confusion, it is best if you use only one file. If your PC uses a boot loader where C: is not the boot drive, your only option is to use the my.ini file. Whichever option file you use, it must be a plain text file.

**Note**

When using the MySQL Installer to install MySQL Server, it will create the my.ini at the default location. And as of MySQL Server 5.5.27, the user running MySQL Installer is granted full permissions to this new my.ini.

In other words, be sure that the MySQL Server user has permission to read the my.ini file. You can also make use of the example option files included with your MySQL distribution; see Section 5.1.2, “Server Configuration Defaults”.

An option file can be created and modified with any text editor, such as Notepad. For example, if MySQL is installed in E:\mysql and the data directory is in E:\mydata\data, you can create an option file containing a [mysqld] section to specify values for the basedir and datadir options:

```ini
[mysqld]
set basedir to your installation path
basedir=E:/mysql
set datadir to the location of your data directory
```

121
datadir=E:/mydata/data

Note that Windows path names are specified in option files using (forward) slashes rather than backslashes. If you do use backslashes, double them:

```
[mysqld]
# set basedir to your installation path
basedir=E:\mysql
# set datadir to the location of your data directory
datadir=E:\mydata\data
```

The rules for use of backslash in option file values are given in Section 4.2.6, “Using Option Files”.

The data directory is located within the AppData directory for the user running MySQL.

If you would like to use a data directory in a different location, you should copy the entire contents of the data directory to the new location. For example, if you want to use E:\mydata as the data directory instead, you must do two things:

1. Move the entire data directory and all of its contents from the default location (for example C:\Program Files\MySQL\MySQL Server 5.5\data) to E:\mydata.

2. Use a --datadir option to specify the new data directory location each time you start the server.

### 2.3.7.3 Selecting a MySQL Server Type

The following table shows the available servers for Windows in MySQL 5.5.

<table>
<thead>
<tr>
<th>Binary</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysqld</td>
<td>Optimized binary with named-pipe support</td>
</tr>
<tr>
<td>mysqld-debug</td>
<td>Like mysqld, but compiled with full debugging and automatic memory allocation</td>
</tr>
</tbody>
</table>

All of the preceding binaries are optimized for modern Intel processors, but should work on any Intel i386-class or higher processor.

Each of the servers in a distribution support the same set of storage engines. The SHOW ENGINES statement displays which engines a given server supports.

All Windows MySQL 5.5 servers have support for symbolic linking of database directories.

MySQL supports TCP/IP on all Windows platforms. MySQL servers on Windows also support named pipes, if you start the server with the --enable-named-pipe option. It is necessary to use this option explicitly because some users have experienced problems with shutting down the MySQL server when named pipes were used. The default is to use TCP/IP regardless of platform because named pipes are slower than TCP/IP in many Windows configurations.

### 2.3.7.4 Starting the Server for the First Time

This section gives a general overview of starting the MySQL server. The following sections provide more specific information for starting the MySQL server from the command line or as a Windows service.

The information here applies primarily if you installed MySQL using the Noinstall version, or if you wish to configure and test MySQL manually rather than with the GUI tools.

The examples in these sections assume that MySQL is installed under the default location of C:\Program Files\MySQL\MySQL Server 5.5. Adjust the path names shown in the examples if you have MySQL installed in a different location.
Clients have two options. They can use TCP/IP, or they can use a named pipe if the server supports named-pipe connections.

MySQL for Windows also supports shared-memory connections if the server is started with the `--shared-memory` option. Clients can connect through shared memory by using the `--protocol=MEMORY` option.

For information about which server binary to run, see Section 2.3.7.3, “Selecting a MySQL Server Type”.

Testing is best done from a command prompt in a console window (or “DOS window”). In this way you can have the server display status messages in the window where they are easy to see. If something is wrong with your configuration, these messages make it easier for you to identify and fix any problems.

To start the server, enter this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysqld" --console
```

For a server that includes InnoDB support, you should see the messages similar to those following as it starts (the path names and sizes may differ):

```
InnoDB: The first specified datafile c:\ibdata\ibdata1 did not exist:
InnoDB: a new database to be created!
InnoDB: Setting file c:\ibdata\ibdata1 size to 209715200
InnoDB: Database physically writes the file full: wait...
InnoDB: Log file c:\iblogs\ib_logfile0 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile0 size to 31457280
InnoDB: Log file c:\iblogs\ib_logfile1 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile1 size to 31457280
InnoDB: Log file c:\iblogs\ib_logfile2 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile2 size to 31457280
InnoDB: Doublewrite buffer not found: creating new
InnoDB: Doublewrite buffer created
InnoDB: creating foreign key constraint system tables
InnoDB: foreign key constraint system tables created
011024 10:58:25  InnoDB: Started
```

When the server finishes its startup sequence, you should see something like this, which indicates that the server is ready to service client connections:

```
mysqld: ready for connections
Version: '5.5.40' socket: '' port: 3306
```

The server continues to write to the console any further diagnostic output it produces. You can open a new console window in which to run client programs.

If you omit the `--console` option, the server writes diagnostic output to the error log in the data directory (`C:\Program Files\MySQL\MySQL Server 5.5\data` by default). The error log is the file with the `.err` extension, or may be specified by passing in the `--log-error` option.

---

**Note**

The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.10.2, “Securing the Initial MySQL Accounts”.

### 2.3.7.5 Starting MySQL from the Windows Command Line

The MySQL server can be started manually from the command line. This can be done on any version of Windows.
To start the `mysqld` server from the command line, you should start a console window (or “DOS window”) and enter this command:

```cmd
C:\> "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysqld"
```

The path to `mysqld` may vary depending on the install location of MySQL on your system.

You can stop the MySQL server by executing this command:

```cmd
C:\> "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysqladmin" -u root shutdown
```

**Note**

If the MySQL root user account has a password, you need to invoke `mysqladmin` with the `-p` option and supply the password when prompted.

This command invokes the MySQL administrative utility `mysqladmin` to connect to the server and tell it to shut down. The command connects as the MySQL root user, which is the default administrative account in the MySQL grant system. Note that users in the MySQL grant system are wholly independent from any login users under Windows.

If `mysqld` doesn't start, check the error log to see whether the server wrote any messages there to indicate the cause of the problem. By default, the error log is located in the `C:\Program Files\MySQL\MySQL Server 5.5\data` directory. It is the file with a suffix of `.err`, or may be specified by passing in the `--log-error` option. Alternatively, you can try to start the server as `mysqld --console`; in this case, you may get some useful information on the screen that may help solve the problem.

The last option is to start `mysqld` with the `--standalone` and `--debug` options. In this case, `mysqld` writes a log file `C:\mysql.trace` that should contain the reason why `mysqld` doesn't start. See Section 24.4.3, “The DBUG Package”.

Use `mysqld --verbose --help` to display all the options that `mysqld` supports.

### 2.3.7.6 Customizing the PATH for MySQL Tools

To make it easier to invoke MySQL programs, you can add the path name of the MySQL `bin` directory to your Windows system `PATH` environment variable:

- On the Windows desktop, right-click the My Computer icon, and select Properties.
- Next select the Advanced tab from the System Properties menu that appears, and click the Environment Variables button.
- Under System Variables, select Path, and then click the Edit button. The Edit System Variable dialogue should appear.
- Place your cursor at the end of the text appearing in the space marked Variable Value. (Use the End key to ensure that your cursor is positioned at the very end of the text in this space.) Then enter the complete path name of your MySQL `bin` directory (for example, `C:\Program Files\MySQL\MySQL Server 5.5\bin`)

**Note**

There must be a semicolon separating this path from any values present in this field.

Dismiss this dialogue, and each dialogue in turn, by clicking OK until all of the dialogues that were opened have been dismissed. You should now be able to invoke any MySQL executable program by
typing its name at the DOS prompt from any directory on the system, without having to supply the path. This includes the servers, the `mysql` client, and all MySQL command-line utilities such as `mysqladmin` and `mysqldump`.

You should not add the MySQL bin directory to your Windows PATH if you are running multiple MySQL servers on the same machine.

**Warning**
You must exercise great care when editing your system PATH by hand; accidental deletion or modification of any portion of the existing PATH value can leave you with a malfunctioning or even unusable system.

### 2.3.7.7 Starting MySQL as a Windows Service

On Windows, the recommended way to run MySQL is to install it as a Windows service, so that MySQL starts and stops automatically when Windows starts and stops. A MySQL server installed as a service can also be controlled from the command line using NET commands, or with the graphical Services utility. Generally, to install MySQL as a Windows service you should be logged in using an account that has administrator rights.

The Services utility (the Windows Service Control Manager) can be found in the Windows Control Panel (under Administrative Tools on Windows 2000, XP, Vista, and Server 2003). To avoid conflicts, it is advisable to close the Services utility while performing server installation or removal operations from the command line.

#### Installing the service

Before installing MySQL as a Windows service, you should first stop the current server if it is running by using the following command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysqladmin" -u root shutdown
```

**Note**
If the MySQL root user account has a password, you need to invoke `mysqladmin` with the `-p` option and supply the password when prompted.

This command invokes the MySQL administrative utility `mysqladmin` to connect to the server and tell it to shut down. The command connects as the MySQL root user, which is the default administrative account in the MySQL grant system. Note that users in the MySQL grant system are wholly independent from any login users under Windows.

Install the server as a service using this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysqld" --install
```

The service-installation command does not start the server. Instructions for that are given later in this section.

To make it easier to invoke MySQL programs, you can add the path name of the MySQL bin directory to your Windows system PATH environment variable:

- On the Windows desktop, right-click the My Computer icon, and select Properties.
- Next select the Advanced tab from the System Properties menu that appears, and click the Environment Variables button.
Installing MySQL on Microsoft Windows Using a `noinstall` Zip Archive

• Under **System Variables**, select Path, and then click the **Edit** button. The **Edit System Variable** dialogue should appear.

• Place your cursor at the end of the text appearing in the space marked **Variable Value**. (Use the **End** key to ensure that your cursor is positioned at the very end of the text in this space.) Then enter the complete path name of your MySQL `bin` directory (for example, `C:\Program Files\MySQL\MySQL Server 5.5\bin`). Note that there should be a semicolon separating this path from any values present in this field. Dismiss this dialogue, and each dialogue in turn, by clicking **OK** until all of the dialogues that were opened have been dismissed. You should now be able to invoke any MySQL executable program by typing its name at the DOS prompt from any directory on the system, without having to supply the path. This includes the servers, the `mysql` client, and all MySQL command-line utilities such as `mysqladmin` and `mysqldump`.

You should not add the MySQL `bin` directory to your Windows **PATH** if you are running multiple MySQL servers on the same machine.

**Warning**

You must exercise great care when editing your system **PATH** by hand; accidental deletion or modification of any portion of the existing **PATH** value can leave you with a malfunctioning or even unusable system.

The following additional arguments can be used when installing the service:

• You can specify a service name immediately following the `--install` option. The default service name is MySQL.

• If a service name is given, it can be followed by a single option. By convention, this should be `--defaults-file=file_name` to specify the name of an option file from which the server should read options when it starts.

The use of a single option other than `--defaults-file` is possible but discouraged. `--defaults-file` is more flexible because it enables you to specify multiple startup options for the server by placing them in the named option file.

• You can also specify a `--local-service` option following the service name. This causes the server to run using the LocalService Windows account that has limited system privileges. This account is available only for Windows XP or newer. If both `--defaults-file` and `--local-service` are given following the service name, they can be in any order.

For a MySQL server that is installed as a Windows service, the following rules determine the service name and option files that the server uses:

• If the service-installation command specifies no service name or the default service name (**MySQL**) following the `--install` option, the server uses the a service name of MySQL and reads options from the `[mysqld]` group in the standard option files.

• If the service-installation command specifies a service name other than MySQL following the `--install` option, the server uses that service name. It reads options from the `[mysqld]` group and the group that has the same name as the service in the standard option files. This enables you to use the `[mysqld]` group for options that should be used by all MySQL services, and an option group with the service name for use by the server installed with that service name.

• If the service-installation command specifies a `--defaults-file` option after the service name, the server reads options the same way as described in the previous item, except that it reads options only from the named file and ignores the standard option files.

As a more complex example, consider the following command:
Installing MySQL on Microsoft Windows Using a noinstall Zip Archive

C:\> "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysqld"
    --install MySQL --defaults-file=C:\my-opts.cnf

Here, the default service name (MySQL) is given after the --install option. If no --defaults-file option had been given, this command would have the effect of causing the server to read the [mysqld] group from the standard option files. However, because the --defaults-file option is present, the server reads options from the [mysqld] option group, and only from the named file.

Note

On Windows, if the server is started with the --defaults-file and --install options, --install must be first. Otherwise, mysqld.exe will attempt to start the MySQL server.

You can also specify options as Start parameters in the Windows Services utility before you start the MySQL service.

Starting the service

Once a MySQL server has been installed as a service, Windows starts the service automatically whenever Windows starts. The service also can be started immediately from the Services utility, or by using a NET START MySQL command. The NET command is not case sensitive.

When run as a service, mysqld has no access to a console window, so no messages can be seen there. If mysqld does not start, check the error log to see whether the server wrote any messages there to indicate the cause of the problem. The error log is located in the MySQL data directory (for example, C:\Program Files\MySQL\MySQL Server 5.5\data). It is the file with a suffix of .err.

When a MySQL server has been installed as a service, and the service is running, Windows stops the service automatically when Windows shuts down. The server also can be stopped manually by using the Services utility, the NET STOP MySQL command, or the mysqladmin shutdown command.

You also have the choice of installing the server as a manual service if you do not wish for the service to be started automatically during the boot process. To do this, use the --install-manual option rather than the --install option:

C:\> "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysqld" --install-manual

Removing the service

To remove a server that is installed as a service, first stop it if it is running by executing NET STOP MySQL. Then use the --remove option to remove it:

C:\> "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysqld" --remove

If mysqld is not running as a service, you can start it from the command line. For instructions, see Section 2.3.7.5, “Starting MySQL from the Windows Command Line”.

Please see Section 2.3.8, “Troubleshooting a Microsoft Windows MySQL Server Installation”, if you encounter difficulties during installation.

2.3.7.8 Testing The MySQL Installation

You can test whether the MySQL server is working by executing any of the following commands:

C:\> "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysqlshow"
If `mysqld` is slow to respond to TCP/IP connections from client programs, there is probably a problem with your DNS. In this case, start `mysqld` with the `--skip-name-resolve` option and use only `localhost` and IP addresses in the `Host` column of the MySQL grant tables.

You can force a MySQL client to use a named-pipe connection rather than TCP/IP by specifying the `--pipe` or `--protocol=PIPE` option, or by specifying . (period) as the host name. Use the `--socket` option to specify the name of the pipe if you do not want to use the default pipe name.

Note that if you have set a password for the `root` account, deleted the anonymous account, or created a new user account, then to connect to the MySQL server you must use the appropriate `-u` and `-p` options with the commands shown previously. See Section 4.2.2, “Connecting to the MySQL Server”.

For more information about `mysqlshow`, see Section 4.5.6, “mysqlshow — Display Database, Table, and Column Information”.

### 2.3.8 Troubleshooting a Microsoft Windows MySQL Server Installation

When installing and running MySQL for the first time, you may encounter certain errors that prevent the MySQL server from starting. The purpose of this section is to help you diagnose and correct some of these errors.

Your first resource when troubleshooting server issues is the error log. The MySQL server uses the error log to record information relevant to the error that prevents the server from starting. The error log is located in the data directory specified in your `my.ini` file. The default data directory location is `C:\Program Files\MySQL\MySQL Server 5.5\data`, or `C:\ProgramData\MySql` on Windows 7 and Windows Server 2008. The `C:\ProgramData` directory is hidden by default. You need to change your folder options to see the directory and contents. For more information on the error log and understanding the content, see Section 5.2.2, “The Error Log”.

Another source of information regarding possible errors is the console messages displayed when the MySQL service is starting. Use the `NET START MySQL` command from the command line after installing `mysqld` as a service to see any error messages regarding the starting of the MySQL server as a service. See Section 2.3.7.7, “Starting MySQL as a Windows Service”.

The following examples show other common error messages you may encounter when installing MySQL and starting the server for the first time:

- If the MySQL server cannot find the `mysql` privileges database or other critical files, you may see these messages:

```plaintext
System error 1067 has occurred.
Fatal error: Can't open privilege tables: Table 'mysql.host' doesn't exist
```

These messages often occur when the MySQL base or data directories are installed in different locations than the default locations (`C:\Program Files\MySQL\MySQL Server 5.5\data` and `C:\Program Files\MySQL\MySQL Server 5.5\data`, respectively).

This situation may occur when MySQL is upgraded and installed to a new location, but the configuration file is not updated to reflect the new location. In addition, there may be old and new configuration files that conflict. Be sure to delete or rename any old configuration files when upgrading MySQL.

If you have installed MySQL to a directory other than `C:\Program Files\MySQL\MySQL Server 5.5`, you need to ensure that the MySQL server is aware of this through the use of a configuration
(my.ini) file. The my.ini file needs to be located in your Windows directory, typically C:\WINDOWS. You can determine its exact location from the value of the WINDIR environment variable by issuing the following command from the command prompt:

C:\> echo %WINDIR%

An option file can be created and modified with any text editor, such as Notepad. For example, if MySQL is installed in E:\mysql and the data directory is D:\MySQLdata, you can create the option file and set up a [mysqld] section to specify values for the basedir and datadir options:

```ini
[mysqld]
# set basedir to your installation path
basedir=E:/mysql
# set datadir to the location of your data directory
datadir=D:/MySQLdata
```

Note that Windows path names are specified in option files using (forward) slashes rather than backslashes. If you do use backslashes, double them:

```ini
[mysqld]
# set basedir to your installation path
basedir=C:\Program Files\MySQL\MySQL Server 5.5
# set datadir to the location of your data directory
datadir=D:\MySQLdata
```

The rules for use of backslash in option file values are given in Section 4.2.6, "Using Option Files".

If you change the datadir value in your MySQL configuration file, you must move the contents of the existing MySQL data directory before restarting the MySQL server.

See Section 2.3.7.2, "Creating an Option File".

- If you reinstall or upgrade MySQL without first stopping and removing the existing MySQL service and install MySQL using the MySQL Configuration Wizard, you may see this error:

```
Error: Cannot create Windows service for MySql. Error: 0
```

This occurs when the Configuration Wizard tries to install the service and finds an existing service with the same name.

One solution to this problem is to choose a service name other than mysql when using the configuration wizard. This enables the new service to be installed correctly, but leaves the outdated service in place. Although this is harmless, it is best to remove old services that are no longer in use.

To permanently remove the old mysql service, execute the following command as a user with administrative privileges, on the command-line:

C:\> sc delete mysql

If the sc utility is not available for your version of Windows, download the delsrv utility from http://www.microsoft.com/windows2000/techinfo/reskit/tools/existing/delsrv-o.asp and use the delsrv mysql syntax.

### 2.3.9 Upgrading MySQL on Windows
To upgrade MySQL on Windows, follow these steps:

1. Review Section 2.11.1, “Upgrading MySQL”, for additional information on upgrading MySQL that is not specific to Windows.

2. You should always back up your current MySQL installation before performing an upgrade. See Section 7.2, “Database Backup Methods”.

4. Before upgrading MySQL, you must stop the server. If the server is installed as a service, stop the service with the following command from the command prompt:

   ```
   C:\> NET STOP MySQL
   ```

   If you are not running the MySQL server as a service, use `mysqladmin` to stop it. For example, before upgrading from MySQL 5.1 to 5.5, use `mysqladmin` from MySQL 5.1 as follows:

   ```
   C:\> "C:\Program Files\MySQL\MySQL Server 5.1\bin\mysqladmin" -u root shutdown
   ```

   **Note**

   If the MySQL root user account has a password, you need to invoke `mysqladmin` with the `-p` option and enter the password when prompted.

5. Before upgrading a MySQL service from MySQL 5.1 to 5.5, you should stop the 5.1 server and remove the instance. Run the MySQL Instance Configuration Wizard, choose the Remove Instance option and in the next screen, confirm removal. After that it is safe to uninstall MySQL Server 5.1.

6. Before upgrading to MySQL 5.5 from a version previous to 4.1.5, or from a version of MySQL installed from a Zip archive to a version of MySQL installed with the MySQL Installation Wizard, you must first manually remove the previous installation and MySQL service (if the server is installed as a service).

   To remove the MySQL service, use the following command:

   ```
   C:\> C:\mysql\bin\mysqld --remove
   ```

   **If you do not remove the existing service, the MySQL Installation Wizard may fail to properly install the new MySQL service.**

7. If you are using the MySQL Installation Wizard, start the wizard as described in Section 2.3.5.1, “Using the MySQL Installation Wizard”.

8. If you are installing MySQL from a Zip archive, extract the archive. You may either overwrite your existing MySQL installation (usually located at C:\mysql), or install it into a different directory, such as C:\mysql5. Overwriting the existing installation is recommended.

9. If you were running MySQL as a Windows service and you had to remove the service earlier in this procedure, reinstall the service. (See Section 2.3.7.7, “Starting MySQL as a Windows Service”.)

10. Restart the server. For example, use `NET START MySQL` if you run MySQL as a service, or invoke `mysqld` directly otherwise.

11. As Administrator, run `mysql_upgrade` to check your tables, attempt to repair them if necessary, and update your grant tables if they have changed so that you can take advantage of any new capabilities. See Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”. 
12. If you encounter errors, see Section 2.3.8, “Troubleshooting a Microsoft Windows MySQL Server Installation”.

### 2.3.10 Windows Postinstallation Procedures

On Windows, you need not create the data directory and the grant tables. MySQL Windows distributions include the grant tables with a set of preinitialized accounts in the `mysql` database under the data directory. Regarding passwords, if you installed MySQL using the Windows Installation Wizard, you may have already assigned passwords to the accounts. (See Section 2.3.5.1, “Using the MySQL Installation Wizard”.) Otherwise, use the password-assignment procedure given in Section 2.10.2, “Securing the Initial MySQL Accounts”.

Before setting up passwords, you might want to try running some client programs to make sure that you can connect to the server and that it is operating properly. Make sure that the server is running (see Section 2.3.7.4, “Starting the Server for the First Time”), and then issue the following commands to verify that you can retrieve information from the server. You may need to specify directory different from `C:\mysql\bin` on the command line. If you used the Windows Installation Wizard, the default directory is `C:\Program Files\MySQL\MySQL Server 5.5`, and the `mysql` and `mysqlshow` client programs are in `C:\Program Files\MySQL\MySQL Server 5.5\bin`. See Section 2.3.5.1, “Using the MySQL Installation Wizard”, for more information.

Use `mysqlshow` to see what databases exist:

```
C:\> C:\mysql\bin\mysqlshow
+--------------------+
|     Databases      |
+--------------------+
| information_schema |
| mysql              |
| test               |
+--------------------+
```

The list of installed databases may vary, but will always include the minimum of `mysql` and `information_schema`. In most cases, the `test` database will also be installed automatically.

The preceding command (and commands for other MySQL programs such as `mysql`) may not work if the correct MySQL account does not exist. For example, the program may fail with an error, or you may not be able to view all databases. If you installed using the MSI packages and used the MySQL Server Instance Config Wizard, then the `root` user will have been created automatically with the password you supplied. In this case, you should use the `-u root` and `-p` options. (You will also need to use the `-u root` and `-p` options if you have already secured the initial MySQL accounts.) With `-p`, you will be prompted for the `root` password. For example:

```
C:\> C:\mysql\bin\mysqlshow -u root -p
Enter password: (enter root password here)
+--------------------+
|     Databases      |
+--------------------+
| information_schema |
| mysql              |
| test               |
+--------------------+
```

If you specify a database name, `mysqlshow` displays a list of the tables within the database:
Use the `mysql` program to select information from a table in the `mysql` database:

```
C:\> C:\mysql\bin\mysqlshow mysql
Database: mysql
+---------------------------+
|          Tables           |
+---------------------------+
| columns_priv              |
| db                        |
| event                     |
| func                      |
| help_category             |
| help_keyword              |
| help_relation             |
| help_topic                |
| host                      |
| plugin                    |
| proc                      |
| procs_priv                |
| servers                   |
| tables_priv               |
| time_zone                 |
| time_zone_leap_second     |
| time_zone_name            |
| time_zone_transition      |
| time_zone_transition_type |
| user                      |
+---------------------------+
```

For more information about `mysqlshow` and `mysql`, see Section 4.5.6, “mysqlshow — Display Database, Table, and Column Information”, and Section 4.5.1, “mysql — The MySQL Command-Line Tool”.

If you are running a version of Windows that supports services, you can set up the MySQL server to run automatically when Windows starts. See Section 2.3.7.7, “Starting MySQL as a Windows Service”.

### 2.4 Installing MySQL on Mac OS X

For a list of supported Mac OS X versions that the MySQL server supports, see [http://www.mysql.com/support/supportedplatforms/database.html](http://www.mysql.com/support/supportedplatforms/database.html).

MySQL for Mac OS X is available in a number of different forms:

- **Native Package Installer format**, which uses the native Mac OS X installer (DMG) to walk you through the installation of MySQL. For more information, see Section 2.4.2, “Installing MySQL on Mac OS X Using Native Packages”. You can use the package installer with Mac OS X 10.6 and later, and the package is available for both 32-bit and 64-bit architectures. The user you use to perform the installation must have administrator privileges.

- **Tar package format**, which uses a file packaged using the Unix `tar` and `gzip` commands. To use this method, you will need to open a Terminal window. You do not need administrator privileges using this method, as you can install the MySQL server anywhere using this method. For more information on using this method, you can use the generic instructions for using a tarball, Section 2.2, “Installing MySQL
You can use the package installer with Mac OS X 10.6 and later, and available for both 32-bit and 64-bit architectures.

In addition to the core installation, the Package Installer also includes Section 2.4.3, “Installing the MySQL Startup Item” and Section 2.4.4, “Installing and Using the MySQL Preference Pane”, both of which simplify the management of your installation.

• Mac OS X server includes a version of MySQL as standard. If you want to use a more recent version than that supplied with the Mac OS X server release, you can make use of the package or tar formats. For more information on using the MySQL bundled with Mac OS X, see Section 2.4.5, “Using the Bundled MySQL on Mac OS X Server”.

For additional information on using MySQL on Mac OS X, see Section 2.4.1, “General Notes on Installing MySQL on Mac OS X”.

### 2.4.1 General Notes on Installing MySQL on Mac OS X

You should keep the following issues and notes in mind:

• The default location for the MySQL Unix socket is different on Mac OS X and Mac OS X Server depending on the installation type you chose. The following table shows the default locations by installation type.

<table>
<thead>
<tr>
<th>Installation Type</th>
<th>Socket Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>Package Installer from MySQL</td>
<td>/tmp/mysql.sock</td>
</tr>
<tr>
<td>Tarball from MySQL</td>
<td>/tmp/mysql.sock</td>
</tr>
<tr>
<td>MySQL Bundled with Mac OS X Server</td>
<td>/var/mysql/mysql.sock</td>
</tr>
</tbody>
</table>

To prevent issues, you should either change the configuration of the socket used within your application (for example, changing `php.ini`), or you should configure the socket location using a MySQL configuration file and the `socket` option. For more information, see Section 5.1.3, “Server Command Options”.

• You may need (or want) to create a specific `mysql` user to own the MySQL directory and data. You can do this through the Directory Utility, and the `mysql` user should already exist. For use in single user mode, an entry for `_mysql` (note the underscore prefix) should already exist within the system `/etc/passwd` file.

• If you get an “insecure startup item disabled” error when MySQL launches, use the following procedure. Adjust the pathnames appropriately for your system.

1. Modify the `mysql.script` using this command (enter it on a single line):

   ```bash
   shell> sudo /Applications/TextEdit.app/Contents/MacOS/TextEdit
   /usr/local/mysql/support-files/mysql.server
   ```

2. Locate the option file that defines the `basedir` value and modify it to contain these lines:

   ```
   basedir=/usr/local/mysql
   datadir=/usr/local/mysql/data
   ```

   In the `/Library/StartupItems/MySQLCOM/` directory, make the following group ID changes from `staff` to `wheel`:
3. Start the server from System Preferences or Terminal.app.

- Because the MySQL package installer installs the MySQL contents into a version and platform specific directory, you can use this to upgrade and migrate your database between versions. You will need to either copy the data directory from the old version to the new version, or alternatively specify an alternative datadir value to set location of the data directory.

- You might want to add aliases to your shell’s resource file to make it easier to access commonly used programs such as mysql and mysqladmin from the command line. The syntax for bash is:

```bash
alias mysql=/usr/local/mysql/bin/mysql
alias mysqladmin=/usr/local/mysql/bin/mysqladmin
```

For tcsh, use:

```tcsh
alias mysql /usr/local/mysql/bin/mysql
alias mysqladmin /usr/local/mysql/bin/mysqladmin
```

Even better, add /usr/local/mysql/bin to your PATH environment variable. You can do this by modifying the appropriate startup file for your shell. For more information, see Section 4.2.1, “Invoking MySQL Programs”.

- After you have copied over the MySQL database files from the previous installation and have successfully started the new server, you should consider removing the old installation files to save disk space. Additionally, you should also remove older versions of the Package Receipt directories located in /Library/Receipts/mysql-VERSION.pkg.

### 2.4.2 Installing MySQL on Mac OS X Using Native Packages

The package is located inside a disk image (.dmg) file that you first need to mount by double-clicking its icon in the Finder. It should then mount the image and display its contents.

**Note**

Before proceeding with the installation, be sure to stop all running MySQL server instances by using either the MySQL Manager Application (on Mac OS X Server) or mysqladmin shutdown on the command line.

When installing from the package version, you should also install the MySQL Preference Pane, which will enable you to control the startup and execution of your MySQL server from System Preferences. For more information, see Section 2.4.4, “Installing and Using the MySQL Preference Pane”.

When installing using the package installer, the files are installed into a directory within /usr/local matching the name of the installation version and platform. For example, the installer file mysql-5.5-osx10.7-x86_64.dmg installs MySQL into /usr/local/mysql-5.5-osx10.7-x86_64/. The following table shows the layout of the installation directory.

<table>
<thead>
<tr>
<th>Directory</th>
<th>Contents of Directory</th>
</tr>
</thead>
<tbody>
<tr>
<td>bin</td>
<td>Client programs and the mysql server</td>
</tr>
</tbody>
</table>
## Directory Structure

<table>
<thead>
<tr>
<th>Directory</th>
<th>Contents of Directory</th>
</tr>
</thead>
<tbody>
<tr>
<td>data</td>
<td>Log files, databases</td>
</tr>
<tr>
<td>docs</td>
<td>Helper documents, like the Release Notes and build information</td>
</tr>
<tr>
<td>include</td>
<td>Include (header) files</td>
</tr>
<tr>
<td>lib</td>
<td>Libraries</td>
</tr>
<tr>
<td>man</td>
<td>Unix manual pages</td>
</tr>
<tr>
<td>mysql-test</td>
<td>MySQL test suite</td>
</tr>
<tr>
<td>scripts</td>
<td>mysql_install_db</td>
</tr>
<tr>
<td>share</td>
<td>Miscellaneous support files, including error messages, sample configuration files, SQL for database installation</td>
</tr>
<tr>
<td>sql-bench</td>
<td>Benchmarks</td>
</tr>
<tr>
<td>support-files</td>
<td>Scripts and sample configuration files</td>
</tr>
<tr>
<td>/tmp/mysql.sock</td>
<td>Location of the MySQL Unix socket</td>
</tr>
</tbody>
</table>

During the package installer process, a symbolic link from /usr/local/mysql to the version/platform specific directory created during installation will be created automatically.

1. Download and open the MySQL package installer, which is provided on a disk image (.dmg) that includes the main MySQL installation package, the MySQLStartupItem.pkg installation package, and the MySQL.prefPane. Double-click the disk image to open it.

![Figure 2.31 MySQL Package Installer: DMG Contents](image)

2. Double-click the MySQL installer package. It will be named according to the version of MySQL you have downloaded. For example, if you have downloaded MySQL server 5.5.40, double-click mysql-5.5.40-osx-10.7-x86_64.pkg.

3. You will be presented with the opening installer dialog. Click Continue to begin installation.
4. A copy of the installation instructions and other important information relevant to this installation are displayed. Click Continue.

5. If you have downloaded the community version of MySQL, you will be shown a copy of the relevant GNU General Public License. Click Continue.

6. Select the drive you want to use to install the MySQL Startup Item. The drive must have a valid, bootable, Mac OS X operating system installed. Click Continue.
Figure 2.33 MySQL Package Installer: Choose your Hard drive

7. You will be asked to confirm the details of the installation, including the space required for the installation. To change the drive on which the MySQL server is installed, click either Go Back or Change Install Location… To install the MySQL server, click Install.

8. Once the installation has been completed successfully, you will be shown an Install Succeeded message.

For convenience, you may also want to install the startup item and preference pane. See Section 2.4.3, “Installing the MySQL Startup Item”, and Section 2.4.4, “Installing and Using the MySQL Preference Pane”.

2.4.3 Installing the MySQL Startup Item

The MySQL Installation Package includes a startup item that can be used to automatically start and stop MySQL.

To install the MySQL Startup Item:

1. Download and open the MySQL package installer, which is provided on a disk image (.dmg) that includes the main MySQL installation package, the MySQLStartupScriptItem.pkg installation package, and the MySQL.prefPane. Double-click the disk image to open it.
Installing the MySQL Startup Item

Figure 2.34 MySQL Package Installer: DMG Contents

2. Double-click the MySQLStartItem.pkg file to start the installation process.

3. You will be presented with the Install MySQL Startup Item dialog.

Figure 2.35 MySQL Startup Item Installer: Introduction

Click Continue to continue the installation process.

4. A copy of the installation instructions and other important information relevant to this installation are displayed. Click Continue.

5. Select the drive you want to use to install the MySQL Startup Item. The drive must have a valid, bootable, Mac OS X operating system installed. Click Continue.
6. You will be asked to confirm the details of the installation. To change the drive on which the startup item is installed, click either **Go Back** or **Change Install Location...**. To install the startup item, click **Install**.

7. Once the installation has been completed successfully, you will be shown an **Install Succeeded** message.
The Startup Item for MySQL is installed into `/Library/StartupItems/MySQLCOM`. The Startup Item installation adds a variable `MYSQLCOM=-YES-` to the system configuration file `/etc/hostconfig`. If you want to disable the automatic startup of MySQL, change this variable to `MYSQLCOM=-NO-`.

**Note**

Deselecting **Automatically Start MySQL Server on Startup** from the MySQL Preference Pane sets the `MYSQLCOM` variable to `-NO-`.

After the installation, you can start and stop the MySQL server from the MySQL Preference Pane (preferred), or by running the following commands in a terminal window. You must have administrator privileges to perform these tasks, and you may be prompted for your password.

If you have installed the Startup Item, use this command to start the server:

```
shell> sudo /Library/StartupItems/MySQLCOM/MySQLCOM start
```

If you have installed the Startup Item, use this command to stop the server:

```
shell> sudo /Library/StartupItems/MySQLCOM/MySQLCOM stop
```
2.4.4 Installing and Using the MySQL Preference Pane

The MySQL Package installer disk image also includes a custom MySQL Preference Pane that enables you to start, stop, and control automated startup during boot of your MySQL installation.

To install the MySQL Preference Pane:

1. Download and open the MySQL package installer package, which is provided on a disk image (.dmg) that includes the main MySQL installation package, the MySQLStartupItem.pkg installation package, and the MySQL.prefPane. Double-click the disk image to open it.

2. Double-click the MySQL.prefPane. The MySQL System Preferences will open.

3. If this is the first time you have installed the preference pane, you will be asked to confirm installation and whether you want to install the preference pane for all users, or only the current user. To install the preference pane for all users you will need administrator privileges. If necessary, you will be prompted for the username and password for a user with administrator privileges.

4. If you already have the MySQL Preference Pane installed, you will be asked to confirm whether you want to overwrite the existing MySQL Preference Pane.

Note

The MySQL Preference Pane only starts and stops MySQL installation installed from the MySQL package installation that have been installed in the default location.

Once the MySQL Preference Pane has been installed, you can control your MySQL server instance using the preference pane. To use the preference pane, open the System Preferences... from the Apple menu. Select the MySQL preference pane by clicking the MySQL logo within the Other section of the preference panes list.
Figure 2.39 MySQL Preference Pane: Location

The MySQL Preference Pane shows the current status of the MySQL server, showing **stopped** (in red) if the server is not running and **running** (in green) if the server has already been started. The preference pane also shows the current setting for whether the MySQL server has been set to start automatically.

- **To start the MySQL server using the preference pane:**
  
  Click **Start MySQL Server**. You may be prompted for the username and password of a user with administrator privileges to start the MySQL server.

- **To stop the MySQL server using the preference pane:**
  
  Click **Stop MySQL Server**. You may be prompted for the username and password of a user with administrator privileges to stop the MySQL server.

- **To automatically start the MySQL server when the system boots:**
Using the Bundled MySQL on Mac OS X Server

Check the check box next to **Automatically Start MySQL Server on Startup**.

- **To disable automatic MySQL server startup when the system boots:**

  Uncheck the check box next to **Automatically Start MySQL Server on Startup**.

  You can close the **System Preferences...** window once you have completed your settings.

### 2.4.5 Using the Bundled MySQL on Mac OS X Server

If you are running Mac OS X Server, a version of MySQL should already be installed. The following table shows the versions of MySQL that ship with Mac OS X Server versions.

**Table 2.10 MySQL Versions Preinstalled with Mac OS X Server**

<table>
<thead>
<tr>
<th>Mac OS X Server Version</th>
<th>MySQL Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.2-10.2.2</td>
<td>3.23.51</td>
</tr>
<tr>
<td>10.2.3-10.2.6</td>
<td>3.23.53</td>
</tr>
<tr>
<td>10.3</td>
<td>4.0.14</td>
</tr>
<tr>
<td>10.3.2</td>
<td>4.0.16</td>
</tr>
<tr>
<td>10.4.0</td>
<td>4.1.10a</td>
</tr>
<tr>
<td>10.5.0</td>
<td>5.0.45</td>
</tr>
<tr>
<td>10.6.0</td>
<td>5.0.82</td>
</tr>
</tbody>
</table>

The following table shows the installation layout of MySQL on Mac OS X Server.

**Table 2.11 MySQL Directory Layout for Preinstalled MySQL Installations on Mac OS X Server**

<table>
<thead>
<tr>
<th>Directory</th>
<th>Contents of Directory</th>
</tr>
</thead>
<tbody>
<tr>
<td>/usr/bin</td>
<td>Client programs</td>
</tr>
<tr>
<td>/var/mysql</td>
<td>Log files, databases</td>
</tr>
<tr>
<td>/usr/libexec</td>
<td>The <em>mysqld</em> server</td>
</tr>
<tr>
<td>/usr/share/man</td>
<td>Unix manual pages</td>
</tr>
<tr>
<td>/usr/share/mysql/mysql-test</td>
<td>MySQL test suite</td>
</tr>
<tr>
<td>/usr/share/mysql</td>
<td>Miscellaneous support files, including error messages, character set files, sample configuration files, SQL for database installation</td>
</tr>
<tr>
<td>/var/mysql/mysql.sock</td>
<td>Location of the MySQL Unix socket</td>
</tr>
</tbody>
</table>

**Additional Resources**

- For more information on managing the bundled MySQL instance in Mac OS X Server 10.5, see *Mac OS X Server: Web Technologies Administration For Version 10.5 Leopard*.

- For more information on managing the bundled MySQL instance in Mac OS X Server 10.6, see *Mac OS X Server: Web Technologies Administration Version 10.6 Snow Leopard*.

- The MySQL server bundled with Mac OS X Server does not include the MySQL client libraries and header files required to access and use MySQL from a third-party driver, such as Perl DBI or PHP.
For more information on obtaining and installing MySQL libraries, see Mac OS X Server version 10.5: MySQL libraries available for download. Alternatively, you can ignore the bundled MySQL server and install MySQL from the package or tarball installation.

2.5 Installing MySQL on Linux

Linux supports a number of different solutions for installing MySQL. The recommended method is to use one of the distributions from Oracle. If you choose this method, there are several options available:

- Installing from a generic binary package in .tar.gz format. See Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries” for more information.

- Extracting and compiling MySQL from a source distribution. For detailed instructions, see Section 2.9, “Installing MySQL from Source”.

- Installing using a precompiled RPM package. For more information, see Section 2.5.1, “Installing MySQL on Linux Using RPM Packages”.

- Installing using a precompiled Debian package. For more information, see Section 2.5.2, “Installing MySQL on Linux Using Debian Packages”.

- Installing using Oracle’s Unbreakable Linux Network (ULN). For more information, see Section 2.6, “Installing MySQL Using Unbreakable Linux Network (ULN)”.

As an alternative, you can use the native package manager within your Linux distribution to automatically download and install MySQL for you. Native package installations can take care of the download and dependencies required to run MySQL, but the MySQL version will often be some versions behind the currently available release. You will also normally be unable to install development releases, as these are not usually made available in the native repository. For more information on using the native package installers, see Section 2.5.3, “Installing MySQL on Linux Using Native Package Managers”.

Note
For many Linux installations, you will want to set up MySQL to be started automatically when your machine starts. Many of the native package installations perform this operation for you, but for source, binary and RPM solutions you may need to set this up separately. The required script, mysql.server, can be found in the support-files directory under the MySQL installation directory or in a MySQL source tree. You can install it as /etc/init.d/mysql for automatic MySQL startup and shutdown. See Section 2.10.1.2, “Starting and Stopping MySQL Automatically”.

2.5.1 Installing MySQL on Linux Using RPM Packages

Note
To install or upgrade to MySQL 5.5.31, be sure to read the special instructions at the end of this section.

The recommended way to install MySQL on RPM-based Linux distributions is by using the RPM packages. The RPMs that we provide to the community should work on all versions of Linux that support RPM packages and use glibc 2.3. To obtain RPM packages, see Section 2.1.3, “How to Get MySQL”.

For non-RPM Linux distributions, you can install MySQL using a .tar.gz package. See Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”.

144
Installations created from our Linux RPM distributions result in files under the system directories shown in the following table.

### Table 2.12 MySQL Installation Layout for Linux RPM Packages

<table>

</tr>
<tr>
<td>/usr/share/sql-bench</td>
<td>Benchmarks</td>
</tr>
</tbody>
</table>

**Note**

RPM distributions of MySQL are also provided by other vendors. Be aware that they may differ from those built by us in features, capabilities, and conventions (including communication setup), and that the instructions in this manual do not necessarily apply to installing them. The vendor's instructions should be consulted instead. Because of these differences, RPM packages built by us check whether such RPMs built by other vendors are installed. If so, the RPM does not install and produces a message explaining this.

Conflicts can arise when an RPM from another vendor is already installed, such as when a vendor's convention about which files belong with the server and which belong with the client library differ from the breakdown used for Oracle packages. In such cases, attempts to install an Oracle RPM with `rpm -i` may result in messages that files in the RPM to be installed conflict with files from an installed package (denoted `mysql-libs` in the following paragraphs).

We provide a MySQL-shared-compat package with each MySQL release. This package is meant to replace `mysql-libs` and provides a replacement-compatible client library for older MySQL series. MySQL-shared-compat is set up to make mysql-libs obsolete, but rpm explicitly refuses to replace obsoleted packages when invoked with `-i` (unlike `-U`), which is why installation with `rpm -i` produces a conflict.

MySQL-shared-compat can safely be installed alongside mysql-libs because libraries are installed to different locations. Therefore, it is possible to install shared-compat first, then manually remove `mysql-libs` before continuing with the installation. After mysql-libs is removed, the dynamic linker stops looking for the client library in the location where mysql-libs puts it, and the library provided by the MySQL-shared-compat package takes over.

Another alternative is to install packages using `yum`. In a directory containing all RPM packages for a MySQL release, `yum install MySQL*rpm` installs them in the correct order and removes `mysql-libs` in one step without conflicts.
Installing MySQL on Linux Using RPM Packages

In most cases, you need to install only the MySQL-server and MySQL-client packages to get a functional MySQL installation. The other packages are not required for a standard installation.

**RPMs for MySQL Cluster.** Standard MySQL server RPMs built by MySQL do not provide support for the NDBCLUSTER storage engine.

**Important**

When upgrading a MySQL Cluster RPM installation, you must upgrade all installed RPMs, including the Server and Client RPMs.

For more information about installing MySQL Cluster from RPMs, see Section 18.2, “MySQL Cluster Installation and Upgrades”.

For upgrades, if your installation was originally produced by installing multiple RPM packages, it is best to upgrade all the packages, not just some. For example, if you previously installed the server and client RPMs, do not upgrade just the server RPM.

If the data directory exists at RPM installation time, the installation process does not modify existing data. This has the effect, for example, that accounts in the grant tables are not initialized to the default set of accounts.

If you get a dependency failure when trying to install MySQL packages (for example, error: removing these packages would break dependencies: libmysqlclient.so.10 is needed by ...), you should also install the MySQL-shared-compat package, which includes the shared libraries for older releases for backward compatibility.

The RPM packages shown in the following list are available. The names shown here use a suffix of .glibc23.i386.rpm, but particular packages can have different suffixes, described later.

- **MySQL-server-VERSION.glibc23.i386.rpm**
  The MySQL server. You need this unless you only want to connect to a MySQL server running on another machine.

- **MySQL-client-VERSION.glibc23.i386.rpm**
  The standard MySQL client programs. You probably always want to install this package.

- **MySQL-devel-VERSION.glibc23.i386.rpm**
  The libraries and include files that are needed if to compile other MySQL clients, such as the Perl modules. Install this RPM if you intend to compile C API applications.

- **MySQL-shared-VERSION.glibc23.i386.rpm**
  This package contains the shared libraries (libmysqlclient.so*) that certain languages and applications need to dynamically load and use MySQL. It contains single-threaded and thread-safe libraries. Install this RPM if you intend to compile or run C API applications that depend on the shared client library. Prior to MySQL 5.5.6, if you install this package, do not install the MySQL-shared-compat package.

- **MySQL-shared-compat-VERSION.glibc23.i386.rpm**
  This package includes the shared libraries for older releases. It contains single-threaded and thread-safe libraries. Install this package if you have applications installed that are dynamically linked against older versions of MySQL but you want to upgrade to the current version without breaking the library...
dependencies. Before MySQL 5.5.6, MySQL-shared-compat also includes the libraries for the current release, so if you install it, you should not also install MySQL-shared. As of 5.5.6, MySQL-shared-compat does not include the current library version, so there is no conflict.

As of MySQL 5.5.23, the MySQL-shared-compat RPM package enables users of Red Hat-provided mysql-*-5.1 RPM packages to migrate to Oracle-provided MySQL-*-5.5 packages. MySQL-shared-compat replaces the Red Hat mysql-libs package by replacing libmysqlclient.so files of the latter package, thus satisfying dependencies of other packages on mysql-libs. This change affects only users of Red Hat (or Red Hat-compatible) RPM packages. Nothing is different for users of Oracle RPM packages.

- MySQL-embedded-VERSION.glibc23.i386.rpm
  The embedded MySQL server library.

- MySQL-test-VERSION.glibc23.i386.rpm
  This package includes the MySQL test suite.

- MySQL-VERSION.src.rpm
  This contains the source code for all of the previous packages. It can also be used to rebuild the RPMs on other architectures (for example, Alpha or SPARC).

The suffix of RPM package names (following the VERSION value) has the following syntax:

.PLATFORM.CPU.rpm

The PLATFORM and CPU values indicate the type of system for which the package is built. PLATFORM indicates the platform and CPU indicates the processor type or family.

All packages are dynamically linked against glibc 2.3. The PLATFORM value indicates whether the package is platform independent or intended for a specific platform, as shown in the following table.

Table 2.13 MySQL Linux Installation Packages

<table>
<thead>
<tr>
<th>PLATFORM Value</th>
<th>Intended Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>glibc23</td>
<td>Platform independent, should run on any Linux distribution that supports glibc 2.3</td>
</tr>
<tr>
<td>rhel4, rhel5</td>
<td>Red Hat Enterprise Linux 4 or 5</td>
</tr>
<tr>
<td>el6</td>
<td>Enterprise Linux 6</td>
</tr>
<tr>
<td>sles10, sles11</td>
<td>SuSE Linux Enterprise Server 10 or 11</td>
</tr>
</tbody>
</table>

In MySQL 5.5, only glibc23 packages are available currently.

The CPU value indicates the processor type or family for which the package is built.

Table 2.14 MySQL Installation Packages for Linux CPU Identifiers

<table>
<thead>
<tr>
<th>CPU Value</th>
<th>Intended Processor Type or Family</th>
</tr>
</thead>
<tbody>
<tr>
<td>i386, i586, i686</td>
<td>Pentium processor or better, 32 bit</td>
</tr>
<tr>
<td>x86_64</td>
<td>64-bit x86 processor</td>
</tr>
</tbody>
</table>
### CPU Value | Intended Processor Type or Family
--- | ---
ia64 | Itanium (IA-64) processor

To see all files in an RPM package (for example, a `MySQL-server` RPM), run a command like this:

```shell
rpm -qpl MySQL-server-VERSION.glibc23.i386.rpm
```

To perform a standard minimal installation, install the server and client RPMs:

```shell
rpm -i MySQL-server-VERSION.glibc23.i386.rpm
rpm -i MySQL-client-VERSION.glibc23.i386.rpm
```

To install only the client programs, install just the client RPM:

```shell
rpm -i MySQL-client-VERSION.glibc23.i386.rpm
```

RPM provides a feature to verify the integrity and authenticity of packages before installing them. To learn more about this feature, see Section 2.1.4, “Verifying Package Integrity Using MD5 Checksums or GnuPG”.

The server RPM places data under the `/var/lib/mysql` directory. The RPM also creates a login account for a user named `mysql` (if one does not exist) to use for running the MySQL server, and creates the appropriate entries in `/etc/init.d/` to start the server automatically at boot time. (This means that if you have performed a previous installation and have made changes to its startup script, you may want to make a copy of the script so that you do not lose it when you install a newer RPM.) See Section 2.10.1.2, “Starting and Stopping MySQL Automatically”, for more information on how MySQL can be started automatically on system startup.

In MySQL 5.5.5 and later, during a new installation, the server boot scripts are installed, but the MySQL server is not started at the end of the installation, since the status of the server during an unattended installation is not known.

In MySQL 5.5.5 and later, during an upgrade installation using the RPM packages, if the MySQL server is running when the upgrade occurs, the MySQL server is stopped, the upgrade occurs, and the MySQL server is restarted. If the MySQL server is not already running when the RPM upgrade occurs, the MySQL server is not started at the end of the installation.

If something goes wrong, you can find more information in the binary installation section. See Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”.

---

**Note**

The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.10, “Postinstallation Setup and Testing”.

During RPM installation, a user named `mysql` and a group named `mysql` are created on the system. This is done using the `useradd`, `groupadd`, and `usermod` commands. Those commands require appropriate administrative privileges, which is required for locally managed users and groups (as listed in the `/etc/passwd` and `/etc/group` files) by the RPM installation process being run by `root`.

If you log in as the `mysql` user, you may find that MySQL displays “Invalid (old?) table or database name” errors that mention `.mysqlgui`, `lost+found`, `.mysqlgui`, `.bash_history`, `.fonts.cache-1`, `.lesshst`, `.mysql_history`, `.profile`, `.viminfo`, and similar files created by MySQL or operating system utilities. You can safely ignore these error messages or remove the files or directories that cause them if you do not need them.
For nonlocal user management (LDAP, NIS, and so forth), the administrative tools may require additional authentication (such as a password), and will fail if the installing user does not provide this authentication. Even if they fail, the RPM installation will not abort but succeed, and this is intentional. If they failed, some of the intended transfer of ownership may be missing, and it is recommended that the system administrator then manually ensures some appropriate user and group exists and manually transfers ownership following the actions in the RPM spec file.

In MySQL 5.5.31, the RPM spec file has been updated, which has the following consequences:

- For a non-upgrade installation (no existing MySQL version installed), it possible to install MySQL using `yum`.
- For upgrades, it is necessary to clean up any earlier MySQL installations. In effect, the update is performed by removing the old installations and installing the new one.

Additional details follow.

For a non-upgrade installation of MySQL 5.5.31, it is possible to install using `yum`:

```
shell> yum install MySQL-server-NEWVERSION.glibc23.i386.rpm
```

For upgrades to MySQL 5.5.31, the upgrade is performed by removing the old installation and installing the new one. To do this, use the following procedure:

1. Remove the existing 5.5.X installation. `OLDVERSION` is the version to remove.

```
shell> rpm -e MySQL-server-OLDVERSION.glibc23.i386.rpm
```

Repeat this step for all installed MySQL RPMs.

2. Install the new version. `NEWVERSION` is the version to install.

```
shell> rpm -ivh MySQL-server-NEWVERSION.glibc23.i386.rpm
```

Alternatively, the removal and installation can be done using `yum`:

```
shell> yum remove MySQL-server-OLDVERSION.glibc23.i386.rpm
shell> yum install MySQL-server-NEWVERSION.glibc23.i386.rpm
```

### 2.5.2 Installing MySQL on Linux Using Debian Packages

Oracle provides Debian packages for installation on Debian or Debian-like Linux systems. To obtain a package, see Section 2.1.3, “How to Get MySQL”.

![Note](image)

Debian distributions of MySQL are also provided by other vendors. Be aware that they may differ from those built by us in features, capabilities, and conventions (including communication setup), and that the instructions in this manual do not necessarily apply to installing them. The vendor’s instructions should be consulted instead.

Debian package files have names in `mysql-MVER-DVER-CPU.deb` format. `MVER` is the MySQL version and `DVER` is the Debian version. The `CPU` value indicates the processor type or family for which the package is built, as shown in the following table.
Table 2.15 MySQL Installation Packages for Linux CPU Identifiers

<table>
<thead>
<tr>
<th>CPU Value</th>
<th>Intended Processor Type or Family</th>
</tr>
</thead>
<tbody>
<tr>
<td>i686</td>
<td>Pentium processor or better, 32 bit</td>
</tr>
<tr>
<td>x86_64</td>
<td>64-bit x86 processor</td>
</tr>
</tbody>
</table>

After downloading a Debian package, use the following command to install it:

```
shell> dpkg -i mysql-MVER-DVER-CPU.deb
```

The Debian package installs files in the `/opt/mysql/server-5.5` directory.

You may also need to install the `libaio` library if it is not already present on your system:

```
shell> apt-get install libaio1
```

## 2.5.3 Installing MySQL on Linux Using Native Package Managers

Many Linux distributions include a version of the MySQL server, client tools, and development components into the standard package management system built into distributions such as Fedora, Debian, Ubuntu, and Gentoo. This section provides basic instructions for installing MySQL using these systems.

### Important

Native package installations can take care of the download and dependencies required to run MySQL, but the MySQL version will often be some way behind the currently available release. You will also normally be unable to install development releases, as these are not usually made available in the native repository.

Distribution specific instructions are shown below:

- **Red Hat Linux, Fedora, CentOS**

  For Red Hat and similar distributions, the MySQL distribution is divided into a number of separate packages, `mysql` for the client tools, `mysql-server` for the server and associated tools, and `mysql-libs` for the libraries. The libraries are required if you want to provide connectivity from different languages and environments such as Perl, Python and others.

  To install, use the `yum` command to specify the packages that you want to install. For example:

  ```
  root-shell> yum install mysql mysql-server mysql-libs mysql-server
  Loaded plugins: presto, refresh-packagekit
  Setting up Install Process
  Resolving Dependencies
  --> Running transaction check
  ---> Package mysql.x86_64 0:5.1.48-2.fc13 set to be updated
  ---> Package mysql-libs.x86_64 0:5.1.48-2.fc13 set to be updated
  ---> Package mysql-server.x86_64 0:5.1.48-2.fc13 set to be updated
  --> Processing Dependency: perl-DBD-MySQL for package: mysql-server-5.1.48-2.fc13.x86_64
  ---> Running transaction check
  ---> Package perl-DBD-MySQL.x86_64 0:4.017-1.fc13 set to be updated
  --> Finished Dependency Resolution
  Dependencies Resolved
  ```

150
MySQL and the MySQL server should now be installed. A sample configuration file is installed into `/etc/my.cnf`. An init script, to start and stop the server, will have been installed into `/etc/init.d/mysqld`. To start the MySQL server use `service`:

```bash
root-shell> service mysqld start
```

To enable the server to be started and stopped automatically during boot, use `chkconfig`:

```bash
root-shell> chkconfig --levels 235 mysqld on
```

Which enables the MySQL server to be started (and stopped) automatically at the specified the run levels.

The database tables will have been automatically created for you, if they do not already exist. You should, however, run `mysql_secure_installation` to set the root passwords on your server.

- Debian, Ubuntu, Kubuntu
On Debian and related distributions, there are two packages, `mysql-client` and `mysql-server`, for the client and server components respectively. You should specify an explicit version, for example `mysql-client-5.1`, to ensure that you install the version of MySQL that you want.

To download and install, including any dependencies, use the `apt-get` command, specifying the packages that you want to install.

![Note]

Before installing, make sure that you update your `apt-get` index files to ensure you are downloading the latest available version.

A sample installation of the MySQL packages might look like this (some sections trimmed for clarity):

```
root-shell> apt-get install mysql-client-5.1 mysql-server-5.1
Reading package lists... Done
Building dependency tree
Reading state information... Done
The following packages were automatically installed and are no longer required:
  linux-headers-2.6.28-11 linux-headers-2.6.28-11-generic
Use 'apt-get autoremove' to remove them.
The following extra packages will be installed:
  bsd-mailx libdbd-mysql-perl libdbi-perl libhtml-template-perl
  libmysqlclient15off libmysqlclient16 libnet-daemon-perl libplrpc-perl mailx
  mysql-common postfix
Suggested packages:
  dbishell libipc-sharedcache-perl tinyca procmail postfix-mysql postfix-pgsql
  postfix-ldap postfix-pcre sasl2-bin resolvelogconf postfix-cdb
The following NEW packages will be installed
  bsd-mailx libdbd-mysql-perl libdbi-perl libhtml-template-perl
  libmysqlclient15off libmysqlclient16 libnet-daemon-perl libplrpc-perl mailx
  mysql-client-5.1 mysql-common mysql-server-5.1 postfix
0 upgraded, 13 newly installed, 0 to remove and 182 not upgraded.
Need to get 1907kB/25.3MB of archives.

100825 11:46:17 [Warning] Forcing shutdown of 1 plugins
  * Starting MySQL database server mysqld
```
Note

The `apt-get` command will install a number of packages, including the MySQL server, in order to provide the typical tools and application environment. This can mean that you install a large number of packages in addition to the main MySQL package.

During installation, the initial database will be created, and you will be prompted for the MySQL root password (and confirmation). A configuration file will have been created in `/etc/mysql/my.cnf`. An init script will have been created in `/etc/init.d/mysql`.

The server will already be started. You can manually start and stop the server using:

```
root-shell> service mysql [start|stop]
```

The service will automatically be added to the 2, 3 and 4 run levels, with stop scripts in the single, shutdown and restart levels.

• **Gentoo Linux**

As a source-based distribution, installing MySQL on Gentoo involves downloading the source, patching the Gentoo specifics, and then compiling the MySQL server and installing it. This process is handled automatically by the `emerge` command. Depending on the version of MySQL that you want to install, you may need to unmask the specific version that you want for your chosen platform.

The MySQL server and client tools are provided within a single package, `dev-db/mysql`. You can obtain a list of the versions available to install by looking at the portage directory for the package:

```
root-shell> ls /usr/portage/dev-db/mysql/mysql-5.1*
mysql-5.1.39-r1.ebuild
mysql-5.1.44-r1.ebuild
mysql-5.1.44-r2.ebuild
mysql-5.1.44-r3.ebuild
mysql-5.1.44.ebuild
mysql-5.1.45-r1.ebuild
mysql-5.1.45.ebuild
mysql-5.1.46.ebuild
```

To install a specific MySQL version, you must specify the entire atom. For example:

```
root-shell> emerge =dev-db/mysql-5.1.46
```

A simpler alternative is to use the `virtual/mysql-5.1` package, which will install the latest version:

```
root-shell> emerge =virtual/mysql-5.1
```

If the package is masked (because it is not tested or certified for the current platform), use the `ACCEPT_KEYWORDS` environment variable. For example:

```
root-shell> ACCEPT_KEYWORDS="~x86" emerge =virtual/mysql-5.1
```
After installation, you should create a new database using `mysql_install_db`, and set the password for the root user on MySQL. You can use the configuration interface to set the password and create the initial database:

```
root-shell> emerge --config =dev-db/mysql-5.1.46
```

A sample configuration file will have been created for you in `/etc/mysql/my.cnf`, and an init script will have been created in `/etc/init.d/mysql`.

To enable MySQL to start automatically at the normal (default) run levels, you can use:

```
root-shell> rc-update add mysql default
```

### 2.6 Installing MySQL Using Unbreakable Linux Network (ULN)

Linux supports a number of different solutions for installing MySQL, covered in Section 2.5, “Installing MySQL on Linux”. One of the methods, covered in this section, is installing from Oracles's Unbreakable Linux Network (ULN). You can find information about Oracle Linux and ULN under [http://linux.oracle.com/](http://linux.oracle.com/).

To use ULN, you need to obtain a ULN login and register the machine used for installation with ULN. This is described in detail in the ULN FAQ. The page also describes how to install and update packages. The MySQL packages are in the “MySQL for Oracle Linux 6” channel for your system architecture on ULN.

**Note**

At the time of writing this (September 2012), ULN provides MySQL 5.5 for Oracle Linux 6.

Once MySQL has been installed using ULN, you can find information on starting and stopping the server, and more, in this section, particularly under Section 2.5.1, “Installing MySQL on Linux Using RPM Packages”.

If you're updating an existing MySQL installation to an installation using ULN, the recommended procedure is to export your data using `mysqldump`, remove the existing installation, install MySQL from ULN, and load the exported data into your freshly installed MySQL.

If the existing MySQL installation you're upgrading from is from a previous release series (prior to MySQL 5.5), make sure to read the section on upgrading MySQL, Section 2.11.1, “Upgrading MySQL”.

### 2.7 Installing MySQL on Solaris and OpenSolaris

MySQL on Solaris and OpenSolaris is available in a number of different formats.

- For information on installing using the native Solaris PKG format, see Section 2.7.1, “Installing MySQL on Solaris Using a Solaris PKG”.

- On OpenSolaris, the standard package repositories include MySQL packages specially built for OpenSolaris that include entries for the Service Management Framework (SMF) to enable control of the installation using the SMF administration commands. For more information, see Section 2.7.2, “Installing MySQL on OpenSolaris Using IPS”.

- To use a standard `tar` binary installation, use the notes provided in Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”. Check the notes and hints at the end of this section for Solaris specific notes that you may need before or after installation.
To obtain a binary MySQL distribution for Solaris in tarball or PKG format, [http://dev.mysql.com/downloads/mysql/5.5.html](http://dev.mysql.com/downloads/mysql/5.5.html).

Additional notes to be aware of when installing and using MySQL on Solaris:

- If you want to use MySQL with the `mysql` user and group, use the `groupadd` and `useradd` commands:
  ```
groupadd mysql
useradd -g mysql mysql
  ```

- If you install MySQL using a binary tarball distribution on Solaris, you may run into trouble even before you get the MySQL distribution unpacked, as the Solaris `tar` cannot handle long file names. This means that you may see errors when you try to unpack MySQL.
  If this occurs, you must use GNU `tar (gtar)` to unpack the distribution. In Solaris 10 and OpenSolaris `gtar` is normally located in `/usr/sfw/bin/gtar`, but may not be included in the default path definition.

- When using Solaris 10 for x86_64, you should mount any file systems on which you intend to store InnoDB files with the `forcedirectio` option. (By default mounting is done without this option.) Failing to do so will cause a significant drop in performance when using the InnoDB storage engine on this platform.

- If you would like MySQL to start automatically, you can copy `support-files/mysql.server` to `/etc/init.d` and create a symbolic link to it named `/etc/rc3.d/S99mysql.server`.

- If too many processes try to connect very rapidly to `mysqld`, you should see this error in the MySQL log:

  Error in accept: Protocol error

  You might try starting the server with the `-b back_log=50` option as a workaround for this.

- To configure the generation of core files on Solaris you should use the `coreadm` command. Because of the security implications of generating a core on a `setuid()` application, by default, Solaris does not support core files on `setuid()` programs. However, you can modify this behavior using `coreadm`. If you enable `setuid()` core files for the current user, they will be generated using the mode 600 and owned by the superuser.

### 2.7.1 Installing MySQL on Solaris Using a Solaris PKG

You can install MySQL on Solaris and OpenSolaris using a binary package using the native Solaris PKG format instead of the binary tarball distribution.

To use this package, download the corresponding `mysql-VERSION-solaris10-PLATFORM.pkg.gz` file, then uncompress it. For example:

```shell
gunzip mysql-5.5.40-solaris10-x86_64.pkg.gz
```

To install a new package, use `pkgadd` and follow the onscreen prompts. You must have root privileges to perform this operation:

```shell
pkgadd -d mysql-5.5.40-solaris10-x86_64.pkg
```

The following packages are available:

1  mysql  MySQL Community Server (GPL)
    (i68pc) 5.5.40
Installing MySQL on OpenSolaris Using IPS

Select package(s) you wish to process (or 'all' to process all packages). (default: all) [?,?,q]:

The PKG installer installs all of the files and tools needed, and then initializes your database if one does not exist. To complete the installation, you should set the root password for MySQL as provided in the instructions at the end of the installation. Alternatively, you can run the `mysql_secure_installation` script that comes with the installation.

By default, the PKG package installs MySQL under the root path `/opt/mysql`. You can change only the installation root path when using `pkgadd`, which can be used to install MySQL in a different Solaris zone. If you need to install in a specific directory, use a binary `tar` file distribution.

The `pkg` installer copies a suitable startup script for MySQL into `/etc/init.d/mysql`. To enable MySQL to startup and shutdown automatically, you should create a link between this file and the init script directories. For example, to ensure safe startup and shutdown of MySQL you could use the following commands to add the right links:

```
shell> ln /etc/init.d/mysql /etc/rc3.d/S91mysql
shell> ln /etc/init.d/mysql /etc/rc0.d/K02mysql
```

To remove MySQL, the installed package name is `mysql`. You can use this in combination with the `pkgrm` command to remove the installation.

To upgrade when using the Solaris package file format, you must remove the existing installation before installing the updated package. Removal of the package does not delete the existing database information, only the server, binaries and support files. The typical upgrade sequence is therefore:

```
shell> mysqladmin shutdown
shell> pkgrm mysql
shell> pkgadd -d mysql-5.5.40-solaris10-x86_64.pkg
shell> mysqld_safe &
shell> mysql_upgrade
```

You should check the notes in Section 2.11, “Upgrading or Downgrading MySQL” before performing any upgrade.

### 2.7.2 Installing MySQL on OpenSolaris Using IPS

OpenSolaris includes standard packages for MySQL in the core repository. The MySQL packages are based on a specific release of MySQL and updated periodically. For the latest release you must use either the native Solaris PKG, `tar`, or source installations. The native OpenSolaris packages include SMF files so that you can easily control your MySQL installation, including automatic startup and recovery, using the native service management tools.

To install MySQL on OpenSolaris, use the `pkg` command. You will need to be logged in as root, or use the `pfexec` tool, as shown in the example below:

```
shell> pfexec pkg install SUNWmysql55
```

The package set installs three individual packages, `SUNWmysql55lib`, which contains the MySQL client libraries; `SUNWmysql55r` which contains the root components, including SMF and configuration files; and `SUNWmysql55u` which contains the scripts, binary tools and other files. You can install these packages individually if you only need the corresponding components.

The MySQL files are installed into `/usr/mysql` which symbolic links for the sub directories (`bin`, `lib`, etc.) to a version specific directory. For MySQL 5.5, the full installation is located in `/usr/mysql/5.5`. The default data directory is `/var/mysql/5.5/data`. The configuration file is installed in `/etc/`
Installing MySQL on FreeBSD

mysql/5.5/my.cnf. This layout permits multiple versions of MySQL to be installed, without overwriting the data and binaries from other versions.

Once installed, you must run `mysql_install_db` to initialize the database, and use the `mysql_secure_installation` to secure your installation.

**Using SMF to manage your MySQL installation**

Once installed, you can start and stop your MySQL server using the installed SMF configuration. The service name is `mysql`, or if you have multiple versions installed, you should use the full version name, for example `mysql:version_55`. To start and enable MySQL to be started at boot time:

```
shell> svcadm enable mysql
```

To disable SMF from starting during boot time, and shut the MySQL server down if it is running, use:

```
shell> svcadm disable mysql
```

To restart MySQL, for example after a configuration file changes, use the `restart` option:

```
shell> svcadm restart mysql
```

You can also use SMF to configure the data directory and enable full 64-bit mode. For example, to set the data directory used by MySQL:

```
shell> svccfg
svc::> select mysql:version_55
svc:/application/database/mysql:version_55> setprop mysql/data=/data0/mysql
```

By default, the 32-bit binaries are used. To enable the 64-bit server on 64-bit platforms, set the `enable_64bit` parameter. For example:

```
svc:/application/database/mysql:version_55> setprop mysql/enable_64bit=1
```

You need to refresh the SMF after settings these options:

```
shell> svcadm refresh mysql
```

### 2.8 Installing MySQL on FreeBSD

This section provides information about installing MySQL on variants of FreeBSD Unix.

You can install MySQL on FreeBSD by using the binary distribution provided by Oracle. For more information, see Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”.

The easiest (and preferred) way to install MySQL is to use the `mysql-server` and `mysql-client` ports available at [http://www.freebsd.org/](http://www.freebsd.org/). Using these ports gives you the following benefits:

- A working MySQL with all optimizations enabled that are known to work on your version of FreeBSD.
- Automatic configuration and build.
- Startup scripts installed in `/usr/local/etc/rc.d`.
- The ability to use `pkg_info -L` to see which files are installed.
- The ability to use `pkg_delete` to remove MySQL if you no longer want it on your machine.

The MySQL build process requires GNU make (gmake) to work. If GNU make is not available, you must install it first before compiling MySQL.
To install using the ports system:

```
# cd /usr/ports/databases/mysql51-server
# make
... # cd /usr/ports/databases/mysql51-client
# make
...
```

The standard port installation places the server into `/usr/local/libexec/mysqld`, with the startup script for the MySQL server placed in `/usr/local/etc/rc.d/mysql-server`.

Some additional notes on the BSD implementation:

- To remove MySQL after installation using the ports system:

  ```
  # cd /usr/ports/databases/mysql51-server
  # make deinstall
  ...
  # cd /usr/ports/databases/mysql51-client
  # make deinstall
  ...
  ```

- If you get problems with the current date in MySQL, setting the TZ variable should help. See Section 2.12, “Environment Variables”.

### 2.9 Installing MySQL from Source

Building MySQL from the source code enables you to customize build parameters, compiler optimizations, and installation location. For a list of systems on which MySQL is known to run, see [http://www.mysql.com/support/supportedplatforms/database.html](http://www.mysql.com/support/supportedplatforms/database.html).

Before you proceed with an installation from source, check whether Oracle produces a precompiled binary distribution for your platform and whether it works for you. We put a great deal of effort into ensuring that our binaries are built with the best possible options for optimal performance. Instructions for installing binary distributions are available in Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”.

**Note**

This section describes how to build MySQL from source using CMake. Before MySQL 5.5, source builds used the GNU autotools on Unix-like systems. Source builds on Windows used CMake, but the process was different from that described here. For source-building instructions for older versions of MySQL, see [Installing MySQL from Source](http://www.mysql.com/support/supportedplatforms/database.html), in the MySQL 5.1 Reference Manual. If you are familiar with autotools but not CMake, you might find these transition instructions helpful: [Autotools to CMake Transition Guide](http://www.mysql.com/support/supportedplatforms/database.html).

**Source Installation Methods**

There are two methods for installing MySQL from source:

- Use a standard MySQL source distribution. To obtain a standard distribution, see Section 2.1.3, “How to Get MySQL”. For instructions on building from a standard distribution, see Section 2.9.2, “Installing MySQL Using a Standard Source Distribution”.

  Standard distributions are available as compressed tar files, Zip archives, or RPM packages. Distribution files have names of the form `mysql-VERSION.tar.gz`, `mysql-VERSION.zip`, or
mysql-VERSION.rpm, where VERSION is a number like 5.5.40. File names for source distributions can be distinguished from those for precompiled binary distributions in that source distribution names are generic and include no platform name, whereas binary distribution names include a platform name indicating the type of system for which the distribution is intended (for example, pc-linux-i686 or winx64).

- Use a MySQL development tree. Development trees have not necessarily received the same level of testing as standard release distributions, so this installation method is usually required only if you need the most recent code changes. For information on building from one of the development trees, see Section 2.9.3, “Installing MySQL Using a Development Source Tree”.

Source Installation System Requirements

Installation of MySQL from source requires several development tools. Some of these tools are needed no matter whether you use a standard source distribution or a development source tree. Other tool requirements depend on which installation method you use.

To install MySQL from source, your system must have the following tools, regardless of installation method:

- **CMake**, which is used as the build framework on all platforms. CMake can be downloaded from [http://www.cmake.org](http://www.cmake.org).

- A good **make** program. Although some platforms come with their own make implementations, it is highly recommended that you use GNU make 3.75 or newer. It may already be available on your system as gmake. GNU make is available from [http://www.gnu.org/software/make/](http://www.gnu.org/software/make/).

- A working **ANSI C++ compiler**. GCC 4.2.1 or later, Sun Studio 12 or later, Visual Studio 2008 or later, and many current vendor-supplied compilers are known to work.

- **Perl** is needed if you intend to run test scripts. Most Unix-like systems include Perl. On Windows, you can use a version such as ActiveState Perl.

To install MySQL from a standard source distribution, one of the following tools is required to unpack the distribution file:

- For a .tar.gz compressed tar file: GNU gunzip to uncompress the distribution and a reasonable tar to unpack it. If your tar program supports the z option, it can both uncompress and unpack the file.

  GNU tar is known to work. The standard tar provided with some operating systems is not able to unpack the long file names in the MySQL distribution. You should download and install GNU tar, or if available, use a preinstalled version of GNU tar. Usually this is available as gnutar, gtar, or as tar within a GNU or Free Software directory, such as /usr/sfw/bin or /usr/local/bin. GNU tar is available from [http://www.gnu.org/software/tar/](http://www.gnu.org/software/tar/).

- For a .zip file: WinZip or another tool that can read .zip files.

- For an .rpm RPM package: The rpmbuild program used to build the distribution unpacks it.

To install MySQL from a development source tree, the following additional tools are required:

- To obtain the source tree, you must have Bazaar installed. The Bazaar VCS Web site has instructions for downloading and installing Bazaar on different platforms. Bazaar is supported on any platform that supports Python, and is therefore compatible with any Linux, Unix, Windows, or Mac OS X host.

  **bison** is needed to generate sql_yacc.cc from sql_yacc.yy. You should use the latest version of bison where possible. Versions 1.75 and 2.1 are known to work. There have been reported problems with bison 1.875. If you experience problems, upgrade to a later, rather than earlier, version.
MySQL Layout for Source Installation

Note

bison is available from http://www.gnu.org/software/bison/. bison for Windows can be downloaded from http://gnuwin32.sourceforge.net/packages/bison.htm. Download the package labeled “Complete package, excluding sources”. On Windows, the default location for bison is the C:\Program Files \GnuWin32 directory. Some utilities may fail to find bison because of the space in the directory name. Also, Visual Studio may simply hang if there are spaces in the path. You can resolve these problems by installing into a directory that does not contain a space; for example C:\GnuWin32.

- On OpenSolaris and Solaris Express, m4 must be installed in addition to bison. m4 is available from http://www.gnu.org/software/m4/.

If you have to install any programs, modify your PATH environment variable to include any directories in which the programs are located. See Section 4.2.10, “Setting Environment Variables”.

If you run into problems and need to file a bug report, please use the instructions in Section 1.7, “How to Report Bugs or Problems”.

2.9.1 MySQL Layout for Source Installation

By default, when you install MySQL after compiling it from source, the installation step installs files under /usr/local/mysql. The component locations under the installation directory are the same as for binary distributions. See Table 2.3, “MySQL Installation Layout for Generic Unix/Linux Binary Package”, and Section 2.3.1, “MySQL Installation Layout on Microsoft Windows”. To configure installation locations different from the defaults, use the options described at Section 2.9.4, “MySQL Source-Configuration Options”.

2.9.2 Installing MySQL Using a Standard Source Distribution

To install MySQL from a standard source distribution:

1. Verify that your system satisfies the tool requirements listed at Section 2.9, “Installing MySQL from Source”.
2. Obtain a distribution file using the instructions in Section 2.1.3, “How to Get MySQL”.
3. Configure, build, and install the distribution using the instructions in this section.
4. Perform postinstallation procedures using the instructions in Section 2.10, “Postinstallation Setup and Testing”.

In MySQL 5.5, CMake is used as the build framework on all platforms. The instructions given here should enable you to produce a working installation. For additional information on using CMake to build MySQL, see How to Build MySQL Server with CMake.

If you start from a source RPM, use the following command to make a binary RPM that you can install. If you do not have rpmbuild, use rpm instead.

shell> rpmbuild --rebuild --clean MySQL-VERSION.src.rpm

The result is one or more binary RPM packages that you install as indicated in Section 2.5.1, “Installing MySQL on Linux Using RPM Packages”.

The sequence for installation from a compressed tar file or Zip archive source distribution is similar to the process for installing from a generic binary distribution (see Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”), except that it is used on all platforms and includes steps to configure and compile...
the distribution. For example, with a compressed `tar` file source distribution on Unix, the basic installation command sequence looks like this:

```bash
# Preconfiguration setup
shell> groupadd mysql
shell> useradd -r -g mysql mysql
# Beginning of source-build specific instructions
shell> tar zxvf mysql-VERSION.tar.gz
shell> cd mysql-VERSION
shell> cmake .
shell> make
shell> make install
# End of source-build specific instructions
# Postinstallation setup
shell> cd /usr/local/mysql
shell> chown -R mysql .
shell> chgrp -R mysql .
shell> scripts/mysql_install_db --user=mysql
shell> chown -R root .
shell> chown -R mysql data
# Next command is optional
shell> cp support-files/my-medium.cnf /etc/my.cnf
shell> bin/mysqld_safe --user=mysql &
# Next command is optional
shell> cp support-files/mysql.server /etc/init.d/mysql.server
```

A more detailed version of the source-build specific instructions is shown following.

![Note]
The procedure shown here does not set up any passwords for MySQL accounts. After following the procedure, proceed to Section 2.10, “Postinstallation Setup and Testing”, for postinstallation setup and testing.

**Perform Preconfiguration Setup**

On Unix, set up the `mysql` user and group that will be used to run and execute the MySQL server and own the database directory. For details, see Creating a `mysql` System User and Group, in Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”. Then perform the following steps as the `mysql` user, except as noted.

**Obtain and Unpack the Distribution**

Pick the directory under which you want to unpack the distribution and change location into it.

Obtain a distribution file using the instructions in Section 2.1.3, “How to Get MySQL”.

Unpack the distribution into the current directory:

- To unpack a compressed `tar` file, `tar` can uncompress and unpack the distribution if it has `z` option support:

  ```bash
  shell> tar zxvf mysql-VERSION.tar.gz
  ```

  If your `tar` does not have `z` option support, use `gunzip` to unpack the distribution and `tar` to unpack it:

  ```bash
  shell> gunzip < mysql-VERSION.tar.gz | tar xvf -
  ```

  Alternatively, `CMake` can uncompress and unpack the distribution:
To unpack a Zip archive, use WinZip or another tool that can read .zip files.

Unpacking the distribution file creates a directory named `mysql-VERSION`.

**Configure the Distribution**

Change location into the top-level directory of the unpacked distribution:

```shell
shell> cd mysql-VERSION
```

Configure the source directory. The minimum configuration command includes no options to override configuration defaults:

```shell
shell> cmake .
```

On Windows, specify the development environment. For example, the following commands configure MySQL for 32-bit or 64-bit builds, respectively:

```shell
shell> cmake . -G "Visual Studio 9 2008"
shell> cmake . -G "Visual Studio 9 2008 Win64"
```

On Mac OS X, to use the Xcode IDE:

```shell
shell> cmake . -G Xcode
```

When you run `cmake`, you might want to add options to the command line. Here are some examples:

- `-DBUILD_CONFIG=mysql_release`: Configure the source with the same build options used by Oracle to produce binary distributions for official MySQL releases.

- `-DCMAKE_INSTALL_PREFIX=dir_name`: Configure the distribution for installation under a particular location.

- `-DPCPACK_MONOLITHIC_INSTALL=1`: Cause `make package` to generate a single installation file rather than multiple files.

- `-DWITH_DEBUG=1`: Build the distribution with debugging support.

For a more extensive list of options, see Section 2.9.4, “MySQL Source-Configuration Options”.

To list the configuration options, use one of the following commands:

```shell
shell> cmake . -L    # overview
shell> cmake . -LH   # overview with help text
shell> cmake . -LAH  # all params with help text
shell> ccmake .      # interactive display
```

If `CMake` fails, you might need to reconfigure by running it again with different options. If you do reconfigure, take note of the following:

- If `CMake` is run after it has previously been run, it may use information that was gathered during its previous invocation. This information is stored in `CMakeCache.txt`. When `CMake` starts up, it looks for that file and reads its contents if it exists, on the assumption that the information is still correct. That assumption is invalid when you reconfigure.
• Each time you run **CMake**, you must run **make** again to recompile. However, you may want to remove old object files from previous builds first because they were compiled using different configuration options.

To prevent old object files or configuration information from being used, run these commands on Unix before re-running **CMake**:

```
shell> make clean
shell> rm CMakeCache.txt
```

Or, on Windows:

```
shell> devenv MySQL.sln /clean
shell> del CMakeCache.txt
```

If you build out of the source tree (as described later), the **CMakeCache.txt** file and all built files are in the build directory, so you can remove that directory to object files and cached configuration information.

If you are going to send mail to a MySQL mailing list to ask for configuration assistance, first check the files in the **CMakeFiles** directory for useful information about the failure. To file a bug report, please use the instructions in Section 1.7, "How to Report Bugs or Problems".

### Build the Distribution

**On Unix:**

```
shell> make
shell> make VERBOSE=1
```

The second command sets **VERBOSE** to show the commands for each compiled source.

Use **gmake** instead on systems where you are using GNU **make** and it has been installed as **gmake**.

**On Windows:**

```
shell> devenv MySQL.sln /build RelWithDebInfo
```

It is possible to build out of the source tree to keep the tree clean. If the top-level source directory is named **mysql-src** under your current working directory, you can build in a directory named **bld** at the same level like this:

```
shell> mkdir bld
shell> cd bld
shell> cmake ../mysql-src
```

The build directory need not actually be outside the source tree. For example, to build in a directory, you can build in a directory named **bld** under the top-level source tree, do this, starting with **mysql-src** as your current working directory:

```
shell> mkdir bld
shell> cd bld
shell> cmake ..
```

If you have multiple source trees at the same level (for example, to build multiple versions of MySQL), the second strategy can be advantageous. The first strategy places all build directories at the same level, which requires that you choose a unique name for each. With the second strategy, you can use the same name for the build directory within each source tree.
Installing MySQL Using a Development Source Tree

If you have gotten to the compilation stage, but the distribution does not build, see Section 2.9.5, “Dealing with Problems Compiling MySQL”, for help. If that does not solve the problem, please enter it into our bugs database using the instructions given in Section 1.7, “How to Report Bugs or Problems”. If you have installed the latest versions of the required tools, and they crash trying to process our configuration files, please report that also. However, if you get a command not found error or a similar problem for required tools, do not report it. Instead, make sure that all the required tools are installed and that your PATH variable is set correctly so that your shell can find them.

Install the Distribution

On Unix:

    shell> make install

This installs the files under the configured installation directory (by default, /usr/local/mysql). You might need to run the command as root.

To install in a specific directory, add a DESTDIR parameter to the command line:

    shell> make install DESTDIR="/opt/mysql"

Alternatively, generate installation package files that you can install where you like:

    shell> make package

This operation produces one or more .tar.gz files that can be installed like generic binary distribution packages. See Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”. If you run CMake with -DCPACK_MONOLITHIC_INSTALL=1, the operation produces a single file. Otherwise, it produces multiple files.

On Windows, generate the data directory, then create a .zip archive installation package:

    shell> devenv MySQL.sln /build RelWithDebInfo /project initial_database
    shell> devenv MySQL.sln /build RelWithDebInfo /project package

You can install the resulting .zip archive where you like. See Section 2.3.7, “Installing MySQL on Microsoft Windows Using a noinstall Zip Archive”.

Perform Postinstallation Setup

The remainder of the installation process involves setting up the configuration file, creating the core databases, and starting the MySQL server. For instructions, see Section 2.10, “Postinstallation Setup and Testing”.

Note

The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Section 2.10, “Postinstallation Setup and Testing”.

2.9.3 Installing MySQL Using a Development Source Tree

This section discusses how to install MySQL from the latest development source code. Development trees have not necessarily received the same level of testing as standard release distributions, so this installation method is usually required only if you need the most recent code changes. Do not use a development tree
for production systems. If your goal is simply to get MySQL up and running on your system, you should use a standard release distribution (either a binary or source distribution). See Section 2.1.3, “How to Get MySQL”.

MySQL development projects are hosted on Launchpad. MySQL projects, including MySQL Server, MySQL Workbench, and others are available from the Oracle/MySQL Engineering page. For the repositories related only to MySQL Server, see the MySQL Server page.

To install MySQL from a development source tree, your system must satisfy the tool requirements listed at Section 2.9, “Installing MySQL from Source”, including the requirements for Bazaar and bison.

To create a local branch of the MySQL development tree on your machine, use this procedure:

1. To obtain a copy of the MySQL source code, you must create a new Bazaar branch. If you do not already have a Bazaar repository directory set up, you must initialize a new directory:

```
shell> mkdir mysql-server
shell> bzr init-repo --trees mysql-server
```

This is a one-time operation.

2. Assuming that you have an initialized repository directory, you can branch from the public MySQL server repositories to create a local source tree. To create a branch of a specific version:

```
shell> cd mysql-server
shell> bzr branch lp:mysql-server/5.5 mysql-5.5
```

This is a one-time operation per source tree. You can branch the source trees for several versions of MySQL under the mysql-server directory.

3. The initial download will take some time to complete, depending on the speed of your connection. Please be patient. Once you have downloaded the first tree, additional trees should take significantly less time to download.

4. When building from the Bazaar branch, you may want to create a copy of your active branch so that you can make configuration and other changes without affecting the original branch contents. You can achieve this by branching from the original branch:

```
shell> bzr branch mysql-5.5 mysql-5.5-build
```

5. To obtain changes made after you have set up the branch initially, update it using the pull option periodically. Use this command in the top-level directory of the local copy:

```
shell> bzr pull
```

To examine the changeset comments for the tree, use the log option to bzr:

```
shell> bzr log
```

You can also browse changesets, comments, and source code online at the Launchpad MySQL Server page.

If you see diffs (changes) or code that you have a question about, do not hesitate to send email to the MySQL internals mailing list. See Section 1.6.1, “MySQL Mailing Lists”. If you think you have a better idea on how to do something, send an email message to the list with a patch.
After you have the local branch, you can build MySQL server from the source code. For information, see Section 2.9.2, “Installing MySQL Using a Standard Source Distribution”, except that you skip the part about obtaining and unpacking the distribution.

Be careful about installing a build from a distribution source tree on a production machine. The installation command may overwrite your live release installation. If you already have MySQL installed and do not want to overwrite it, run CMake with values for the `CMAKE_INSTALL_PREFIX`, `MYSQL_TCP_PORT`, and `MYSQL_UNIX_ADDR` options different from those used by your production server. For additional information about preventing multiple servers from interfering with each other, see Section 5.3, “Running Multiple MySQL Instances on One Machine”.

Play hard with your new installation. For example, try to make new features crash. Start by running `make test`. See Section 24.1.2, “The MySQL Test Suite”.

### 2.9.4 MySQL Source-Configuration Options

The CMake program provides a great deal of control over how you configure a MySQL source distribution. Typically, you do this using options on the CMake command line. For information about options supported by CMake, run either of these commands in the top-level source directory:

```
shell> cmake . -LH
shell> ccmake .
```

You can also affect CMake using certain environment variables. See Section 2.12, “Environment Variables”.

The following table shows the available CMake options. In the Default column, PREFIX stands for the value of the `CMAKE_INSTALL_PREFIX` option, which specifies the installation base directory. This value is used as the parent location for several of the installation subdirectories.

#### Table 2.16 MySQL Source-Configuration Option Reference (CMake)

The following sections provide more information about CMake options.

- **General Options**
  - **-DBUILD_CONFIG=mysql_release**
    
    This option configures a source distribution with the same build options used by Oracle to produce binary distributions for official MySQL releases.
  
  - **-DCMAKE_BUILD_TYPE=type**
    
    The type of build to produce:
    
    - **RelWithDebInfo**: Enable optimizations and generate debugging information. This is the default MySQL build type.
    - **Debug**: Disable optimizations and generate debugging information. This build type is also used if the **WITH_DEBUG** option is enabled. That is, **-DDWITH_DEBUG=1** has the same effect as **-DCMAKE_BUILD_TYPE=Debug**.
    - **-DCPACK_MONOLITHIC_INSTALL=bool**
MySQL Source-Configuration Options

This option affects whether the make package operation produces multiple installation package files or a single file. If disabled, the operation produces multiple installation package files, which may be useful if you want to install only a subset of a full MySQL installation. If enabled, it produces a single file for installing everything.

Installation Layout Options

The CMAKE_INSTALL_PREFIX option indicates the base installation directory. Other options with names of the form INSTALL_xxx that indicate component locations are interpreted relative to the prefix and their values are relative pathnames. Their values should not include the prefix.

-DCMAKE_INSTALL_PREFIX=dir_name

The installation base directory.

This value can be set at server startup with the --basedir option.

-DINSTALLED_BINDIR=dir_name

Where to install user programs.

-DINSTALLED_DOCDIR=dir_name

Where to install documentation.

-DINSTALLED_DOCREADMEDIR=dir_name

Where to install README files.

-DINSTALLED_INCLUDEDIR=dir_name

Where to install header files.

-DINSTALLED_INFODIR=dir_name

Where to install Info files.

-DINSTALLED_LAYOUT=name

Select a predefined installation layout:

- STANDALONE: Same layout as used for .tar.gz and .zip packages. This is the default.
- RPM: Layout similar to RPM packages.
- SVR4: Solaris package layout.
- DEB: DEB package layout (experimental).

You can select a predefined layout but modify individual component installation locations by specifying other options. For example:

shell> cmake . -DINSTALL_LAYOUT=SVR4 -DMYSQL_DATADIR=/var/mysql/data

-DINSTALLED_LIBDIR=dir_name

Where to install library files.
MySQL Source-Configuration Options

- **-DINSTALL_MANDIR=dir_name**
  Where to install manual pages.

- **-DINSTALL_MYSQLSHAREDDIR=dir_name**
  Where to install shared data files.

- **-DINSTALL_MYSQLTESTDIR=dir_name**
  Where to install the `mysql-test` directory. As of MySQL 5.5.32, to suppress installation of this directory, explicitly set the option to the empty value (`-DINSTALL_MYSQLTESTDIR=`).

- **-DINSTALL_PLUGINDIR=dir_name**
  The location of the plugin directory.
  This value can be set at server startup with the `--plugin_dir` option.

- **-DINSTALL_SBINDDIR=dir_name**
  Where to install the `mysqld` server.

- **-DINSTALL_SCRIPTDIR=dir_name**
  Where to install `mysql_install_db`.

- **-DINSTALL_SHAREDDIR=dir_name**
  Where to install `aclocal/mysql.m4`.

- **-DINSTALL_SQLBENCHDIR=dir_name**
  Where to install the `sql-bench` directory. To suppress installation of this directory, explicitly set the option to the empty value (`-DINSTALL_SQLBENCHDIR=`).

- **-DINSTALL_SUPPORTFILESDIR=dir_name**
  Where to install extra support files.

- **-DMYSQL_DATADIR=dir_name**
  The location of the MySQL data directory.
  This value can be set at server startup with the `--datadir` option.

- **-DMYSQL_INCLUDES=dir_name**
  The location of the ODBC includes directory, and may be used while configuring Connector/ODBC.

- **-DMYSQL_LIB_DIR=dir_name**
  The location of the ODBC library directory, and may be used while configuring Connector/ODBC.

- **-DSYSCONFDIR=dir_name**
  The default `my.cnf` option file directory.
  This location cannot be set at server startup, but you can start the server with a given option file using the `--defaults-file=file_name` option, where `file_name` is the full path name to the file.
MySQL Source-Configuration Options

- **-DTMPDIR=dir_name**

  The default location to use for the tmpdir system variable. If unspecified, the value defaults to P_tmpdir in <stdio.h>. This option was added in MySQL 5.6.16.

Storage Engine Options

Storage engines are built as plugins. You can build a plugin as a static module (compiled into the server) or a dynamic module (built as a dynamic library that must be installed into the server using the INSTALL PLUGIN statement or the --plugin-load option before it can be used). Some plugins might not support static or dynamic building.

The MyISAM, MERGE, MEMORY, and CSV engines are mandatory (always compiled into the server) and need not be installed explicitly.

To compile a storage engine statically into the server, use -DWITH_engine_STORAGE_ENGINE=1. Some permissible engine values are ARCHIVE, BLACKHOLE, EXAMPLE, FEDERATED, INNODB (InnoDB), NDBCLUSTER (NDB), PARTITION (partitioning support), and PERFSchema (Performance Schema).

Examples:

- -DWITH_INNODB_STORAGE_ENGINE=1
- -DWITH_ARCHIVE_STORAGE_ENGINE=1
- -DWITH_BLACKHOLE_STORAGE_ENGINE=1
- -DWITH_PERFSchema_STORAGE_ENGINE=1

**Note**

WITH_NDBCLUSTER_STORAGE_ENGINE is supported only when building MySQL Cluster using the MySQL Cluster sources. It cannot be used to enable clustering support in other MySQL source trees or distributions. In MySQL Cluster NDB 7.2 source distributions, it is enabled by default. See Section 18.2.1.3, “Building MySQL Cluster from Source on Linux”, and Section 18.2.2.2, “Compiling and Installing MySQL Cluster from Source on Windows”, for more information.

To exclude a storage engine from the build, use -DWITHOUT_engine_STORAGE_ENGINE=1. Examples:

- -DWITHOUT_EXAMPLE_STORAGE_ENGINE=1
- -DWITHOUT_FEDERATED_STORAGE_ENGINE=1
- -DWITHOUT_PARTITION_STORAGE_ENGINE=1

If neither -DWITH_engine_STORAGE_ENGINE nor -DWITHOUT_engine_STORAGE_ENGINE are specified for a given storage engine, the engine is built as a shared module, or excluded if it cannot be built as a shared module.

Feature Options

- **-DCOMPILATION_COMMENT=string**

  A descriptive comment about the compilation environment.

- **-DDEFAULT_CHARSET=charset_name**

  The server character set. By default, MySQL uses the latin1 (cp1252 West European) character set.

  *charset_name* may be one of binary, armscii8, ascii, big5, cp1250, cp1251, cp1256, cp1257, cp850, cp852, cp866, cp932, dec8, eucjpms, euckr, gb2312, gbk, geostd8, greek, hebrew, hp8, keybcs2, koi8r, koi8u, latin1, latin2, latin5, latin7, macce, macroman,
The permissible character sets are listed in the `cmake/character_sets.cmake` file as the value of NVARCHAR. This value can be set at server startup with the `--character-set-server` option.

- `--default-collation=collation_name`

The server collation. By default, MySQL uses `latin1_swedish_ci`. Use the `SHOW COLLATION` statement to determine which collations are available for each character set. This value can be set at server startup with the `--collation-server` option.

- `--enable-debug-sync=bool`

Whether to compile the Debug Sync facility into the server. This facility is used for testing and debugging. This option is enabled by default, but has no effect unless MySQL is configured with debugging enabled. If debugging is enabled and you want to disable Debug Sync, use `--enable-debug-sync=0`.

When compiled in, Debug Sync is disabled by default at runtime. To enable it, start `mysql` with the `--debug-sync-timeout=N` option, where `N` is a timeout value greater than 0. (The default value is 0, which disables Debug Sync.) `N` becomes the default timeout for individual synchronization points.

For a description of the Debug Sync facility and how to use synchronization points, see MySQL Internals: Tracing mysqld Using DTrace.

- `--enable-downloads=bool`

Whether to download optional files. For example, with this option enabled, CMake downloads the Google Test distribution that is used by the test suite to run unit tests.

- `--enable-dtrace=bool`

Whether to include support for DTrace probes. For information about DTrace, see Section 5.4, “Tracing mysqld Using DTrace”.

- `--enable-gcov=bool`

Whether to include gcov support (Linux only).

- `--enable-local-infile=bool`

Whether to enable LOCAL capability in the client library for LOAD DATA INFILE. This option controls client-side LOCAL capability, but the capability can be set on the server side at server startup with the `--local-infile` option. See Section 6.1.6, “Security Issues with LOAD DATA LOCAL”.

- `--enable-profiling=bool`

Whether to enable query profiling code (for the SHOW PROFILE and SHOW PROFILES statements).

- `--ignore-aio-check=bool`

If the `--build-config=mysql_release` option is given on Linux, the libaio library must be linked in by default. If you do not have libaio or do not want to install it, you can suppress the check for it by specifying `--ignore-aio-check=1`. This option was added in MySQL 5.5.9.

- `--mysql-maintainer-mode=bool`
Whether to enable a MySQL maintainer-specific development environment. If enabled, this option causes compiler warnings to become errors.

- `--DMYSQL_PROJECT_NAME`=
  For Windows or Mac OS X, the project name to incorporate into the project file name. This option was added in MySQL 5.5.21.

- `--DMYSQL_TCP_PORT`=
  The port number on which the server listens for TCP/IP connections. The default is 3306. This value can be set at server startup with the `--port` option.

- `--DMYSQL_UNIX_ADDR`=
  The Unix socket file path on which the server listens for socket connections. This must be an absolute path name. The default is `/tmp/mysql.sock`. This value can be set at server startup with the `--socket` option.

- `--DWITH_ASAN`=
  Whether to enable AddressSanitizer, for compilers that support it. The default is off. This option was added in MySQL 5.5.35.

- `--DWITH_DEBUG`=
  Whether to include debugging support.
  Configuring MySQL with debugging support enables you to use the `--debug="d,parser_debug"` option when you start the server. This causes the Bison parser that is used to process SQL statements to dump a parser trace to the server's standard error output. Typically, this output is written to the error log.

- `--DWITH_EMBEDDED_SERVER`=
  Whether to build the `libmysqld` embedded server library.

- `--DWITH_EXTRA_CHARSETS`=
  Which extra character sets to include:
  - `all`: All character sets. This is the default.
  - `complex`: Complex character sets.
  - `none`: No extra character sets.

- `--DWITH_LIBEDIT`=
  Whether to use the `libedit` library bundled with the distribution.

- `--DWITH_LIBWRAP`=
  Whether to include `libwrap` (TCP wrappers) support.

- `--DWITH_READLINE`=
  Whether to include `libreadline` support.
Whether to use the `readline` library bundled with the distribution.

- `-DWITH_SSL=ssl_type`

The type of SSL support to include, if any:

- `no`: No SSL support. This is the default.
- `yes`: Use the system SSL library if present, else the library bundled with the distribution.
- `bundled`: Use the SSL library bundled with the distribution.
- `system`: Use the system SSL library.

For information about using SSL support, see Section 6.3.9, “Using SSL for Secure Connections”.

- `-DWITH_UNIXODBC=1`

Enables unixODBC support, for Connector/ODBC.

- `-DWITH_VALGRIND=bool`

Whether to compile in the Valgrind header files, which exposes the Valgrind API to MySQL code. The default is `OFF`.

To generate a Valgrind-aware debug build, `-DWITH_VALGRIND=1` normally is combined with `-DWITH_DEBUG=1`. See Building Debug Configurations.

- `-DWITH_ZLIB=zlib_type`

Some features require that the server be built with compression library support, such as the `COMPRESS()` and `UNCOMPRESS()` functions, and compression of the client/server protocol. The `WITH_ZLIB` indicates the source of `zlib` support:

- `bundled`: Use the `zlib` library bundled with the distribution.
- `system`: Use the system `zlib` library. This is the default.

- `-DWITHOUT_SERVER=bool`

Whether to build without the MySQL server. The default is `OFF`, which does build the server.

**Compiler Flags**

- `-DCMAKE_C_FLAGS="flags"`

  Flags for the C Compiler.

- `-DCMAKE_CXX_FLAGS="flags"`

  Flags for the C++ Compiler.

To specify your own C and C++ compiler flags, for flags that do not affect optimization, use the `CMAKE_C_FLAGS` and `CMAKE_CXX_FLAGS` CMake options.

When providing your own compiler flags, you might want to specify `CMAKE_BUILD_TYPE` as well.

For example, to create a 32-bit release build on a 64-bit Linux machine, do this:
If you set flags that affect optimization (-O<number>, you must set the `CMAKE_C_FLAGS_build_type` and/or `CMAKE_CXX_FLAGS_build_type` options, where `build_type` corresponds to the `CMAKE_BUILD_TYPE` value. To specify a different optimization for the default build type (RelWithDebInfo) set the `CMAKE_C_FLAGS_RELWITHDEBINFO` and `CMAKE_CXX_FLAGS_RELWITHDEBINFO` options. For example, to compile on Linux with `-O3` and with debug symbols, do this:

```
shell> cmake .. -D CMAKE_C_FLAGS=-m32 \ 
    -D CMAKE_CXX_FLAGS=-m32 \ 
    -D CMAKE_BUILD_TYPE=RelWithDebInfo
```

### CMake Options for Compiling MySQL Cluster

The following options are for use when building MySQL Cluster NDB 7.2 or later. These options are supported only with the MySQL Cluster NDB 7.2 and later MySQL Cluster sources; they are not supported when using sources from the MySQL 5.5 Server tree.

- **-DMEMCACHED_HOME=path**

  Perform the build using the memcached (version 1.6 or later) installed in the system directory indicated by `path`. Files from this installation that are used in the build include the memcached binary, header files, and libraries, as well as the `memcached_utilities` library and the header file `engine_testapp.h`.

  You must leave this option unset when building `ndbmemcache` using the bundled memcached sources (`WITH_BUNDLED_MEMCACHED` option); in other words, the bundled sources are used by default).

  This option was added in MySQL Cluster NDB 7.2.2.

- **-DWITH_BUNDLED_LIBEVENT={ON|OFF}**

  Use the libevent included in the MySQL Cluster sources when building MySQL Cluster with ndbmemcached support (MySQL Cluster NDB 7.2.2 and later). Enabled by default. OFF causes the system's libevent to be used instead.

- **-DWITH_BUNDLED_MEMCACHED={ON|OFF}**

  Build the memcached sources included in the MySQL Cluster source tree (MySQL Cluster NDB 7.2.3 and later), then use the resulting memcached server when building the ndbmemcache engine. In this case, `make install` places the memcached binary in the installation `bin` directory, and the ndbmemcache engine shared object file `ndb_engine.so` in the installation `lib` directory.

  This option is ON by default.

- **-DWITH_CLASSPATH=path**

  Sets the classpath for building MySQL Cluster Connector for Java. The default is empty. In MySQL Cluster NDB 7.2.9 and later, this option is ignored if `−DWITH_NDB_JAVA=OFF` is used.
Dealing with Problems Compiling MySQL

- **-DWITH_ERROR_INSERT={ON|OFF}**

  Enables error injection in the NDB kernel. For testing only; not intended for use in building production binaries. The default is OFF.

- **-DWITH_NDBCLUSTER_STORAGE_ENGINE={ON|OFF}**

  Build and link in support for the NDB (NDBCLUSTER) storage engine in mysqld. The default is ON.

- **-DWITH_NDBCLUSTER={ON|OFF}**

  This is an alias for WITH_NDBCLUSTER_STORAGE_ENGINE.

- **-DWITH_NDBMTD={ON|OFF}**

  Build the multi-threaded data node executable ndbmtd. The default is ON.

- **-DWITH_NDB_BINLOG={ON|OFF}**

  Enable binary logging by default in the mysqld built using this option. ON by default.

- **-DWITH_NDB_DEBUG={ON|OFF}**

  Enable building the debug versions of the MySQL Cluster binaries. OFF by default.

- **-DWITH_NDB_JAVA={ON|OFF}**

  Enable building MySQL Cluster with Java support, including ClusterJ.

  This option was added in MySQL Cluster NDB 7.2.9, and is ON by default. If you do not wish to compile MySQL Cluster with Java support, you must disable it explicitly by specifying -DWITH_NDB_JAVA=OFF when running CMake. Otherwise, if Java cannot be found, configuration of the build fails.

- **-DWITH_NDB_PORT=port**

  Causes the MySQL Cluster management server (ndb_mgmd) that is built to use this port by default. If this option is unset, the resulting management server tries to use port 1186 by default.

- **-DWITH_NDB_TEST={ON|OFF}**

  If enabled, include a set of NDB API test programs. The default is OFF.

### 2.9.5 Dealing with Problems Compiling MySQL

The solution to many problems involves reconfiguring. If you do reconfigure, take note of the following:

- If CMake is run after it has previously been run, it may use information that was gathered during its previous invocation. This information is stored in CMakeCache.txt. When CMake starts up, it looks for that file and reads its contents if it exists, on the assumption that the information is still correct. That assumption is invalid when you reconfigure.

- Each time you run CMake, you must run make again to recompile. However, you may want to remove old object files from previous builds first because they were compiled using different configuration options.

  To prevent old object files or configuration information from being used, run the following commands before re-running CMake:

  **On Unix:**
Dealing with Problems Compiling MySQL

Shell>
make clean
Shell>
rm CMakeCache.txt

On Windows:

Shell>
devenv MySQL.sln /clean
Shell>
del CMakeCache.txt

If you build outside of the source tree, remove and recreate your build directory before re-running CMake. For instructions on building outside of the source tree, see How to Build MySQL Server with CMake.

On some systems, warnings may occur due to differences in system include files. The following list describes other problems that have been found to occur most often when compiling MySQL:

• To define which C and C++ compilers to use, you can define the CC and CXX environment variables. For example:

Shell>
CC=gcc
Shell>
CXX=g++
Shell>
export CC CXX

To specify your own C and C++ compiler flags, use the CMAKE_C_FLAGS and CMAKE_CXX_FLAGS CMake options. See Compiler Flags.

To see what flags you might need to specify, invoke mysql_config with the --cflags option.

• To see what commands are executed during the compile stage, after using CMake to configure MySQL, run make VERbose=1 rather than just make.

• If compilation fails, check whether the MYSQL_MAINTAINER_MODE option is enabled. This mode causes compiler warnings to become errors, so disabling it may enable compilation to proceed.

• If your compile fails with errors such as any of the following, you must upgrade your version of make to GNU make:

make: Fatal error in reader: Makefile, line 18:
Badly formed macro assignment

Or:

make: file `Makefile' line 18: Must be a separator (:)

Or:

pthread.h: No such file or directory

Solaris and FreeBSD are known to have troublesome make programs.

GNU make 3.75 is known to work.

• The sql_yacc.cc file is generated from sql_yacc.yy. Normally, the build process does not need to create sql_yacc.cc because MySQL comes with a pregenerated copy. However, if you do need to re-create it, you might encounter this error:
"sql_yacc.yy", line xxx fatal: default action causes potential...

This is a sign that your version of yacc is deficient. You probably need to install a recent version of bison (the GNU version of yacc) and use that instead.

Versions of bison older than 1.75 may report this error:

sql_yacc.yy:#####: fatal error: maximum table size (32767) exceeded

The maximum table size is not actually exceeded; the error is caused by bugs in older versions of bison.

For information about acquiring or updating tools, see the system requirements in Section 2.9, “Installing MySQL from Source”.

2.9.6 MySQL Configuration and Third-Party Tools

Third-party tools that need to determine the MySQL version from the MySQL source can read the VERSION file in the top-level source directory. The file lists the pieces of the version separately. For example, if the version is MySQL 5.7.4-m14, the file looks like this:

MYSQL_VERSION_MAJOR=5
MYSQL_VERSION_MINOR=7
MYSQL_VERSION_PATCH=4
MYSQL_VERSION_EXTRA=-m14

If the source is not for a General Availability (GA) release, the MYSQL_VERSION_EXTRA value will be nonempty. For the example, the value corresponds to Milestone 14.

To construct a five-digit number from the version components, use this formula:

MYSQL_VERSION_MAJOR*10000 + MYSQL_VERSION_MINOR*100 + MYSQL_VERSION_PATCH

2.10 Postinstallation Setup and Testing

This section discusses post-installation items for Unix-like systems. If you are using Windows, see Section 2.3.10, “Windows Postinstallation Procedures”.

After installing MySQL, there are some items that you should address. For example:

• You should initialize the data directory and create the MySQL grant tables, as describe in Section 2.10.1, “Postinstallation Procedures for Unix-like Systems”.

• An important security concern is that the initial accounts in the grant tables have no passwords. You should assign passwords to prevent unauthorized access to the MySQL server. For instructions, see Section 2.10.2, “Securing the Initial MySQL Accounts”.

• Optionally, you can create time zone tables to enable recognition of named time zones. For instructions, see Section 4.4.6, “mysql_tzinfo_to_sql — Load the Time Zone Tables”.

• If you have trouble getting the server to start, see Section 2.10.1.3, “Starting and Troubleshooting the MySQL Server”.

• When you are ready to create additional user accounts, you can find information on the MySQL access control system and account management in Section 6.2, “The MySQL Access Privilege System”, and Section 6.3, “MySQL User Account Management”.

179
2.10.1 Postinstallation Procedures for Unix-like Systems

After installing MySQL on a Unix-like system, you must initialize the grant tables, start the server, and make sure that the server works satisfactorily. You may also wish to arrange for the server to be started and stopped automatically when your system starts and stops. You should also assign passwords to the accounts in the grant tables.

On a Unix-like system, the grant tables are set up by the `mysql_install_db` program. For some installation methods, this program is run for you automatically if an existing database cannot be found.

- If you install MySQL on Linux using RPM distributions, the server RPM runs `mysql_install_db`.
- Using the native packaging system on many platforms, including Debian Linux, Ubuntu Linux, Gentoo Linux and others, the `mysql_install_db` command is run for you.
- If you install MySQL on Mac OS X using a DMG distribution, the installer runs `mysql_install_db`.

For other platforms and installation types, including generic binary and source installs, you will need to run `mysql_install_db` yourself.

The following procedure describes how to initialize the grant tables (if that has not previously been done) and start the server. It also suggests some commands that you can use to test whether the server is accessible and working properly. For information about starting and stopping the server automatically, see Section 2.10.1.2, "Starting and Stopping MySQL Automatically".

After you complete the procedure and have the server running, you should assign passwords to the accounts created by `mysql_install_db` and perhaps restrict access to test databases. For instructions, see Section 2.10.2, "Securing the Initial MySQL Accounts".

In the examples shown here, the server runs under the user ID of the `mysql` login account. This assumes that such an account exists. Either create the account if it does not exist, or substitute the name of a different existing login account that you plan to use for running the server. For information about creating the account, see Creating a `mysql` System User and Group, in Section 2.2, "Installing MySQL on Unix/Linux Using Generic Binaries".

1. Change location into the top-level directory of your MySQL installation, represented here by `BASEDIR`:

   ```
   shell> cd BASEDIR
   ```

   `BASEDIR` is the installation directory for your MySQL instance. It is likely to be something like `/usr/local/mysql` or `/usr/local`. The following steps assume that you have changed location to this directory.

   You will find several files and subdirectories in the `BASEDIR` directory. The most important for installation purposes are the `bin` and `scripts` subdirectories:

   - The `bin` directory contains client programs and the server. You should add the full path name of this directory to your `PATH` environment variable so that your shell finds the MySQL programs properly. See Section 2.12, "Environment Variables".

   - The `scripts` directory contains the `mysql_install_db` script used to initialize the `mysql` database containing the grant tables that store the server access permissions.

2. If necessary, ensure that the distribution contents are accessible to `mysql`. If you installed the distribution as `mysql`, no further action is required. If you installed the distribution as `root`, its contents
will be owned by root. Change its ownership to mysql by executing the following commands as root in the installation directory. The first command changes the owner attribute of the files to the mysql user. The second changes the group attribute to the mysql group.

```
shell> chown -R mysql .
shell> chgrp -R mysql .
```

3. If necessary, run the `mysql_install_db` program to set up the initial MySQL grant tables containing the privileges that determine how users are permitted to connect to the server. You will need to do this if you used a distribution type for which the installation procedure does not run the program for you.

```
shell> scripts/mysql_install_db --user=mysql
```

Typically, `mysql_install_db` needs to be run only the first time you install MySQL, so you can skip this step if you are upgrading an existing installation. However, `mysql_install_db` does not overwrite any existing privilege tables, so it should be safe to run in any circumstances.

It might be necessary to specify other options such as `--basedir` or `--datadir` if `mysql_install_db` does not identify the correct locations for the installation directory or data directory. For example:

```
shell> scripts/mysql_install_db --user=mysql --basedir=/opt/mysql/mysql --datadir=/opt/mysql/mysql/data
```

The `mysql_install_db` script creates the server's data directory with mysql as the owner. Under the data directory, it creates directories for the mysql database that holds the grant tables and the test database that you can use to test MySQL. The script also creates privilege table entries for root and anonymous-user accounts. The accounts have no passwords initially. Section 2.10.2, “Securing the Initial MySQL Accounts”, describes the initial privileges. Briefly, these privileges permit the MySQL root user to do anything, and permit anybody to create or use databases with a name of test or starting with test_. See Section 6.2, “The MySQL Access Privilege System”, for a complete listing and description of the grant tables.

It is important to make sure that the database directories and files are owned by the mysql login account so that the server has read and write access to them when you run it later. To ensure this if you run `mysql_install_db` as root, include the `--user` option as shown. Otherwise, you should execute the script while logged in as mysql, in which case you can omit the `--user` option from the command.

If you do not want to have the test database, you can remove it after starting the server, using the instructions in Section 2.10.2, “Securing the Initial MySQL Accounts”.

If you have trouble with `mysql_install_db` at this point, see Section 2.10.1.1, “Problems Running mysql_install_db”.

4. Most of the MySQL installation can be owned by root if you like. The exception is that the data directory must be owned by mysql. To accomplish this, run the following commands as root in the installation directory:

```
shell> chown -R root .
shell> chown -R mysql data
```

5. If the plugin directory (the directory named by the plugin_dir system variable) is writable by the server, it may be possible for a user to write executable code to a file in the directory using
**SELECT ... INTO DUMPFILE.** This can be prevented by making `plugin_dir` read only to the server or by setting `--secure-file-priv` to a directory where `SELECT` writes can be made safely.

6. If you installed MySQL using a source distribution, you may want to optionally copy one of the provided configuration files from the `support-files` directory into your `/etc` directory. There are different sample configuration files for different use cases, server types, and CPU and RAM configurations. If you want to use one of these standard files, you should copy it to `/etc/my.cnf`, or `/etc/mysql/my.cnf` and edit and check the configuration before starting your MySQL server for the first time.

If you do not copy one of the standard configuration files, the MySQL server will be started with the default settings.

If you want MySQL to start automatically when you boot your machine, you can copy `support-files/mysql.server` to the location where your system has its startup files. More information can be found in the `mysql.server` script itself, and in Section 2.10.1.2, “Starting and Stopping MySQL Automatically”.

7. Start the MySQL server:

```bash
shell> bin/mysqld_safe --user=mysql &
```

It is important that the MySQL server be run using an unprivileged (non-root) login account. To ensure this if you run `mysqld_safe` as root, include the `--user` option as shown. Otherwise, you should execute the script while logged in as `mysql`, in which case you can omit the `--user` option from the command.

For further instructions for running MySQL as an unprivileged user, see Section 6.1.5, “How to Run MySQL as a Normal User”.

If the command fails immediately and prints `mysqld ended`, look for information in the error log (which by default is the `host_name.err` file in the data directory).

If you neglected to create the grant tables by running `mysql_install_db` before proceeding to this step, the following message appears in the error log file when you start the server:

```text
mysqld: Can't find file: 'host.frm'
```

This error also occurs if you run `mysql_install_db` as root without the `--user` option. Remove the `data` directory and run `mysql_install_db` with the `--user` option as described previously.

If you have other problems starting the server, see Section 2.10.1.3, “Starting and Troubleshooting the MySQL Server”. For more information about `mysqld_safe`, see Section 4.3.2, “`mysqld_safe — MySQL Server Startup Script`”.

8. Use `mysqladmin` to verify that the server is running. The following commands provide simple tests to check whether the server is up and responding to connections:

```bash
shell> bin/mysqladmin version
shell> bin/mysqladmin variables
```

The output from `mysqladmin version` varies slightly depending on your platform and version of MySQL, but should be similar to that shown here:

```text
shell> bin/mysqladmin version
mysqladmin  Ver 14.12 Distrib 5.5.40, for pc-linux-gnu on i686
```
Postinstallation Procedures for Unix-like Systems

...  
Server version          5.5.40  
Protocol version        10  
Connection              Localhost via UNIX socket  
UNIX socket             /var/lib/mysql/mysql.sock  
Uptime:                 14 days 5 hours 5 min 21 sec  

Threads: 1  Questions: 366  Slow queries: 0  
Opens: 0  Flush tables: 1  Open tables: 19  
Queries per second avg: 0.000  

To see what else you can do with mysqladmin, invoke it with the --help option.

9. Verify that you can shut down the server:

   shell> bin/mysqladmin -u root shutdown

10. Verify that you can start the server again. Do this by using mysqld_safe or by invoking mysqld directly. For example:

   shell> bin/mysqld_safe --user=mysql &

   If mysqld_safe fails, see Section 2.10.1.3, “Starting and Troubleshooting the MySQL Server”.

11. Run some simple tests to verify that you can retrieve information from the server. The output should be similar to what is shown here:

   shell> bin/mysqlshow

+--------------------+
|     Databases      |
+--------------------+
| information_schema |
| mysql              |
| test               |
+--------------------+

   shell> bin/mysqlshow mysql

Database: mysql

+---------------------------+
12. There is a benchmark suite in the sql-bench directory (under the MySQL installation directory) that you can use to compare how MySQL performs on different platforms. The benchmark suite is written in Perl. It requires the Perl DBI module that provides a database-independent interface to the various databases, and some other additional Perl modules:

```
DBI
DBD::mysql
Data::Dumper
Data::ShowTable
```

These modules can be obtained from CPAN (http://www.cpan.org/). See also Section 2.13.1, “Installing Perl on Unix”.

The sql-bench/Results directory contains the results from many runs against different databases and platforms. To run all tests, execute these commands:

```
shell> cd sql-bench
shell> perl run-all-tests
```

If you do not have the sql-bench directory, you probably installed MySQL using RPM files other than the source RPM. (The source RPM includes the sql-bench benchmark directory.) In this case, you must first install the benchmark suite before you can use it. There are separate benchmark RPM files named mysql-bench-VERSION.i386.rpm that contain benchmark code and data.

If you have a source distribution, there are also tests in its tests subdirectory that you can run. For example, to run auto_increment.tst, execute this command from the top-level directory of your source distribution:

```
shell> mysql -vvf test < ./tests/auto_increment.tst
```

The expected result of the test can be found in the ./tests/auto_increment.res file.

13. At this point, you should have the server running. However, none of the initial MySQL accounts have a password, and the server permits permissive access to test databases. To tighten security, follow the instructions in Section 2.10.2, “Securing the Initial MySQL Accounts”.

The MySQL 5.5 installation procedure creates time zone tables in the mysql database but does not populate them. To do so, use the instructions in Section 10.6, “MySQL Server Time Zone Support”.

To make it more convenient to invoke programs installed in the bin directory under the installation directory, you can add that directory to your PATH environment variable setting. That enables you to run a program by typing only its name, not its entire path name. See Section 4.2.10, “Setting Environment Variables”.

You can set up new accounts using the bin/mysql_setpermission script if you install the DBI and DBD::mysql Perl modules. See Section 4.6.13, “mysql_setpermission — Interactively Set Permissions in Grant Tables”. For Perl module installation instructions, see Section 2.13, “Perl Installation Notes”.
If you would like to use `mysqlaccess` and have the MySQL distribution in some nonstandard location, you must change the location where `mysqlaccess` expects to find the `mysql` client. Edit the `bin/mysqlaccess` script at approximately line 18. Search for a line that looks like this:

```
$MYSQL     = '/usr/local/bin/mysql';    # path to mysql executable
```

Change the path to reflect the location where `mysql` actually is stored on your system. If you do not do this, a Broken pipe error will occur when you run `mysqlaccess`.

### 2.10.1.1 Problems Running `mysql_install_db`

The purpose of the `mysql_install_db` script is to generate new MySQL privilege tables. It does not overwrite existing MySQL privilege tables, and it does not affect any other data.

If you want to re-create your privilege tables, first stop the `mysqld` server if it is running. Then rename the `mysql` directory under the data directory to save it, and then run `mysql_install_db`. Suppose that your current directory is the MySQL installation directory and that `mysql_install_db` is located in the `bin` directory and the data directory is named `data`. To rename the `mysql` database and re-run `mysql_install_db`, use these commands.

```
shell> mv data/mysql data/mysql.old
shell> scripts/mysql_install_db --user=mysql
```

When you run `mysql_install_db`, you might encounter the following problems:

- **`mysql_install_db` fails to install the grant tables**

  You may find that `mysql_install_db` fails to install the grant tables and terminates after displaying the following messages:

  ```
  Starting mysqld daemon with databases from XXXXXX
  mysqld ended
  ```

  In this case, you should examine the error log file very carefully. The log should be located in the directory `XXXXXX` named by the error message and should indicate why `mysqld` did not start. If you do not understand what happened, include the log when you post a bug report. See Section 1.7, “How to Report Bugs or Problems”.

- **There is a `mysqld` process running**

  This indicates that the server is running, in which case the grant tables have probably been created already. If so, there is no need to run `mysql_install_db` at all because it needs to be run only once (when you install MySQL the first time).

- **Installing a second `mysqld` server does not work when one server is running**

  This can happen when you have an existing MySQL installation, but want to put a new installation in a different location. For example, you might have a production installation, but you want to create a second installation for testing purposes. Generally the problem that occurs when you try to run a second server is that it tries to use a network interface that is in use by the first server. In this case, you should see one of the following error messages:

  ```
  Can't start server: Bind on TCP/IP port:
  Address already in use
  Can't start server: Bind on unix socket...
  ```
For instructions on setting up multiple servers, see Section 5.3, “Running Multiple MySQL Instances on One Machine”.

- **You do not have write access to the /tmp directory**

If you do not have write access to create temporary files or a Unix socket file in the default location (the /tmp directory) or the TMP_DIR environment variable, if it has been set, an error occurs when you run mysql_install_db or the mysqld server.

You can specify different locations for the temporary directory and Unix socket file by executing these commands prior to starting mysql_install_db or mysqld, where some_tmp_dir is the full path name to some directory for which you have write permission:

```
shell> TMPDIR=/some_tmp_dir/
shell> MYSQL_UNIX_PORT=/some_tmp_dir/mysql.sock
shell> export TMPDIR MYSQL_UNIX_PORT
```

Then you should be able to run mysql_install_db and start the server with these commands:

```
shell> scripts/mysql_install_db --user=mysql
shell> bin/mysqld_safe --user=mysql &
```

If mysql_install_db is located in the scripts directory, modify the first command to scripts/mysql_install_db.

See Section B.5.4.5, “How to Protect or Change the MySQL Unix Socket File”, and Section 2.12, “Environment Variables”.

There are some alternatives to running the mysql_install_db script provided in the MySQL distribution:

- If you want the initial privileges to be different from the standard defaults, you can modify
  mysql_install_db before you run it. However, it is preferable to use GRANT and REVOKE to change
  the privileges after the grant tables have been set up. In other words, you can run mysql_install_db,
  and then use mysql -u root mysql to connect to the server as the MySQL root user so that you
  can issue the necessary GRANT and REVOKE statements.

If you want to install MySQL on several machines with the same privileges, you can put the
GRANT and REVOKE statements in a file and execute the file as a script using mysql after running
mysql_install_db. For example:

```
shell> scripts/mysql_install_db --user=mysql
shell> bin/mysql -u root < your_script_file
```

By doing this, you can avoid having to issue the statements manually on each machine.

- It is possible to re-create the grant tables completely after they have previously been created. You
  might want to do this if you are just learning how to use GRANT and REVOKE and have made so many
  modifications after running mysql_install_db that you want to wipe out the tables and start over.

To re-create the grant tables, remove all the .frm, .MYI, and .MYD files in the mysql database
directory. Then run the mysql_install_db script again.

- You can start mysqld manually using the --skip-grant-tables option and add the privilege
  information yourself using mysql:
Postinstallation Procedures for Unix-like Systems

shell> bin/mysqld_safe --user=mysql --skip-grant-tables &
shell> bin/mysql mysql

From mysql, manually execute the SQL commands contained in mysql_install_db. Make sure that you run mysqladmin flush-privileges or mysqladmin reload afterward to tell the server to reload the grant tables.

Note that by not using mysql_install_db, you not only have to populate the grant tables manually, you also have to create them first.

2.10.1.2 Starting and Stopping MySQL Automatically

Generally, you start the mysqld server in one of these ways:

- Invoke mysqld directly. This works on any platform.

- Invoke mysqld_safe, which tries to determine the proper options for mysqld and then runs it with those options. This script is used on Unix and Unix-like systems. See Section 4.3.2, “mysqld_safe — MySQL Server Startup Script”.

- Invoke mysql.server. This script is used primarily at system startup and shutdown on systems that use System V-style run directories (that is, /etc/init.d and run-level specific directories), where it usually is installed under the name mysql. The mysql.server script starts the server by invoking mysqld_safe. See Section 4.3.3, “mysql.server — MySQL Server Startup Script”.

- On Mac OS X, install a separate MySQL Startup Item package to enable the automatic startup of MySQL on system startup. The Startup Item starts the server by invoking mysql.server. See Section 2.4.3, “Installing the MySQL Startup Item”, for details. A MySQL Preference Pane also provides control for starting and stopping MySQL through the System Preferences, see Section 2.4.4, “Installing and Using the MySQL Preference Pane”.

- Use the Solaris/OpenSolaris service management framework (SMF) system to initiate and control MySQL startup. For more information, see Section 2.7.2, “Installing MySQL on OpenSolaris Using IPS”.

The mysqld_safe and mysql.server scripts, Solaris/OpenSolaris SMF, and the Mac OS X Startup Item (or MySQL Preference Pane) can be used to start the server manually, or automatically at system startup time. mysql.server and the Startup Item also can be used to stop the server.

To start or stop the server manually using the mysql.server script, invoke it with start or stop arguments:

shell> mysql.server start
shell> mysql.server stop

Before mysql.server starts the server, it changes location to the MySQL installation directory, and then invokes mysqld_safe. If you want the server to run as some specific user, add an appropriate user option to the [mysqld] group of the /etc/my.cnf option file, as shown later in this section. (It is possible that you will need to edit mysql.server if you've installed a binary distribution of MySQL in a nonstandard location. Modify it to change location into the proper directory before it runs mysqld_safe. If you do this, your modified version of mysql.server may be overwritten if you upgrade MySQL in the future, so you should make a copy of your edited version that you can reinstall.)

mysql.server stop stops the server by sending a signal to it. You can also stop the server manually by executing mysqladmin shutdown.

To start and stop MySQL automatically on your server, you need to add start and stop commands to the appropriate places in your /etc/rc* files.
If you use the Linux server RPM package (MySQL-server-VERSION.rpm), or a native Linux package installation, the mysql.server script may be installed in the /etc/init.d directory with the name mysql. See Section 2.5.1, “Installing MySQL on Linux Using RPM Packages”, for more information on the Linux RPM packages.

Some vendors provide RPM packages that install a startup script under a different name such as mysqld.

If you install MySQL from a source distribution or using a binary distribution format that does not install mysql.server automatically, you can install it manually. The script can be found in the support-files directory under the MySQL installation directory or in a MySQL source tree.

To install mysql.server manually, copy it to the /etc/init.d directory with the name mysql, and then make it executable. Do this by changing location into the appropriate directory where mysql.server is located and executing these commands:

```
shell> cp mysql.server /etc/init.d/mysql
shell> chmod +x /etc/init.d/mysql
```

**Note**
Older Red Hat systems use the /etc/rc.d/init.d directory rather than /etc/init.d. Adjust the preceding commands accordingly. Alternatively, first create /etc/init.d as a symbolic link that points to /etc/rc.d/init.d:

```
shell> cd /etc
shell> ln -s rc.d/init.d .
```

After installing the script, the commands needed to activate it to run at system startup depend on your operating system. On Linux, you can use `chkconfig`:

```
shell> chkconfig --add mysql
```

On some Linux systems, the following command also seems to be necessary to fully enable the mysql script:

```
shell> chkconfig --level 345 mysql on
```

On FreeBSD, startup scripts generally should go in /usr/local/etc/rc.d/. The rc(8) manual page states that scripts in this directory are executed only if their basename matches the *sh shell file name pattern. Any other files or directories present within the directory are silently ignored. In other words, on FreeBSD, you should install the mysql.server script as /usr/local/etc/rc.d/mysql.server.sh to enable automatic startup.

As an alternative to the preceding setup, some operating systems also use /etc/rc.local or /etc/init.d/boot.local to start additional services on startup. To start up MySQL using this method, you could append a command like the one following to the appropriate startup file:

```
/bin/sh -c 'cd /usr/local/mysql; ./mysqld_safe --user=mysql &'
```

For other systems, consult your operating system documentation to see how to install startup scripts.

You can add options for mysql.server in a global /etc/my.cnf file. A typical /etc/my.cnf file might look like this:

```
[mysqld]
datadir=/usr/local/mysql/var
```
socket=/var/tmp/mysql.sock
port=3306
user=mysql

[mysql.server]
basedir=/usr/local/mysql

The `mysql.server` script supports the following options: `basedir`, `datadir`, and `pid-file`. If specified, they must be placed in an option file, not on the command line. `mysql.server` supports only `start` and `stop` as command-line arguments.

The following table shows which option groups the server and each startup script read from option files.

**Table 2.17 MySQL Startup scripts and supported server option groups**

<table>
<thead>
<tr>
<th>Script</th>
<th>Option Groups</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysqld</td>
<td>[mysqld], [server], [mysqld-major_version]</td>
</tr>
<tr>
<td>mysql_safe</td>
<td>[mysqld], [server], [mysqld_safe]</td>
</tr>
<tr>
<td>mysql.server</td>
<td>[mysqld], [mysql.server], [server]</td>
</tr>
</tbody>
</table>

`[mysqld-major_version]` means that groups with names like `[mysqld-5.1]` and `[mysqld-5.5]` are read by servers having versions 5.1.x, 5.5.x, and so forth. This feature can be used to specify options that can be read only by servers within a given release series.

For backward compatibility, `mysql.server` also reads the `[mysql_server]` group and `mysql_safe` also reads the `[safe_mysqld]` group. However, you should update your option files to use the `[mysql.server]` and `[mysqld_safe]` groups instead when using MySQL 5.5.

For more information on MySQL configuration files and their structure and contents, see Section 4.2.6, “Using Option Files”.

### 2.10.1.3 Starting and Troubleshooting the MySQL Server

This section provides troubleshooting suggestions for problems starting the server on a Unix-like system. If you are using Windows, see Section 2.3.8, “Troubleshooting a Microsoft Windows MySQL Server Installation”.

If you have problems starting the server, here are some things to try:

- Check the error log to see why the server does not start.
- Specify any special options needed by the storage engines you are using.
- Make sure that the server knows where to find the data directory.
- Make sure that the server can access the data directory. The ownership and permissions of the data directory and its contents must be set such that the server can read and modify them.
- Verify that the network interfaces the server wants to use are available.

Some storage engines have options that control their behavior. You can create a `my.cnf` file and specify startup options for the engines that you plan to use. If you are going to use storage engines that support transactional tables (InnoDB, NDB), be sure that you have them configured the way you want before starting the server:

If you are using InnoDB tables, see Section 14.6, “InnoDB Configuration”.

Storage engines will use default option values if you specify none, but it is recommended that you review the available options and specify explicit values for those for which the defaults are not appropriate for your installation.
When the `mysqld` server starts, it changes location to the data directory. This is where it expects to find databases and where it expects to write log files. The server also writes the pid (process ID) file in the data directory.

The data directory location is hardwired in when the server is compiled. This is where the server looks for the data directory by default. If the data directory is located somewhere else on your system, the server will not work properly. You can determine what the default path settings are by invoking `mysqld` with the `--verbose` and `--help` options.

If the default locations do not match the MySQL installation layout on your system, you can override them by specifying options to `mysqld` or `mysqld_safe` on the command line or in an option file.

To specify the location of the data directory explicitly, use the `--datadir` option. However, normally you can tell `mysqld` the location of the base directory under which MySQL is installed and it looks for the data directory there. You can do this with the `--basedir` option.

To check the effect of specifying path options, invoke `mysqld` with those options followed by the `--verbose` and `--help` options. For example, if you change location into the directory where `mysqld` is installed and then run the following command, it shows the effect of starting the server with a base directory of `/usr/local`:

```
shell> ./mysqld --basedir=/usr/local --verbose --help
```

You can specify other options such as `--datadir` as well, but `--verbose` and `--help` must be the last options.

Once you determine the path settings you want, start the server without `--verbose` and `--help`.

If `mysqld` is currently running, you can find out what path settings it is using by executing this command:

```
shell> mysqladmin variables
```

Or:

```
shell> mysqladmin -h host_name variables
```

`host_name` is the name of the MySQL server host.

If you get `Errcode 13` (which means `Permission denied`) when starting `mysqld`, this means that the privileges of the data directory or its contents do not permit server access. In this case, you change the permissions for the involved files and directories so that the server has the right to use them. You can also start the server as `root`, but this raises security issues and should be avoided.

Change location into the data directory and check the ownership of the data directory and its contents to make sure the server has access. For example, if the data directory is `/usr/local/mysql/var`, use this command:

```
shell> ls -la /usr/local/mysql/var
```

If the data directory or its files or subdirectories are not owned by the login account that you use for running the server, change their ownership to that account. If the account is named `mysql`, use these commands:

```
shell> chown -R mysql /usr/local/mysql/var
shell> chgrp -R mysql /usr/local/mysql/var
```
Securing the Initial MySQL Accounts

If it possible that even with correct ownership, MySQL may fail to start up if there is other security software running on your system that manages application access to various parts of the file system. In this case, you may need to reconfigure that software to enable `mysqld` to access the directories it uses during normal operation.

If the server fails to start up correctly, check the error log. Log files are located in the data directory (typically `C:\Program Files\MySQL\MySQL Server 5.5\data` on Windows, `/usr/local/mysql/data` for a Unix/Linux binary distribution, and `/usr/local/var` for a Unix/Linux source distribution). Look in the data directory for files with names of the form `host_name.err` and `host_name.log`, where `host_name` is the name of your server host. Then examine the last few lines of these files. You can use `tail` to display them:

```
shell> tail host_name.err
shell> tail host_name.log
```

The error log should contain information that indicates why the server could not start.

If either of the following errors occur, it means that some other program (perhaps another `mysqld` server) is using the TCP/IP port or Unix socket file that `mysqld` is trying to use:

```
Can't start server: Bind on TCP/IP port: Address already in use
Can't start server: Bind on unix socket...
```

Use `ps` to determine whether you have another `mysqld` server running. If so, shut down the server before starting `mysqld` again. (If another server is running, and you really want to run multiple servers, you can find information about how to do so in Section 5.3, “Running Multiple MySQL Instances on One Machine”.)

If no other server is running, try to execute the command `telnet your_host_name tcp_ip_port_number`. (The default MySQL port number is 3306.) Then press Enter a couple of times. If you do not get an error message like `telnet: Unable to connect to remote host: Connection refused`, some other program is using the TCP/IP port that `mysqld` is trying to use. You will need to track down what program this is and disable it, or else tell `mysqld` to listen to a different port with the `--port` option. In this case, you will also need to specify the port number for client programs when connecting to the server using TCP/IP.

Another reason the port might be inaccessible is that you have a firewall running that blocks connections to it. If so, modify the firewall settings to permit access to the port.

If the server starts but you cannot connect to it, you should make sure that you have an entry in `/etc/hosts` that looks like this:

```
127.0.0.1       localhost
```

If you cannot get `mysqld` to start, you can try to make a trace file to find the problem by using the `--debug` option. See Section 24.4.3, “The DBUG Package”.

### 2.10.2 Securing the Initial MySQL Accounts

Part of the MySQL installation process is to set up the `mysql` database that contains the grant tables:

- Windows distributions contain preinitialized grant tables.
- On Unix, the `mysql_install_db` program populates the grant tables. Some installation methods run this program for you. Others require that you execute it manually. For details, see Section 2.10.1, “Postinstallation Procedures for Unix-like Systems”.

The `mysql.user` grant table defines the initial MySQL user accounts and their access privileges:
Securing the Initial MySQL Accounts

• Some accounts have the user name root. These are superuser accounts that have all privileges and can do anything. The initial root account passwords are empty, so anyone can connect to the MySQL server as root without a password and be granted all privileges.

• On Windows, root accounts are created that permit connections from the local host only. Connections can be made by specifying the host name localhost, the IP address 127.0.0.1, or the IPv6 address ::1. If the user selects the Enable root access from remote machines option during installation, the Windows installer creates another root account that permits connections from any host.

• On Unix, each root account permits connections from the local host. Connections can be made by specifying the host name localhost, the IP address 127.0.0.1, the IPv6 address ::1, or the actual host name or IP address.

An attempt to connect to the host 127.0.0.1 normally resolves to the localhost account. However, this fails if the server is run with the --skip-name-resolve option, so the 127.0.0.1 account is useful in that case. The ::1 account is used for IPv6 connections.

• Some accounts are for anonymous users. These have an empty user name. The anonymous accounts have no password, so anyone can use them to connect to the MySQL server.

• On Windows, there is one anonymous account that permits connections from the local host. Connections can be made by specifying a host name of localhost.

• On Unix, each anonymous account permits connections from the local host. Connections can be made by specifying a host name of localhost for one of the accounts, or the actual host name or IP address for the other.

To display which accounts exist in the mysql.user table and check whether their passwords are empty, use the following statement:

```
mysql> SELECT User, Host, Password FROM mysql.user;
+------+--------------------+----------+
| User | Host               | Password |
+------+--------------------+----------+
| root | localhost          |          |
| root | myhost.example.com |          |
| root | 127.0.0.1          |          |
| root | ::1                |          |
|      | localhost          |          |
|      | myhost.example.com |          |
+------+--------------------+----------+
```

This output indicates that there are several root and anonymous-user accounts, none of which have passwords. The output might differ on your system, but the presence of accounts with empty passwords means that your MySQL installation is unprotected until you do something about it:

• You should assign a password to each MySQL root account.

• If you want to prevent clients from connecting as anonymous users without a password, you should either assign a password to each anonymous account or else remove the accounts.

In addition, the mysql.db table contains rows that permit all accounts to access the test database and other databases with names that start with test_. This is true even for accounts that otherwise have no special privileges such as the default anonymous accounts. This is convenient for testing but inadvisable on production servers. Administrators who want database access restricted only to accounts that have permissions granted explicitly for that purpose should remove these mysql.db table rows.
Securing the Initial MySQL Accounts

The following instructions describe how to set up passwords for the initial MySQL accounts, first for the root accounts, then for the anonymous accounts. The instructions also cover how to remove the anonymous accounts, should you prefer not to permit anonymous access at all, and describe how to remove permissive access to test databases. Replace newpwd in the examples with the password that you want to use. Replace host_name with the name of the server host. You can determine this name from the output of the preceding SELECT statement. For the output shown, host_name is myhost.example.com.

Note

For additional information about setting passwords, see Section 6.3.5, “Assigning Account Passwords”. If you forget your root password after setting it, see Section B.5.4.1, “How to Reset the Root Password”.

You might want to defer setting the passwords until later, to avoid the need to specify them while you perform additional setup or testing. However, be sure to set them before using your installation for production purposes.

To set up additional accounts, see Section 6.3.2, “Adding User Accounts”.

Assigning root Account Passwords

The root account passwords can be set several ways. The following discussion demonstrates three methods:

- Use the SET PASSWORD statement
- Use the UPDATE statement
- Use the mysqladmin command-line client program

To assign passwords using SET PASSWORD, connect to the server as root and issue a SET PASSWORD statement for each root account listed in the mysql.user table. Be sure to encrypt the password using the PASSWORD() function.

For Windows, do this:

```
shell> mysql -u root
mysql> SET PASSWORD FOR 'root'@'localhost' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR 'root'@'127.0.0.1' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR 'root'@'::1' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR 'root'@'host_name' = PASSWORD('newpwd');
```

The last statement is unnecessary if the mysql.user table has no root account with a host value of %.

For Unix, do this:

```
shell> mysql -u root
mysql> SET PASSWORD FOR 'root'@'localhost' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR 'root'@'127.0.0.1' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR 'root'@'::1' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR 'root'@'host_name' = PASSWORD('newpwd');
```

You can also use a single statement that assigns a password to all root accounts by using UPDATE to modify the mysql.user table directly. This method works on any platform:

```
shell> mysql -u root
mysql> UPDATE mysql.user SET Password = PASSWORD('newpwd')
```
Securing the Initial MySQL Accounts

```sql
->  WHERE User = 'root';
mysql> FLUSH PRIVILEGES;
```

The `FLUSH` statement causes the server to reread the grant tables. Without it, the password change remains unnoticed by the server until you restart it.

To assign passwords to the `root` accounts using `mysqladmin`, execute the following commands:

```shell
shell> mysqladmin -u root password "newpwd"
shell> mysqladmin -u root -h host_name password "newpwd"
```

Those commands apply both to Windows and to Unix. The double quotation marks around the password are not always necessary, but you should use them if the password contains spaces or other characters that are special to your command interpreter.

The `mysqladmin` method of setting the `root` account passwords does not work for the `'root'@'127.0.0.1'` or `'root'@'::1'` account. Use the `SET PASSWORD` method shown earlier.

After the `root` passwords have been set, you must supply the appropriate password whenever you connect as `root` to the server. For example, to shut down the server with `mysqladmin`, use this command:

```shell
shell> mysqladmin -u root -p shutdown
Enter password: (enter root password here)
```

### Assigning Anonymous Account Passwords

The `mysql` commands in the following instructions include a `-p` option based on the assumption that you have set the `root` account passwords using the preceding instructions and must specify that password when connecting to the server.

To assign passwords to the anonymous accounts, connect to the server as `root`, then use either `SET PASSWORD` or `UPDATE`. Be sure to encrypt the password using the `PASSWORD()` function.

To use `SET PASSWORD` on Windows, do this:

```shell
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> SET PASSWORD FOR ''@'localhost' = PASSWORD('newpwd');
```

To use `SET PASSWORD` on Unix, do this:

```shell
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> SET PASSWORD FOR ''@'localhost' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR ''@'host_name' = PASSWORD('newpwd');
```

To set the anonymous-user account passwords with a single `UPDATE` statement, do this (on any platform):

```shell
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> UPDATE mysql.user SET Password = PASSWORD('newpwd')
  ->  WHERE User = '';
mysql> FLUSH PRIVILEGES;
```

The `FLUSH` statement causes the server to reread the grant tables. Without it, the password change remains unnoticed by the server until you restart it.
Removing Anonymous Accounts

If you prefer to remove any anonymous accounts rather than assigning them passwords, do so as follows on Windows:

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> DROP USER ''@'localhost';
```

On Unix, remove the anonymous accounts like this:

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> DROP USER ''@'localhost';
mysql> DROP USER ''@'host_name';
```

Securing Test Databases

By default, the `mysql.db` table contains rows that permit access by any user to the `test` database and other databases with names that start with `test_`. (These rows have an empty `User` column value, which for access-checking purposes matches any user name.) This means that such databases can be used even by accounts that otherwise possess no privileges. If you want to remove any-user access to test databases, do so as follows:

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> DELETE FROM mysql.db WHERE Db LIKE 'test%';
mysql> FLUSH PRIVILEGES;
```

The `FLUSH` statement causes the server to reread the grant tables. Without it, the privilege change remains unnoticed by the server until you restart it.

With the preceding change, only users who have global database privileges or privileges granted explicitly for the `test` database can use it. However, if you do not want the database to exist at all, drop it:

```
mysql> DROP DATABASE test;
```

Note

On Windows, you can also perform the process described in this section using the Configuration Wizard (see Section 2.3.6.11, "The Security Options Dialog"). On all platforms, the MySQL distribution includes `mysql_secure_installation`, a command-line utility that automates much of the process of securing a MySQL installation.

2.11 Upgrading or Downgrading MySQL

2.11.1 Upgrading MySQL

As a general rule, to upgrade from one release series to another, go to the next series rather than skipping a series. To upgrade from a release series previous to MySQL 5.1, upgrade to each successive release series in turn until you have reached MySQL 5.1, and then proceed with the upgrade to MySQL 5.5. For example, if you currently are running MySQL 5.0 and wish to upgrade to a newer series, upgrade to MySQL 5.1 first before upgrading to 5.5, and so forth. For information on upgrading to MySQL 5.1, see the MySQL 5.1 Reference Manual.
Upgrading MySQL

There is a special case for upgrading to MySQL 5.5, which is that there was a short-lived MySQL 5.4 development series. This series is no longer being worked on, but to accommodate users of both series, this section includes one subsection for users upgrading from MySQL 5.1 to 5.5 and another for users upgrading from MySQL 5.4 to 5.5.

To upgrade to MySQL 5.5, use the items in the following checklist as a guide:

- Before any upgrade, back up your databases, including the `mysql` database that contains the grant tables. See Section 7.2, “Database Backup Methods”.

- Read all the notes in Section 2.11.1.1, “Upgrading from MySQL 5.1 to 5.5”, or Section 2.11.1.2, “Upgrading from MySQL 5.4 to 5.5”, depending on whether you currently use MySQL 5.1 or 5.4. These notes enable you to identify upgrade issues that apply to your current MySQL installation. Some incompatibilities discussed in that section require your attention before upgrading. Others should be dealt with after upgrading.

- Read the Release Notes as well, which provide information about features that are new in MySQL 5.5 or differ from those found in earlier MySQL releases.

- After upgrading to a new version of MySQL, run `mysql_upgrade` (see Section 4.4.7, "mysql_upgrade — Check and Upgrade MySQL Tables"). This program checks your tables, and attempts to repair them if necessary. It also updates your grant tables to make sure that they have the current structure so that you can take advantage of any new capabilities. (Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features.) `mysql_upgrade` does not upgrade the contents of the help tables. For upgrade instructions, see Section 5.1.10, “Server-Side Help”.

- If you run MySQL Server on Windows, see Section 2.3.9, “Upgrading MySQL on Windows”.

- If you use replication, see Section 17.4.3, “Upgrading a Replication Setup”, for information on upgrading your replication setup.

- If you use InnoDB, consider setting `innodb_fast_shutdown` to 0 before shutting down and upgrading your server. When you set `innodb_fast_shutdown` to 0, InnoDB does a slow shutdown, a full purge and an insert buffer merge before shutting down, which ensures that all data files are fully prepared in case the upgrade process modifies the file format.

- If you upgrade an installation originally produced by installing multiple RPM packages, it is best to upgrade all the packages, not just some. For example, if you previously installed the server and client RPMs, do not upgrade just the server RPM.

- If you have created a user-defined function (UDF) with a given name and upgrade MySQL to a version that implements a new built-in function with the same name, the UDF becomes inaccessible. To correct this, use `DROP FUNCTION` to drop the UDF, and then use `CREATE FUNCTION` to re-create the UDF with a different nonconflicting name. The same is true if the new version of MySQL implements a built-in function with the same name as an existing stored function. See Section 9.2.4, “Function Name Parsing and Resolution”, for the rules describing how the server interprets references to different kinds of functions.

For upgrades between versions of a MySQL release series that has reached General Availability status, you can move the MySQL format files and data files between different versions on systems with the same architecture. For upgrades to a version of a MySQL release series that is in development status, that is not necessarily true. Use of development releases is at your own risk.

If you are cautious about using new versions, you can always rename your old `mysqld` before installing a newer one. For example, if you are using a version of MySQL 5.1 and want to upgrade to 5.5, rename your
current server from `mysqld` to `mysqld-5.1`. If your new `mysqld` then does something unexpected, you can simply shut it down and restart with your old `mysqld`.

If problems occur, such as that the new `mysqld` server does not start or that you cannot connect without a password, verify that you do not have an old `my.cnf` file from your previous installation. You can check this with the `--print-defaults` option (for example, `mysqld --print-defaults`). If this command displays anything other than the program name, you have an active `my.cnf` file that affects server or client operation.

If, after an upgrade, you experience problems with compiled client programs, such as `Commands out of sync` or unexpected core dumps, you probably have used old header or library files when compiling your programs. In this case, you should check the date for your `mysql.h` file and `libmysqlclient.a` library to verify that they are from the new MySQL distribution. If not, recompile your programs with the new headers and libraries. Recompilation might also be necessary for programs compiled against the shared client library if the library major version number has changed (for example, from `libmysqlclient.so.15` to `libmysqlclient.so.16`).

If your MySQL installation contains a large amount of data that might take a long time to convert after an in-place upgrade, you might find it useful to create a “dummy” database instance for assessing what conversions might be needed and the work involved to perform them. Make a copy of your MySQL instance that contains a full copy of the `mysql` database, plus all other databases without data. Run your upgrade procedure on this dummy instance to see what actions might be needed so that you can better evaluate the work involved when performing actual data conversion on your original database instance.

It is a good idea to rebuild and reinstall the Perl `DBD::mysql` module whenever you install a new release of MySQL. The same applies to other MySQL interfaces as well, such as PHP `mysql` extensions and the Python `MySQLdb` module.

### 2.11.1.1 Upgrading from MySQL 5.1 to 5.5

**Note**

It is good practice to back up your data before installing any new version of software. Although MySQL works very hard to ensure a high level of quality, you should protect your data by making a backup.

To upgrade to 5.5 from any previous version, MySQL recommends that you dump your tables with `mysqldump` before upgrading and reload the dump file after upgrading. Use the `--all-databases` option to include all databases in the dump. If your databases include stored programs, use the `--routines` and `--events` options as well.

In general, you should do the following when upgrading from MySQL 5.1 to 5.5:

- Read all the items in these sections to see whether any of them might affect your applications:
  
  - **Section 2.11.1, “Upgrading MySQL”,** has general update information.
  
  - The items in the change lists provided later in this section enable you to identify upgrade issues that apply to your current MySQL installation. Some incompatibilities discussed there require your attention *before* upgrading. Others should be dealt with *after* upgrading.
  
  - The MySQL 5.5 **Release Notes** describe significant new features you can use in 5.5 or that differ from those found in earlier MySQL releases. Some of these changes may result in incompatibilities.

Note particularly any changes that are marked **Known issue** or **Incompatible change**. These incompatibilities with earlier versions of MySQL may require your attention *before you upgrade*. Our aim
is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases. If any upgrade issue applicable to your installation involves an incompatibility that requires special handling, follow the instructions given in the incompatibility description. Sometimes this involves dumping and reloading tables, or use of a statement such as CHECK TABLE or REPAIR TABLE.

For dump and reload instructions, see Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”. Any procedure that involves REPAIR TABLE with the USE_FRM option must be done before upgrading. Use of this statement with a version of MySQL different from the one used to create the table (that is, using it after upgrading) may damage the table. See Section 13.7.2.5, "REPAIR TABLE Syntax".

• Before upgrading to a new version of MySQL, Section 2.11.3, “Checking Whether Tables or Indexes Must Be Rebuilt”, to see whether changes to table formats or to character sets or collations were made between your current version of MySQL and the version to which you are upgrading. If so and these changes result in an incompatibility between MySQL versions, you will need to upgrade the affected tables using the instructions in Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”.

• After upgrading to a new version of MySQL, run mysql_upgrade (see Section 4.4.7, "mysql_upgrade — Check and Upgrade MySQL Tables"). This program checks your tables, and attempts to repair them if necessary. It also updates your grant tables to make sure that they have the current structure so that you can take advantage of any new capabilities. (Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features.)

mysql_upgrade does not upgrade the contents of the help tables. For upgrade instructions, see Section 5.1.10, “Server-Side Help”.

• If you run MySQL Server on Windows, see Section 2.3.9, “Upgrading MySQL on Windows”.

• If you use replication, see Section 17.4.3, “Upgrading a Replication Setup”, for information on upgrading your replication setup.

If your MySQL installation contains a large amount of data that might take a long time to convert after an in-place upgrade, you might find it useful to create a “dummy” database instance for assessing what conversions might be needed and the work involved to perform them. Make a copy of your MySQL instance that contains a full copy of the mysql database, plus all other databases without data. Run your upgrade procedure on this dummy instance to see what actions might be needed so that you can better evaluate the work involved when performing actual data conversion on your original database instance.

The following lists describe changes that may affect applications and that you should watch out for when upgrading from MySQL 5.1 to 5.5.

Configuration Changes

• Incompatible change: The InnoDB Plugin is included in MySQL 5.5 releases. It becomes the built-in version of InnoDB in MySQL Server, replacing the version previously included as the built-in InnoDB engine. InnoDB Plugin is also available in MySQL 5.1 as of 5.1.38, but it is an optional storage engine that must be enabled explicitly using two server options:

```
[mysqld]
ignore-built-in-innodb
plugin-load=innodb=ha_innodb_plugin.so
```

If you were using InnoDB Plugin in MySQL 5.1 by means of those options, you must remove them after an upgrade to 5.5 or the server will fail to start.

In addition, in InnoDB Plugin, the innodb_file_io_threads system variable has been removed and replaced with innodb_read_io_threads and innodb_write_io_threads. If you
upgrade from MySQL 5.1 to MySQL 5.5 and previously explicitly set `innodb_file_io_threads` at server startup, you must change your configuration. Either remove any reference to `innodb_file_io_threads` or replace it with references to `innodb_read_io_threads` and `innodb_write_io_threads`.

- **Incompatible change**: In MySQL 5.5, the server includes a plugin services interface that complements the plugin API. The services interface enables server functionality to be exposed as a "service" that plugins can access through a function-call interface. The `libmysqlservices` library provides access to the available services and dynamic plugins now must be linked against this library (use the `-lmysqlservices` flag). For an example showing how to configure for CMake, see Section 24.2.5, "MySQL Services for Plugins".

**Server Changes**

- **Known issue**: As of MySQL 5.5.32, for new installations, the `url` columns in the `mysql` database help tables are now created as type `TEXT` to accommodate longer URLs. For upgrades, `mysql_upgrade` does not update the columns. Modify them manually using these statements:

```sql
ALTER TABLE mysql.help_category MODIFY url TEXT NOT NULL;
ALTER TABLE mysql.help_topic MODIFY url TEXT NOT NULL;
```

- **Incompatible change**: As of MySQL 5.5.3, due to work done for Bug #989, `FLUSH TABLES` is not permitted when there is an active `LOCK TABLES ... READ`. To provide a workaround for this restriction, `FLUSH TABLES` has a new variant, `FLUSH TABLES tbl_list WITH READ LOCK`, that enables tables to be flushed and locked in a single operation. As a result of this change, applications that previously used this statement sequence to lock and flush tables will fail:

```sql
LOCK TABLES tbl_list READ;
FLUSH TABLES tbl_list;
```

Such applications should now use this statement instead:

```sql
FLUSH TABLES tbl_list WITH READ LOCK;
```

- **Incompatible change**: As of MySQL 5.5.7, the server requires that a new grant table, `proxies_priv`, be present in the `mysql` database. If you are upgrading to 5.5.7 from a previous MySQL release rather than performing a new installation, the server will find that this table is missing and exit during startup with the following message:

```
Table 'mysql.proxies_priv' doesn't exist
```

To create the `proxies_priv` table, start the server with the `--skip-grant-tables` option to cause it to skip the normal grant table checks, then run `mysql_upgrade`. For example:

```
shell> mysqld --skip-grant-tables &
shell> mysql_upgrade
```

Then stop the server and restart it normally.

You can specify other options on the `mysqld` command line if necessary. Alternatively, if your installation is configured so that the server normally reads options from an option file, use the `--defaults-file` option to specify the file (enter each command on a single line):

```
shell> mysqld --defaults-file=/usr/local/mysql/etc/my.cnf
```
--skip-grant-tables &
shell> mysql_upgrade

With the --skip-grant-tables option, the server does no password or privilege checking, so any client can connect and effectively have all privileges. For additional security, use the --skip-networking option as well to prevent remote clients from connecting.

Note
This problem is fixed in MySQL 5.5.8; the server treats a missing proxies_priv table as equivalent to an empty table. However, after starting the server, you should still run mysql_upgrade to create the table.

• Incompatible change: As of MySQL 5.5.7, InnoDB always uses the fast truncation technique, equivalent to DROP TABLE and CREATE TABLE. It no longer performs a row-by-row delete for tables with parent-child foreign key relationships. TRUNCATE TABLE returns an error for such tables. Modify your SQL to issue DELETE FROM table_name for such tables instead.

• Incompatible change: Prior to MySQL 5.5.7, if you flushed the logs using FLUSH LOGS or mysqladmin flush-logs and mysqld was writing the error log to a file (for example, if it was started with the --log-error option), it renames the current log file with the suffix -old, then created a new empty log file. This had the problem that a second log-flushing operation thus caused the original error log file to be lost unless you saved it under a different name. For example, you could use the following commands to save the file:

shell> mysqladmin flush-logs
shell> mv host_name.err-old backup-directory

To avoid the preceding file-loss problem, no renaming occurs as of MySQL 5.5.7; the server merely closes and reopen the log file. To rename the file, you can do so manually before flushing. Then flushing the logs reopen a new file with the original file name. For example, you can rename the file and create a new one using the following commands:

shell> mv host_name.err host_name.err-old
shell> mysqladmin flush-logs
shell> mv host_name.err-old backup-directory

• Incompatible change: As of MySQL 5.5.6, handling of CREATE TABLE IF NOT EXISTS ... SELECT statements has been changed for the case that the destination table already exists:

  • Previously, for CREATE TABLE IF NOT EXISTS ... SELECT, MySQL produced a warning that the table exists, but inserted the rows and wrote the statement to the binary log anyway. By contrast, CREATE TABLE ... SELECT (without IF NOT EXISTS) failed with an error, but MySQL inserted no rows and did not write the statement to the binary log.

  • MySQL now handles both statements the same way when the destination table exists, in that neither statement inserts rows or is written to the binary log. The difference between them is that MySQL produces a warning when IF NOT EXISTS is present and an error when it is not.

This change in handling of IF NOT EXISTS results in an incompatibility for statement-based replication from a MySQL 5.1 master with the original behavior and a MySQL 5.5 slave with the new behavior. Suppose that CREATE TABLE IF NOT EXISTS ... SELECT is executed on the master and the destination table exists. The result is that rows are inserted on the master but not on the slave. (Row-based replication does not have this problem.)
To address this issue, statement-based binary logging for `CREATE TABLE IF NOT EXISTS ... SELECT` is changed in MySQL 5.1 as of 5.1.51:

- If the destination table does not exist, there is no change: The statement is logged as is.

- If the destination table does exist, the statement is logged as the equivalent pair of `CREATE TABLE IF NOT EXISTS` and `INSERT ... SELECT` statements. (If the `SELECT` in the original statement is preceded by `IGNORE` or `REPLACE`, the `INSERT` becomes `INSERT IGNORE` or `REPLACE`, respectively.)

This change provides forward compatibility for statement-based replication from MySQL 5.1 to 5.5 because when the destination table exists, the rows will be inserted on both the master and slave. To take advantage of this compatibility measure, the 5.1 server must be at least 5.1.51 and the 5.5 server must be at least 5.5.6.

To upgrade an existing 5.1-to-5.5 replication scenario, upgrade the master first to 5.1.51 or higher. Note that this differs from the usual replication upgrade advice of upgrading the slave first.

A workaround for applications that wish to achieve the original effect (rows inserted regardless of whether the destination table exists) is to use `CREATE TABLE IF NOT EXISTS` and `INSERT ... SELECT` statements rather than `CREATE TABLE IF NOT EXISTS ... SELECT` statements.

Along with the change just described, the following related change was made: Previously, if an existing view was named as the destination table for `CREATE TABLE IF NOT EXISTS ... SELECT`, rows were inserted into the underlying base table and the statement was written to the binary log. As of MySQL 5.1.51 and 5.5.6, nothing is inserted or logged.

- **Incompatible change:** Prior to MySQL 5.5.6, if the server was started with `character_set_server` set to `utf16`, it crashed during full-text stopword initialization. Now the stopword file is loaded and searched using `latin1` if `character_set_server` is `ucs2`, `utf16`, or `utf32`. If any table was created with `FULLTEXT` indexes while the server character set was `ucs2`, `utf16`, or `utf32`, it should be repaired using this statement:

  ```sql
  REPAIR TABLE tbl_name QUICK;
  ```

- **Incompatible change:** As of MySQL 5.5.5, all numeric operators and functions on integer, floating-point and `DECIMAL` values throw an "out of range" error (`ER_DATA_OUT_OF_RANGE`) rather than returning an incorrect value or `NULL`, when the result is out of the supported range for the corresponding data type. See Section 11.2.6, “Out-of-Range and Overflow Handling”.

- **Incompatible change:** In very old versions of MySQL (prior to 4.1), the `TIMESTAMP` data type supported a display width, which was silently ignored beginning with MySQL 4.1. This is deprecated in MySQL 5.1, and removed altogether in MySQL 5.5. These changes in behavior can lead to two problem scenarios when trying to use `TIMESTAMP(N)` columns with a MySQL 5.5 or later server:

  - When importing a dump file (for example, one created using `mysqldump`) created in a MySQL 5.0 or earlier server into a server from a newer release series, a `CREATE TABLE` or `ALTER TABLE` statement containing `TIMESTAMP(N)` causes the import to fail with a syntax error.

    To fix this problem, edit the dump file in a text editor to replace any instances of `TIMESTAMP(N)` with `TIMESTAMP` prior to importing the file. Be sure to use a plain text editor for this, and not a word processor; otherwise, the result is almost certain to be unusable for importing into the MySQL server.

  - When trying replicate any `CREATE TABLE` or `ALTER TABLE` statement containing `TIMESTAMP(N)` from a master MySQL server that supports the `TIMESTAMP(N)` syntax to a MySQL 5.5.3 or newer slave, the statement causes replication to fail. Similarly, when you try to restore from a binary log...
Upgrading MySQL

written by a server that supports `TIMESTAMP (N)` to a MySQL 5.5.3 or newer server, any `CREATE TABLE` or `ALTER TABLE` statement containing `TIMESTAMP (N)` causes the backup to fail. This holds true regardless of the logging format.

It may be possible to fix such issues using a hex editor, by replacing any width arguments used with `TIMESTAMP`, and the parentheses containing them, with space characters (hexadecimal 20). Be sure to use a programmer's binary hex editor and not a regular text editor or word processor for this; otherwise, the result is almost certain to be a corrupted binary log file. To guard against accidental corruption of the binary log, you should always work on a copy of the file rather than the original.

You should try to handle potential issues of these types proactively by updating with `ALTER TABLE` any `TIMESTAMP (N)` columns in your databases so that they use `TIMESTAMP` instead, before performing any upgrades.

• **Incompatible change:** As of MySQL 5.5.3, the Unicode implementation has been extended to provide support for supplementary characters that lie outside the Basic Multilingual Plane (BMP). Noteworthy features:

  • `utf16` and `utf32` character sets have been added. These correspond to the UTF-16 and UTF-32 encodings of the Unicode character set, and they both support supplementary characters.

  • The `utf8mb4` character set has been added. This is similar to `utf8`, but its encoding allows up to four bytes per character to enable support for supplementary characters.

  • The `ucs2` character set is essentially unchanged except for the inclusion of some newer BMP characters.

In most respects, upgrading to MySQL 5.5 should present few problems with regard to Unicode usage, although there are some potential areas of incompatibility. These are the primary areas of concern:

• For the variable-length character data types (`VARCHAR` and the `TEXT` types), the maximum length in characters is less for `utf8mb4` columns than for `utf8` columns.

• For all character data types (`CHAR`, `VARCHAR`, and the `TEXT` types), the maximum number of characters that can be indexed is less for `utf8mb4` columns than for `utf8` columns.

Consequently, if you want to upgrade tables from `utf8` to `utf8mb4` to take advantage of supplementary-character support, it may be necessary to change some column or index definitions.

For additional details about the new Unicode character sets and potential incompatibilities, see Section 10.1.10, “Unicode Support”, and Section 10.1.11, “Upgrading from Previous to Current Unicode Support”.

• **Incompatible change:** As of MySQL 5.5.3, the server includes `dtoa`, a library for conversion between strings and numbers by David M. Gay. In MySQL, this library provides the basis for improved conversion between string or `DECIMAL` values and approximate-value (`FLOAT` or `DOUBLE`) numbers.

Because the conversions produced by this library differ in some cases from previous results, the potential exists for incompatibilities in applications that rely on previous results. For example, applications that depend on a specific exact result from previous conversions might need adjustment to accommodate additional precision.

For additional information about the properties of `dtoa` conversions, see Section 12.2, “Type Conversion in Expression Evaluation”.

• **Incompatible change:** In MySQL 5.5, several changes were made regarding the language and character set of error messages:
• The `--language` option for specifying the directory for the error message file is now deprecated. The new `lc_messages_dir` and `lc_messages` system variables should be used instead, and the server treats `--language` as an alias for `lc_messages_dir`.

• The `language` system variable has been removed and replaced with the new `lc_messages_dir` and `lc_messages` system variables. `lc_messages_dir` has only a global value and is read only. `lc_messages` has global and session values and can be modified at runtime, so the error message language can be changed while the server is running, and individual clients each can have a different error message language by changing their session `lc_messages` value to a different locale name.

• Error messages previously were constructed in a mix of character sets. This issue is resolved by constructing error messages internally within the server using UTF-8 and returning them to the client in the character set specified by the `character_set_results` system variable. The content of error messages therefore may in some cases differ from the messages returned previously.

For more information, see Section 10.2, "Setting the Error Message Language", and Section 10.1.6, "Character Set for Error Messages".

• **Incompatible change**: MySQL 5.5 implements new functions used to calculate row placement for tables partitioned by `KEY` and `LINEAR_KEY`. Tables that were created using `KEY` or `LINEAR_KEY` partitioning in MySQL 5.1 can be upgraded in MySQL 5.5.31 and later using `ALTER TABLE ... PARTITION BY ALGORITHM=2 [LINEAR] KEY (...)`. (Bug #14521864, Bug #66462)

**SQL Changes**

• **Incompatible change**: Previously, the parser accepted an `INTO` clause in nested `SELECT` statements, which is invalid because such statements must return their results to the outer context. As of MySQL 5.5.3, this syntax is no longer permitted and statements that use it must be changed.

• **Incompatible change**: In MySQL 5.5.3, several changes were made to alias resolution in multiple-table `DELETE` statements so that it is no longer possible to have inconsistent or ambiguous table aliases.

    In MySQL 5.1.23, alias declarations outside the `table_references` part of the statement were disallowed for the `USING` variant of multiple-table `DELETE` syntax, to reduce the possibility of ambiguous aliases that could lead to ambiguous statements that have unexpected results such as deleting rows from the wrong table.

    As of MySQL 5.5.3, alias declarations outside `table_references` are disallowed for all multiple-table `DELETE` statements. Alias declarations are permitted only in the `table_references` part.

    Incorrect:

    ```sql
    DELETE FROM t1 AS a2 USING t1 AS a1 INNER JOIN t2 AS a2;
    DELETE t1 AS a2 FROM t1 AS a1 INNER JOIN t2 AS a2;
    ```

    Correct:

    ```sql
    DELETE FROM t1 USING t1 AS a1 INNER JOIN t2 AS a2;
    DELETE t1 FROM t1 AS a1 INNER JOIN t2 AS a2;
    ```

• Previously, for alias references in the list of tables from which to delete rows in a multiple-table delete, the default database is used unless one is specified explicitly. For example, if the default database is `db1`, the following statement does not work because the unqualified alias reference `a2` is interpreted as having a database of `db1`:
To correctly match an alias that refers to a table outside the default database, you must explicitly qualify the reference with the name of the proper database:

```
DELETE a1, a2 FROM db1.t1 AS a1 INNER JOIN db2.t2 AS a2
WHERE a1.id=a2.id;
```

As of MySQL 5.5.3, alias resolution does not require qualification and alias references should not be qualified with the database name. Qualified names are interpreted as referring to tables, not aliases.

Statements containing alias constructs that are no longer permitted must be rewritten.

- Some keywords may be reserved in MySQL 5.5 that were not reserved in MySQL 5.1. See Section 9.3, "Reserved Words".

### 2.11.1.2 Upgrading from MySQL 5.4 to 5.5

This section is for the special case of upgrading to MySQL 5.5 from the short-lived MySQL 5.4 development series, which is no longer being worked on.

**Note**

It is good practice to back up your data before installing any new version of software. Although MySQL works very hard to ensure a high level of quality, you should protect your data by making a backup.

To upgrade to 5.5 from any previous version, MySQL recommends that you dump your tables with `mysqldump` before upgrading and reload the dump file after upgrading. Use the `--all-databases` option to include all databases in the dump. If your databases include stored programs, use the `--routines` and `--events` options as well.

In general, you should do the following when upgrading from MySQL 5.4 to 5.5:

- Read all the items in these sections to see whether any of them might affect your applications:
  - Section 2.11.1, “Upgrading MySQL”, has general update information.
  - The items in the change lists provided later in this section enable you to identify upgrade issues that apply to your current MySQL installation. Some incompatibilities discussed there require your attention before upgrading. Others should be dealt with after upgrading.
  - The MySQL 5.5 Release Notes describe significant new features you can use in 5.5 or that differ from those found in earlier MySQL releases. Some of these changes may result in incompatibilities.

Note particularly any changes that are marked Known issue or Incompatible change. These incompatibilities with earlier versions of MySQL may require your attention before you upgrade. Our aim is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases. If any upgrade issue applicable to your installation involves an incompatibility that requires special handling, follow the instructions given in the incompatibility description. Sometimes this involves dumping and reloading tables, or use of a statement such as `CHECK TABLE` or `REPAIR TABLE`.

---

204
For dump and reload instructions, see Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”. Any procedure that involves `REPAIR TABLE` with the `USE_FRM` option must be done before upgrading. Use of this statement with a version of MySQL different from the one used to create the table (that is, using it after upgrading) may damage the table. See Section 13.7.2.5, “REPAIR TABLE Syntax”.

- Before upgrading to a new version of MySQL, Section 2.11.3, “Checking Whether Tables or Indexes Must Be Rebuilt”, to see whether changes to table formats or to character sets or collations were made between your current version of MySQL and the version to which you are upgrading. If so and these changes result in an incompatibility between MySQL versions, you will need to upgrade the affected tables using the instructions in Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”.

- After upgrading to a new version of MySQL, run `mysql_upgrade` (see Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”). This program checks your tables, and attempts to repair them if necessary. It also updates your grant tables to make sure that they have the current structure so that you can take advantage of any new capabilities. (Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features.)

  `mysql_upgrade` does not upgrade the contents of the help tables. For upgrade instructions, see Section 5.1.10, “Server-Side Help”.

- If you run MySQL Server on Windows, see Section 2.3.9, “Upgrading MySQL on Windows”.

- If you use replication, see Section 17.4.3, “Upgrading a Replication Setup”, for information on upgrading your replication setup.

If your MySQL installation contains a large amount of data that might take a long time to convert after an in-place upgrade, you might find it useful to create a “dummy” database instance for assessing what conversions might be needed and the work involved to perform them. Make a copy of your MySQL instance that contains a full copy of the `mysql` database, plus all other databases without data. Run your upgrade procedure on this dummy instance to see what actions might be needed so that you can better evaluate the work involved when performing actual data conversion on your original database instance.

The following lists describe changes that may affect applications and that you should watch out for when upgrading from MySQL 5.4 to 5.5.

**Configuration Changes**

- **Incompatible change**: In MySQL 5.5, the server includes a plugin services interface that complements the plugin API. The services interface enables server functionality to be exposed as a “service” that plugins can access through a function-call interface. The `libmysqlservices` library provides access to the available services and dynamic plugins now must be linked against this library (use the `--lmysqlservices` flag). For an example showing how to configure for CMake, see Section 24.2.5, “MySQL Services for Plugins”.

**Server Changes**

- **Incompatible change**: As of MySQL 5.5.7, the server requires that a new grant table, `proxies_priv`, be present in the `mysql` database. If you are upgrading from a previous MySQL release rather than performing a new installation, the server will find that this table is missing and exit during startup with the following message:

  ```
  Table 'mysql.proxies_priv' doesn't exist
  ```

  To create the `proxies_priv` table, start the server with the `--skip-grant-tables` option to cause it to skip the normal grant table checks, then run `mysql_upgrade`. For example:
Upgrading MySQL

shell> mysqld --skip-grant-tables &
shell> mysql_upgrade

Then stop the server and restart it normally.

You can specify other options on the `mysqld` command line if necessary. Alternatively, if your installation is configured so that the server normally reads options from an option file, use the `--defaults-file` option to specify the file (enter each command on a single line):

shell> mysqld --defaults-file=/usr/local/mysql/etc/my.cnf
               --skip-grant-tables &
shell> mysql_upgrade

With the `--skip-grant-tables` option, the server does no password or privilege checking, so any client can connect and effectively have all privileges. For additional security, use the `--skip-networking` option as well to prevent remote clients from connecting.

• **Incompatible change**: As of MySQL 5.5.3, the Unicode implementation has been extended to provide support for supplementary characters that lie outside the Basic Multilingual Plane (BMP). Noteworthy features:

  • `utf16` and `utf32` character sets have been added. These correspond to the UTF-16 and UTF-32 encodings of the Unicode character set, and they both support supplementary characters.

  • The `utf8mb4` character set has been added. This is similar to `utf8`, but its encoding allows up to four bytes per character to enable support for supplementary characters.

  • The `ucs2` character set is essentially unchanged except for the inclusion of some newer BMP characters.

In most respects, upgrading to MySQL 5.5 should present few problems with regard to Unicode usage, although there are some potential areas of incompatibility. These are the primary areas of concern:

• For the variable-length character data types (`VARCHAR` and the `TEXT` types), the maximum length in characters is less for `utf8mb4` columns than for `utf8` columns.

• For all character data types (`CHAR`, `VARCHAR`, and the `TEXT` types), the maximum number of characters that can be indexed is less for `utf8mb4` columns than for `utf8` columns.

Consequently, if you want to upgrade tables from `utf8` to `utf8mb4` to take advantage of supplementary-character support, it may be necessary to change some column or index definitions.

For additional details about the new Unicode character sets and potential incompatibilities, see Section 10.1.10, “Unicode Support”, and Section 10.1.11, “Upgrading from Previous to Current Unicode Support”.

• **Incompatible change**: As of MySQL 5.5.3, the server includes `dtoa`, a library for conversion between strings and numbers by David M. Gay. In MySQL, this library provides the basis for improved conversion between string or `DECIMAL` values and approximate-value (`FLOAT`/`DOUBLE`) numbers.

Because the conversions produced by this library differ in some cases from previous results, the potential exists for incompatibilities in applications that rely on previous results. For example, applications that depend on a specific exact result from previous conversions might need adjustment to accommodate additional precision.
For additional information about the properties of `dtoa` conversions, see Section 12.2, “Type Conversion in Expression Evaluation”.

**Incompatible change**: In MySQL 5.5, several changes were made regarding the language and character set of error messages:

- The `--language` option for specifying the directory for the error message file is now deprecated. The new `lc_messages_dir` and `lc_messages` system variables should be used instead, and the server treats `--language` as an alias for `lc_messages_dir`.

- The `language` system variable has been removed and replaced with the new `lc_messages_dir` and `lc_messages` system variables. `lc_messages_dir` has only a global value and is read only. `lc_messages` has global and session values and can be modified at runtime, so the error message language can be changed while the server is running, and individual clients each can have a different error message language by changing their session `lc_messages` value to a different locale name.

- Error messages previously were constructed in a mix of character sets. This issue is resolved by constructing error messages internally within the server using UTF-8 and returning them to the client in the character set specified by the `character_set_results` system variable. The content of error messages therefore may in some cases differ from the messages returned previously.

For more information, see Section 10.2, “Setting the Error Message Language”, and Section 10.1.6, “Character Set for Error Messages”.

**Before MySQL 5.1.36, plugin options were boolean options (see Section 4.2.5, “Program Option Modifiers”). If you upgrade to MySQL 5.5 from a version older than 5.1.36 and previously used options of the form `--plugin_name=0` or `--plugin_name=1`, the equivalent options are now `--plugin_name=OFF` and `--plugin_name=ON`, respectively. You also have the choice of requiring plugins to start successfully by using `--plugin_name=FORCE` or `--plugin_name=FORCE_PLUS_PERMANENT`.

**SQL Changes**

- **Incompatible change**: Previously, the parser accepted an `INTO` clause in nested `SELECT` statements, which is invalid because such statements must return their results to the outer context. As of MySQL 5.5.3, this syntax is no longer permitted and statements that use it must be changed.

- Some keywords may be reserved in MySQL 5.5 that were not reserved in MySQL 5.4. See Section 9.3, “Reserved Words”.

### 2.11.2 Downgrading MySQL

This section describes what you should do to downgrade to an older MySQL version in the unlikely case that the previous version worked better than the new one.

It is always a good idea to make a backup beforehand, in case a downgrade fails and leaves the instance in an unusable state.

To downgrade between General Availability (GA) status versions within the same release series, typically you just install the new binaries on top of the old ones and do not make any changes to the databases.

Downgrades between milestone releases (or from a GA release to a milestone release) within the same release series are not supported and you may encounter issues.

The following items form a checklist of things you should do whenever you perform a downgrade:
Downgrading MySQL

- Read the upgrading section for the release series from which you are downgrading to be sure that it does not have any features you really need. See Section 2.11.1, “Upgrading MySQL”.

- If there is a downgrading section for that version, you should read that as well.

- To see which new features were added between the version to which you are downgrading and your current version, see the Release Notes.

- Check Section 2.11.3, “Checking Whether Tables or Indexes Must Be Rebuilt”, to see whether changes to table formats or to character sets or collations were made between your current version of MySQL and the version to which you are downgrading. If so and these changes result in an incompatibility between MySQL versions, you will need to downgrade the affected tables using the instructions in Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”.

In most cases, you can move the MySQL format files and data files between different GA versions on the same architecture as long as you stay within versions for the same release series of MySQL.

If you downgrade from one release series to another, there may be incompatibilities in table storage formats. In this case, use mysqldump to dump your tables before downgrading. After downgrading, reload the dump file using mysql or mysqlimport to re-create your tables. For examples, see Section 2.11.5, “Copying MySQL Databases to Another Machine”.

A typical symptom of a downward-incompatible table format change when you downgrade is that you cannot open tables. In that case, use the following procedure:

1. Stop the older MySQL server that you are downgrading to.
2. Restart the newer MySQL server you are downgrading from.
3. Dump any tables that were inaccessible to the older server by using mysqldump to create a dump file.
4. Stop the newer MySQL server and restart the older one.
5. Reload the dump file into the older server. Your tables should be accessible.

It might also be the case that system tables in the mysql database have changed and that downgrading introduces some loss of functionality or requires some adjustments. Here are some examples:

- Trigger creation requires the TRIGGER privilege as of MySQL 5.1. In MySQL 5.0, there is no TRIGGER privilege and SUPER is required instead. If you downgrade from MySQL 5.1 to 5.0, you will need to give the SUPER privilege to those accounts that had the TRIGGER privilege in 5.1.
- Triggers were added in MySQL 5.0, so if you downgrade from 5.0 to 4.1, you cannot use triggers at all.
- The mysql.proc.comment column definition changed between MySQL 5.1 and 5.5. After a downgrade from 5.5 to 5.1, this table is seen as corrupt and in need of repair. To workaround this problem, execute mysql_upgrade from the version of MySQL to which you downgraded.

2.11.2.1 Downgrading to MySQL 5.1

When downgrading to MySQL 5.1 from MySQL 5.5, you should keep in mind the following issues relating to features found in MySQL 5.5, but not in MySQL 5.1:

- **InnoDB.** MySQL 5.5 uses InnoDB Plugin as the built-in version of InnoDB. MySQL 5.1 includes InnoDB Plugin as of 5.1.38, but as an option that must be enabled explicitly. See the Release Notes for MySQL 5.1.38.
- **Tables partitioned by [LINEAR] KEY.** MySQL 5.5 implements new functions used to calculate row placement for tables partitioned by KEY and LINEAR KEY. Tables that were created using KEY
or **LINEAR KEY** partitioning in MySQL 5.5 cannot be used by a MySQL 5.1 server. In MySQL 5.5.31 and later, you can downgrade such tables with `ALTER TABLE ... PARTITION BY ALGORITHM=1 [LINEAR] KEY (...)` to make them compatible with MySQL 5.1.

### 2.11.2.2 Downgrading from MySQL Enterprise Edition to MySQL Community Server

This section describes the steps required to downgrade from MySQL Enterprise Edition to MySQL Community Edition. This can be done at any time, and is required at the expiration of a MySQL Enterprise Edition subscription if you wish to continue using MySQL Server.

When you perform such a downgrade, all commercially licensed components of the MySQL Enterprise Edition subscription must be uninstalled. These components and related considerations are described in the rest of this section.

---

**Note**

The issues described in this section are in addition to any that may be encountered as a result of any upgrade or downgrade of the MySQL Server version (such as between MySQL 5.5 and 5.1). Information about upgrading and downgrading between MySQL release series can be found elsewhere in this chapter; see Section 2.11.1, “Upgrading MySQL”, and Section 2.11.2, “Downgrading MySQL”.

---

**MySQL Enterprise Database Server.** All commercial versions of MySQL Database Server must be uninstalled.

**Commercially licensed extensions.** All commercially licensed MySQL Enterprise Database Server extensions must be uninstalled. This includes the following commercial extensions:

- **MySQL External Authentication for Windows:** Following uninstallation of this plugin, existing MySQL user accounts must be re-created using local authentication. See Section 6.3, “MySQL User Account Management”, for more information.

- **MySQL External Authentication for PAM:** Following uninstallation of this plugin, existing MySQL user accounts must be re-created using local authentication. See Section 6.3, “MySQL User Account Management”, for more information.

- **MySQL Enterprise Scalability (Thread Pool):** Following uninstallation of this plugin, existing MySQL servers revert to default thread and connection handling.

- **MySQL Enterprise Audit:** Following uninstallation of this plugin, no logging of user logins or query activity occurs.

- **MySQL High Availability:** Following uninstallation of this plugin, automated failover is no longer available.

**MySQL Enterprise Backup.** MySQL Enterprise Backup must be uninstalled. Uninstalling this application has the effects listed here:

- Automated backup scripts no longer work.

- Existing backup images taken with MySQL Enterprise Backup can no longer be used for recovery.

- Third-party integration with multimedia systems such as NetBackup, Tivoli, and Oracle Secure Backup no longer works.

**MySQL Enterprise Monitor, MySQL Query Analyzer, agents.** MySQL Enterprise Monitor, MySQL Query Analyzer, and all server-side agents must be uninstalled. Uninstalling these applications and agents has the following effects:

- Automated SNMP and SMTP alerts no longer work.
Checking Whether Tables or Indexes Must Be Rebuilt

- All historical MySQL, OS monitoring, query, and performance metrics as well as all trending data are lost.
- All environment-specific monitoring templates, custom advisors, graphs and scripts are also lost.

2.11.3 Checking Whether Tables or Indexes Must Be Rebuilt

A binary upgrade or downgrade is one that installs one version of MySQL “in place” over an existing version, without dumping and reloading tables:

1. Stop the server for the existing version if it is running.
2. Install a different version of MySQL. This is an upgrade if the new version is higher than the original version, a downgrade if the version is lower.
3. Start the server for the new version.

In many cases, the tables from the previous version of MySQL can be used without problem by the new version. However, sometimes changes occur that require tables or table indexes to be rebuilt, as described in this section. If you have tables that are affected by any of the issues described here, rebuild the tables or indexes as necessary using the instructions given in Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”.

Table Incompatibilities

After a binary upgrade to MySQL 5.1 from a MySQL 5.0 installation that contains ARCHIVE tables, accessing those tables causes the server to crash, even if you have run mysql_upgrade or CHECK TABLE ... FOR UPGRADE. To work around this problem, use mysqldump to dump all ARCHIVE tables before upgrading, and reload them into MySQL 5.1 after upgrading. The same problem occurs for binary downgrades from MySQL 5.1 to 5.0.

The upgrade problem is fixed in MySQL 5.6.4: The server can open ARCHIVE tables created in MySQL 5.0. However, it remains the recommended upgrade procedure to dump 5.0 ARCHIVE tables before upgrading and reload them after upgrading.

Index Incompatibilities

In MySQL 5.6.3, the length limit for index prefix keys is increased from 767 bytes to 3072 bytes, for InnoDB tables using ROW_FORMAT=DYNAMIC or ROW_FORMAT=COMPRESSED. See Section 14.9.7, “Limits on InnoDB Tables” for details. This change is also backported to MySQL 5.5.14. If you downgrade from one of these releases or higher, to an earlier release with a lower length limit, the index prefix keys could be truncated at 767 bytes or the downgrade could fail. This issue could only occur if the configuration option innodb_large_prefix was enabled on the server being downgraded.

If you perform a binary upgrade without dumping and reloading tables, you cannot upgrade directly from MySQL 4.1 to 5.1 or higher. This occurs due to an incompatible change in the MyISAM table index format in MySQL 5.0. Upgrade from MySQL 4.1 to 5.0 and repair all MyISAM tables. Then upgrade from MySQL 5.0 to 5.1 and check and repair your tables.

Modifications to the handling of character sets or collations might change the character sort order, which causes the ordering of entries in any index that uses an affected character set or collation to be incorrect. Such changes result in several possible problems:

- Comparison results that differ from previous results
- Inability to find some index values due to misordered index entries
- Misordered ORDER BY results
Checking Whether Tables or Indexes Must Be Rebuilt

• Tables that `CHECK TABLE` reports as being in need of repair

The solution to these problems is to rebuild any indexes that use an affected character set or collation, either by dropping and re-creating the indexes, or by dumping and reloading the entire table. In some cases, it is possible to alter affected columns to use a different collation. For information about rebuilding indexes, see Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”.

To check whether a table has indexes that must be rebuilt, consult the following list. It indicates which versions of MySQL introduced character set or collation changes that require indexes to be rebuilt. Each entry indicates the version in which the change occurred and the character sets or collations that the change affects. If the change is associated with a particular bug report, the bug number is given.

The list applies both for binary upgrades and downgrades. For example, Bug #27877 was fixed in MySQL 5.1.24, so it applies to upgrades from versions older than 5.1.24 to 5.1.24 or newer, and to downgrades from 5.1.24 or newer to versions older than 5.1.24.

In many cases, you can use `CHECK TABLE ... FOR UPGRADE` to identify tables for which index rebuilding is required. It will report this message:

```plaintext
Table upgrade required.
Please do "REPAIR TABLE `tbl_name`" or dump/reload to fix it!
```

In these cases, you can also use `mysqlcheck --check-upgrade` or `mysql_upgrade`, which execute `CHECK TABLE`. However, the use of `CHECK TABLE` applies only after upgrades, not downgrades. Also, `CHECK TABLE` is not applicable to all storage engines. For details about which storage engines `CHECK TABLE` supports, see Section 13.7.2.2, “CHECK TABLE Syntax”.

These changes cause index rebuilding to be necessary:

• MySQL 5.1.24 (Bug #27877)

  Affects indexes that use the `utf8_general_ci` or `ucs2_general_ci` collation for columns that contain ‘ß’ LATIN SMALL LETTER SHARP S (German). The bug fix corrected an error in the original collations but introduced an incompatibility such that ‘ß’ compares equal to characters with which it previously compared different.

  Affected tables can be detected by `CHECK TABLE ... FOR UPGRADE` as of MySQL 5.1.30 (see Bug #40053).

  A workaround for this issue is implemented as of MySQL 5.1.62, 5.5.21, and 5.6.5. The workaround involves altering affected columns to use the `utf8_general_mysql500_ci` and `ucs2_general_mysql500_ci` collations, which preserve the original pre-5.1.24 ordering of `utf8_general_ci` and `ucs2_general_ci`.

• MySQL 5.0.48, 5.1.23 (Bug #27562)

  Affects indexes that use the `ascii_general_ci` collation for columns that contain any of these characters: `'` GRAVE ACCENT, `[` LEFT SQUARE BRACKET, `\` REVERSE SOLIDUS, `]` RIGHT SQUARE BRACKET, `'~` TILDE

  Affected tables can be detected by `CHECK TABLE ... FOR UPGRADE` as of MySQL 5.1.29 (see Bug #39585).

• MySQL 5.0.48, 5.1.21 (Bug #29461)

  Affects indexes for columns that use any of these character sets: `eucjpms,euc_kr,gb2312,latin7,macce,ujis`
Affected tables can be detected by `CHECK TABLE ... FOR UPGRADE` as of MySQL 5.1.29 (see Bug #39585).

# 2.11.4 Rebuilding or Repairing Tables or Indexes

This section describes how to rebuild a table. This can be necessitated by changes to MySQL such as how data types are handled or changes to character set handling. For example, an error in a collation might have been corrected, necessitating a table rebuild to update the indexes for character columns that use the collation. (For examples, see Section 2.11.3, "Checking Whether Tables or Indexes Must Be Rebuilt"). It might also be that a table repair or upgrade should be done as indicated by a table check operation such as that performed by `CHECK TABLE`, `mysqlcheck`, or `mysql_upgrade`.

Methods for rebuilding a table include dumping and reloading it, or using `ALTER TABLE` or `REPAIR TABLE`. `REPAIR TABLE` only applies to `MyISAM`, `ARCHIVE`, and `CSV` tables.

**Note**

If you are rebuilding tables because a different version of MySQL will not handle them after a binary (in-place) upgrade or downgrading, you must use the dump-and-reload method. Dump the tables before upgrading or downgrading using your original version of MySQL. Then reload the tables after upgrading or downgrading.

If you use the dump-and-reload method of rebuilding tables only for the purpose of rebuilding indexes, you can perform the dump either before or after upgrading or downgrading. Reloading still must be done afterward.

To rebuild a table by dumping and reloading it, use `mysqldump` to create a dump file and `mysql` to reload the file:

```sh
tool> mysqldump db_name t1 > dump.sql
tool> mysql db_name < dump.sql
```

To rebuild all the tables in a single database, specify the database name without any following table name:

```sh
tool> mysqldump db_name > dump.sql
tool> mysql db_name < dump.sql
```

To rebuild all tables in all databases, use the `--all-databases` option:

```sh
tool> mysqldump --all-databases > dump.sql
tool> mysql < dump.sql
```

To rebuild a table with `ALTER TABLE`, use a “null” alteration; that is, an `ALTER TABLE` statement that “changes” the table to use the storage engine that it already has. For example, if `t1` is an `InnoDB` table, use this statement:

```sql
mysql> ALTER TABLE t1 ENGINE = InnoDB;
```

If you are not sure which storage engine to specify in the `ALTER TABLE` statement, use `SHOW CREATE TABLE` to display the table definition.

If you need to rebuild an `InnoDB` table because a `CHECK TABLE` operation indicates that a table upgrade is required, use `mysqldump` to create a dump file and `mysql` to reload the file, as described earlier. If the `CHECK TABLE` operation indicates that there is a corruption or causes `InnoDB` to fail,
refer to Section 14.21.2, “Starting InnoDB on a Corrupted Database” for information about using the
innodb_force_recovery option to restart InnoDB. To understand the type of problem that CHECK
TABLE may be encountering, refer to the InnoDB notes in Section 13.7.2.2, “CHECK TABLE Syntax”.

For MyISAM, ARCHIVE, or CSV tables, you can use REPAIR TABLE if the table checking operation
indicates that there is a corruption or that an upgrade is required. For example, to repair a MyISAM table,
use this statement:

```
mysql> REPAIR TABLE t1;
```

mysqlcheck --repair provides command-line access to the REPAIR TABLE statement. This can
be a more convenient means of repairing tables because you can use the --databases or --all-
databases option to repair all tables in specific databases or all databases, respectively:

```
shell> mysqlcheck --repair --databases db_name ...
shell> mysqlcheck --repair --all-databases
```

For incompatibilities introduced in MySQL 5.1.24 by the fix for Bug #27877 that corrected the
utf8_general_ci and ucs2_general_ci collations, a workaround is implemented as of MySQL
5.1.62, 5.5.21, and 5.6.5. Upgrade to one of those versions, then convert each affected table using
one of the following methods. In each case, the workaround altering affected columns to use the utf8_general_mysql500_ci and ucs2_general_mysql500_ci collations, which preserve the
original pre-5.1.24 ordering of utf8_general_ci and ucs2_general_ci.

- To convert an affected table after a binary upgrade that leaves the table files in place, alter the table to
  use the new collation. Suppose that the table t1 contains one or more problematic utf8 columns. To
  convert the table at the table level, use a statement like this:

  ```
  ALTER TABLE t1
  CONVERT TO CHARACTER SET utf8 COLLATE utf8_general_mysql500_ci;
  ```

  To apply the change on a column-specific basis, use a statement like this (be sure to repeat the column
  definition as originally specified except for the COLLATE clause):

  ```
  ALTER TABLE t1
  MODIFY c1 CHAR(N) CHARACTER SET utf8 COLLATE utf8_general_mysql500_ci;
  ```

- To upgrade the table using a dump and reload procedure, dump the table using mysqldump, modify the
  CREATE TABLE statement in the dump file to use the new collation, and reload the table.

After making the appropriate changes, CHECK TABLE should report no error.

### 2.11.5 Copying MySQL Databases to Another Machine

In cases where you need to transfer databases between different architectures, you can use mysqldump
to create a file containing SQL statements. You can then transfer the file to the other machine and feed it
as input to the mysql client.

Note

You can copy the .frm, .MYI, and .MYD files for MyISAM tables between different
architectures that support the same floating-point format. (MySQL takes care of any
byte-swapping issues.) See Section 15.3, “The MyISAM Storage Engine”.

Use mysqldump --help to see what options are available.
The easiest (although not the fastest) way to move a database between two machines is to run the
following commands on the machine on which the database is located:

```
shell> mysqladmin -h 'other_hostname' create db_name
shell> mysqldump db_name | mysql -h 'other_hostname' db_name
```

If you want to copy a database from a remote machine over a slow network, you can use these commands:

```
shell> mysqladmin create db_name
shell> mysqldump -h 'other_hostname' --compress db_name | mysql db_name
```

You can also store the dump in a file, transfer the file to the target machine, and then load the file into
the database there. For example, you can dump a database to a compressed file on the source machine like
this:

```
shell> mysqldump --quick db_name | gzip > db_name.gz
```

Transfer the file containing the database contents to the target machine and run these commands there:

```
shell> gunzip < db_name.gz | mysql db_name
```

You can also use `mysqldump` and `mysqlimport` to transfer the database. For large tables, this is much
faster than simply using `mysqldump`. In the following commands, `DUMPDIR` represents the full path name
of the directory you use to store the output from `mysqldump`.

First, create the directory for the output files and dump the database:

```
shell> mkdir DUMPDIR
shell> mysqldump --tab=DUMPDIR db_name
```

Then transfer the files in the `DUMPDIR` directory to some corresponding directory on the target machine
and load the files into MySQL there:

```
shell> mysqladmin create db_name  # create database
shell> cat DUMPDIR/*.sql | mysql db_name  # create tables in database
shell> mysqlimport db_name DUMPDIR/*.txt   # load data into tables
```

Do not forget to copy the `mysql` database because that is where the grant tables are stored. You might
have to run commands as the MySQL root user on the new machine until you have the `mysql` database
in place.

After you import the `mysql` database on the new machine, execute `mysqladmin flush-privileges`
so that the server reloads the grant table information.

## 2.12 Environment Variables

This section lists all the environment variables that are used directly or indirectly by MySQL. Most of these
can also be found in other places in this manual.

Note that any options on the command line take precedence over values specified in option files and
environment variables, and values in option files take precedence over values in environment variables.

In many cases, it is preferable to use an option file instead of environment variables to modify the behavior
of MySQL. See Section 4.2.6, “Using Option Files”.
### Variable Description

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CXX</td>
<td>The name of your C++ compiler (for running CMake).</td>
</tr>
<tr>
<td>CC</td>
<td>The name of your C compiler (for running CMake).</td>
</tr>
<tr>
<td>DBI_USER</td>
<td>The default user name for Perl DBI.</td>
</tr>
<tr>
<td>DBI_TRACE</td>
<td>Trace options for Perl DBI.</td>
</tr>
<tr>
<td>HOME</td>
<td>The default path for the <code>mysql</code> history file is <code>$HOME/.mysql_history</code>.</td>
</tr>
<tr>
<td>LD_RUN_PATH</td>
<td>Used to specify the location of <code>libmysqlclient.so</code>.</td>
</tr>
<tr>
<td>LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN</td>
<td><code>mysql_clear_password</code> authentication plugin; see Section 6.3.7.5,</td>
</tr>
<tr>
<td></td>
<td>“The Cleartext Client-Side Authentication Plugin”.</td>
</tr>
<tr>
<td>MYSQL_DEBUG</td>
<td>Debug trace options when debugging.</td>
</tr>
<tr>
<td>MYSQL_GROUP_SUFFIX</td>
<td>Option group suffix value (like specifying <code>--defaults-group-suffix</code>).</td>
</tr>
<tr>
<td>MYSQL_HISTFILE</td>
<td>The path to the <code>mysql</code> history file. If this variable is set, its value</td>
</tr>
<tr>
<td></td>
<td>overrides the default for <code>$HOME/.mysql_history</code>.</td>
</tr>
<tr>
<td>MYSQL_HOME</td>
<td>The path to the directory in which the server-specific <code>my.cnf</code> file resides.</td>
</tr>
<tr>
<td>MYSQL_HOST</td>
<td>The default host name used by the <code>mysql</code> command-line client.</td>
</tr>
<tr>
<td>MYSQL_PS1</td>
<td>The command prompt to use in the <code>mysql</code> command-line client.</td>
</tr>
<tr>
<td>MYSQL_PWD</td>
<td>The default password when connecting to <code>mysqld</code>. Note that using this is</td>
</tr>
<tr>
<td></td>
<td>insecure. See Section 6.1.2.1, “End-User Guidelines for Password Security”.</td>
</tr>
<tr>
<td>MYSQL_TCP_PORT</td>
<td>The default TCP/IP port number.</td>
</tr>
<tr>
<td>MYSQL_UNIX_PORT</td>
<td>The default Unix socket file name; used for connections to <code>localhost</code>.</td>
</tr>
<tr>
<td>PATH</td>
<td>Used by the shell to find MySQL programs.</td>
</tr>
<tr>
<td>TMPDIR</td>
<td>The directory where temporary files are created.</td>
</tr>
<tr>
<td>TZ</td>
<td>This should be set to your local time zone. See Section B.5.4.6, “Time Zone</td>
</tr>
<tr>
<td></td>
<td>Problems”.</td>
</tr>
<tr>
<td>UMASK</td>
<td>The user-file creation mode when creating files. See note following table.</td>
</tr>
<tr>
<td>UMASK_DIR</td>
<td>The user-directory creation mode when creating directories. See note</td>
</tr>
<tr>
<td></td>
<td>following table.</td>
</tr>
<tr>
<td>USER</td>
<td>The default user name on Windows when connecting to <code>mysqld</code>.</td>
</tr>
</tbody>
</table>

For information about the `mysql` history file, see Section 4.5.1.3, “mysql Logging”.

The `UMASK` and `UMASK_DIR` variables, despite their names, are used as modes, not masks:

- If `UMASK` is set, `mysqld` uses ($UMASK | 0600) as the mode for file creation, so that newly created files have a mode in the range from 0600 to 0666 (all values octal).

- If `UMASK_DIR` is set, `mysqld` uses ($UMASK_DIR | 0700) as the base mode for directory creation, which then is AND-ed with (~$UMASK & 0666), so that newly created directories have a mode in the range from 0700 to 0777 (all values octal). The AND operation may remove read and write permissions from the directory mode, but not execute permissions.

MySQL assumes that the value for `UMASK` or `UMASK_DIR` is in octal if it starts with a zero.

## 2.13 Perl Installation Notes
The Perl DBI module provides a generic interface for database access. You can write a DBI script that works with many different database engines without change. To use DBI, you must install the DBI module, as well as a DataBase Driver (DBD) module for each type of database server you want to access. For MySQL, this driver is the DBD::mysql module.

Perl, and the DBD::MySQL module for DBI must be installed if you want to run the MySQL benchmark scripts; see Section 8.12.2, “The MySQL Benchmark Suite”. They are also required for the MySQL Cluster ndb_size.pl utility; see Section 18.4.23, “ndb_size.pl — NDBCLUSTER Size Requirement Estimator”.

Note
Perl support is not included with MySQL distributions. You can obtain the necessary modules from http://search.cpan.org for Unix, or by using the ActiveState ppm program on Windows. The following sections describe how to do this.

The DBI/DBD interface requires Perl 5.6.0, and 5.6.1 or later is preferred. DBI does not work if you have an older version of Perl. You should use DBD::mysql 4.009 or higher. Although earlier versions are available, they do not support the full functionality of MySQL 5.5.

2.13.1 Installing Perl on Unix

MySQL Perl support requires that you have installed MySQL client programming support (libraries and header files). Most installation methods install the necessary files. If you install MySQL from RPM files on Linux, be sure to install the developer RPM as well. The client programs are in the client RPM, but client programming support is in the developer RPM.

The files you need for Perl support can be obtained from the CPAN (Comprehensive Perl Archive Network) at http://search.cpan.org.

The easiest way to install Perl modules on Unix is to use the CPAN module. For example:

```
shell> perl -MCPAN -e shell
cpan> install DBI
cpan> install DBD::mysql
```

The DBD::mysql installation runs a number of tests. These tests attempt to connect to the local MySQL server using the default user name and password. (The default user name is your login name on Unix, and ODBC on Windows. The default password is “no password.”) If you cannot connect to the server with those values (for example, if your account has a password), the tests fail. You can use force install DBD::mysql to ignore the failed tests.

DBI requires the Data::Dumper module. It may be installed; if not, you should install it before installing DBI.

It is also possible to download the module distributions in the form of compressed tar archives and build the modules manually. For example, to unpack and build a DBI distribution, use a procedure such as this:

1. Unpack the distribution into the current directory:

```
shell> gunzip < DBI-VERSION.tar.gz | tar xvf -
```

This command creates a directory named DBI-VERSION.

2. Change location into the top-level directory of the unpacked distribution:
Installing ActiveState Perl on Windows

3. Build the distribution and compile everything:

```
shell> cd DBI-VERSION
shell> perl Makefile.PL
shell> make
shell> make test
shell> make install
```

The `make test` command is important because it verifies that the module is working. Note that when you run that command during the `DBD::mysql` installation to exercise the interface code, the MySQL server must be running or the test fails.

It is a good idea to rebuild and reinstall the `DBD::mysql` distribution whenever you install a new release of MySQL. This ensures that the latest versions of the MySQL client libraries are installed correctly.

If you do not have access rights to install Perl modules in the system directory or if you want to install local Perl modules, the following reference may be useful: http://learn.perl.org/faq/perlfaq8.html#How-do-I-keep-my-own-module-library-directory-

### 2.13.2 Installing ActiveState Perl on Windows

On Windows, you should do the following to install the MySQL DBD module with ActiveState Perl:

1. Get ActiveState Perl from http://www.activestate.com/Products/ActivePerl/ and install it.
2. Open a console window.
3. If necessary, set the `HTTP_proxy` variable. For example, you might try a setting like this:

```
C:\> set HTTP_proxy=my.proxy.com:3128
```
4. Start the PPM program:

```
C:\> C:\perl\bin\ppm.pl
```
5. If you have not previously done so, install `DBI`:

```
ppm> install DBI
```
6. If this succeeds, run the following command:

```
ppm> install DBD-mysql
```

This procedure should work with ActiveState Perl 5.6 or newer.

If you cannot get the procedure to work, you should install the ODBC driver instead and connect to the MySQL server through ODBC:

```
use DBI;
$dbh= DBI->connect("DBI:ODBC:$dsn",$user,$password) ||
  die "Got error $DBI::errstr when connecting to $dsn\n";
```

### 2.13.3 Problems Using the Perl DBI/DBD Interface
If Perl reports that it cannot find the `../mysql/mysql.so` module, the problem is probably that Perl cannot locate the `libmysqlclient.so` shared library. You should be able to fix this problem by one of the following methods:

- Copy `libmysqlclient.so` to the directory where your other shared libraries are located (probably `/usr/lib` or `/lib`).
- Modify the `-L` options used to compile `DBD::mysql` to reflect the actual location of `libmysqlclient.so`.
- On Linux, you can add the path name of the directory where `libmysqlclient.so` is located to the `/etc/ld.so.conf` file.
- Add the path name of the directory where `libmysqlclient.so` is located to the `LD_RUN_PATH` environment variable. Some systems use `LD_LIBRARY_PATH` instead.

Note that you may also need to modify the `-L` options if there are other libraries that the linker fails to find. For example, if the linker cannot find `libc` because it is in `/lib` and the link command specifies `-L/usr/lib`, change the `-L` option to `-L/lib` or add `-L/lib` to the existing link command.

If you get the following errors from `DBD::mysql`, you are probably using `gcc` (or using an old binary compiled with `gcc`):

```
/usr/bin/perl: can't resolve symbol '__moddi3'
/usr/bin/perl: can't resolve symbol '__divdi3'
```

Add `-L/usr/lib/gcc-lib/... -lgcc` to the link command when the `mysql.so` library gets built (check the output from `make` for `mysql.so` when you compile the Perl client). The `-L` option should specify the path name of the directory where `libgcc.a` is located on your system.

Another cause of this problem may be that Perl and MySQL are not both compiled with `gcc`. In this case, you can solve the mismatch by compiling both with `gcc`.

This chapter provides a tutorial introduction to MySQL by showing how to use the mysql client program to create and use a simple database. mysql (sometimes referred to as the “terminal monitor” or just “monitor”) is an interactive program that enables you to connect to a MySQL server, run queries, and view the results. mysql may also be used in batch mode: you place your queries in a file beforehand, then tell mysql to execute the contents of the file. Both ways of using mysql are covered here.

To see a list of options provided by mysql, invoke it with the --help option:

shell> mysql --help

This chapter assumes that mysql is installed on your machine and that a MySQL server is available to which you can connect. If this is not true, contact your MySQL administrator. (If you are the administrator, you need to consult the relevant portions of this manual, such as Chapter 5, MySQL Server Administration.)

This chapter describes the entire process of setting up and using a database. If you are interested only in accessing an existing database, you may want to skip over the sections that describe how to create the database and the tables it contains.

Because this chapter is tutorial in nature, many details are necessarily omitted. Consult the relevant sections of the manual for more information on the topics covered here.

3.1 Connecting to and Disconnecting from the Server

To connect to the server, you will usually need to provide a MySQL user name when you invoke mysql and, most likely, a password. If the server runs on a machine other than the one where you log in, you will
also need to specify a host name. Contact your administrator to find out what connection parameters you should use to connect (that is, what host, user name, and password to use). Once you know the proper parameters, you should be able to connect like this:

```
shell> mysql -h host -u user -p
Enter password: ********
```

`host` and `user` represent the host name where your MySQL server is running and the user name of your MySQL account. Substitute appropriate values for your setup. The `********` represents your password; enter it when `mysql` displays the `Enter password:` prompt.

If that works, you should see some introductory information followed by a `mysql>` prompt:

```
shell> mysql -h host -u user -p
Enter password: ********
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 25338 to server version: 5.5.40-standard
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
mysql>
```

The `mysql>` prompt tells you that `mysql` is ready for you to enter commands.

If you are logging in on the same machine that MySQL is running on, you can omit the host, and simply use the following:

```
shell> mysql -u user -p
```

If, when you attempt to log in, you get an error message such as `ERROR 2002 (HY000): Can't connect to local MySQL server through socket '/tmp/mysql.sock' (2)`, it means that the MySQL server daemon (Unix) or service (Windows) is not running. Consult the administrator or see the section of Chapter 2, *Installing and Upgrading MySQL* that is appropriate to your operating system.

For help with other problems often encountered when trying to log in, see Section B.5.2, “Common Errors When Using MySQL Programs”.

Some MySQL installations permit users to connect as the anonymous (unnamed) user to the server running on the local host. If this is the case on your machine, you should be able to connect to that server by invoking `mysql` without any options:

```
shell> mysql
```

After you have connected successfully, you can disconnect any time by typing `QUIT` (or `\q`) at the `mysql>` prompt:

```
mysql> QUIT
Bye
```

On Unix, you can also disconnect by pressing Control+D.

Most examples in the following sections assume that you are connected to the server. They indicate this by the `mysql>` prompt.

## 3.2 Entering Queries
Make sure that you are connected to the server, as discussed in the previous section. Doing so does not in itself select any database to work with, but that is okay. At this point, it is more important to find out a little about how to issue queries than to jump right in creating tables, loading data into them, and retrieving data from them. This section describes the basic principles of entering commands, using several queries you can try out to familiarize yourself with how mysql works.

Here is a simple command that asks the server to tell you its version number and the current date. Type it in as shown here following the mysql> prompt and press Enter:

```
mysql> SELECT VERSION(), CURRENT_DATE;
+--------------+--------------+
| VERSION()    | CURRENT_DATE |
+--------------+--------------+
| 5.5.0-m2-log | 2009-05-04   |
+--------------+--------------+
1 row in set (0.01 sec)
```

This query illustrates several things about mysql:

• A command normally consists of an SQL statement followed by a semicolon. (There are some exceptions where a semicolon may be omitted. QUIT, mentioned earlier, is one of them. We’ll get to others later.)

• When you issue a command, mysql sends it to the server for execution and displays the results, then prints another mysql> prompt to indicate that it is ready for another command.

• mysql displays query output in tabular form (rows and columns). The first row contains labels for the columns. The rows following are the query results. Normally, column labels are the names of the columns you fetch from database tables. If you’re retrieving the value of an expression rather than a table column (as in the example just shown), mysql labels the column using the expression itself.

• mysql shows how many rows were returned and how long the query took to execute, which gives you a rough idea of server performance. These values are imprecise because they represent wall clock time (not CPU or machine time), and because they are affected by factors such as server load and network latency. (For brevity, the “rows in set” line is sometimes not shown in the remaining examples in this chapter.)

Keywords may be entered in any lettercase. The following queries are equivalent:

```
mysql> SELECT VERSION(), CURRENT_DATE;
mysql> select version(), current_date;
mysql> SeLeCt vErSiOn(), current_DATE;
```

Here is another query. It demonstrates that you can use mysql as a simple calculator:

```
mysql> SELECT SIN(PI()/4), (4+1)*5;
+------------------+-
| SIN(PI()/4)      | (4+1)*5 |
+------------------+-
| 0.70710678118655 |      25 |
+------------------+-
1 row in set (0.02 sec)
```

The queries shown thus far have been relatively short, single-line statements. You can even enter multiple statements on a single line. Just end each one with a semicolon:
A command need not be given all on a single line, so lengthy commands that require several lines are not a problem. `mysql` determines where your statement ends by looking for the terminating semicolon, not by looking for the end of the input line. (In other words, `mysql` accepts free-format input: it collects input lines but does not execute them until it sees the semicolon.)

Here is a simple multiple-line statement:

```
mysql> SELECT
    -> USER()
    -> CURRENT_DATE;
```

In this example, notice how the prompt changes from `mysql>` to `->` after you enter the first line of a multiple-line query. This is how `mysql` indicates that it has not yet seen a complete statement and is waiting for the rest. The prompt is your friend, because it provides valuable feedback. If you use that feedback, you can always be aware of what `mysql` is waiting for.

If you decide you do not want to execute a command that you are in the process of entering, cancel it by typing `\c`:

```
mysql> SELECT
    -> USER()
    -> \c
mysql>
```

Here, too, notice the prompt. It switches back to `mysql>` after you type `\c`, providing feedback to indicate that `mysql` is ready for a new command.

The following table shows each of the prompts you may see and summarizes what they mean about the state that `mysql` is in.

<table>
<thead>
<tr>
<th>Prompt</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mysql&gt;</code></td>
<td>Ready for new command.</td>
</tr>
<tr>
<td><code>-&gt;</code></td>
<td>Waiting for next line of multiple-line command.</td>
</tr>
<tr>
<td><code>&quot;-&gt;</code></td>
<td>Waiting for next line, waiting for completion of a string that began with a single quote (&quot;'&quot;).</td>
</tr>
<tr>
<td><code>&quot;-&gt;</code></td>
<td>Waiting for next line, waiting for completion of a string that began with a double quote (&quot;&quot;&quot;).</td>
</tr>
</tbody>
</table>
Entering Queries

<table>
<thead>
<tr>
<th>Prompt</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&gt;</code></td>
<td>Waiting for next line, waiting for completion of an identifier that began with a backtick (&quot;`&quot;).</td>
</tr>
<tr>
<td>/*&gt;</td>
<td>Waiting for next line, waiting for completion of a comment that began with <code>/*</code>.</td>
</tr>
</tbody>
</table>

Multiple-line statements commonly occur by accident when you intend to issue a command on a single line, but forget the terminating semicolon. In this case, mysql waits for more input:

```sql
mysql> SELECT USER()
-> ;
```

If this happens to you (you think you've entered a statement but the only response is a `->` prompt), most likely mysql is waiting for the semicolon. If you don't notice what the prompt is telling you, you might sit there for a while before realizing what you need to do. Enter a semicolon to complete the statement, and mysql executes it:

```sql
mysql> SELECT USER()
-> ;
+---------------+
| USER()        |
+---------------+
| jon@localhost |
```

The `>` and `"` prompts occur during string collection (another way of saying that MySQL is waiting for completion of a string). In MySQL, you can write strings surrounded by either `"` or `"` characters (for example, 'hello' or "goodbye"), and mysql lets you enter strings that span multiple lines. When you see a `>` or `"` prompt, it means that you have entered a line containing a string that begins with a `"` or `"` quote character, but have not yet entered the matching quote that terminates the string. This often indicates that you have inadvertently left out a quote character. For example:

```sql
mysql> SELECT * FROM my_table WHERE name = 'Smith AND age < 30;
```

If you enter this `SELECT` statement, then press Enter and wait for the result, nothing happens. Instead of wondering why this query takes so long, notice the clue provided by the `>` prompt. It tells you that mysql expects to see the rest of an unterminated string. (Do you see the error in the statement? The string 'Smith is missing the second single quotation mark.)

At this point, what do you do? The simplest thing is to cancel the command. However, you cannot just type `\c` in this case, because mysql interprets it as part of the string that it is collecting. Instead, enter the closing quote character (so mysql knows you've finished the string), then type `\c`:

```sql
mysql> SELECT * FROM my_table WHERE name = 'Smith AND age < 30;
   
mysql>
```

The prompt changes back to `mysql>`, indicating that mysql is ready for a new command.

The `>` prompt is similar to the `>` and `"` prompts, but indicates that you have begun but not completed a backtick-quoted identifier.

It is important to know what the `>`, `"`, and `>` prompts signify, because if you mistakenly enter an unterminated string, any further lines you type appear to be ignored by mysql—including a line containing QUIT. This can be quite confusing, especially if you do not know that you need to supply the terminating quote before you can cancel the current command.
3.3 Creating and Using a Database

Once you know how to enter commands, you are ready to access a database.

Suppose that you have several pets in your home (your menagerie) and you would like to keep track of various types of information about them. You can do so by creating tables to hold your data and loading them with the desired information. Then you can answer different sorts of questions about your animals by retrieving data from the tables. This section shows you how to perform the following operations:

- Create a database
- Create a table
- Load data into the table
- Retrieve data from the table in various ways
- Use multiple tables

The menagerie database is simple (deliberately), but it is not difficult to think of real-world situations in which a similar type of database might be used. For example, a database like this could be used by a farmer to keep track of livestock, or by a veterinarian to keep track of patient records. A menagerie distribution containing some of the queries and sample data used in the following sections can be obtained from the MySQL Web site. It is available in both compressed tar file and Zip formats at http://dev.mysql.com/doc/.

Use the SHOW statement to find out what databases currently exist on the server:

```
mysql> SHOW DATABASES;
+----------+
| Database |
+----------+
| mysql    |
| test     |
| tmp      |
+----------+
```

The mysql database describes user access privileges. The test database often is available as a workspace for users to try things out.

The list of databases displayed by the statement may be different on your machine; SHOW DATABASES does not show databases that you have no privileges for if you do not have the SHOW DATABASES privilege. See Section 13.7.5.15, "SHOW DATABASES Syntax".

If the test database exists, try to access it:

```
mysql> USE test
Database changed
```

USE, like QUIT, does not require a semicolon. (You can terminate such statements with a semicolon if you like; it does no harm.) The USE statement is special in another way, too: it must be given on a single line.

You can use the test database (if you have access to it) for the examples that follow, but anything you create in that database can be removed by anyone else with access to it. For this reason, you should probably ask your MySQL administrator for permission to use a database of your own. Suppose that you want to call yours menagerie. The administrator needs to execute a command like this:
3.3.1 Creating and Selecting a Database

If the administrator creates your database for you when setting up your permissions, you can begin using it. Otherwise, you need to create it yourself:

```sql
mysql> CREATE DATABASE menagerie;
```

Under Unix, database names are case sensitive (unlike SQL keywords), so you must always refer to your database as `menagerie`, not as `Menagerie`, `MENAGERIE`, or some other variant. This is also true for table names. (Under Windows, this restriction does not apply, although you must refer to databases and tables using the same lettercase throughout a given query. However, for a variety of reasons, the recommended best practice is always to use the same lettercase that was used when the database was created.)

**Note**
If you get an error such as `ERROR 1044 (42000): Access denied for user 'monty'@'localhost' to database 'menagerie'` when attempting to create a database, this means that your user account does not have the necessary privileges to do so. Discuss this with the administrator or see Section 6.2, “The MySQL Access Privilege System”.

Creating a database does not select it for use; you must do that explicitly. To make `menagerie` the current database, use this command:

```sql
mysql> USE menagerie
```

Your database needs to be created only once, but you must select it for use each time you begin a `mysql` session. You can do this by issuing a `USE` statement as shown in the example. Alternatively, you can select the database on the command line when you invoke `mysql`. Just specify its name after any connection parameters that you might need to provide. For example:

```
shell> mysql -h host -u user -p menagerie
Enter password: ********
```

**Important**

`menagerie` in the command just shown is not your password. If you want to supply your password on the command line after the `-p` option, you must do so with no intervening space (for example, as `-pmypassword`, not as `-p mypassword`). However, putting your password on the command line is not recommended, because doing so exposes it to snooping by other users logged in on your machine.

**Note**
You can see at any time which database is currently selected using `SELECT DATABASE()`.

3.3.2 Creating a Table
Creating the database is the easy part, but at this point it is empty, as `SHOW TABLES` tells you:

```sql
mysql> SHOW TABLES;
Empty set (0.00 sec)
```

The harder part is deciding what the structure of your database should be: what tables you need and what columns should be in each of them.

You want a table that contains a record for each of your pets. This can be called the `pet` table, and it should contain, as a bare minimum, each animal's name. Because the name by itself is not very interesting, the table should contain other information. For example, if more than one person in your family keeps pets, you might want to list each animal's owner. You might also want to record some basic descriptive information such as species and sex.

How about age? That might be of interest, but it is not a good thing to store in a database. Age changes as time passes, which means you'd have to update your records often. Instead, it is better to store a fixed value such as date of birth. Then, whenever you need age, you can calculate it as the difference between the current date and the birth date. MySQL provides functions for doing date arithmetic, so this is not difficult. Storing birth date rather than age has other advantages, too:

- You can use the database for tasks such as generating reminders for upcoming pet birthdays. (If you think this type of query is somewhat silly, note that it is the same question you might ask in the context of a business database to identify clients to whom you need to send out birthday greetings in the current week or month, for that computer-assisted personal touch.)
- You can calculate age in relation to dates other than the current date. For example, if you store death date in the database, you can easily calculate how old a pet was when it died.

You can probably think of other types of information that would be useful in the `pet` table, but the ones identified so far are sufficient: name, owner, species, sex, birth, and death.

Use a `CREATE TABLE` statement to specify the layout of your table:

```sql
mysql> CREATE TABLE pet (name VARCHAR(20), owner VARCHAR(20),
-> species VARCHAR(20), sex CHAR(1), birth DATE, death DATE);
```

`VARCHAR` is a good choice for the `name`, `owner`, and `species` columns because the column values vary in length. The lengths in those column definitions need not all be the same, and need not be 20. You can normally pick any length from 1 to 65535, whatever seems most reasonable to you. If you make a poor choice and it turns out later that you need a longer field, MySQL provides an `ALTER TABLE` statement.

Several types of values can be chosen to represent sex in animal records, such as 'm' and 'f', or perhaps 'male' and 'female'. It is simplest to use the single characters 'm' and 'f'.

The use of the `DATE` data type for the `birth` and `death` columns is a fairly obvious choice.

Once you have created a table, `SHOW TABLES` should produce some output:

```sql
mysql> SHOW TABLES;
+---------------------+
| Tables in menagerie |
+---------------------+
| pet                 |
+---------------------+
```

To verify that your table was created the way you expected, use a `DESCRIBE` statement:
You can use **DESCRIBE** any time, for example, if you forget the names of the columns in your table or what types they have.

For more information about MySQL data types, see *Chapter 11, Data Types*.

### 3.3.3 Loading Data into a Table

After creating your table, you need to populate it. The **LOAD DATA** and **INSERT** statements are useful for this.

Suppose that your pet records can be described as shown here. (Observe that MySQL expects dates in 'YYYY-MM-DD' format; this may be different from what you are used to.)

<table>
<thead>
<tr>
<th>name</th>
<th>owner</th>
<th>species</th>
<th>sex</th>
<th>birth</th>
<th>death</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fluffy</td>
<td>Harold</td>
<td>cat</td>
<td>f</td>
<td>1993-02-04</td>
<td></td>
</tr>
<tr>
<td>Claws</td>
<td>Gwen</td>
<td>cat</td>
<td>m</td>
<td>1994-03-17</td>
<td></td>
</tr>
<tr>
<td>Buffy</td>
<td>Harold</td>
<td>dog</td>
<td>f</td>
<td>1989-05-13</td>
<td></td>
</tr>
<tr>
<td>Fang</td>
<td>Benny</td>
<td>dog</td>
<td>m</td>
<td>1990-08-27</td>
<td></td>
</tr>
<tr>
<td>Bowser</td>
<td>Diane</td>
<td>dog</td>
<td>m</td>
<td>1979-08-31</td>
<td>1995-07-29</td>
</tr>
<tr>
<td>Chirpy</td>
<td>Gwen</td>
<td>bird</td>
<td>f</td>
<td>1998-09-11</td>
<td></td>
</tr>
<tr>
<td>Whistler</td>
<td>Gwen</td>
<td>bird</td>
<td></td>
<td>1997-12-09</td>
<td></td>
</tr>
<tr>
<td>Slim</td>
<td>Benny</td>
<td>snake</td>
<td>m</td>
<td>1996-04-29</td>
<td></td>
</tr>
</tbody>
</table>

Because you are beginning with an empty table, an easy way to populate it is to create a text file containing a row for each of your animals, then load the contents of the file into the table with a single statement.

You could create a text file **pet.txt** containing one record per line, with values separated by tabs, and given in the order in which the columns were listed in the **CREATE TABLE** statement. For missing values (such as unknown sexes or death dates for animals that are still living), you can use **NULL** values. To represent these in your text file, use **\N** (backslash, capital-N). For example, the record for Whistler the bird would look like this (where the whitespace between values is a single tab character):

| Whistler | Gwen | bird | \N | 1997-12-09 | \N |

To load the text file **pet.txt** into the **pet** table, use this statement:

```sql
mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet;
```

If you created the file on Windows with an editor that uses **\r\n** as a line terminator, you should use this statement instead:
Retrieving Information from a Table

mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet
     > LINES TERMINATED BY '\r\n';

(On an Apple machine running OS X, you would likely want to use `LINES TERMINATED BY '\r'.`)

You can specify the column value separator and end of line marker explicitly in the `LOAD DATA` statement if you wish, but the defaults are tab and linefeed. These are sufficient for the statement to read the file `pet.txt` properly.

If the statement fails, it is likely that your MySQL installation does not have local file capability enabled by default. See Section 6.1.6, “Security Issues with `LOAD DATA LOCAL`”, for information on how to change this.

When you want to add new records one at a time, the `INSERT` statement is useful. In its simplest form, you supply values for each column, in the order in which the columns were listed in the `CREATE TABLE` statement. Suppose that Diane gets a new hamster named “Puffball.” You could add a new record using an `INSERT` statement like this:

mysql> INSERT INTO pet
     > VALUES ('Puffball','Diane','hamster','f','1999-03-30',NULL);

String and date values are specified as quoted strings here. Also, with `INSERT`, you can insert `NULL` directly to represent a missing value. You do not use `\N` like you do with `LOAD DATA`.

From this example, you should be able to see that there would be a lot more typing involved to load your records initially using several `INSERT` statements rather than a single `LOAD DATA` statement.

3.3.4 Retrieving Information from a Table

The `SELECT` statement is used to pull information from a table. The general form of the statement is:

```
SELECT what_to_select
FROM which_table
WHERE conditions_to_satisfy;
```

`what_to_select` indicates what you want to see. This can be a list of columns, or `*` to indicate “all columns.” `which_table` indicates the table from which you want to retrieve data. The `WHERE` clause is optional. If it is present, `conditions_to_satisfy` specifies one or more conditions that rows must satisfy to qualify for retrieval.

3.3.4.1 Selecting All Data

The simplest form of `SELECT` retrieves everything from a table:

```
mysql> SELECT * FROM pet;
```

<table>
<thead>
<tr>
<th>name</th>
<th>owner</th>
<th>species</th>
<th>sex</th>
<th>birth</th>
<th>death</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fluffy</td>
<td>Harold</td>
<td>cat</td>
<td>f</td>
<td>1993-02-04</td>
<td>NULL</td>
</tr>
<tr>
<td>Claws</td>
<td>Gwen</td>
<td>cat</td>
<td>m</td>
<td>1994-03-17</td>
<td>NULL</td>
</tr>
<tr>
<td>Buffy</td>
<td>Harold</td>
<td>dog</td>
<td>f</td>
<td>1989-05-13</td>
<td>NULL</td>
</tr>
<tr>
<td>Fang</td>
<td>Benny</td>
<td>dog</td>
<td>m</td>
<td>1990-08-27</td>
<td>NULL</td>
</tr>
<tr>
<td>Bowser</td>
<td>Diane</td>
<td>dog</td>
<td>m</td>
<td>1979-08-31</td>
<td>1995-07-29</td>
</tr>
<tr>
<td>Chirpy</td>
<td>Gwen</td>
<td>bird</td>
<td>f</td>
<td>1998-09-11</td>
<td>NULL</td>
</tr>
<tr>
<td>Whistler</td>
<td>Gwen</td>
<td>bird</td>
<td>NULL</td>
<td>1997-12-09</td>
<td>NULL</td>
</tr>
<tr>
<td>Slim</td>
<td>Benny</td>
<td>snake</td>
<td>m</td>
<td>1996-04-29</td>
<td>NULL</td>
</tr>
</tbody>
</table>
Retrieving Information from a Table

<table>
<thead>
<tr>
<th>Puffball</th>
<th>Diane</th>
<th>hamster</th>
<th>f</th>
<th>1999-03-30</th>
<th>NULL</th>
</tr>
</thead>
</table>

This form of `SELECT` is useful if you want to review your entire table, for example, after you've just loaded it with your initial data set. For example, you may happen to think that the birth date for Bowser doesn't seem quite right. Consulting your original pedigree papers, you find that the correct birth year should be 1989, not 1979.

There are at least two ways to fix this:

- Edit the file `pet.txt` to correct the error, then empty the table and reload it using `DELETE` and `LOAD DATA`:

  ```sql
  mysql> DELETE FROM pet;
  mysql> LOAD DATA LOCAL INFILE 'pet.txt' INTO TABLE pet;
  ```

  However, if you do this, you must also re-enter the record for Puffball.

- Fix only the erroneous record with an `UPDATE` statement:

  ```sql
  mysql> UPDATE pet SET birth = '1989-08-31' WHERE name = 'Bowser';
  ```

  The `UPDATE` changes only the record in question and does not require you to reload the table.

### 3.3.4.2 Selecting Particular Rows

As shown in the preceding section, it is easy to retrieve an entire table. Just omit the `WHERE` clause from the `SELECT` statement. But typically you don't want to see the entire table, particularly when it becomes large. Instead, you're usually more interested in answering a particular question, in which case you specify some constraints on the information you want. Let's look at some selection queries in terms of questions about your pets that they answer.

You can select only particular rows from your table. For example, if you want to verify the change that you made to Bowser's birth date, select Bowser's record like this:

```sql
mysql> SELECT * FROM pet WHERE name = 'Bowser';
```

The output confirms that the year is correctly recorded as 1989, not 1979.

String comparisons normally are case-insensitive, so you can specify the name as `''bowser''`, `''BOWSER''`, and so forth. The query result is the same.

You can specify conditions on any column, not just `name`. For example, if you want to know which animals were born during or after 1998, test the `birth` column:

```sql
mysql> SELECT * FROM pet WHERE birth >= '1998-1-1';
```
Retrieving Information from a Table

You can combine conditions, for example, to locate female dogs:

```
mysql> SELECT * FROM pet WHERE species = 'dog' AND sex = 'f';
```

| name | owner | species | sex | birth      | death |
|------|-------|---------|-----|------------+-------|
| Buffy| Harold| dog     | f   | 1989-05-13 | NULL  |

The preceding query uses the **AND** logical operator. There is also an **OR** operator:

```
mysql> SELECT * FROM pet WHERE species = 'snake' OR species = 'bird';
```

| name   | owner | species | sex | birth      | death |
|--------|-------|---------|-----|------------+-------|
| Chirpy | Gwen  | bird    | f   | 1998-09-11 | NULL  |
| Whistler| Gwen  | bird    | NULL| 1997-12-09 | NULL  |
| Slim   | Benny | snake   | m   | 1996-04-29 | NULL  |

**AND** and **OR** may be intermixed, although **AND** has higher precedence than **OR**. If you use both operators, it is a good idea to use parentheses to indicate explicitly how conditions should be grouped:

```
mysql> SELECT * FROM pet WHERE (species = 'cat' AND sex = 'm') OR (species = 'dog' AND sex = 'f');
```

| name | owner | species | sex | birth      | death |
|------|-------|---------|-----|------------+-------|
| Claws| Gwen  | cat     | m   | 1994-03-17 | NULL  |
| Buffy| Harold| dog     | f   | 1989-05-13 | NULL  |

### 3.3.4.3 Selecting Particular Columns

If you do not want to see entire rows from your table, just name the columns in which you are interested, separated by commas. For example, if you want to know when your animals were born, select the **name** and **birth** columns:

```
mysql> SELECT name, birth FROM pet;
```

<table>
<thead>
<tr>
<th>name</th>
<th>birth</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fluffy</td>
<td>1993-02-04</td>
</tr>
<tr>
<td>Claws</td>
<td>1994-03-17</td>
</tr>
<tr>
<td>Buffy</td>
<td>1989-05-13</td>
</tr>
<tr>
<td>Fang</td>
<td>1990-08-27</td>
</tr>
<tr>
<td>Bowser</td>
<td>1989-08-31</td>
</tr>
<tr>
<td>Chirpy</td>
<td>1998-09-11</td>
</tr>
<tr>
<td>Whistler</td>
<td>1997-12-09</td>
</tr>
<tr>
<td>Slim</td>
<td>1996-04-29</td>
</tr>
<tr>
<td>Puffball</td>
<td>1999-03-30</td>
</tr>
</tbody>
</table>

To find out who owns pets, use this query:

```
mysql> SELECT owner FROM pet;
```

<table>
<thead>
<tr>
<th>owner</th>
</tr>
</thead>
</table>

230
Retrieving Information from a Table

Notice that the query simply retrieves the `owner` column from each record, and some of them appear more than once. To minimize the output, retrieve each unique output record just once by adding the keyword `DISTINCT`:

```sql
mysql> SELECT DISTINCT owner FROM pet;
+--------+
| owner  |
+--------+
| Benny  |
| Diane  |
| Gwen   |
+--------+
```

You can use a `WHERE` clause to combine row selection with column selection. For example, to get birth dates for dogs and cats only, use this query:

```sql
mysql> SELECT name, species, birth FROM pet
-> WHERE species = 'dog' OR species = 'cat';
+----------+---------+------------+
| name     | species | birth      |
+----------+---------+------------+
| Fluffy   | cat     | 1993-02-04 |
| Claws    | cat     | 1994-03-17 |
| Buffy    | dog     | 1989-05-13 |
| Fang     | dog     | 1990-08-27 |
| Bowser   | dog     | 1989-08-31 |
+----------+---------+------------+
```

### 3.3.4.4 Sorting Rows

You may have noticed in the preceding examples that the result rows are displayed in no particular order. It is often easier to examine query output when the rows are sorted in some meaningful way. To sort a result, use an `ORDER BY` clause.

Here are animal birthdays, sorted by date:

```sql
mysql> SELECT name, birth FROM pet ORDER BY birth;
+----------+------------+
| name     | birth      |
+----------+------------+
| Buffy    | 1989-05-13 |
| Bowser   | 1989-08-31 |
| Fang     | 1990-08-27 |
| Fluffy   | 1993-02-04 |
| Claws    | 1994-03-17 |
| Slim     | 1996-04-29 |
| Whistler | 1997-12-09 |
| Chirpy   | 1998-09-11 |
| Whistler | 1997-12-09 |
| Chirpy   | 1998-09-11 |
+----------+------------+
```
On character type columns, sorting—like all other comparison operations—is normally performed in a case-insensitive fashion. This means that the order is undefined for columns that are identical except for their case. You can force a case-sensitive sort for a column by using `BINARY` like so: `ORDER BY BINARY col_name`.

The default sort order is ascending, with smallest values first. To sort in reverse (descending) order, add the `DESC` keyword to the name of the column you are sorting by:

```sql
mysql> SELECT name, birth FROM pet ORDER BY birth DESC;
+----------+------------+
| name     | birth      |
+----------+------------+
| Puffball | 1999-03-30 |
| Chirpy   | 1998-09-11 |
| Whistler | 1997-12-09 |
| Slim     | 1996-04-29 |
| Claws    | 1994-03-17 |
| Fluffy   | 1993-02-04 |
| Fang     | 1990-08-27 |
| Bowser   | 1989-08-31 |
| Buffy    | 1989-05-13 |
+----------+------------+
```

You can sort on multiple columns, and you can sort different columns in different directions. For example, to sort by type of animal in ascending order, then by birth date within animal type in descending order (youngest animals first), use the following query:

```sql
mysql> SELECT name, species, birth FROM pet
   -> ORDER BY species, birth DESC;
+----------+---------+------------+
| name     | species | birth      |
+----------+---------+------------+
| Chirpy   | bird    | 1998-09-11 |
| Whistler | bird    | 1997-12-09 |
| Claws    | cat     | 1994-03-17 |
| Fluffy   | cat     | 1993-02-04 |
| Fang     | dog     | 1990-08-27 |
| Bowser   | dog     | 1989-08-31 |
| Buffy    | dog     | 1989-05-13 |
| Puffball | hamster | 1999-03-30 |
| Slim     | snake   | 1996-04-29 |
+----------+---------+------------+
```

The `DESC` keyword applies only to the column name immediately preceding it (`birth`); it does not affect the `species` column sort order.

### 3.3.4.5 Date Calculations

MySQL provides several functions that you can use to perform calculations on dates, for example, to calculate ages or extract parts of dates.

To determine how many years old each of your pets is, use the `TIMESTAMPDIFF()` function. Its arguments are the unit in which you want the result expressed, and the two date for which to take the difference. The following query shows, for each pet, the birth date, the current date, and the age in years. An alias (`age`) is used to make the final output column label more meaningful.
Retrieving Information from a Table

mysql> SELECT name, birth, CURDATE(),
   -> TIMESTAMPDIFF(YEAR,birth,CURDATE()) AS age
   -> FROM pet;

+----------+------------+------------+------+
<table>
<thead>
<tr>
<th>name</th>
<th>birth</th>
<th>CURDATE()</th>
<th>age</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fluffy</td>
<td>1993-02-04</td>
<td>2003-08-19</td>
<td>10</td>
</tr>
<tr>
<td>Claws</td>
<td>1994-03-17</td>
<td>2003-08-19</td>
<td>9</td>
</tr>
<tr>
<td>Buffy</td>
<td>1989-05-13</td>
<td>2003-08-19</td>
<td>14</td>
</tr>
<tr>
<td>Fang</td>
<td>1990-08-27</td>
<td>2003-08-19</td>
<td>12</td>
</tr>
<tr>
<td>Bowser</td>
<td>1989-08-31</td>
<td>2003-08-19</td>
<td>13</td>
</tr>
<tr>
<td>Chirpy</td>
<td>1998-09-11</td>
<td>2003-08-19</td>
<td>4</td>
</tr>
<tr>
<td>Whistler</td>
<td>1997-12-09</td>
<td>2003-08-19</td>
<td>5</td>
</tr>
<tr>
<td>Slim</td>
<td>1996-04-29</td>
<td>2003-08-19</td>
<td>7</td>
</tr>
<tr>
<td>Puffball</td>
<td>1999-03-30</td>
<td>2003-08-19</td>
<td>4</td>
</tr>
</tbody>
</table>
+----------+------------+------------+------+

The query works, but the result could be scanned more easily if the rows were presented in some order. This can be done by adding an `ORDER BY name` clause to sort the output by name:

mysql> SELECT name, birth, CURDATE(),
   ->_TIMESTAMPDIFF(YEAR,birth,CURDATE()) AS age
   -> FROM pet ORDER BY name;

+----------+------------+------------+------+
<table>
<thead>
<tr>
<th>name</th>
<th>birth</th>
<th>CURDATE()</th>
<th>age</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bowser</td>
<td>1989-08-31</td>
<td>2003-08-19</td>
<td>13</td>
</tr>
<tr>
<td>Buffy</td>
<td>1989-05-13</td>
<td>2003-08-19</td>
<td>14</td>
</tr>
<tr>
<td>Chirpy</td>
<td>1998-09-11</td>
<td>2003-08-19</td>
<td>4</td>
</tr>
<tr>
<td>Claws</td>
<td>1994-03-17</td>
<td>2003-08-19</td>
<td>9</td>
</tr>
<tr>
<td>Fang</td>
<td>1990-08-27</td>
<td>2003-08-19</td>
<td>12</td>
</tr>
<tr>
<td>Fluffy</td>
<td>1993-02-04</td>
<td>2003-08-19</td>
<td>10</td>
</tr>
<tr>
<td>Puffball</td>
<td>1999-03-30</td>
<td>2003-08-19</td>
<td>4</td>
</tr>
<tr>
<td>Slim</td>
<td>1996-04-29</td>
<td>2003-08-19</td>
<td>7</td>
</tr>
<tr>
<td>Whistler</td>
<td>1997-12-09</td>
<td>2003-08-19</td>
<td>5</td>
</tr>
</tbody>
</table>
+----------+------------+------------+------+

To sort the output by `age` rather than `name`, just use a different `ORDER BY` clause:

mysql> SELECT name, birth, CURDATE(),
   ->_TIMESTAMPDIFF(YEAR,birth,CURDATE()) AS age
   -> FROM pet ORDER BY age;

+----------+------------+------------+------+
<table>
<thead>
<tr>
<th>name</th>
<th>birth</th>
<th>CURDATE()</th>
<th>age</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chirpy</td>
<td>1998-09-11</td>
<td>2003-08-19</td>
<td>4</td>
</tr>
<tr>
<td>Puffball</td>
<td>1999-03-30</td>
<td>2003-08-19</td>
<td>4</td>
</tr>
<tr>
<td>Whistler</td>
<td>1997-12-09</td>
<td>2003-08-19</td>
<td>5</td>
</tr>
<tr>
<td>Slim</td>
<td>1996-04-29</td>
<td>2003-08-19</td>
<td>7</td>
</tr>
<tr>
<td>Claws</td>
<td>1994-03-17</td>
<td>2003-08-19</td>
<td>9</td>
</tr>
<tr>
<td>Fluffy</td>
<td>1993-02-04</td>
<td>2003-08-19</td>
<td>10</td>
</tr>
<tr>
<td>Fang</td>
<td>1990-08-27</td>
<td>2003-08-19</td>
<td>12</td>
</tr>
<tr>
<td>Bowser</td>
<td>1989-08-31</td>
<td>2003-08-19</td>
<td>13</td>
</tr>
<tr>
<td>Buffy</td>
<td>1989-05-13</td>
<td>2003-08-19</td>
<td>14</td>
</tr>
</tbody>
</table>
+----------+------------+------------+------+

A similar query can be used to determine age at death for animals that have died. You determine which animals these are by checking whether the `death` value is `NULL`. Then, for those with non-`NULL` values, compute the difference between the `death` and `birth` values:

mysql> SELECT name, birth, death,
   ->_TIMESTAMPDIFF(YEAR,birth,death) AS age
   -> FROM pet WHERE death IS NOT NULL ORDER BY age;
Retrieving Information from a Table

<table>
<thead>
<tr>
<th>name</th>
<th>birth</th>
<th>death</th>
<th>age</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bowser</td>
<td>1989-08-31</td>
<td>1995-07-29</td>
<td>5</td>
</tr>
</tbody>
</table>

The query uses `death IS NOT NULL` rather than `death <> NULL` because NULL is a special value that cannot be compared using the usual comparison operators. This is discussed later. See Section 3.3.4.6, “Working with NULL Values”.

What if you want to know which animals have birthdays next month? For this type of calculation, year and day are irrelevant; you simply want to extract the month part of the `birth` column. MySQL provides several functions for extracting parts of dates, such as `YEAR()`, `MONTH()`, and `DAYOFMONTH()`. `MONTH()` is the appropriate function here. To see how it works, run a simple query that displays the value of both `birth` and `MONTH(birth)`:

```sql
mysql> SELECT name, birth, MONTH(birth) FROM pet;
```

<table>
<thead>
<tr>
<th>name</th>
<th>birth</th>
<th>MONTH(birth)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fluffy</td>
<td>1993-02-04</td>
<td>2</td>
</tr>
<tr>
<td>Claws</td>
<td>1994-03-17</td>
<td>3</td>
</tr>
<tr>
<td>Buffy</td>
<td>1989-05-13</td>
<td>5</td>
</tr>
<tr>
<td>Fang</td>
<td>1990-08-27</td>
<td>8</td>
</tr>
<tr>
<td>Bowser</td>
<td>1989-08-31</td>
<td>8</td>
</tr>
<tr>
<td>Chirpy</td>
<td>1998-09-11</td>
<td>9</td>
</tr>
<tr>
<td>Whistler</td>
<td>1997-12-09</td>
<td>12</td>
</tr>
<tr>
<td>Slim</td>
<td>1996-04-29</td>
<td>4</td>
</tr>
<tr>
<td>Puffball</td>
<td>1999-03-30</td>
<td>3</td>
</tr>
</tbody>
</table>

Finding animals with birthdays in the upcoming month is also simple. Suppose that the current month is April. Then the month value is 4 and you can look for animals born in May (month 5) like this:

```sql
mysql> SELECT name, birth FROM pet WHERE MONTH(birth) = 5;
```

```
<table>
<thead>
<tr>
<th>name</th>
<th>birth</th>
</tr>
</thead>
<tbody>
<tr>
<td>Buffy</td>
<td>1989-05-13</td>
</tr>
</tbody>
</table>
```

There is a small complication if the current month is December. You cannot merely add one to the month number (12) and look for animals born in month 13, because there is no such month. Instead, you look for animals born in January (month 1).

You can write the query so that it works no matter what the current month is, so that you do not have to use the number for a particular month. `DATE_ADD()` enables you to add a time interval to a given date. If you add a month to the value of `CURDATE()`, then extract the month part with `MONTH()`, the result produces the month in which to look for birthdays:

```sql
mysql> SELECT name, birth FROM pet
    -> WHERE MONTH(birth) = MONTH(DATE_ADD(CURDATE(), INTERVAL 1 MONTH));
```

A different way to accomplish the same task is to add 1 to get the next month after the current one after using the modulo function (`MOD`) to wrap the month value to 0 if it is currently 12:

```sql
mysql> SELECT name, birth FROM pet
    -> WHERE MONTH(birth) = MOD(MONTH(CURDATE()), 12) + 1;
```
MONTH() returns a number between 1 and 12. And MOD(something,12) returns a number between 0 and 11. So the addition has to be after the MOD(), otherwise we would go from November (11) to January (1).

3.3.4.6 Working with NULL Values

The NULL value can be surprising until you get used to it. Conceptually, NULL means “a missing unknown value” and it is treated somewhat differently from other values.

To test for NULL, use the IS NULL and IS NOT NULL operators, as shown here:

```
mysql> SELECT 1 IS NULL, 1 IS NOT NULL;
+-----------+---------------+
| 1 IS NULL | 1 IS NOT NULL |
+-----------+---------------+
|         0 |             1 |
+-----------+---------------+
```

You cannot use arithmetic comparison operators such as =, <, or <> to test for NULL. To demonstrate this for yourself, try the following query:

```
mysql> SELECT 1 = NULL, 1 <> NULL, 1 < NULL, 1 > NULL;
+----------+-----------+----------+----------+
| 1 = NULL | 1 <> NULL | 1 < NULL | 1 > NULL |
+----------+-----------+----------+----------+
|     NULL |      NULL |     NULL |     NULL |
+----------+-----------+----------+----------+
```

Because the result of any arithmetic comparison with NULL is also NULL, you cannot obtain any meaningful results from such comparisons.

In MySQL, 0 or NULL means false and anything else means true. The default truth value from a boolean operation is 1.

This special treatment of NULL is why, in the previous section, it was necessary to determine which animals are no longer alive using death IS NOT NULL instead of death <> NULL.

Two NULL values are regarded as equal in a GROUP BY.

When doing an ORDER BY, NULL values are presented first if you do ORDER BY ... ASC and last if you do ORDER BY ... DESC.

A common error when working with NULL is to assume that it is not possible to insert a zero or an empty string into a column defined as NOT NULL, but this is not the case. These are in fact values, whereas NULL means “not having a value.” You can test this easily enough by using IS [NOT] NULL as shown:

```
mysql> SELECT 0 IS NULL, 0 IS NOT NULL, '' IS NULL, '' IS NOT NULL;
+-----------+---------------+------------+----------------+
| 0 IS NULL | 0 IS NOT NULL | '' IS NULL | '' IS NOT NULL |
+-----------+---------------+------------+----------------+
|         0 |             1 |          0 |              1 |
+-----------+---------------+------------+----------------+
```

Thus it is entirely possible to insert a zero or empty string into a NOT NULL column, as these are in fact NOT NULL. See Section B.5.5.3, “Problems with NULL Values”.

3.3.4.7 Pattern Matching
MySQL provides standard SQL pattern matching as well as a form of pattern matching based on extended regular expressions similar to those used by Unix utilities such as \texttt{vi}, \texttt{grep}, and \texttt{sed}.

SQL pattern matching enables you to use \texttt{"_"} to match any single character and \texttt{"%"} to match an arbitrary number of characters (including zero characters). In MySQL, SQL patterns are case-insensitive by default. Some examples are shown here. You do not use \texttt{=} or \texttt{<>} when you use SQL patterns; use the \texttt{LIKE} or \texttt{NOT LIKE} comparison operators instead.

To find names beginning with \texttt{"b"}:

\begin{verbatim}
mysql> SELECT * FROM pet WHERE name LIKE 'b%';
+--------+--------+---------+------+------------+------------+
| name   | owner  | species | sex  | birth      | death      |
+--------+--------+---------+------+------------+------------+
| Buffy  | Harold | dog     | f    | 1989-05-13 | NULL       |
| Bowser | Diane  | dog     | m    | 1989-08-31 | 1995-07-29 |
+--------+--------+---------+------+------------+------------+
\end{verbatim}

To find names ending with \texttt{"fy"}:

\begin{verbatim}
mysql> SELECT * FROM pet WHERE name LIKE '%fy';
+--------+--------+---------+------+------------+-------+
| name   | owner  | species | sex  | birth      | death |
+--------+--------+---------+------+------------+-------+
| Fluffy | Harold | cat     | f    | 1993-02-04 | NULL  |
| Buffy  | Harold | dog     | f    | 1989-05-13 | NULL  |
+--------+--------+---------+------+------------+-------+
\end{verbatim}

To find names containing a \texttt{"w"}:

\begin{verbatim}
mysql> SELECT * FROM pet WHERE name LIKE '%w%';
+----------+-------+---------+------+------------+------------+
| name     | owner | species | sex  | birth      | death      |
+----------+-------+---------+------+------------+------------+
| Claws    | Gwen  | cat     | m    | 1994-03-17 | NULL       |
| Bowser   | Diane | dog     | m    | 1989-08-31 | 1995-07-29 |
| Whistler | Gwen  | bird    | NULL | 1997-12-09 | NULL       |
+----------+-------+---------+------+------------+------------+
\end{verbatim}

To find names containing exactly five characters, use five instances of the \texttt{"_"} pattern character:

\begin{verbatim}
mysql> SELECT * FROM pet WHERE name LIKE '_____';
+-------+--------+---------+------+------------+-------+
| name  | owner  | species | sex  | birth      | death |
+-------+--------+---------+------+------------+-------+
| Claws | Gwen   | cat     | m    | 1994-03-17 | NULL  |
| Buffy | Harold | dog     | f    | 1989-05-13 | NULL  |
+-------+--------+---------+------+------------+-------+
\end{verbatim}

The other type of pattern matching provided by MySQL uses extended regular expressions. When you test for a match for this type of pattern, use the \texttt{REGEXP} and \texttt{NOT REGEXP} operators (or \texttt{RLIKE} and \texttt{NOT RLIKE}, which are synonyms).

The following list describes some characteristics of extended regular expressions:

- \texttt{\textasciitilde} matches any single character.
- A character class \texttt{\{[\ldots]\}} matches any character within the brackets. For example, \texttt{\{[abc]\}} matches \texttt{a}, \texttt{b}, or \texttt{c}. To name a range of characters, use a dash. \texttt{\{[a-z]\}} matches any letter, whereas \texttt{\{[0–9]\}} matches any digit.
• “*” matches zero or more instances of the thing preceding it. For example, “x*” matches any number of “x” characters, “[0-9]***” matches any number of digits, and “.*” matches any number of anything.

• A REGEXP pattern match succeeds if the pattern matches anywhere in the value being tested. (This differs from a LIKE pattern match, which succeeds only if the pattern matches the entire value.)

• To anchor a pattern so that it must match the beginning or end of the value being tested, use “^” at the beginning or “$” at the end of the pattern.

To demonstrate how extended regular expressions work, the LIKE queries shown previously are rewritten here to use REGEXP.

To find names beginning with “b”, use “^” to match the beginning of the name:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^b';
+--------+--------+---------+------+------------+------------+
| name   | owner  | species | sex  | birth      | death      |
+--------+--------+---------+------+------------+------------+
| Buffy  | Harold | dog     | f    | 1989-05-13 | NULL       |
| Bowser | Diane  | dog     | m    | 1989-08-31 | 1995-07-29 |
+--------+--------+---------+------+------------+------------+
```

If you really want to force a REGEXP comparison to be case sensitive, use the BINARY keyword to make one of the strings a binary string. This query matches only lowercase “b” at the beginning of a name:

```
mysql> SELECT * FROM pet WHERE name REGEXP BINARY '^b';
```

To find names ending with “fy”, use “$” to match the end of the name:

```
mysql> SELECT * FROM pet WHERE name REGEXP 'fy$';
+--------+--------+---------+------+------------+-------+
| name   | owner  | species | sex  | birth      | death |
+--------+--------+---------+------+------------+-------+
| Fluffy | Harold | cat     | f    | 1993-02-04 | NULL  |
| Buffy  | Harold | dog     | f    | 1989-05-13 | NULL  |
+--------+--------+---------+------+------------+-------+
```

To find names containing a “w”, use this query:

```
mysql> SELECT * FROM pet WHERE name REGEXP 'w';
+----------+-------+---------+------+------------+------------+
| name     | owner | species | sex  | birth      | death      |
+----------+-------+---------+------+------------+------------+
| Claws    | Gwen  | cat     | m    | 1994-03-17 | NULL       |
| Bowser   | Diane | dog     | m    | 1989-08-31 | 1995-07-29 |
| Whistler | Gwen  | bird    | NULL | 1997-12-09 | NULL       |
+----------+-------+---------+------+------------+------------+
```

Because a regular expression pattern matches if it occurs anywhere in the value, it is not necessary in the previous query to put a wildcard on either side of the pattern to get it to match the entire value like it would be if you used an SQL pattern.

To find names containing exactly five characters, use “^” and “$” to match the beginning and end of the name, and five instances of “.” in between:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^.....$';
```
You could also write the previous query using the \( n \) ("repeat-\( n \)-times") operator:

```sql
mysql> SELECT * FROM pet WHERE name REGEXP '^.{5}$';
```

You could also write the previous query using the \( n \) ("repeat-\( n \)-times") operator:

```sql
mysql> SELECT * FROM pet WHERE name REGEXP '^.{5}$';
```

---

**3.3.4.8 Counting Rows**

Databases are often used to answer the question, “How often does a certain type of data occur in a table?” For example, you might want to know how many pets you have, or how many pets each owner has, or you might want to perform various kinds of census operations on your animals.

Counting the total number of animals you have is the same question as “How many rows are in the `pet` table?” because there is one record per pet. `COUNT(*)` counts the number of rows, so the query to count your animals looks like this:

```sql
mysql> SELECT COUNT(*) FROM pet;
```

```
+----------+
| COUNT(*) |
+----------+
|        9 |
+----------+
```

Earlier, you retrieved the names of the people who owned pets. You can use `COUNT()` if you want to find out how many pets each owner has:

```sql
mysql> SELECT owner, COUNT(*) FROM pet GROUP BY owner;
```

```
+--------+----------+
| owner  | COUNT(*) |
+--------+----------+
| Benny  |        2 |
| Diane  |        2 |
| Gwen   |        3 |
| Harold |        2 |
+--------+----------+
```

The preceding query uses `GROUP BY` to group all records for each `owner`. The use of `COUNT()` in conjunction with `GROUP BY` is useful for characterizing your data under various groupings. The following examples show different ways to perform animal census operations.

**Number of animals per species:**

```sql
mysql> SELECT species, COUNT(*) FROM pet GROUP BY species;
```

```
+---------+----------+
| species | COUNT(*) |
+---------+----------+
| bird    |        2 |
| cat     |        2 |
+---------+----------+
```
Retrieving Information from a Table

Number of animals per sex:

```
mysql> SELECT sex, COUNT(*) FROM pet GROUP BY sex;
```

```
+------+----------+
<table>
<thead>
<tr>
<th>sex</th>
<th>COUNT(*)</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
<td>1</td>
</tr>
<tr>
<td>f</td>
<td>4</td>
</tr>
<tr>
<td>m</td>
<td>4</td>
</tr>
</tbody>
</table>
+------+----------+
```

(In this output, `NULL` indicates that the sex is unknown.)

Number of animals per combination of species and sex:

```
mysql> SELECT species, sex, COUNT(*) FROM pet GROUP BY species, sex;
```

```
+---------+------+----------+
<table>
<thead>
<tr>
<th>species</th>
<th>sex</th>
<th>COUNT(*)</th>
</tr>
</thead>
<tbody>
<tr>
<td>bird</td>
<td>NULL</td>
<td>1</td>
</tr>
<tr>
<td>bird</td>
<td>f</td>
<td>1</td>
</tr>
<tr>
<td>cat</td>
<td>f</td>
<td>1</td>
</tr>
<tr>
<td>cat</td>
<td>m</td>
<td>1</td>
</tr>
<tr>
<td>dog</td>
<td>f</td>
<td>1</td>
</tr>
<tr>
<td>dog</td>
<td>m</td>
<td>2</td>
</tr>
<tr>
<td>hamster</td>
<td>f</td>
<td>1</td>
</tr>
<tr>
<td>snake</td>
<td>m</td>
<td>1</td>
</tr>
</tbody>
</table>
+---------+------+----------+
```

You need not retrieve an entire table when you use `COUNT(*)`. For example, the previous query, when performed just on dogs and cats, looks like this:

```
mysql> SELECT species, sex, COUNT(*) FROM pet
    -> WHERE species = 'dog' OR species = 'cat'
    -> GROUP BY species, sex;
```

```
+---------+------+----------+
<table>
<thead>
<tr>
<th>species</th>
<th>sex</th>
<th>COUNT(*)</th>
</tr>
</thead>
<tbody>
<tr>
<td>cat</td>
<td>f</td>
<td>1</td>
</tr>
<tr>
<td>cat</td>
<td>m</td>
<td>1</td>
</tr>
<tr>
<td>dog</td>
<td>f</td>
<td>1</td>
</tr>
<tr>
<td>dog</td>
<td>m</td>
<td>2</td>
</tr>
</tbody>
</table>
+---------+------+----------+
```

Or, if you wanted the number of animals per sex only for animals whose sex is known:

```
mysql> SELECT species, sex, COUNT(*) FROM pet
    -> WHERE sex IS NOT NULL
    -> GROUP BY species, sex;
```

```
+---------+------+----------+
<table>
<thead>
<tr>
<th>species</th>
<th>sex</th>
<th>COUNT(*)</th>
</tr>
</thead>
<tbody>
<tr>
<td>bird</td>
<td>f</td>
<td>1</td>
</tr>
<tr>
<td>cat</td>
<td>f</td>
<td>1</td>
</tr>
<tr>
<td>cat</td>
<td>m</td>
<td>1</td>
</tr>
<tr>
<td>dog</td>
<td>f</td>
<td>1</td>
</tr>
<tr>
<td>dog</td>
<td>m</td>
<td>2</td>
</tr>
</tbody>
</table>
+---------+------+----------+
```
Retrieving Information from a Table

<table>
<thead>
<tr>
<th>hamster</th>
<th>f</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>snake</td>
<td>m</td>
<td>1</td>
</tr>
</tbody>
</table>

If you name columns to select in addition to the `COUNT()` value, a `GROUP BY` clause should be present that names those same columns. Otherwise, the following occurs:

- If the `ONLY_FULL_GROUP_BY` SQL mode is enabled, an error occurs:

```
mysql> SET sql_mode = 'ONLY_FULL_GROUP_BY';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT owner, COUNT(*) FROM pet;
ERROR 1140 (42000): Mixing of GROUP columns (MIN(),MAX(),COUNT())...
with no GROUP columns is illegal if there is no GROUP BY clause
```

- If `ONLY_FULL_GROUP_BY` is not enabled, the query is processed by treating all rows as a single group, but the value selected for each named column is indeterminate. The server is free to select the value from any row:

```
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT owner, COUNT(*) FROM pet;
+--------+----------+
<table>
<thead>
<tr>
<th>owner</th>
<th>COUNT(*)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Harold</td>
<td>8</td>
</tr>
</tbody>
</table>
+--------+----------+
1 row in set (0.00 sec)
```

See also Section 12.16.3, “MySQL Extensions to `GROUP BY`”.

### 3.3.4.9 Using More Than One Table

The `pet` table keeps track of which pets you have. If you want to record other information about them, such as events in their lives like visits to the vet or when litters are born, you need another table. What should this table look like? It needs to contain the following information:

- The pet name so that you know which animal each event pertains to.
- A date so that you know when the event occurred.
- A field to describe the event.
- An event type field, if you want to be able to categorize events.

Given these considerations, the `CREATE TABLE` statement for the `event` table might look like this:

```
mysql> CREATE TABLE event (name VARCHAR(20), date DATE, type VARCHAR(15), remark VARCHAR(255));
```

As with the `pet` table, it is easiest to load the initial records by creating a tab-delimited text file containing the following information.

<table>
<thead>
<tr>
<th>name</th>
<th>date</th>
<th>type</th>
<th>remark</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fluffy</td>
<td>1995-05-15</td>
<td>litter</td>
<td>4 kittens, 3 female, 1 male</td>
</tr>
<tr>
<td>Buffy</td>
<td>1993-06-23</td>
<td>litter</td>
<td>5 puppies, 2 female, 3 male</td>
</tr>
</tbody>
</table>
Retrieving Information from a Table

<table>
<thead>
<tr>
<th>name</th>
<th>date</th>
<th>type</th>
<th>remark</th>
</tr>
</thead>
<tbody>
<tr>
<td>Buffy</td>
<td>1994-06-19</td>
<td>litter</td>
<td>3 puppies, 3 female</td>
</tr>
<tr>
<td>Chirpy</td>
<td>1999-03-21</td>
<td>vet</td>
<td>needed beak straightened</td>
</tr>
<tr>
<td>Slim</td>
<td>1997-08-03</td>
<td>vet</td>
<td>broken rib</td>
</tr>
<tr>
<td>Bowser</td>
<td>1991-10-12</td>
<td>kennel</td>
<td></td>
</tr>
<tr>
<td>Fang</td>
<td>1991-10-12</td>
<td>kennel</td>
<td></td>
</tr>
<tr>
<td>Fang</td>
<td>1998-08-28</td>
<td>birthday</td>
<td>Gave him a new chew toy</td>
</tr>
<tr>
<td>Claws</td>
<td>1998-03-17</td>
<td>birthday</td>
<td>Gave him a new flea collar</td>
</tr>
<tr>
<td>Whistler</td>
<td>1998-12-09</td>
<td>birthday</td>
<td>First birthday</td>
</tr>
</tbody>
</table>

Load the records like this:

```sql
mysql> LOAD DATA LOCAL INFILE 'event.txt' INTO TABLE event;
```

Based on what you have learned from the queries that you have run on the pet table, you should be able to perform retrievals on the records in the event table; the principles are the same. But when is the event table by itself insufficient to answer questions you might ask?

Suppose that you want to find out the ages at which each pet had its litters. We saw earlier how to calculate ages from two dates. The litter date of the mother is in the event table, but to calculate her age on that date you need her birth date, which is stored in the pet table. This means the query requires both tables:

```sql
mysql> SELECT pet.name, 
            -> (YEAR(date) - YEAR(birth)) - (RIGHT(date, 5) < RIGHT(birth, 5)) AS age, 
            -> remark 
            -> FROM pet INNER JOIN event 
            -> ON pet.name = event.name 
            -> WHERE event.type = 'litter';
```

<table>
<thead>
<tr>
<th>name</th>
<th>age</th>
<th>remark</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fluffy</td>
<td>2</td>
<td>4 kittens, 3 female, 1 male</td>
</tr>
<tr>
<td>Buffy</td>
<td>4</td>
<td>5 puppies, 2 female, 3 male</td>
</tr>
<tr>
<td>Buffy</td>
<td>5</td>
<td>3 puppies, 3 female</td>
</tr>
</tbody>
</table>

There are several things to note about this query:

- The FROM clause joins two tables because the query needs to pull information from both of them.

- When combining (joining) information from multiple tables, you need to specify how records in one table can be matched to records in the other. This is easy because they both have a name column. The query uses an ON clause to match up records in the two tables based on the name values.

The query uses an INNER JOIN to combine the tables. An INNER JOIN permits rows from either table to appear in the result if and only if both tables meet the conditions specified in the ON clause. In this example, the ON clause specifies that the name column in the pet table must match the name column in the event table. If a name appears in one table but not the other, the row will not appear in the result because the condition in the ON clause fails.

- Because the name column occurs in both tables, you must be specific about which table you mean when referring to the column. This is done by prepending the table name to the column name.
You need not have two different tables to perform a join. Sometimes it is useful to join a table to itself, if you want to compare records in a table to other records in that same table. For example, to find breeding pairs among your pets, you can join the pet table with itself to produce candidate pairs of males and females of like species:

```sql
mysql> SELECT p1.name, p1.sex, p2.name, p2.sex, p1.species
        -> FROM pet AS p1 INNER JOIN pet AS p2
        -> ON p1.species = p2.species AND p1.sex = 'f' AND p2.sex = 'm';
+--------+------+--------+------+---------+
| name   | sex  | name   | sex  | species |
+--------+------+--------+------+---------+
| Fluffy | f    | Claws  | m    | cat     |
| Buffy  | f    | Fang   | m    | dog     |
| Buffy  | f    | Bowser | m    | dog     |
+--------+------+--------+------+---------+
```

In this query, we specify aliases for the table name to refer to the columns and keep straight which instance of the table each column reference is associated with.

### 3.4 Getting Information About Databases and Tables

What if you forget the name of a database or table, or what the structure of a given table is (for example, what its columns are called)? MySQL addresses this problem through several statements that provide information about the databases and tables it supports.

You have previously seen `SHOW DATABASES`, which lists the databases managed by the server. To find out which database is currently selected, use the `DATABASE()` function:

```sql
mysql> SELECT DATABASE();
+------------+
| DATABASE() |
+------------+
| menagerie  |
+------------+
```

If you have not yet selected any database, the result is `NULL`.

To find out what tables the default database contains (for example, when you are not sure about the name of a table), use this command:

```sql
mysql> SHOW TABLES;
+---------------------+
| Tables_in_menagerie |
| event               |
| pet                 |
+---------------------+
```

The name of the column in the output produced by this statement is always `Tables_in_db_name`, where `db_name` is the name of the database. See Section 13.7.5.38, "SHOW TABLES Syntax", for more information.

If you want to find out about the structure of a table, the `DESCRIBE` statement is useful; it displays information about each of a table’s columns:

```sql
mysql> DESCRIBE pet;
+---------+-------------+------+-----+---------+-------+
| name    | sex         | name  | sex | species |
+---------+-------------+-------+-----+---------+-------+
| Fluffy  | f           | Claws | m   | cat     |
| Buffy   | f           | Fang  | m   | dog     |
| Buffy   | f           | Bowser| m   | dog     |
+---------+-------------+-------+-----+---------+-------+
```
### Using `mysql` in Batch Mode

In the previous sections, you used `mysql` interactively to enter queries and view the results. You can also run `mysql` in batch mode. To do this, put the commands you want to run in a file, then tell `mysql` to read its input from the file:

```
shell> mysql < batch-file
```

If you are running `mysql` under Windows and have some special characters in the file that cause problems, you can do this:

```
C:\> mysql -e "source batch-file"
```

If you need to specify connection parameters on the command line, the command might look like this:

```
shell> mysql -h host -u user -p < batch-file
Enter password: *******
```

When you use `mysql` this way, you are creating a script file, then executing the script.

If you want the script to continue even if some of the statements in it produce errors, you should use the `--force` command-line option.

**Why use a script?** Here are a few reasons:

- If you run a query repeatedly (say, every day or every week), making it a script enables you to avoid retyping it each time you execute it.
- You can generate new queries from existing ones that are similar by copying and editing script files.
- Batch mode can also be useful while you're developing a query, particularly for multiple-line commands or multiple-statement sequences of commands. If you make a mistake, you don't have to retype everything. Just edit your script to correct the error, then tell `mysql` to execute it again.
Examples of Common Queries

- If you have a query that produces a lot of output, you can run the output through a pager rather than watching it scroll off the top of your screen:

  ```shell
  mysql < batch-file | more
  ```

- You can catch the output in a file for further processing:

  ```shell
  mysql < batch-file > mysql.out
  ```

- You can distribute your script to other people so that they can also run the commands.

- Some situations do not allow for interactive use, for example, when you run a query from a **cron** job. In this case, you must use batch mode.

The default output format is different (more concise) when you run **mysql** in batch mode than when you use it interactively. For example, the output of **SELECT DISTINCT species FROM pet** looks like this when **mysql** is run interactively:

```
+---------+
| species |
+---------+
| bird    |
| cat     |
| dog     |
| hamster |
| snake   |
```

In batch mode, the output looks like this instead:

```
species
bird
cat
dog
hamster
snake
```

If you want to get the interactive output format in batch mode, use **mysql -t**. To echo to the output the commands that are executed, use **mysql -vvv**.

You can also use scripts from the **mysql** prompt by using the **source** command or **.** command:

```
mysql> source filename;
mysql> . filename
```

See Section 4.5.1.5, “Executing SQL Statements from a Text File”, for more information.

### 3.6 Examples of Common Queries

Here are examples of how to solve some common problems with MySQL.

Some of the examples use the table **shop** to hold the price of each article (item number) for certain traders (dealers). Supposing that each trader has a single fixed price per article, then **(article, dealer)** is a primary key for the records.

Start the command-line tool **mysql** and select a database:
You can create and populate the example table with these statements:

```sql
CREATE TABLE shop (
  article INT(4) UNSIGNED ZEROFILL DEFAULT '0000' NOT NULL,
  dealer CHAR(20)                 DEFAULT ''     NOT NULL,
  price   DOUBLE(16,2)             DEFAULT '0.00' NOT NULL,
  PRIMARY KEY(article, dealer));
```

```sql
INSERT INTO shop VALUES
(1,'A',3.45),(1,'B',3.99),(2,'A',10.99),(3,'B',1.45),
(3,'C',1.69),(3,'D',1.25),(4,'D',19.95);
```

After issuing the statements, the table should have the following contents:

```sql
+---------+--------+-------+
| article | dealer | price |
+---------+--------+-------+
|    0001 | A      |  3.45 |
|    0001 | B      |  3.99 |
|    0002 | A      | 10.99 |
|    0003 | B      |  1.45 |
|    0003 | C      |  1.69 |
|    0003 | D      |  1.25 |
|    0004 | D      | 19.95 |
```

### 3.6.1 The Maximum Value for a Column

“What is the highest item number?”

```sql
SELECT MAX(article) AS article FROM shop;
```

```sql
+---------+
| article |
+---------+
|       4 |
```

### 3.6.2 The Row Holding the Maximum of a Certain Column

**Task:** Find the number, dealer, and price of the most expensive article.

This is easily done with a subquery:

```sql
SELECT article, dealer, price
FROM   shop
WHERE  price=(SELECT MAX(price) FROM shop);
```

```sql
+---------+--------+-------+
| article | dealer | price |
+---------+--------+-------+
|    0004 | D      | 19.95 |
```

245
Other solutions are to use a `LEFT JOIN` or to sort all rows descending by price and get only the first row using the MySQL-specific `LIMIT` clause:

```sql
SELECT s1.article, s1.dealer, s1.price
FROM shop s1
LEFT JOIN shop s2 ON s1.price < s2.price
WHERE s2.article IS NULL;
```

```sql
SELECT article, dealer, price
FROM shop
ORDER BY price DESC
LIMIT 1;
```

**Note**
If there were several most expensive articles, each with a price of 19.95, the `LIMIT` solution would show only one of them.

### 3.6.3 Maximum of Column per Group

**Task:** Find the highest price per article.

```sql
SELECT article, MAX(price) AS price
FROM shop
GROUP BY article;
```

<table>
<thead>
<tr>
<th>article</th>
<th>price</th>
</tr>
</thead>
<tbody>
<tr>
<td>0001</td>
<td>3.99</td>
</tr>
<tr>
<td>0002</td>
<td>10.99</td>
</tr>
<tr>
<td>0003</td>
<td>1.69</td>
</tr>
<tr>
<td>0004</td>
<td>19.95</td>
</tr>
</tbody>
</table>

### 3.6.4 The Rows Holding the Group-wise Maximum of a Certain Column

**Task:** For each article, find the dealer or dealers with the most expensive price.

This problem can be solved with a subquery like this one:

```sql
SELECT article, dealer, price
FROM shop s1
WHERE price=(SELECT MAX(s2.price)
    FROM shop s2
    WHERE s1.article = s2.article);
```

```
<table>
<thead>
<tr>
<th>article</th>
<th>dealer</th>
<th>price</th>
</tr>
</thead>
<tbody>
<tr>
<td>0001</td>
<td>B</td>
<td>3.99</td>
</tr>
<tr>
<td>0002</td>
<td>A</td>
<td>10.99</td>
</tr>
<tr>
<td>0003</td>
<td>C</td>
<td>1.69</td>
</tr>
<tr>
<td>0004</td>
<td>D</td>
<td>19.95</td>
</tr>
</tbody>
</table>
```

The preceding example uses a correlated subquery, which can be inefficient (see Section 13.2.10.7, "Correlated Subqueries"). Other possibilities for solving the problem are to use an uncorrelated subquery in the `FROM` clause or a `LEFT JOIN`. 

246
3.6.5 Using User-Defined Variables

You can employ MySQL user variables to remember results without having to store them in temporary variables in the client. (See Section 9.4, “User-Defined Variables”.)

For example, to find the articles with the highest and lowest price you can do this:

```sql
mysql> SELECT @min_price:=MIN(price),@max_price:=MAX(price) FROM shop;
mysql> SELECT * FROM shop WHERE price=@min_price OR price=@max_price;
```

<table>
<thead>
<tr>
<th>article</th>
<th>dealer</th>
<th>price</th>
</tr>
</thead>
<tbody>
<tr>
<td>0003</td>
<td>D</td>
<td>1.25</td>
</tr>
<tr>
<td>0004</td>
<td>D</td>
<td>19.95</td>
</tr>
</tbody>
</table>

Note

It is also possible to store the name of a database object such as a table or a column in a user variable and then to use this variable in an SQL statement; however, this requires the use of a prepared statement. See Section 13.5, “SQL Syntax for Prepared Statements”, for more information.

3.6.6 Using Foreign Keys

In MySQL, InnoDB tables support checking of foreign key constraints. See Chapter 14, The InnoDB Storage Engine, and Section 1.8.2.4, “Foreign Key Differences”.

A foreign key constraint is not required merely to join two tables. For storage engines other than InnoDB, it is possible when defining a column to use a REFERENCES tbl_name(col_name) clause, which has no actual effect, and serves only as a memo or comment to you that the column which you are currently defining is intended to refer to a column in another table. It is extremely important to realize when using this syntax that:

- MySQL does not perform any sort of CHECK to make sure that col_name actually exists in tbl_name (or even that tbl_name itself exists).
• MySQL does not perform any sort of action on tbl_name such as deleting rows in response to actions taken on rows in the table which you are defining; in other words, this syntax induces no ON DELETE or ON UPDATE behavior whatsoever. (Although you can write an ON DELETE or ON UPDATE clause as part of the REFERENCES clause, it is also ignored.)

• This syntax creates a column; it does not create any sort of index or key.

You can use a column so created as a join column, as shown here:

```sql
CREATE TABLE person (  
id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,  
name CHAR(60) NOT NULL,  
PRIMARY KEY (id)
);

CREATE TABLE shirt (  
id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,  
style ENUM('t-shirt', 'polo', 'dress') NOT NULL,  
color ENUM('red', 'blue', 'orange', 'white', 'black') NOT NULL,  
owner SMALLINT UNSIGNED NOT NULL REFERENCES person(id),  
PRIMARY KEY (id)
);

INSERT INTO person VALUES (NULL, 'Antonio Paz');
SELECT @last := LAST_INSERT_ID();
INSERT INTO shirt VALUES  
(NULL, 'polo', 'blue', @last),  
(NULL, 'dress', 'white', @last),  
(NULL, 't-shirt', 'blue', @last);

INSERT INTO person VALUES (NULL, 'Lilliana Angelovska');
SELECT @last := LAST_INSERT_ID();
INSERT INTO shirt VALUES  
(NULL, 'dress', 'orange', @last),  
(NULL, 'polo', 'red', @last),  
(NULL, 'dress', 'blue', @last),  
(NULL, 't-shirt', 'white', @last);

SELECT * FROM person;
  +----+---------------------+  
  | id | name                +----+---------------------+  
  +----+---------------------+ 1 | Antonio Paz          +----+---------------------+  
  | 1 | Antonio Paz         +----+---------------------+ 2 | Lilliana Angelovska  
  +----+---------------------+  

SELECT * FROM shirt;
  +----+---------+--------+-------+  
  | id | style   | color  | owner |  +----+---------+--------+-------+  
  | 1 | polo    | blue   | 1     | 2 | dress  | white  | 1     | 3 | t-shirt | blue   | 1     | 4 | dress  | orange | 2     | 5 | polo   | red    | 2     | 6 | dress  | blue   | 2     | 7 | t-shirt | white  | 2     |  

SELECT s.* FROM person p INNER JOIN shirt s
```
3.6.7 Searching on Two Keys

An OR using a single key is well optimized, as is the handling of AND.

The one tricky case is that of searching on two different keys combined with OR:

```
SELECT field1_index, field2_index FROM test_table
WHERE field1_index = '1' OR field2_index = '1'
```

This case is optimized. See Section 8.2.1.4, “Index Merge Optimization”.

You can also solve the problem efficiently by using a UNION that combines the output of two separate SELECT statements. See Section 13.2.9.4, “UNION Syntax”.

Each SELECT searches only one key and can be optimized:

```
SELECT field1_index, field2_index
FROM test_table WHERE field1_index = '1'
UNION
SELECT field1_index, field2_index
FROM test_table WHERE field2_index = '1';
```

3.6.8 Calculating Visits Per Day

The following example shows how you can use the bit group functions to calculate the number of days per month a user has visited a Web page.

```
CREATE TABLE t1 (year YEAR(4), month INT(2) UNSIGNED ZEROFILL,
                 day INT(2) UNSIGNED ZEROFILL);
INSERT INTO t1 VALUES(2000,1,1),(2000,1,20),(2000,1,30),(2000,2,2),
```
The example table contains year-month-day values representing visits by users to the page. To determine how many different days in each month these visits occur, use this query:

```sql
SELECT year, month, BIT_COUNT(BIT_OR(1<<day)) AS days FROM t1 GROUP BY year, month;
```

Which returns:

<table>
<thead>
<tr>
<th>year</th>
<th>month</th>
<th>days</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000</td>
<td>01</td>
<td>3</td>
</tr>
<tr>
<td>2000</td>
<td>02</td>
<td>2</td>
</tr>
</tbody>
</table>

The query calculates how many different days appear in the table for each year/month combination, with automatic removal of duplicate entries.

### 3.6.9 Using **AUTO_INCREMENT**

The `AUTO_INCREMENT` attribute can be used to generate a unique identity for new rows:

```sql
CREATE TABLE animals (
    id MEDIUMINT NOT NULL AUTO_INCREMENT,
    name CHAR(30) NOT NULL,
    PRIMARY KEY (id)
);

INSERT INTO animals (name) VALUES
    ('dog'),('cat'),('penguin'),
    ('lax'),('whale'),('ostrich');

SELECT * FROM animals;
```

Which returns:

<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>dog</td>
</tr>
<tr>
<td>2</td>
<td>cat</td>
</tr>
<tr>
<td>3</td>
<td>penguin</td>
</tr>
<tr>
<td>4</td>
<td>lax</td>
</tr>
<tr>
<td>5</td>
<td>whale</td>
</tr>
<tr>
<td>6</td>
<td>ostrich</td>
</tr>
</tbody>
</table>

No value was specified for the `AUTO_INCREMENT` column, so MySQL assigned sequence numbers automatically. You can also explicitly assign 0 to the column to generate sequence numbers. If the column is declared `NOT NULL`, it is also possible to assign `NULL` to the column to generate sequence numbers.

You can retrieve the most recent `AUTO_INCREMENT` value with the `LAST_INSERT_ID()` SQL function or the `mysql_insert_id()` C API function. These functions are connection-specific, so their return values are not affected by another connection which is also performing inserts.

Use the smallest integer data type for the `AUTO_INCREMENT` column that is large enough to hold the maximum sequence value you will need. When the column reaches the upper limit of the data type, the
next attempt to generate a sequence number fails. Use the `UNSIGNED` attribute if possible to allow a
greater range. For example, if you use `TINYINT`, the maximum permissible sequence number is 127. For
`TINYINT UN unsigned`, the maximum is 255. See Section 11.2.1, “Integer Types (Exact Value) - INTEGER,
INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT” for the ranges of all the integer types.

Note

For a multiple-row insert, `LAST_INSERT_ID()` and `mysql_insert_id()` actually return the `AUTO_INCREMENT` key from the first of the inserted rows. This enables multiple-row inserts to be reproduced correctly on other servers in a replication setup.

To start with an `AUTO_INCREMENT` value other than 1, set that value with `CREATE TABLE` or `ALTER TABLE`, like this:

```sql
mysql> ALTER TABLE tbl AUTO_INCREMENT = 100;
```

**InnoDB Notes**

For InnoDB tables, be careful if you modify the column containing the auto-increment value in the middle of a sequence of `INSERT` statements. For example, if you use an `UPDATE` statement to put a new, larger value in the auto-increment column, a subsequent `INSERT` could encounter a “Duplicate entry” error. The test whether an auto-increment value is already present occurs if you do a `DELETE` followed by more `INSERT` statements, or when you `COMMIT` the transaction, but not after an `UPDATE` statement.

**MyISAM Notes**

- For MyISAM tables, you can specify `AUTO_INCREMENT` on a secondary column in a multiple-column index. In this case, the generated value for the `AUTO_INCREMENT` column is calculated as `MAX(auto_increment_column) + 1 WHERE prefix=given-prefix`. This is useful when you want to put data into ordered groups.

```sql
CREATE TABLE animals (  
  grp ENUM('fish','mammal','bird') NOT NULL,  
  id MEDIUMINT NOT NULL AUTO_INCREMENT,  
  name CHAR(30) NOT NULL,  
  PRIMARY KEY (grp,id)  
) ENGINE=MyISAM;

INSERT INTO animals (grp,name) VALUES  
  ("mammal","dog"),("mammal","cat"),  
  ("bird","penguin"),("fish","lax"),("mammal","whale"),  
  ("bird","ostrich");

SELECT * FROM animals ORDER BY grp,id;
```

Which returns:

```none
+--------+----+---------+
| grp    | id | name    |
|--------+----+---------|
| fish   |  1 | lax     |
| mammal |  1 | dog     |
| mammal |  2 | cat     |
| mammal |  3 | whale   |
| bird   |  1 | penguin |
| bird   |  2 | ostrich |
```

---

251
In this case (when the `AUTO_INCREMENT` column is part of a multiple-column index), `AUTO_INCREMENT` values are reused if you delete the row with the biggest `AUTO_INCREMENT` value in any group. This happens even for `MyISAM` tables, for which `AUTO_INCREMENT` values normally are not reused.

- If the `AUTO_INCREMENT` column is part of multiple indexes, MySQL generates sequence values using the index that begins with the `AUTO_INCREMENT` column, if there is one. For example, if the `animals` table contained indexes `PRIMARY KEY (grp, id)` and `INDEX (id)`, MySQL would ignore the `PRIMARY KEY` for generating sequence values. As a result, the table would contain a single sequence, not a sequence per `grp` value.

**Further Reading**

More information about `AUTO_INCREMENT` is available here:

- How to assign the `AUTO_INCREMENT` attribute to a column: Section 13.1.17, "CREATE TABLE Syntax", and Section 13.1.7, "ALTER TABLE Syntax".

- How `AUTO_INCREMENT` behaves depending on the `NO_AUTO_VALUE_ON_ZERO` SQL mode: Section 5.1.7, "Server SQL Modes".

- How to use the `LAST_INSERT_ID()` function to find the row that contains the most recent `AUTO_INCREMENT` value: Section 12.14, "Information Functions".

- Setting the `AUTO_INCREMENT` value to be used: Section 5.1.4, "Server System Variables".

- `AUTO_INCREMENT` and replication: Section 17.4.1.1, "Replication and `AUTO_INCREMENT`".

- Server-system variables related to `AUTO_INCREMENT` (auto_increment_increment and auto_increment_offset) that can be used for replication: Section 5.1.4, "Server System Variables".

### 3.7 Using MySQL with Apache

There are programs that let you authenticate your users from a MySQL database and also let you write your log files into a MySQL table.

You can change the Apache logging format to be easily readable by MySQL by putting the following into the Apache configuration file:

```text
LogFormat "\"%h\",%{Y%m%d%H%M%S}t,%>s,"%b","%{Content-Type}o","%U","%{Referer}i","%{User-Agent}i\""
```

To load a log file in that format into MySQL, you can use a statement something like this:

```sql
LOAD DATA INFILE '/local/access_log' INTO TABLE tbl_name
FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"' ESCAPED BY '\'
```

The named table should be created to have columns that correspond to those that the `LogFormat` line writes to the log file.

4.1 Overview of MySQL Programs

There are many different programs in a MySQL installation. This section provides a brief overview of them. Later sections provide a more detailed description of each one, with the exception of MySQL Cluster programs. Each program's description indicates its invocation syntax and the options that it supports. Chapter 18, MySQL Cluster NDB 7.2, describes programs specific to MySQL Cluster.

Most MySQL distributions include all of these programs, except for those programs that are platform-specific. (For example, the server startup scripts are not used on Windows.) The exception is that RPM distributions are more specialized. There is one RPM for the server, another for client programs, and so forth. If you appear to be missing one or more programs, see Chapter 2, Installing and Upgrading MySQL, for information on types of distributions and what they contain. It may be that you have a distribution that does not include all programs and you need to install an additional package.

Each MySQL program takes many different options. Most programs provide a --help option that you can use to get a description of the program's different options. For example, try mysql --help.

You can override default option values for MySQL programs by specifying options on the command line or in an option file. See Section 4.2, "Using MySQL Programs", for general information on invoking programs and specifying program options.

The MySQL server, mysqld, is the main program that does most of the work in a MySQL installation. The server is accompanied by several related scripts that assist you in starting and stopping the server:

- **mysqld**
  
  The SQL daemon (that is, the MySQL server). To use client programs, mysqld must be running, because clients gain access to databases by connecting to the server. See Section 4.3.1, "mysqld — The MySQL Server".

- **mysqld_safe**
  
  A server startup script. mysqld_safe attempts to start mysqld. See Section 4.3.2, "mysqld_safe — MySQL Server Startup Script".

- **mysql.server**
  
  A server startup script. This script is used on systems that use System V-style run directories containing scripts that start system services for particular run levels. It invokes mysqld_safe to start the MySQL server. See Section 4.3.3, "mysql.server — MySQL Server Startup Script".
Overview of MySQL Programs

- **mysqld_multi**
  A server startup script that can start or stop multiple servers installed on the system. See Section 4.3.4, "mysqld_multi — Manage Multiple MySQL Servers".

Several programs perform setup operations during MySQL installation or upgrading:

- **comp_err**
  This program is used during the MySQL build/installation process. It compiles error message files from the error source files. See Section 4.4.1, "comp_err — Compile MySQL Error Message File".

- **mysql_install_db**
  This script creates the MySQL database and initializes the grant tables with default privileges. It is usually executed only once, when first installing MySQL on a system. See Section 4.4.3, "mysql_install_db — Initialize MySQL Data Directory", Section 2.10.1, "Postinstallation Procedures for Unix-like Systems", and Section 4.4.3, "mysql_install_db — Initialize MySQL Data Directory".

- **mysql_plugin**
  This program configures MySQL server plugins. See Section 4.4.4, "mysql_plugin — Configure MySQL Server Plugins".

- **mysql_secure_installation**
  This program enables you to improve the security of your MySQL installation. SQL. See Section 4.4.5, "mysql_secure_installation — Improve MySQL Installation Security".

- **mysql_tzinfo_to_sql**
  This program loads the time zone tables in the mysql database using the contents of the host system zoneinfo database (the set of files describing time zones). SQL. See Section 4.4.6, "mysql_tzinfo_to_sql — Load the Time Zone Tables".

- **mysql_upgrade**
  This program is used after a MySQL upgrade operation. It checks tables for incompatibilities and repairs them if necessary, and updates the grant tables with any changes that have been made in newer versions of MySQL. See Section 4.4.7, "mysql_upgrade — Check and Upgrade MySQL Tables".

MySQL client programs that connect to the MySQL server:

- **mysql**
  The command-line tool for interactively entering SQL statements or executing them from a file in batch mode. See Section 4.5.1, "mysql — The MySQL Command-Line Tool".

- **mysqladmin**
  A client that performs administrative operations, such as creating or dropping databases, reloading the grant tables, flushing tables to disk, and reopening log files. mysqladmin can also be used to retrieve version, process, and status information from the server. See Section 4.5.2, "mysqladmin — Client for Administering a MySQL Server".

- **mysqlcheck**
  A table-maintenance client that checks, repairs, analyzes, and optimizes tables. See Section 4.5.3, "mysqlcheck — A Table Maintenance Program".
Overview of MySQL Programs

- **mysqldump**
  A client that dumps a MySQL database into a file as SQL, text, or XML. See Section 4.5.4, "mysqldump — A Database Backup Program".

- **mysqlimport**
  A client that imports text files into their respective tables using `LOAD DATA INFILE`. See Section 4.5.5, "mysqlimport — A Data Import Program".

- **mysqlshow**
  A client that displays information about databases, tables, columns, and indexes. See Section 4.5.6, "mysqlshow — Display Database, Table, and Column Information".

- **mysqlslap**
  A client that is designed to emulate client load for a MySQL server and report the timing of each stage. It works as if multiple clients are accessing the server. See Section 4.5.7, "mysqlslap — Load Emulation Client".

MySQL administrative and utility programs:

- **innochecksum**
  An offline InnoDB offline file checksum utility. See Section 4.6.1, "innochecksum — Offline InnoDB File Checksum Utility".

- **myisam_ftdump**
  A utility that displays information about full-text indexes in MyISAM tables. See Section 4.6.2, "myisam_ftdump — Display Full-Text Index information".

- **myisamchk**
  A utility to describe, check, optimize, and repair MyISAM tables. See Section 4.6.3, "myisamchk — MyISAM Table-Maintenance Utility".

- **myisamlog**
  A utility that processes the contents of a MyISAM log file. See Section 4.6.4, "myisamlog — Display MyISAM Log File Contents".

- **myisampack**
  A utility that compresses MyISAM tables to produce smaller read-only tables. See Section 4.6.5, "myisampack — Generate Compressed, Read-Only MyISAM Tables".

- **mysqlaccess**
  A script that checks the access privileges for a host name, user name, and database combination. See Section 4.6.6, "mysqlaccess — Client for Checking Access Privileges".

- **mysqlbinlog**
  A utility for reading statements from a binary log. The log of executed statements contained in the binary log files can be used to help recover from a crash. See Section 4.6.7, "mysqlbinlog — Utility for Processing Binary Log Files".
• **mysqldumpslow**

  A utility to read and summarize the contents of a slow query log. See Section 4.6.8, "mysqldumpslow — Summarize Slow Query Log Files".

• **mysqlhotcopy**

  A utility that quickly makes backups of MyISAM tables while the server is running. See Section 4.6.9, "mysqlhotcopy — A Database Backup Program".

• **mysql_convert_table_format**

  A utility that converts tables in a database to use a given storage engine. See Section 4.6.10, "mysql_convert_table_format — Convert Tables to Use a Given Storage Engine".

• **mysql_find_rows**

  A utility that reads files containing SQL statements (such as update logs) and extracts statements that match a given regular expression. See Section 4.6.11, "mysql_find_rows — Extract SQL Statements from Files".

• **mysql_fix_extensions**

  A utility that converts the extensions for MyISAM table files to lowercase. This can be useful after transferring the files from a system with case-insensitive file names to a system with case-sensitive file names. See Section 4.6.12, "mysql_fix_extensions — Normalize Table File Name Extensions".

• **mysql_setpermission**

  A utility for interactively setting permissions in the MySQL grant tables. See Section 4.6.13, "mysql_setpermission — Interactively Set Permissions in Grant Tables".

• **mysql_waitpid**

  A utility that kills the process with a given process ID. See Section 4.6.14, "mysql_waitpid — Kill Process and Wait for Its Termination".

• **mysql_zap**

  A utility that kills processes that match a pattern. See Section 4.6.15, "mysql_zap — Kill Processes That Match a Pattern".

MySQL program-development utilities:

• **msql2mysql**

  A shell script that converts mSQL programs to MySQL. It doesn't handle every case, but it gives a good start when converting. See Section 4.7.1, "msql2mysql — Convert mSQL Programs for Use with MySQL".

• **mysql_config**

  A shell script that produces the option values needed when compiling MySQL programs. See Section 4.7.2, "mysql_config — Display Options for Compiling Clients".

• **my_print_defaults**

  A utility that shows which options are present in option groups of option files. See Section 4.7.3, "my_print_defaults — Display Options from Option Files".
Using MySQL Programs

• **resolve_stack_dump**
  
  A utility program that resolves a numeric stack trace dump to symbols. See Section 4.7.4, "resolve_stack_dump — Resolve Numeric Stack Trace Dump to Symbols".

Miscellaneous utilities:

• **perror**
  
  A utility that displays the meaning of system or MySQL error codes. See Section 4.8.1, "perror — Explain Error Codes".

• **replace**
  
  A utility program that performs string replacement in the input text. See Section 4.8.2, "replace — A String-Replacement Utility".

• **resolveip**
  
  A utility program that resolves a host name to an IP address or vice versa. See Section 4.8.3, "resolveip — Resolve Host name to IP Address or Vice Versa".

Oracle Corporation also provides the MySQL Workbench GUI tool, which is used to administer MySQL servers and databases, to create, execute, and evaluate queries, and to migrate schemas and data from other relational database management systems for use with MySQL. Additional GUI tools include MySQL Notifier for Microsoft Windows MySQL for Excel.

MySQL client programs that communicate with the server using the MySQL client/server library use the following environment variables.

<table>
<thead>
<tr>
<th>Environment Variable</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>MYSQL_UNIX_PORT</td>
<td>The default Unix socket file; used for connections to localhost</td>
</tr>
<tr>
<td>MYSQL_TCP_PORT</td>
<td>The default port number; used for TCP/IP connections</td>
</tr>
<tr>
<td>MYSQL_PWD</td>
<td>The default password</td>
</tr>
<tr>
<td>MYSQL_DEBUG</td>
<td>Debug trace options when debugging</td>
</tr>
<tr>
<td>TMPDIR</td>
<td>The directory where temporary tables and files are created</td>
</tr>
</tbody>
</table>

For a full list of environment variables used by MySQL programs, see Section 2.12, “Environment Variables”.

Use of **MYSQL_PWD** is insecure. See Section 6.1.2.1, “End-User Guidelines for Password Security”.

### 4.2 Using MySQL Programs

#### 4.2.1 Invoking MySQL Programs

To invoke a MySQL program from the command line (that is, from your shell or command prompt), enter the program name followed by any options or other arguments needed to instruct the program what you want it to do. The following commands show some sample program invocations. "shell>" represents the prompt for your command interpreter; it is not part of what you type. The particular prompt you see depends on your command interpreter. Typical prompts are $ for sh, ksh, or bash, % for csh or tcsh, and C:> for the Windows command.com or cmd.exe command interpreters.

```
shell> mysql --user=root test
```
Connecting to the MySQL Server

Arguments that begin with a single or double dash ("--", "-"-"-) specify program options. Options typically indicate the type of connection a program should make to the server or affect its operational mode. Option syntax is described in Section 4.2.3, “Specifying Program Options”.

Nonoption arguments (arguments with no leading dash) provide additional information to the program. For example, the mysql program interprets the first nonoption argument as a database name, so the command mysql --user=root test indicates that you want to use the test database.

Later sections that describe individual programs indicate which options a program supports and describe the meaning of any additional nonoption arguments.

Some options are common to a number of programs. The most frequently used of these are the --host (or -h), --user (or -u), and --password (or -p) options that specify connection parameters. They indicate the host where the MySQL server is running, and the user name and password of your MySQL account. All MySQL client programs understand these options; they enable you to specify which server to connect to and the account to use on that server. Other connection options are --port (or -P) to specify a TCP/IP port number and --socket (or -S) to specify a Unix socket file on Unix (or named pipe name on Windows). For more information on options that specify connection options, see Section 4.2.2, “Connecting to the MySQL Server”.

You may find it necessary to invoke MySQL programs using the path name to the bin directory in which they are installed. This is likely to be the case if you get a “program not found” error whenever you attempt to run a MySQL program from any directory other than the bin directory. To make it more convenient to use MySQL, you can add the path name of the bin directory to your PATH environment variable setting. That enables you to run a program by typing only its name, not its entire path name. For example, if mysql is installed in /usr/local/mysql/bin, you can run the program by invoking it as mysql, and it is not necessary to invoke it as /usr/local/mysql/bin/mysql.

Consult the documentation for your command interpreter for instructions on setting your PATH variable. The syntax for setting environment variables is interpreter-specific. (Some information is given in Section 4.2.10, “Setting Environment Variables”.) After modifying your PATH setting, open a new console window on Windows or log in again on Unix so that the setting goes into effect.

4.2.2 Connecting to the MySQL Server

For a client program to be able to connect to the MySQL server, it must use the proper connection parameters, such as the name of the host where the server is running and the user name and password of your MySQL account. Each connection parameter has a default value, but you can override them as necessary using program options specified either on the command line or in an option file.

The examples here use the mysql client program, but the principles apply to other clients such as mysqldump, mysqladmin, or mysqlshow.

This command invokes mysql without specifying any connection parameters explicitly:

shell> mysql

Because there are no parameter options, the default values apply:

- The default host name is localhost. On Unix, this has a special meaning, as described later.
- The default user name is ODBC on Windows or your Unix login name on Unix.
• No password is sent if neither \texttt{-p} nor \texttt{--password} is given.

• For \texttt{mysql}, the first nonoption argument is taken as the name of the default database. If there is no such option, \texttt{mysql} does not select a default database.

To specify the host name and user name explicitly, as well as a password, supply appropriate options on the command line:

\begin{verbatim}
shell> mysql --host=localhost --user=myname --password=mypass mydb
shell> mysql -h localhost -u myname -pmypass mydb
\end{verbatim}

For password options, the password value is optional:

• If you use a \texttt{-p} or \texttt{--password} option and specify the password value, there must be \texttt{no space} between \texttt{-p} or \texttt{--password=} and the password following it.

• If you use a \texttt{-p} or \texttt{--password} option but do not specify the password value, the client program prompts you to enter the password. The password is not displayed as you enter it. This is more secure than giving the password on the command line. Other users on your system may be able to see a password specified on the command line by executing a command such as \texttt{ps auxw}. See Section 6.1.2.1, "End-User Guidelines for Password Security".

As just mentioned, including the password value on the command line can be a security risk. To avoid this problem, specify the \texttt{--password} or \texttt{-p} option without any following password value:

\begin{verbatim}
shell> mysql --host=localhost --user=myname --password mydb
shell> mysql -h localhost -u myname -p mydb
\end{verbatim}

When the password option has no password value, the client program prints a prompt and waits for you to enter the password. (In these examples, \texttt{mydb} is \texttt{not} interpreted as a password because it is separated from the preceding password option by a space.)

On some systems, the library routine that MySQL uses to prompt for a password automatically limits the password to eight characters. That is a problem with the system library, not with MySQL. Internally, MySQL does not have any limit for the length of the password. To work around the problem, change your MySQL password to a value that is eight or fewer characters long, or put your password in an option file.

On Unix, MySQL programs treat the host name \texttt{localhost} specially, in a way that is likely different from what you expect compared to other network-based programs. For connections to \texttt{localhost}, MySQL programs attempt to connect to the local server by using a Unix socket file. This occurs even if a \texttt{--port} or \texttt{-P} option is given to specify a port number. To ensure that the client makes a TCP/IP connection to the local server, use \texttt{--host} or \texttt{-h} to specify a host name value of \texttt{127.0.0.1}, or the IP address or name of the local server. You can also specify the connection protocol explicitly, even for \texttt{localhost}, by using the \texttt{--protocol=TCP} option. For example:

\begin{verbatim}
shell> mysql --host=127.0.0.1
shell> mysql --protocol=TCP
\end{verbatim}

The \texttt{--protocol} option enables you to establish a particular type of connection even when the other options would normally default to some other protocol.

If the server is configured to accept IPv6 connections, client can connect over IPv6 using \texttt{--host=::1}. See Section 5.1.9, “IPv6 Support”.

On Windows, you can force a MySQL client to use a named-pipe connection by specifying the \texttt{--pipe} or \texttt{--protocol=PIPE} option, or by specifying \texttt{.} (period) as the host name. If named-pipe connections are
not enabled, an error occurs. Use the --socket option to specify the name of the pipe if you do not want
to use the default pipe name.

Connections to remote servers always use TCP/IP. This command connects to the server running on
remote.example.com using the default port number (3306):

```
shell> mysql --host=remote.example.com
```

To specify a port number explicitly, use the --port or -P option:

```
shell> mysql --host=remote.example.com --port=13306
```

You can specify a port number for connections to a local server, too. However, as indicated previously,
connections to localhost on Unix will use a socket file by default. You will need to force a TCP/IP
connection as already described or any option that specifies a port number will be ignored.

For this command, the program uses a socket file on Unix and the --port option is ignored:

```
shell> mysql --port=13306 --host=localhost
```

To cause the port number to be used, invoke the program in either of these ways:

```
shell> mysql --port=13306 --host=127.0.0.1
shell> mysql --port=13306 --protocol=TCP
```

The following list summarizes the options that can be used to control how client programs connect to the
server:

- **--host=host_name, -h host_name**

  The host where the server is running. The default value is localhost.

- **--password=[=pass_val], -p[pass_val]**

  The password of the MySQL account. As described earlier, the password value is optional, but if given,
  there must be no space between -p or --password= and the password following it. The default is to
  send no password.

- **--pipe, -W**

  On Windows, connect to the server using a named pipe. The server must be started with the --enable-named-pipe option to enable named-pipe connections.

- **--port=port_num, -P port_num**

  The port number to use for the connection, for connections made using TCP/IP. The default port number
  is 3306.

- **--protocol={TCP|SOCKET|PIPE|MEMORY]**

  This option explicitly specifies a protocol to use for connecting to the server. It is useful when the other
  connection parameters normally would cause a protocol to be used other than the one you want. For
  example, connections on Unix to localhost are made using a Unix socket file by default:

```
shell> mysql --host=localhost
```
Connecting to the MySQL Server

To force a TCP/IP connection to be used instead, specify a `--protocol` option:

```
shell> mysql --host=localhost --protocol=TCP
```

The following table shows the permissible `--protocol` option values and indicates the platforms on which each value may be used. The values are not case sensitive.

<table>
<thead>
<tr>
<th><code>--protocol</code> Value</th>
<th>Connection Protocol</th>
<th>Permissible Operating Systems</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>TCP/IP connection to local or remote server</td>
<td>All</td>
</tr>
<tr>
<td>SOCKET</td>
<td>Unix socket file connection to local server</td>
<td>Unix only</td>
</tr>
<tr>
<td>PIPE</td>
<td>Named-pipe connection to local or remote server</td>
<td>Windows only</td>
</tr>
<tr>
<td>MEMORY</td>
<td>Shared-memory connection to local server</td>
<td>Windows only</td>
</tr>
</tbody>
</table>

- `--shared-memory-base-name=name`

On Windows, the shared-memory name to use, for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case sensitive.

The server must be started with the `--shared-memory` option to enable shared-memory connections.

- `--socket=file_name, -S file_name`

On Unix, the name of the Unix socket file to use, for connections made using a named pipe to a local server. The default Unix socket file name is `/tmp/mysql.sock`.

On Windows, the name of the named pipe to use, for connections to a local server. The default Windows pipe name is `MySQL`. The pipe name is not case sensitive.

The server must be started with the `--enable-named-pipe` option to enable named-pipe connections.

- `--ssl*`

Options that begin with `--ssl` are used for establishing a secure connection to the server using SSL, if the server is configured with SSL support. For details, see Section 6.3.9.4, “SSL Command Options”.

- `--user=user_name, -u user_name`

The user name of the MySQL account you want to use. The default user name is `ODBC` on Windows or your Unix login name on Unix.

It is possible to specify different default values to be used when you make a connection so that you need not enter them on the command line each time you invoke a client program. This can be done in a couple of ways:

- You can specify connection parameters in the [client] section of an option file. The relevant section of the file might look like this:

  ```
  [client]
  host=host_name
  user=user_name
  password=your_pass
  ```

  Section 4.2.6, “Using Option Files”, discusses option files further.
You can specify some connection parameters using environment variables. The host can be specified for `mysql` using `MYSQL_HOST`. The MySQL user name can be specified using `USER` (this is for Windows only). The password can be specified using `MYSQL_PWD`, although this is insecure; see Section 6.1.2.1, “End-User Guidelines for Password Security”. For a list of variables, see Section 2.12, “Environment Variables”.

### 4.2.3 Specifying Program Options

There are several ways to specify options for MySQL programs:

- List the options on the command line following the program name. This is common for options that apply to a specific invocation of the program.

- List the options in an option file that the program reads when it starts. This is common for options that you want the program to use each time it runs.

- List the options in environment variables (see Section 4.2.10, “Setting Environment Variables”). This method is useful for options that you want to apply each time the program runs. In practice, option files are used more commonly for this purpose, but Section 5.3.3, “Running Multiple MySQL Instances on Unix”, discusses one situation in which environment variables can be very helpful. It describes a handy technique that uses such variables to specify the TCP/IP port number and Unix socket file for the server and for client programs.

Options are processed in order, so if an option is specified multiple times, the last occurrence takes precedence. The following command causes `mysql` to connect to the server running on `localhost`:

```
shell> mysql -h example.com -h localhost
```

If conflicting or related options are given, later options take precedence over earlier options. The following command runs `mysql` in “no column names” mode:

```
shell> mysql --column-names --skip-column-names
```

MySQL programs determine which options are given first by examining environment variables, then by reading option files, and then by checking the command line. This means that environment variables have the lowest precedence and command-line options the highest.

You can take advantage of the way that MySQL programs process options by specifying default option values for a program in an option file. That enables you to avoid typing them each time you run the program while enabling you to override the defaults if necessary by using command-line options.

An option can be specified by writing it in full or as any unambiguous prefix. For example, the `--compress` option can be given to `mysqldump` as `--compr`, but not as `--comp` because the latter is ambiguous:

```
shell> mysqldump --comp
mysqldump: ambiguous option '--comp' (compatible, compress)
```

Be aware that the use of option prefixes can cause problems in the event that new options are implemented for a program. A prefix that is unambiguous now might become ambiguous in the future.

**Note**

As of MySQL 5.5.33, unambiguous prefixes are deprecated. If an unambiguous prefix is given, a warning occurs to provide feedback. Option prefixes are no longer supported in MySQL 5.7; only full options are accepted.
4.2.4 Using Options on the Command Line

Program options specified on the command line follow these rules:

- Options are given after the command name.

- An option argument begins with one dash or two dashes, depending on whether it is a short form or long form of the option name. Many options have both short and long forms. For example, \(-?\) and \(--\text{help}\) are the short and long forms of the option that instructs a MySQL program to display its help message.

- Option names are case sensitive. \(-v\) and \(-V\) are both legal and have different meanings. (They are the corresponding short forms of the \(--\text{verbose}\) and \(--\text{version}\) options.)

- Some options take a value following the option name. For example, \(-h\ \text{localhost}\) or \(--\text{host=localhost}\) indicate the MySQL server host to a client program. The option value tells the program the name of the host where the MySQL server is running.

- For a long option that takes a value, separate the option name and the value by an “=” sign. For a short option that takes a value, the option value can immediately follow the option letter, or there can be a space between: \(-h\ \text{localhost}\) and \(-h\ \text{ localhost}\) are equivalent. An exception to this rule is the option for specifying your MySQL password. This option can be given in long form as \(--\text{password=pass_val}\) or as \(--\text{password}\). In the latter case (with no password value given), the program prompts you for the password. The password option also may be given in short form as \(-p\ \text{pass_val}\) or as \(-p\). However, for the short form, if the password value is given, it must follow the option letter with \textit{no intervening space}. The reason for this is that if a space follows the option letter, the program has no way to tell whether a following argument is supposed to be the password value or some other kind of argument. Consequently, the following two commands have two completely different meanings:

```shell
shell> mysql -ptest
shell> mysql -p test
```

The first command instructs \texttt{mysql} to use a password value of \texttt{test}, but specifies no default database. The second instructs \texttt{mysql} to prompt for the password value and to use \texttt{test} as the default database.

- Within option names, dash (\texttt{–}) and underscore (\texttt{_}) may be used interchangeably. For example, \(--\text{skip-grant-tables}\) and \(--\text{skip_grant_tables}\) are equivalent. (However, the leading dashes cannot be given as underscores.)

- For options that take a numeric value, the value can be given with a suffix of \texttt{K}, \texttt{M}, or \texttt{G} (either uppercase or lowercase) to indicate a multiplier of 1024, 1024² or 1024³. For example, the following command tells \texttt{mysqladmin} to ping the server 1024 times, sleeping 10 seconds between each ping:

```mysql
mysql> mysqladmin --count=1K --sleep=10 ping
```

Option values that contain spaces must be quoted when given on the command line. For example, the \(--\text{execute}\) (or \(-e\)) option can be used with \texttt{mysql} to pass SQL statements to the server. When this option is used, \texttt{mysql} executes the statements in the option value and exits. The statements must be enclosed by quotation marks. For example, you can use the following command to obtain a list of user accounts:

```mysql
mysql> mysql -u root -p --execute="SELECT User, Host FROM mysql.user"
Enter password: ******
<table>
<thead>
<tr>
<th>User</th>
<th>Host</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>gigan</td>
</tr>
</tbody>
</table>
```
Note that the long form (\texttt{--execute}) is followed by an equal sign (\texttt{=}).

If you wish to use quoted values within a statement, you will either need to escape the inner quotation marks, or use a different type of quotation marks within the statement from those used to quote the statement itself. The capabilities of your command processor dictate your choices for whether you can use single or double quotation marks and the syntax for escaping quote characters. For example, if your command processor supports quoting with single or double quotation marks, you can use double quotation marks around the statement, and single quotation marks for any quoted values within the statement.

Multiple SQL statements may be passed in the option value on the command line, separated by semicolons:

```
shell> mysql -u root -p -e "SELECT VERSION();SELECT NOW()"
```

```
Enter password: ******
```

```
+-----------------+
| VERSION()       |
+-----------------+
| 5.1.5-alpha-log |
+-----------------+

```
| NOW()               |
+---------------------+
| 2006-01-05 21:19:04 |
+---------------------+
```

### 4.2.5 Program Option Modifiers

Some options are “boolean” and control behavior that can be turned on or off. For example, the \texttt{mysql} client supports a \texttt{--column-names} option that determines whether or not to display a row of column names at the beginning of query results. By default, this option is enabled. However, you may want to disable it in some instances, such as when sending the output of \texttt{mysql} into another program that expects to see only data and not an initial header line.

To disable column names, you can specify the option using any of these forms:

- \texttt{--disable-column-names}
- \texttt{--skip-column-names}
- \texttt{--column-names=0}

The \texttt{--disable} and \texttt{--skip} prefixes and the \texttt{=0} suffix all have the same effect: They turn the option off.

The “enabled” form of the option may be specified in any of these ways:

- \texttt{--column-names}
- \texttt{--enable-column-names}
- \texttt{--column-names=1}

As of MySQL 5.5.10, the values \texttt{ON}, \texttt{TRUE}, \texttt{OFF}, and \texttt{FALSE} are also recognized for boolean options (not case sensitive).

If an option is prefixed by \texttt{--loose}, a program does not exit with an error if it does not recognize the option, but instead issues only a warning:
Using Option Files

The --loose prefix can be useful when you run programs from multiple installations of MySQL on the same machine and list options in an option file. An option that may not be recognized by all versions of a program can be given using the --loose prefix (or loose in an option file). Versions of the program that recognize the option process it normally, and versions that do not recognize it issue a warning and ignore it.

mysqlld enables a limit to be placed on how large client programs can set dynamic system variables. To do this, use a --maximum prefix with the variable name. For example, --maximum-query_cache_size=4M prevents any client from making the query cache size larger than 4MB.

4.2.6 Using Option Files

Most MySQL programs can read startup options from option files (also sometimes called configuration files). Option files provide a convenient way to specify commonly used options so that they need not be entered on the command line each time you run a program. For the MySQL server, MySQL provides a number of preconfigured option files.

To determine whether a program reads option files, invoke it with the --help option. (For mysqld, use --verbose and --help.) If the program reads option files, the help message indicates which files it looks for and which option groups it recognizes.

Note
Option files used with MySQL Cluster programs are covered in Section 18.3, “Configuration of MySQL Cluster NDB 7.2”.

On Windows, MySQL programs read startup options from the following files, in the specified order (top items are used first).

<table>
<thead>
<tr>
<th>File Name</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>%PROGRAMDATA%\MySQL\MySQL Server5.5\my.ini, %PROGRAMDATA%\MySQL\MySQL Server5.5\my.cnf</td>
<td>Global options</td>
</tr>
<tr>
<td>%WINDIR%\my.ini, %WINDIR%\my.cnf</td>
<td>Global options</td>
</tr>
<tr>
<td>C:\my.ini, C:\my.cnf</td>
<td>Global options</td>
</tr>
<tr>
<td>INSTALLDIR\my.ini, INSTALLDIR\my.cnf</td>
<td>Global options</td>
</tr>
<tr>
<td>defaults-extra-file</td>
<td>The file specified with --defaults-extra-file=path, if any</td>
</tr>
</tbody>
</table>

%PROGRAMDATA% represents the file system directory that contains application data for all users on the host. This path defaults to C:\ProgramData on Microsoft Windows Vista and greater, and C:\Documents and Settings\All Users\Application Data on older versions of Microsoft Windows.

%WINDIR% represents the location of your Windows directory. This is commonly C:\WINDOWS. You can determine its exact location from the value of the WINDIR environment variable using the following command:

```bash
shell> mysql --loose-no-such-option
mysql: WARNING: unknown option '--no-such-option'
```
Using Option Files

C:\> echo \WINDIR\

INSTALLDIR represents the MySQL installation directory. This is typically `C:\PROGRAMDIR\MySQL \MySQL 5.5 Server` where PROGRAMDIR represents the programs directory (usually `Program Files` on English-language versions of Windows), when MySQL 5.5 has been installed using the installation and configuration wizards. See Section 2.3.3, “Installing MySQL on Microsoft Windows Using MySQL Installer”.

On Unix, Linux and Mac OS X, MySQL programs read startup options from the following files, in the specified order (top items are used first).

<table>
<thead>
<tr>
<th>File Name</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>/etc/my.cnf</td>
<td>Global options</td>
</tr>
<tr>
<td>/etc/mysql/my.cnf</td>
<td>Global options</td>
</tr>
<tr>
<td>SYSCONFDIR/my.cnf</td>
<td>Global options</td>
</tr>
<tr>
<td>$MYSQL_HOME/my.cnf</td>
<td>Server-specific options</td>
</tr>
<tr>
<td>defaults-extra-file</td>
<td>The file specified with <code>--defaults-extra-file=path</code>, if any</td>
</tr>
<tr>
<td>~/.my.cnf</td>
<td>User-specific options</td>
</tr>
</tbody>
</table>

~ represents the current user's home directory (the value of `$HOME`).

SYSCONFDIR represents the directory specified with the `SYSCONFDIR` option to CMake when MySQL was built. By default, this is the `etc` directory located under the compiled-in installation directory.

MYSQL_HOME is an environment variable containing the path to the directory in which the server-specific `my.cnf` file resides. If `MYSQL_HOME` is not set and you start the server using the `mysqld_safe` program, `mysqld_safe` attempts to set `MYSQL_HOME` as follows:

- Let `BASEDIR` and `DATADIR` represent the path names of the MySQL base directory and data directory, respectively.
- If there is a `my.cnf` file in `DATADIR` but not in `BASEDIR`, `mysqld_safe` sets `MYSQL_HOME` to `DATADIR`.
- Otherwise, if `MYSQL_HOME` is not set and there is no `my.cnf` file in `DATADIR`, `mysqld_safe` sets `MYSQL_HOME` to `BASEDIR`.

In MySQL 5.5, use of `DATADIR` as the location for `my.cnf` is deprecated.

Typically, `DATADIR` is `/usr/local/mysql/data` for a binary installation or `/usr/local/var` for a source installation. Note that this is the data directory location that was specified at configuration time, not the one specified with the `--datadir` option when `mysqld` starts. Use of `--datadir` at runtime has no effect on where the server looks for option files, because it looks for them before processing any options.

MySQL looks for option files in the order just described and reads any that exist. If an option file that you want to use does not exist, create it with a plain text editor.

If multiple instances of a given option are found, the last instance takes precedence. There is one exception: For `mysqld`, the first instance of the `--user` option is used as a security precaution, to prevent a user specified in an option file from being overridden on the command line.

**Note**

On Unix platforms, MySQL ignores configuration files that are world-writable. This is intentional as a security measure.
Any long option that may be given on the command line when running a MySQL program can be given in an option file as well. To get the list of available options for a program, run it with the --help option.

The syntax for specifying options in an option file is similar to command-line syntax (see Section 4.2.4, “Using Options on the Command Line”). However, in an option file, you omit the leading two dashes from the option name and you specify only one option per line. For example, --quick and --host=localhost on the command line should be specified as quick and host=localhost on separate lines in an option file. To specify an option of the form --loose-opt_name in an option file, write it as loose-opt_name.

Empty lines in option files are ignored. Nonempty lines can take any of the following forms:

- #comment, ;comment
  Comment lines start with “#” or “;”. A “#” comment can start in the middle of a line as well.

- [group]
  group is the name of the program or group for which you want to set options. After a group line, any option-setting lines apply to the named group until the end of the option file or another group line is given. Option group names are not case sensitive.

- opt_name
  This is equivalent to --opt_name on the command line.

- opt_name=value
  This is equivalent to --opt_name=value on the command line. In an option file, you can have spaces around the “=” character, something that is not true on the command line. You can optionally enclose the value within single quotation marks or double quotation marks, which is useful if the value contains a “#” comment character.

Leading and trailing spaces are automatically deleted from option names and values.

You can use the escape sequences “\b”, “\t”, “\n”, “\r”, “\", and “\s” in option values to represent the backspace, tab, newline, carriage return, backslash, and space characters. The escaping rules in option files are:

- If a backslash is followed by a valid escape sequence character, the sequence is converted to the character represented by the sequence. For example, “\s” is converted to a space.

- If a backslash is not followed by a valid escape sequence character, it remains unchanged. For example, “\S” is retained as is.

The preceding rules mean that a literal backslash can be given as “\”, or as “\” if it is not followed by a valid escape sequence character.

The rules for escape sequences in option files differ slightly from the rules for escape sequences in string literals in SQL statements. In the latter context, if “x” is not a valid escape sequence character, “\x” becomes “x” rather than “\x”. See Section 9.1.1, “String Literals”.

The escaping rules for option file values are especially pertinent for Windows path names, which use “\” as a path name separator. A separator in a Windows path name must be written as “\” if it is followed by an escape sequence character. It can be written as “\\” or “\" if it is not. Alternatively, “/” may be used in Windows path names and will be treated as “/”. Suppose that you want to specify a base directory of C:\Program Files\MySQL\MySQL Server 5.5 in an option file. This can be done several ways. Some examples:
Using Option Files

If an option group name is the same as a program name, options in the group apply specifically to that program. For example, the [mysqld] and [mysql] groups apply to the mysqld server and the mysql client program, respectively.

The [client] option group is read by all client programs (but not by mysqld). This enables you to specify options that apply to all clients. For example, [client] is the perfect group to use to specify the password that you use to connect to the server. (But make sure that the option file is readable and writable only by yourself, so that other people cannot find out your password.) Be sure not to put an option in the [client] group unless it is recognized by all client programs that you use. Programs that do not understand the option quit after displaying an error message if you try to run them.

Here is a typical global option file:

```ini
[client]
port=3306
socket=/tmp/mysql.sock

[mysqld]
port=3306
socket=/tmp/mysql.sock
key_buffer_size=16M
max_allowed_packet=8M

[mysqldump]
quick
```

The preceding option file uses var_name=value syntax for the lines that set the key_buffer_size and max_allowed_packet variables.

Here is a typical user option file:

```ini
[client]
# The following password will be sent to all standard MySQL clients
password="my_password"

[mysql]
o-auto-rehash
connect_timeout=2

[mysqlhotcopy]
interactive-timeout
```

If you want to create option groups that should be read by mysqld servers from a specific MySQL release series only, you can do this by using groups with names of [mysqld-5.1], [mysqld-5.5], and so forth. The following group indicates that the --new option should be used only by MySQL servers with 5.5.x version numbers:

```ini
[mysqld-5.5]
new
```

It is possible to use !include directives in option files to include other option files and !includedir to search specific directories for option files. For example, to include the /home/mydir/myopt.cnf file, use the following directive:
![include /home/mydir/myopt.cnf]

To search the /home/mydir directory and read option files found there, use this directive:

![includedir /home/mydir]

There is no guarantee about the order in which the option files in the directory will be read.

**Note**
Currently, any files to be found and included using the ![includedir] directive on Unix operating systems *must* have file names ending in .cnf. On Windows, this directive checks for files with the .ini or .cnf extension.

Write the contents of an included option file like any other option file. That is, it should contain groups of options, each preceded by a [group] line that indicates the program to which the options apply.

While an included file is being processed, only those options in groups that the current program is looking for are used. Other groups are ignored. Suppose that a my.cnf file contains this line:

![include /home/mydir/myopt.cnf]

And suppose that /home/mydir/myopt.cnf looks like this:

```plaintext
[mysqld]
force

[key_buffer_size=16M]
```

If my.cnf is processed by mysqld, only the [mysqld] group in /home/mydir/myopt.cnf is used. If the file is processed by mysqladmin, only the [mysqladmin] group is used. If the file is processed by any other program, no options in /home/mydir/myopt.cnf are used.

The ![includedir] directive is processed similarly except that all option files in the named directory are read.

### 4.2.7 Command-Line Options that Affect Option-File Handling

Most MySQL programs that support option files handle the following options. They affect option-file handling, so they must be given on the command line and not in an option file. To work properly, each of these options must be given before other options, with these exceptions:

- **--print-defaults** may be used immediately after **--defaults-file** or **--defaults-extra-file**.

- On Windows, if the server is started with the **--defaults-file** and **--install** options, **--install** must be first. See [Section 2.3.7.7, “Starting MySQL as a Windows Service”](#).

When specifying file names, you should avoid the use of the “~” shell metacharacter because it might not be interpreted as you expect.

- **--defaults-extra-file=file_name**

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, file_name must be the full
Using Options to Set Program Variables

path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- `-defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, `file_name` must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- `-defaults-group-suffix=string`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, the `mysql` client normally reads the `[client]` and `[mysql]` groups. If the `-defaults-group-suffix=_other` option is given, `mysql` also reads the `[client_other]` and `[mysql_other]` groups.

- `-no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `-no-defaults` can be used to prevent them from being read.

- `-print-defaults`

Print the program name and all options that it gets from option files.

4.2.8 Using Options to Set Program Variables

Many MySQL programs have internal variables that can be set at runtime using the `SET` statement. See Section 13.7.4, "SET Syntax", and Section 5.1.5, "Using System Variables".

Most of these program variables also can be set at server startup by using the same syntax that applies to specifying program options. For example, `mysql` has a `max_allowed_packet` variable that controls the maximum size of its communication buffer. To set the `max_allowed_packet` variable for `mysql` to a value of 16MB, use either of the following commands:

```
shell> mysql --max_allowed_packet=16777216
shell> mysql --max_allowed_packet=16M
```

The first command specifies the value in bytes. The second specifies the value in megabytes. For variables that take a numeric value, the value can be given with a suffix of `K`, `M`, or `G` (either uppercase or lowercase) to indicate a multiplier of 1024, 1024² or 1024³. (For example, when used to set `max_allowed_packet`, the suffixes indicate units of kilobytes, megabytes, or gigabytes.)

In an option file, variable settings are given without the leading dashes:

```
[mysql]
max_allowed_packet=16777216
```

Or:

```
[mysql]
max_allowed_packet=16M
```

If you like, underscores in a variable name can be specified as dashes. The following option groups are equivalent. Both set the size of the server's key buffer to 512MB:
A variable can be specified by writing it in full or as any unambiguous prefix. For example, the `max_allowed_packet` variable can be set for `mysql` as `--max_a`, but not as `--max` because the latter is ambiguous:

```
shell> mysql --max=1000000
mysql: ambiguous option '--max=1000000' (max_allowed_packet, max_join_size)
```

Be aware that the use of variable prefixes can cause problems in the event that new variables are implemented for a program. A prefix that is unambiguous now might become ambiguous in the future.

Suffixes for specifying a value multiplier can be used when setting a variable at server startup, but not to set the value with `SET` at runtime. On the other hand, with `SET` you can assign a variable's value using an expression, which is not true when you set a variable at server startup. For example, the first of the following lines is legal at server startup, but the second is not:

```
shell> mysql --max_allowed_packet=16M
shell> mysql --max_allowed_packet=16*1024*1024
```

Conversely, the second of the following lines is legal at runtime, but the first is not:

```
mysql> SET GLOBAL max_allowed_packet = 16M;
mysql> SET GLOBAL max_allowed_packet = 16*1024*1024;
```

### Note

Before MySQL 4.0.2, the only syntax for setting program variables was `--set-variable=option=value` (or `set-variable=option=value` in option files). Underscores cannot be given as dashes, and the variable name must be specified in full. This syntax is deprecated and was removed in MySQL 5.5.3.

### 4.2.9 Option Defaults, Options Expecting Values, and the = Sign

By convention, long forms of options that assign a value are written with an equals (=``) sign, like this:

```
shell> mysql --host=tonfisk --user=jon
```

For options that require a value (that is, not having a default value), the equal sign is not required, and so the following is also valid:

```
shell> mysql --host tonfisk --user jon
```

In both cases, the `mysql` client attempts to connect to a MySQL server running on the host named “tonfisk” using an account with the user name “jon”.

Due to this behavior, problems can occasionally arise when no value is provided for an option that expects one. Consider the following example, where a user connects to a MySQL server running on host `tonfisk` as user `jon`:
Option Defaults, Options Expecting Values, and the = Sign

shell> mysql --host 85.224.35.45 --user jon
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 3
Server version: 5.5.40 Source distribution
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT CURRENT_USER();
+----------------+
| CURRENT_USER() |
+----------------+
| jon@%          |
+----------------+
1 row in set (0.00 sec)

Omitting the required value for one of these option yields an error, such as the one shown here:

shell> mysql --host 85.224.35.45 --user
mysql: option '--user' requires an argument

In this case, mysql was unable to find a value following the --user option because nothing came after it on the command line. However, if you omit the value for an option that is not the last option to be used, you obtain a different error that you may not be expecting:

shell> mysql --host --user jon
ERROR 2005 (HY000): Unknown MySQL server host '--user' (1)

Because mysql assumes that any string following --host on the command line is a host name, --host --user is interpreted as --host=--user, and the client attempts to connect to a MySQL server running on a host named --user'.

Options having default values always require an equal sign when assigning a value; failing to do so causes an error. For example, the MySQL server --log-error option has the default value host_name.err, where host_name is the name of the host on which MySQL is running. Assume that you are running MySQL on a computer whose host name is "tonfisk", and consider the following invocation of mysqld_safe:

shell> mysqld_safe &
[1] 11699
shell> 080112 12:53:40 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080112 12:53:40 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
shell>

After shutting down the server, restart it as follows:

shell> mysqld_safe --log-error &
[1] 11699
shell> 080112 12:53:40 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080112 12:53:40 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
shell>

The result is the same, since --log-error is not followed by anything else on the command line, and it supplies its own default value. (The & character tells the operating system to run MySQL in the background; it is ignored by MySQL itself.) Now suppose that you wish to log errors to a file named my-errors.err. You might try starting the server with --log-error my-errors, but this does not have the intended effect, as shown here:

shell> mysqld_safe --log-error my-errors &
Option Defaults, Options Expecting Values, and the = Sign

The server attempted to start using `/usr/local/mysql/var/tonfisk.err` as the error log, but then shut down. Examining the last few lines of this file shows the reason:

```shell
tail /usr/local/mysql/var/tonfisk.err
```

```
080111 22:53:32  InnoDB: Started; log sequence number 0 46409
/usr/local/mysql/libexec/mysqld: Too many arguments (first extra is 'my-errors').
Use --verbose --help to get a list of available options
080111 22:53:32  InnoDB: Starting shutdown...
080111 22:53:34  InnoDB: Shutdown completed; log sequence number 0 46409
080111 22:53:34 mysqld_safe mysqld from pid file /usr/local/mysql/var/tonfisk.pid ended
```

Because the `--log-error` option supplies a default value, you must use an equal sign to assign a different value to it, as shown here:

```shell
mysqld_safe --log-error=my-errors &
```

Now the server has been started successfully, and is logging errors to the file `/usr/local/mysql/var/my-errors.err`.

Similar issues can arise when specifying option values in option files. For example, consider a `my.cnf` file that contains the following:

```
[mysql]
host
user
```

When the `mysql` client reads this file, these entries are parsed as `--host --user` or `--host=--user`, with the result shown here:

```shell
mysql
ERROR 2005 (HY000): Unknown MySQL server host '--user' (1)
```

However, in option files, an equal sign is not assumed. Suppose the `my.cnf` file is as shown here:

```
[mysql]
user jon
```

Trying to start `mysql` in this case causes a different error:

```shell
mysql
mysql: unknown option '--user jon'
```
A similar error would occur if you were to write `host tonfisk` in the option file rather than `host=tonfisk`. Instead, you must use the equal sign:

```
[mysql]
user=jon
```

Now the login attempt succeeds:

```
shell> mysql
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 5
Server version: 5.5.40 Source distribution
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
```

```
mysql> SELECT USER();
+---------------+
| USER()        |
+---------------+
| jon@localhost |
+---------------+
1 row in set (0.00 sec)
```

This is not the same behavior as with the command line, where the equals sign is not required:

```
shell> mysql --user jon --host tonfisk
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 6
Server version: 5.5.40 Source distribution
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
```

```
mysql> SELECT USER();
+---------------+
| USER()        |
+---------------+
| jon@tonfisk   |
+---------------+
1 row in set (0.00 sec)
```

In MySQL 5.5, specifying an option requiring a value without a value in an option file causes the server to abort with an error. Suppose that `my.cnf` contains the following:

```
[mysqld]
log_error
relay_log
relay_log_index
```

This causes the server to fail on startup, as shown here:

```
shell> mysqld_safe &
090514 09:48:39 mysqld_safe Logging to '../home/jon/bin/mysql/var/tonfisk.err'.
090514 09:48:39 mysqld_safe Starting mysqld daemon with databases from /home/jon/bin/mysql/var
090514 09:48:39 mysqld_safe mysqld from pid file /home/jon/bin/mysql/var/tonfisk.pid ended
```

The `--log-error` option does not require an argument; however, the `--relay-log` option requires one, as shown in the error log (which in the absence of a specified value, defaults to `datadir/hostname.err`):

```
090514 09:48:39 mysqld_safe Starting mysqld daemon with databases from /home/jon/bin/mysql/var
090514 09:48:39 mysqld_safe mysqld from pid file /home/jon/bin/mysql/var/tonfisk.pid ended
```
shell> tail -n 3 ../var/tonfisk.err
090514 09:48:39 mysqld_safe Starting mysqld daemon with databases from /home/jon/bin/mysql/var
090514 09:48:39 [ERROR] /home/jon/bin/mysql/libexec/mysqld: option '--relay-log' requires an argument
090514 09:48:39 [ERROR] Aborting

This is a change from previous behavior, where the server would have interpreted the last two lines
in the example my.cnf file as --relay-log=relay_log_index and created a relay log file using
"relay_log_index" as the basename. (Bug #25192)

4.2.10 Setting Environment Variables

Environment variables can be set at the command prompt to affect the current invocation of your command
processor, or set permanently to affect future invocations. To set a variable permanently, you can
set it in a startup file or by using the interface provided by your system for this purpose. Consult the
documentation for your command interpreter for specific details. Section 2.12, “Environment Variables”,
lists all environment variables that affect MySQL program operation.

To specify a value for an environment variable, use the syntax appropriate for your command processor.
For example, on Windows, you can set the USER variable to specify your MySQL account name. To do so,
use this syntax:

```
SET USER=your_name
```

The syntax on Unix depends on your shell. Suppose that you want to specify the TCP/IP port number using
the MYSQL_TCP_PORT variable. Typical syntax (such as for sh, ksh, bash, zsh, and so on) is as follows:

```bash
MYSQL_TCP_PORT=3306
export MYSQL_TCP_PORT
```

The first command sets the variable, and the `export` command exports the variable to the shell
environment so that its value becomes accessible to MySQL and other processes.

For csh and tcsh, use `setenv` to make the shell variable available to the environment:

```
setenv MYSQL_TCP_PORT 3306
```

The commands to set environment variables can be executed at your command prompt to take effect
immediately, but the settings persist only until you log out. To have the settings take effect each time you
log in, use the interface provided by your system or place the appropriate command or commands in a
startup file that your command interpreter reads each time it starts.

On Windows, you can set environment variables using the System Control Panel (under Advanced).

On Unix, typical shell startup files are `.bashrc` or `.bash_profile` for bash, or `.tcshrc` for tcsh.

Suppose that your MySQL programs are installed in `/usr/local/mysql/bin` and that you want to make
it easy to invoke these programs. To do this, set the value of the PATH environment variable to include that
directory. For example, if your shell is bash, add the following line to your `.bashrc` file:

```
PATH=$PATH:/usr/local/mysql/bin
```

bash uses different startup files for login and nonlogin shells, so you might want to add the setting to
`.bashrc` for login shells and to `.bash_profile` for nonlogin shells to make sure that PATH is set
regardless.
If your shell is `tcsh`, add the following line to your `.tcshrc` file:

```
setenv PATH ${PATH}:/usr/local/mysql/bin
```

If the appropriate startup file does not exist in your home directory, create it with a text editor.

After modifying your `PATH` setting, open a new console window on Windows or log in again on Unix so that the setting goes into effect.

## 4.3 MySQL Server and Server-Startup Programs

This section describes `mysqld`, the MySQL server, and several programs that are used to start the server.

### 4.3.1 mysqld — The MySQL Server

`mysqld`, also known as MySQL Server, is the main program that does most of the work in a MySQL installation. MySQL Server manages access to the MySQL data directory that contains databases and tables. The data directory is also the default location for other information such as log files and status files.

When MySQL server starts, it listens for network connections from client programs and manages access to databases on behalf of those clients.

The `mysqld` program has many options that can be specified at startup. For a complete list of options, run this command:

```
shell> mysqld --verbose --help
```

MySQL Server also has a set of system variables that affect its operation as it runs. System variables can be set at server startup, and many of them can be changed at runtime to effect dynamic server reconfiguration. MySQL Server also has a set of status variables that provide information about its operation. You can monitor these status variables to access runtime performance characteristics.

For a full description of MySQL Server command options, system variables, and status variables, see Section 5.1, “The MySQL Server”. For information about installing MySQL and setting up the initial configuration, see Chapter 2, *Installing and Upgrading MySQL*.

### 4.3.2 mysqld_safe — MySQL Server Startup Script

`mysqld_safe` is the recommended way to start a `mysqld` server on Unix. `mysqld_safe` adds some safety features such as restarting the server when an error occurs and logging runtime information to an error log file. A description of error logging is given later in this section.

`mysqld_safe` tries to start an executable named `mysqld`. To override the default behavior and specify explicitly the name of the server you want to run, specify a `--mysqld` or `--mysqld-version` option to `mysqld_safe`. You can also use `--ledir` to indicate the directory where `mysqld_safe` should look for the server.

Many of the options to `mysqld_safe` are the same as the options to `mysqld`. See Section 5.1.3, “Server Command Options”.

Options unknown to `mysqld_safe` are passed to `mysqld` if they are specified on the command line, but ignored if they are specified in the `[mysqld_safe]` group of an option file. See Section 4.2.6, “Using Option Files”.
mysqld_safe reads all options from the [mysqld], [server], and [mysqld_safe] sections in option files. For example, if you specify a [mysqld] section like this, mysqld_safe will find and use the --log-error option:

```
[mysqld]
log-error=error.log
```

For backward compatibility, mysqld_safe also reads [safe_mysqld] sections, although you should rename such sections to [mysqld_safe] in MySQL 5.5 installations.

mysqld_safe supports the following options. It also reads option files and supports the options for processing them described at Section 4.2.7, “Command-Line Options that Affect Option-File Handling”.

### Table 4.1 mysqld_safe Options

<table>
<thead>
<tr>
<th>Format</th>
<th>Option File</th>
<th>Description</th>
<th>Introduced</th>
</tr>
</thead>
<tbody>
<tr>
<td>--basedir=path</td>
<td>basedir</td>
<td>The path to the MySQL installation directory</td>
<td></td>
</tr>
<tr>
<td>--core-file-size=size</td>
<td>core-file-size</td>
<td>The size of the core file that mysqld should be able to create</td>
<td></td>
</tr>
<tr>
<td>--datadir=path</td>
<td>datadir</td>
<td>The path to the data directory</td>
<td></td>
</tr>
<tr>
<td>--defaults-extra-file=path</td>
<td>defaults-extra-file</td>
<td>Read option file in addition to the usual option files</td>
<td></td>
</tr>
<tr>
<td>--defaults-file=file_name</td>
<td>defaults-file</td>
<td>Read only the given option file</td>
<td></td>
</tr>
<tr>
<td>--help</td>
<td></td>
<td>Display a help message and exit</td>
<td></td>
</tr>
<tr>
<td>--ledir=path</td>
<td>ledir</td>
<td>Use this option to indicate the path name to the directory where the server is located</td>
<td></td>
</tr>
<tr>
<td>--log-error=file_name</td>
<td>log-error</td>
<td>Write the error log to the given file</td>
<td></td>
</tr>
<tr>
<td>--malloc-lib=[lib-name]</td>
<td>malloc-lib</td>
<td>Alternative malloc library to use for mysqld</td>
<td></td>
</tr>
<tr>
<td>--mysqld=prog_name</td>
<td>mysqld</td>
<td>The name of the server program (in the ledir directory) that you want to start</td>
<td></td>
</tr>
<tr>
<td>--mysqld-version=suffix</td>
<td>mysqld-version</td>
<td>This option is similar to the --mysqld option, but you specify only the suffix for the server program name</td>
<td></td>
</tr>
<tr>
<td>--nice=priority</td>
<td>nice</td>
<td>Use the nice program to set the server's scheduling priority to the given value</td>
<td></td>
</tr>
<tr>
<td>--no-defaults</td>
<td>no-defaults</td>
<td>Do not read any option files</td>
<td></td>
</tr>
<tr>
<td>--open-files-limit=count</td>
<td>open-files-limit</td>
<td>The number of files that mysqld should be able to open</td>
<td></td>
</tr>
<tr>
<td>--pid-file=file_name</td>
<td>pid-file=file_name</td>
<td>The path name of the process ID file</td>
<td></td>
</tr>
<tr>
<td>--plugin-dir=path</td>
<td>plugin-dir=path</td>
<td>The directory where plugins are located</td>
<td>5.5.3</td>
</tr>
<tr>
<td>--port=number</td>
<td>port</td>
<td>The port number that the server should use when listening for TCP/IP connections</td>
<td></td>
</tr>
<tr>
<td>--skip-kill-mysqld</td>
<td>skip-kill-mysqld</td>
<td>Do not try to kill stray mysqld processes</td>
<td></td>
</tr>
<tr>
<td>--skip-syslog</td>
<td>skip-syslog</td>
<td>Do not write error messages to syslog; use error log file</td>
<td></td>
</tr>
<tr>
<td>Format</td>
<td>Option File</td>
<td>Description</td>
<td>Introduced</td>

</tbody>
</table>

- **--help**
  Display a help message and exit.

- **--basedir=path**
  The path to the MySQL installation directory.

- **--core-file-size=size**
  The size of the core file that mysqld should be able to create. The option value is passed to `ulimit -c`.

- **--datadir=path**
  The path to the data directory.

- **--defaults-extra-file=path**
  The name of an option file to be read in addition to the usual option files. This must be the first option on the command line if it is used. If the file does not exist or is otherwise inaccessible, the server will exit with an error.

- **--defaults-file=file_name**
  The name of an option file to be read instead of the usual option files. This must be the first option on the command line if it is used.

- **--ledir=path**
  If mysqld_safe cannot find the server, use this option to indicate the path name to the directory where the server is located.

- **--log-error=file_name**
  Write the error log to the given file. See Section 5.2.2, “The Error Log”.

- **--malloc-lib=[lib_name]**
  The name of the library to use for memory allocation instead of the system `malloc()` library. Any library can be used by specifying its path name, but there is a shortcut form to enable use of the `tcmalloc` library that is shipped with binary MySQL distributions for Linux in MySQL 5.5. It is possible that the shortcut form will not work under certain configurations, in which case you should specify a path name instead.
The `--malloc-lib` option works by modifying the `LD_PRELOAD` environment value to affect dynamic linking to enable the loader to find the memory-allocation library when `mysqld` runs:

- If the option is not given, or is given without a value (`--malloc-lib=`), `LD_PRELOAD` is not modified and no attempt is made to use `tcmalloc`.
- If the option is given as `--malloc-lib=tcmalloc`, `mysqld_safe` looks for a `tcmalloc` library in `/usr/lib` and then in the MySQL `pkglibdir` location (for example, `/usr/local/mysql/lib` or whatever is appropriate). If `tcmalloc` is found, its path name is added to the beginning of the `LD_PRELOAD` value for `mysqld`. If `tcmalloc` is not found, `mysqld_safe` aborts with an error.
- If the option is given as `--malloc-lib=/path/to/some/library`, that full path is added to the beginning of the `LD_PRELOAD` value. If the full path points to a nonexistent or unreadable file, `mysqld_safe` aborts with an error.
- For cases where `mysqld_safe` adds a path name to `LD_PRELOAD`, it adds the path to the beginning of any existing value the variable already has.

Linux users can use the `libtcmalloc_minimal.so` included in binary packages by adding these lines to the `my.cnf` file:

```
[mysqld_safe]
malloc-lib=tcmalloc
```

Those lines also suffice for users on any platform who have installed a `tcmalloc` package in `/usr/lib`. To use a specific `tcmalloc` library, specify its full path name. Example:

```
[mysqld_safe]
malloc-lib=/opt/lib/libtcmalloc_minimal.so
```

- **--mysqld=prog_name**

  The name of the server program (in the `ledir` directory) that you want to start. This option is needed if you use the MySQL binary distribution but have the data directory outside of the binary distribution. If `mysqld_safe` cannot find the server, use the `--ledir` option to indicate the path name to the directory where the server is located.

- **--mysqld-version=suffix**

  This option is similar to the `--mysqld` option, but you specify only the suffix for the server program name. The basename is assumed to be `mysqld`. For example, if you use `--mysqld-version=debug`, `mysqld_safe` starts the `mysqld-debug` program in the `ledir` directory. If the argument to `--mysqld-version` is empty, `mysqld_safe` uses `mysqld` in the `ledir` directory.

- **--nice=priority**

  Use the `nice` program to set the server's scheduling priority to the given value.

- **--no-defaults**

  Do not read any option files. This must be the first option on the command line if it is used.

- **--open-files-limit=count**

  The number of files that `mysqld` should be able to open. The option value is passed to `ulimit -n`. Note that you need to start `mysqld_safe` as `root` for this to work properly!
• **--pid-file=file_name**
  The path name of the process ID file.

• **--plugin-dir=path**
  The path name of the plugin directory. This option was added in MySQL 5.5.3.

• **--port=port_num**
  The port number that the server should use when listening for TCP/IP connections. The port number must be 1024 or higher unless the server is started by the `root` system user.

• **--skip-kill-mysqld**
  Do not try to kill stray `mysqld` processes at startup. This option works only on Linux.

• **--socket=path**
  The Unix socket file that the server should use when listening for local connections.

• **--syslog,** **--skip-syslog**
  **--syslog** causes error messages to be sent to `syslog` on systems that support the `logger` program. **--skip-syslog** suppresses the use of `syslog`; messages are written to an error log file.

  When `syslog` is used, the `daemon.err` syslog priority/facility is used for all log messages.

• **--syslog-tag=tag**
  For logging to `syslog`, messages from `mysqld_safe` and `mysqld` are written with a tag of `mysqld_safe` and `mysqld`, respectively. To specify a suffix for the tag, use `--syslog-tag=tag`, which modifies the tags to be `mysqld_safe-tag` and `mysqld-tag`.

• **--timezone=timezone**
  Set the `TZ` time zone environment variable to the given option value. Consult your operating system documentation for legal time zone specification formats.

• **--user={user_name|user_id}**
  Run the `mysqld` server as the user having the name `user_name` or the numeric user ID `user_id`. ("User" in this context refers to a system login account, not a MySQL user listed in the grant tables.)

If you execute `mysqld_safe` with the `--defaults-file` or `--defaults-extra-file` option to name an option file, the option must be the first one given on the command line or the option file will not be used. For example, this command will not use the named option file:

```sql
mysql> mysqld_safe --port=port_num --defaults-file=file_name
```

Instead, use the following command:

```sql
mysql> mysqld_safe --defaults-file=file_name --port=port_num
```

The `mysqld_safe` script is written so that it normally can start a server that was installed from either a source or a binary distribution of MySQL, even though these types of distributions typically install the
server in slightly different locations. (See Section 2.1.5, “Installation Layouts.”) mysqld_safe expects one of the following conditions to be true:

- The server and databases can be found relative to the working directory (the directory from which mysqld_safe is invoked). For binary distributions, mysqld_safe looks under its working directory for `bin` and `data` directories. For source distributions, it looks for `libexec` and `var` directories. This condition should be met if you execute mysqld_safe from your MySQL installation directory (for example, `/usr/local/mysql` for a binary distribution).

- If the server and databases cannot be found relative to the working directory, mysqld_safe attempts to locate them by absolute path names. Typical locations are `/usr/local/libexec` and `/usr/local/var`. The actual locations are determined from the values configured into the distribution at the time it was built. They should be correct if MySQL is installed in the location specified at configuration time.

Because mysqld_safe tries to find the server and databases relative to its own working directory, you can install a binary distribution of MySQL anywhere, as long as you run mysqld_safe from the MySQL installation directory:

```
shell> cd mysql_installation_directory
shell> bin/mysqld_safe &
```

If mysqld_safe fails, even when invoked from the MySQL installation directory, you can specify the `--ledir` and `--datadir` options to indicate the directories in which the server and databases are located on your system.

Beginning with MySQL 5.5.21, mysqld_safe tries to use the `sleep` and `date` system utilities to determine how many times it has attempted to start this second, and—if these are present and this is greater than 5 times—is forced to wait 1 full second before starting again. This is intended to prevent excessive CPU usage in the event of repeated failures. (Bug #11761530, Bug #54035)

When you use mysqld_safe to start mysqld, mysqld_safe arranges for error (and notice) messages from itself and from mysqld to go to the same destination.

There are several mysqld_safe options for controlling the destination of these messages:

- `--syslog`: Write error messages to syslog on systems that support the logger program.
- `--skip-syslog`: Do not write error messages to syslog. Messages are written to the default error log file (`host_name.err` in the data directory), or to a named file if the `--log-error` option is given.
- `--log-error=file_name`: Write error messages to the named error file.

If none of these options is given, the default is `--skip-syslog`.

If `--syslog` and `--log-error` are both given, a warning is issued and `--log-error` takes precedence.

When mysqld_safe writes a message, notices go to the logging destination (syslog or the error log file) and stdout. Errors go to the logging destination and stderr.

Normally, you should not edit the mysqld_safe script. Instead, configure mysqld_safe by using command-line options or options in the `[mysqld_safe]` section of a my.cnf option file. In rare cases, it might be necessary to edit mysqld_safe to get it to start the server properly. However, if you do this, your modified version of mysqld_safe might be overwritten if you upgrade MySQL in the future, so you should make a copy of your edited version that you can reinstall.

4.3.3 mysql.server — MySQL Server Startup Script
MySQL distributions on Unix include a script named `mysqld.server`. It can be used on systems such as Linux and Solaris that use System V-style run directories to start and stop system services. It is also used by the Mac OS X Startup Item for MySQL.

`mysqld.server` can be found in the `support-files` directory under your MySQL installation directory or in a MySQL source distribution.

If you use the Linux server RPM package (`MySQL-server-VERSION.rpm`), the `mysqld.server` script will be installed in the `/etc/init.d` directory with the name `mysql`. You need not install it manually. See Section 2.5.1, “Installing MySQL on Linux Using RPM Packages”, for more information on the Linux RPM packages.

Some vendors provide RPM packages that install a startup script under a different name such as `mysqld`.

If you install MySQL from a source distribution or using a binary distribution format that does not install `mysqld.server` automatically, you can install it manually. Instructions are provided in Section 2.10.1.2, “Starting and Stopping MySQL Automatically”.

`mysqld.server` reads options from the `[mysql.server]` and `[mysqld]` sections of option files. For backward compatibility, it also reads `[mysql_server]` sections, although you should rename such sections to `[mysql.server]` when using MySQL 5.5.

`mysql.server` supports the following options.

- `--basedir=path`
  The path to the MySQL installation directory.

- `--datadir=path`
  The path to the MySQL data directory.

- `--pid-file=file_name`
  The path name of the file in which the server should write its process ID.

- `--service-startup-timeout=file_name`
  How long in seconds to wait for confirmation of server startup. If the server does not start within this time, `mysql.server` exits with an error. The default value is 900. A value of 0 means not to wait at all for startup. Negative values mean to wait forever (no timeout).

- `--use-mysqld_safe`
  Use `mysqld_safe` to start the server. This is the default.

- `--user=user_name`
  The login user name to use for running `mysqld`.

### 4.3.4 mysqld_multi — Manage Multiple MySQL Servers

`mysqld_multi` is designed to manage several `mysqld` processes that listen for connections on different Unix socket files and TCP/IP ports. It can start or stop servers, or report their current status.

`mysqld_multi` searches for groups named `[mysqldN]` in `my.cnf` (or in the file named by the `--defaults-file` option). `N` can be any positive integer. This number is referred to in the following
discussion as the option group number, or GNR. Group numbers distinguish option groups from one another and are used as arguments to mysqld_multi to specify which servers you want to start, stop, or obtain a status report for. Options listed in these groups are the same that you would use in the [mysqld] group used for starting mysqld. (See, for example, Section 2.10.1.2, “Starting and Stopping MySQL Automatically”.) However, when using multiple servers, it is necessary that each one use its own value for options such as the Unix socket file and TCP/IP port number. For more information on which options must be unique per server in a multiple-server environment, see Section 5.3, “Running Multiple MySQL Instances on One Machine”.

To invoke mysqld_multi, use the following syntax:

```
shell> mysqld_multi [options] {start|stop|report} [GNR[,GNR] ...]
```

start, stop, and report indicate which operation to perform. You can perform the designated operation for a single server or multiple servers, depending on the GNR list that follows the option name. If there is no list, mysqld_multi performs the operation for all servers in the option file.

Each GNR value represents an option group number or range of group numbers. The value should be the number at the end of the group name in the option file. For example, the GNR for a group named [mysqld17] is 17. To specify a range of numbers, separate the first and last numbers by a dash. The GNR value 10-13 represents groups [mysqld10] through [mysqld13]. Multiple groups or group ranges can be specified on the command line, separated by commas. There must be no whitespace characters (spaces or tabs) in the GNR list; anything after a whitespace character is ignored.

This command starts a single server using option group [mysqld17]:

```
shell> mysqld_multi start 17
```

This command stops several servers, using option groups [mysqld8] and [mysqld10] through [mysqld13]:

```
shell> mysqld_multi stop 8,10-13
```

For an example of how you might set up an option file, use this command:

```
shell> mysqld_multi --example
```

mysqld_multi searches for option files as follows:

- With `--no-defaults`, no option files are read.
- With `--defaults-file=file_name`, only the named file is read.
- Otherwise, option files in the standard list of locations are read, including any file named by the `--defaults-extra-file=file_name` option, if one is given. (If the option is given multiple times, the last value is used.)

Option files read are searched for [mysqld_multi] and [mysqldN] option groups. The [mysqld_multi] group can be used for options to mysqld_multi itself. [mysqldN] groups can be used for options passed to specific mysqld instances.

The [mysqld] or [mysqld_safe] groups can be used for common options read by all instances of mysqld or mysqld_safe. You can specify a `--defaults-file=file_name` option to use a different
configuration file for that instance, in which case the \[mysqld\] or \[mysqld_safe\] groups from that file will be used for that instance.

**mysqld_multi** supports the following options.

- **--help**
  Display a help message and exit.

- **--config-file=file_name**
  This option is deprecated. If given, it is treated the same way as **--defaults-extra-file**, described earlier. **--config-file** was removed in MySQL 5.5.3.

- **--example**
  Display a sample option file.

- **--log=file_name**
  Specify the name of the log file. If the file exists, log output is appended to it.

- **--mysqladmin=prog_name**
  The **mysqladmin** binary to be used to stop servers.

- **--mysqld=prog_name**
  The **mysqld** binary to be used. Note that you can specify **mysqld_safe** as the value for this option also. If you use **mysqld_safe** to start the server, you can include the **mysqld** or **ledir** options in the corresponding **[mysqldN]** option group. These options indicate the name of the server that **mysqld_safe** should start and the path name of the directory where the server is located. (See the descriptions for these options in Section 4.3.2, "**mysqld_safe** — MySQL Server Startup Script"). Example:

  ```
  [mysqld38]
  mysqld = mysql debug
  ledir  = /opt/local/mysql/libexec
  ```

- **--no-log**
  Print log information to **stdout** rather than to the log file. By default, output goes to the log file.

- **--password=password**
  The password of the MySQL account to use when invoking **mysqladmin**. Note that the password value is not optional for this option, unlike for other MySQL programs.

- **--silent**
  Silent mode; disable warnings.

- **--tcp-ip**
  Connect to each MySQL server through the TCP/IP port instead of the Unix socket file. (If a socket file is missing, the server might still be running, but accessible only through the TCP/IP port.) By default, connections are made using the Unix socket file. This option affects **stop** and **report** operations.

- **--user=user_name**
The user name of the MySQL account to use when invoking `mysqladmin`.

- **--verbose**
  Be more verbose.

- **--version**
  Display version information and exit.

Some notes about `mysqld_multi`:

- **Most important**: Before using `mysqld_multi` be sure that you understand the meanings of the options that are passed to the `mysqld` servers and why you would want to have separate `mysqld` processes. Beware of the dangers of using multiple `mysqld` servers with the same data directory. Use separate data directories, unless you know what you are doing. Starting multiple servers with the same data directory does not give you extra performance in a threaded system. See Section 5.3, “Running Multiple MySQL Instances on One Machine”.

- **Important**
  Make sure that the data directory for each server is fully accessible to the Unix account that the specific `mysqld` process is started as. Do not use the Unix `root` account for this, unless you know what you are doing. See Section 6.1.5, “How to Run MySQL as a Normal User”.

- Make sure that the MySQL account used for stopping the `mysqld` servers (with the `mysqladmin` program) has the same user name and password for each server. Also, make sure that the account has the `SHUTDOWN` privilege. If the servers that you want to manage have different user names or passwords for the administrative accounts, you might want to create an account on each server that has the same user name and password. For example, you might set up a common `multi_admin` account by executing the following commands for each server:

```
shell> mysql -u root -S /tmp/mysql.sock -p
Enter password:
mysql> GRANT SHUTDOWN ON *.*
    -> TO 'multi_admin'@'localhost' IDENTIFIED BY 'multipass';
```

See Section 6.2, “The MySQL Access Privilege System”. You have to do this for each `mysql` server. Change the connection parameters appropriately when connecting to each one. Note that the host name part of the account name must permit you to connect as `multi_admin` from the host where you want to run `mysqld_multi`.

- The Unix socket file and the TCP/IP port number must be different for every `mysqld` (Alternatively, if the host has multiple network addresses, you can use `--bind-address` to cause different servers to listen to different interfaces.)

- The `--pid-file` option is very important if you are using `mysqld_safe` to start `mysqld` (for example, `--mysqld=mysqld_safe`) Every `mysqld` should have its own process ID file. The advantage of using `mysqld_safe` instead of `mysqld` is that `mysqld_safe` monitors its `mysqld` process and restarts it if the process terminates due to a signal sent using `kill -9` or for other reasons, such as a segmentation fault. Please note that the `mysqld_safe` script might require that you start it from a certain place. This means that you might have to change location to a certain directory before running `mysqld_multi`. If you have problems starting, please see the `mysqld_safe` script. Check especially the lines:
The test performed by these lines should be successful, or you might encounter problems. See Section 4.3.2, “mysqld_safe — MySQL Server Startup Script”.

• You might want to use the `--user` option for `mysqld`, but to do this you need to run the `mysqld_multi` script as the Unix superuser (`root`). Having the option in the option file doesn’t matter; you just get a warning if you are not the superuser and the `mysqld` processes are started under your own Unix account.

The following example shows how you might set up an option file for use with `mysqld_multi`. The order in which the `mysqld` programs are started or stopped depends on the order in which they appear in the option file. Group numbers need not form an unbroken sequence. The first and fifth `[mysqldN]` groups were intentionally omitted from the example to illustrate that you can have “gaps” in the option file. This gives you more flexibility.

```bash
# This file should probably be in your home dir (~/.my.cnf)
# or /etc/my.cnf
# Version 2.1 by Jani Tolonen

[mysqld_multi]
mysqld = /usr/local/bin/mysqld_safe
mysqladmin = /usr/local/bin/mysqladmin
user = multi_admin
password = multipass

[mysqld2]
socket = /tmp/mysql.sock2
port = 3307
pid-file = /usr/local/mysql/var2/hostname.pid2
datadir = /usr/local/mysql/var2
language = /usr/local/share/mysql/english
user = john

[mysqld3]
socket = /tmp/mysql.sock3
port = 3308
pid-file = /usr/local/mysql/var3/hostname.pid3
datadir = /usr/local/mysql/var3
language = /usr/local/share/mysql/swedish
user = monty

[mysqld4]
socket = /tmp/mysql.sock4
port = 3309
pid-file = /usr/local/mysql/var4/hostname.pid4
datadir = /usr/local/mysql/var4
language = /usr/local/share/mysql/estonia
user = tonu

[mysqld6]
socket = /tmp/mysql.sock6
port = 3311
pid-file = /usr/local/mysql/var6/hostname.pid6
datadir = /usr/local/mysql/var6
language = /usr/local/share/mysql/japanese
user = jani
```
See Section 4.2.6, “Using Option Files”.

4.4 MySQL Installation-Related Programs

The programs in this section are used when installing or upgrading MySQL.

4.4.1 comp_err — Compile MySQL Error Message File

comp_err creates the `errmsg.sys` file that is used by `mysqld` to determine the error messages to display for different error codes. `comp_err` normally is run automatically when MySQL is built. It compiles the `errmsg.sys` file from the plaintext file located at `sql/share/errmsg.txt` in MySQL source distributions.

comp_err also generates `mysqld_error.h`, `mysqld_ername.h`, and `sql_state.h` header files.

For more information about how error messages are defined, see the MySQL Internals Manual.

Invoke `comp_err` like this:

```
shell> comp_err [options]
```

comp_err supports the following options.

- **--help, -?**
  Display a help message and exit.

- **--charset=path, -C path**
  The character set directory. The default is `../sql/share/charsets`.

- **--debug=debug_options, -# debug_options**
  Write a debugging log. A typical `debug_options` string is `d:t:O, file_name`. The default is `d:t:O,/tmp/comp_err.trace`.

- **--debug-info, -T**
  Print some debugging information when the program exits.

- **--header_file=file_name, -H file_name**
  The name of the error header file. The default is `mysqld_error.h`.

- **--in_file=file_name, -F file_name**
  The name of the input file. The default is `../sql/share/errmsg.txt`.

- **--name_file=file_name, -N file_name**
  The name of the error name file. The default is `mysqld_ername.h`.

- **--out_dir=path, -D path**
  The name of the output base directory. The default is `../sql/share/`.

- **--out_file=file_name, -O file_name**
The name of the output file. The default is `errmsg.sys`.

- `--statefile=file_name, -S file_name`

  The name for the SQLSTATE header file. The default is `sql_state.h`.

- `--version, -V`

  Display version information and exit.

### 4.4.2 mysqlbug — Generate Bug Report

This program is obsolete.

The normal way to report bugs is to visit [http://bugs.mysql.com/](http://bugs.mysql.com/), which is the address for our bugs database. This database is public and can be browsed and searched by anyone. If you log in to the system, you can enter new reports.

### 4.4.3 mysql_install_db — Initialize MySQL Data Directory

`mysql_install_db` initializes the MySQL data directory and creates the system tables that it contains, if they do not exist. `mysql_install_db` is a shell script and is available only on Unix platforms. (As of MySQL 5.6, `mysql_install_db` is a Perl script and can be used on any system with Perl installed.)

To invoke `mysql_install_db`, use the following syntax:

```
shell> mysql_install_db [options]
```

Because the MySQL server, `mysqld`, must access the data directory when it runs later, you should either run `mysql_install_db` from the same system account that will be used for running `mysqld` or run it as `root` and use the `--user` option to indicate the user name that `mysqld` will run as. It might be necessary to specify other options such as `--basedir` or `--datadir` if `mysql_install_db` does not use the correct locations for the installation directory or data directory. For example:

```
shell> scripts/mysql_install_db --user=mysql
     --basedir=/opt/mysql/mysql
     --datadir=/opt/mysql/mysql/data
```

Note

If you have set a custom `TMPDIR` environment variable when performing the installation, and the specified directory is not accessible, `mysql_install_db` may fail. If so, unset `TMPDIR` or set `TMPDIR` to point to the system temporary directory (usually `/tmp`).

`mysql_install_db` supports the following options, which can be specified on the command line or in the `[mysql_install_db]` group of an option file. (Options that are common to `mysqld` can also be specified in the `[mysqld]` group.) Other options are passed to `mysqld`. For information about option files, see Section 4.2.6, “Using Option Files”.

</table>

- **--help**

Display a help message and exit.

- **--basedir=path**

The path to the MySQL installation directory.

- **--builddir=path**

For use with --srcdir and out-of-source builds. Set this to the location of the directory where the built files reside.

- **--cross-bootstrap**

For internal use. This option is used for building system tables on one host intended for another.

- **--datadir=path,--ldata=path**

The path to the MySQL data directory.

- **--defaults-extra-file=file_name**

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. *file_name* is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- **--defaults-file=file_name**

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. *file_name* is interpreted relative to the current directory if given as a relative path name rather than a full path name.
• **--force**

Cause `mysql_install_db` to run even if DNS does not work. Grant table entries normally created using host names will use IP addresses instead.

• **--no-defaults**

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

• **--rpm**

For internal use. This option is used during the MySQL installation process for install operations performed using RPM packages.

• **--skip-name-resolve**

Use IP addresses rather than host names when creating grant table entries. This option can be useful if your DNS does not work.

• **--srcdir=path**

For internal use. This option specifies the directory under which `mysql_install_db` looks for support files such as the error message file and the file for populating the help tables.

• **--user=user_name**

The system (login) user name to use for running `mysqld`. Files and directories created by `mysqld` will be owned by this user. You must be `root` to use this option. By default, `mysqld` runs using your current login name and files and directories that it creates will be owned by you.

• **--verbose**

Verbose mode. Print more information about what the program does.

• **--windows**

For internal use. This option is used for creating Windows distributions.

### 4.4.4 `mysql_plugin` — Configure MySQL Server Plugins

The `mysql_plugin` utility enables MySQL administrators to manage which plugins a MySQL server loads. It provides an alternative to manually specifying the `--plugin-load` option at server startup or using the `INSTALL PLUGIN` and `UNINSTALL PLUGIN` statements at runtime. `mysql_plugin` is available as of MySQL 5.5.16.

Depending on whether `mysql_plugin` is invoked to enable or disable plugins, it inserts or deletes rows in the `mysql.plugin` table that serves as a plugin registry. (To perform this operation, `mysql_plugin` invokes the MySQL server in bootstrap mode. This means that the server must not already be running.) For normal server startups, the server loads and enables plugins listed in `mysql.plugin` automatically. For additional control over plugin activation, use `--plugin_name` options named for specific plugins, as described in Section 5.1.8.1, “Installing and Uninstalling Plugins”.

Each invocation of `mysql_plugin` reads a configuration file to determine how to configure the plugins contained in a single plugin library object file. To invoke `mysql_plugin`, use this syntax:

```
mysql_plugin  [options] plugin {ENABLE|DISABLE}
```
**mysql_plugin** — Configure MySQL Server Plugins

*plugin* is the name of the plugin to configure. **ENABLE** or **DISABLE** (not case sensitive) specify whether to enable or disable components of the plugin library named in the configuration file. The order of the *plugin* and **ENABLE** or **DISABLE** arguments does not matter.

For example, to configure components of a plugin library file named *myplugins.so* on Linux or *myplugins.dll* on Windows, specify a *plugin* value of *myplugins*. Suppose that this plugin library contains three plugins, *plugin1*, *plugin2*, and *plugin3*, all of which should be configured under *mysql_plugin* control. By convention, configuration files have a suffix of *.ini* and the same basename as the plugin library, so the default configuration file name for this plugin library is *myplugins.ini*. The configuration file contents look like this:

```plaintext
myplugins
plugin1
plugin2
plugin3
```

The first line in the *myplugins.ini* file is the name of the library object file, without any extension such as *.so* or *.dll*. The remaining lines are the names of the components to be enabled or disabled. Each value in the file should be on a separate line. Lines on which the first character is ' #' are taken as comments and ignored.

To enable the plugins listed in the configuration file, invoke **mysql_plugin** this way:

```
shell> mysql_plugin myplugins ENABLE
```

To disable the plugins, use **DISABLE** rather than **ENABLE**.

An error occurs if **mysql_plugin** cannot find the configuration file or plugin library file, or if **mysql_plugin** cannot start the MySQL server.

**mysql_plugin** supports the following options, which can be specified on the command line or in the [mysqld] group of any option file. For options specified in a [mysqld] group, **mysql_plugin** recognizes the **--basedir**, **--datadir**, and **--plugin-dir** options and ignores others. For information about option files, see Section 4.2.6, “Using Option Files”.

**Table 4.3 mysql_plugin Options**

<table>
<thead>
<tr>
<th>Format</th>
<th>Option File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--basedir=path</td>
<td>basedir=path</td>
<td>The server base directory</td>
</tr>
<tr>
<td>--datadir=path</td>
<td>datadir=path</td>
<td>The server data directory</td>
</tr>
<tr>
<td>--help</td>
<td></td>
<td>Display help message and exit</td>
</tr>
<tr>
<td>--my-print-</td>
<td>my-print-defaults=</td>
<td>The path to my_print_defaults</td>
</tr>
<tr>
<td>defaults=path</td>
<td>defaults=path</td>
<td></td>
</tr>
<tr>
<td>--mysqld=path</td>
<td>mysqld=path</td>
<td>The path to the server</td>
</tr>
<tr>
<td>--no-defaults</td>
<td>no-defaults</td>
<td>Do not read configuration file</td>
</tr>
<tr>
<td>--plugin-dir=path</td>
<td>plugin-dir=path</td>
<td>The directory where plugins are located</td>
</tr>
<tr>
<td>--plugin_ini=file_name</td>
<td>plugin_ini=file_name</td>
<td>The plugin configuration file</td>
</tr>
<tr>
<td>--print-defaults</td>
<td>print-defaults</td>
<td>Show configuration file defaults</td>
</tr>
<tr>
<td>--verbose</td>
<td></td>
<td>Verbose mode</td>
</tr>
<tr>
<td>--version</td>
<td></td>
<td>Display version information and exit</td>
</tr>
</tbody>
</table>

- **--help, --**
Display a help message and exit.

- **--basedir=path, -b path**
  The server base directory.

- **--datadir=path, -d path**
  The server data directory.

- **--my-print-defaults=path, -b path**
  The path to the my_print_defaults program.

- **--mysqld=path, -b path**
  The path to the mysqld server.

- **--no-defaults, -p**
  Do not read values from the configuration file. This option enables an administrator to skip reading defaults from the configuration file.

  With mysql_plugin, this option need not be given first on the command line, unlike most other MySQL programs that support --no-defaults.

- **--plugin-dir=path, -b path**
  The server plugin directory.

- **--plugin-ini=file_name, -i file_name**
  The mysql_plugin configuration file. Relative path names are interpreted relative to the current directory. If this option is not given, the default is plugin.ini in the plugin directory, where plugin is the plugin argument on the command line.

- **--print-defaults, -P**
  Display the default values from the configuration file. This option causes mysql_plugin to print the defaults for --basedir, --datadir, and --plugin-dir if they are found in the configuration file. If no value for a variable is found, nothing is shown.

  With mysql_plugin, this option need not be given first on the command line, unlike most other MySQL programs that support --print-defaults.

- **--verbose, -v**
  Verbose mode. Print more information about what the program does. This option can be used multiple times to increase the amount of information.

- **--version, -V**
  Display version information and exit.

4.4.5 mysql_secure_installation — Improve MySQL Installation Security

This program enables you to improve the security of your MySQL installation in the following ways:
• You can set a password for root accounts.
• You can remove root accounts that are accessible from outside the local host.
• You can remove anonymous-user accounts.
• You can remove the test database (which by default can be accessed by all users, even anonymous users), and privileges that permit anyone to access databases with names that start with test_.

mysql_secure_installation helps you implement security recommendations similar to those described at Section 2.10.2, “Securing the Initial MySQL Accounts”.

Invoke mysql_secure_installation without arguments:

```
shell> mysql_secure_installation
```

When executed, the script prompts you to determine which actions to perform.

### 4.4.6 mysql_tzinfo_to_sql — Load the Time Zone Tables

The mysql_tzinfo_to_sql program loads the time zone tables in the mysql database. It is used on systems that have a zoneinfo database (the set of files describing time zones). Examples of such systems are Linux, FreeBSD, Solaris, and Mac OS X. One likely location for these files is the /usr/share/zoneinfo directory (/usr/share/lib/zoneinfo on Solaris). If your system does not have a zoneinfo database, you can use the downloadable package described in Section 10.6, “MySQL Server Time Zone Support”.

mysql_tzinfo_to_sql can be invoked several ways:

```
shell> mysql_tzinfo_to_sql tz_dir
shell> mysql_tzinfo_to_sql tz_file tz_name
shell> mysql_tzinfo_to_sql --leap tz_file
```

For the first invocation syntax, pass the zoneinfo directory path name to mysql_tzinfo_to_sql and send the output into the mysql program. For example:

```
shell> mysql_tzinfo_to_sql /usr/share/zoneinfo | mysql -u root mysql
```

mysql_tzinfo_to_sql reads your system's time zone files and generates SQL statements from them. mysql processes those statements to load the time zone tables.

The second syntax causes mysql_tzinfo_to_sql to load a single time zone file tz_file that corresponds to a time zone name tz_name:

```
shell> mysql_tzinfo_to_sql tz_file tz_name | mysql -u root mysql
```

If your time zone needs to account for leap seconds, invoke mysql_tzinfo_to_sql using the third syntax, which initializes the leap second information. tz_file is the name of your time zone file:

```
shell> mysql_tzinfo_to_sql --leap tz_file | mysql -u root mysql
```

After running mysql_tzinfo_to_sql, it is best to restart the server so that it does not continue to use any previously cached time zone data.
4.4.7 `mysql_upgrade` — Check and Upgrade MySQL Tables

`mysql_upgrade` examines all tables in all databases for incompatibilities with the current version of MySQL Server. `mysql_upgrade` also upgrades the system tables so that you can take advantage of new privileges or capabilities that might have been added.

`mysql_upgrade` should be executed each time you upgrade MySQL.

If `mysql_upgrade` finds that a table has a possible incompatibility, it performs a table check and, if problems are found, attempts a table repair. If the table cannot be repaired, see Section 2.11.4, “Rebuilding or Repairing Tables or Indexes” for manual table repair strategies.

**Note**

On Windows Server 2008, Vista, and newer, you must run `mysql_upgrade` with administrator privileges. You can do this by running a Command Prompt as Administrator and running the command. Failure to do so may result in the upgrade failing to execute correctly.

**Caution**

You should always back up your current MySQL installation before performing an upgrade. See Section 7.2, “Database Backup Methods”.

Some upgrade incompatibilities may require special handling before you upgrade your MySQL installation and run `mysql_upgrade`. See Section 2.11.1, “Upgrading MySQL”, for instructions on determining whether any such incompatibilities apply to your installation and how to handle them.

To use `mysql_upgrade`, make sure that the server is running, and then invoke it like this:

```
shell> mysql_upgrade [options]
```

After running `mysql_upgrade`, stop the server and restart it so that any changes made to the system tables take effect.

`mysql_upgrade` executes the following commands to check and repair tables and to upgrade the system tables:

```
mysqlcheck --no-defaults --all-databases
--fix-db-names --fix-table-names
mysqlcheck --no-defaults --check-upgrade --all-databases
--auto-repair
mysql < fix_priv_tables
```

Notes about the preceding commands:

- `mysql_upgrade` also adds `--write-binlog` or `--skip-write-binlog` to the `mysqlcheck` commands, depending on whether the `--write-binlog` option was specified on the `mysql_upgrade` command.

- Because `mysql_upgrade` invokes `mysqlcheck` with the `--all-databases` option, it processes all tables in all databases, which might take a long time to complete. Each table is locked and therefore unavailable to other sessions while it is being processed. Check and repair operations can be time-consuming, particularly for large tables.
mysql_upgrade — Check and Upgrade MySQL Tables

- For details about what checks the --check-upgrade option entails, see the description of the FOR
  UPGRADE option of the CHECK TABLE statement (see Section 13.7.2.2, “CHECK TABLE Syntax”).

- fix_priv_tables represents a script generated internally by mysql_upgrade that contains SQL
  statements to upgrade the tables in the mysql database.

All checked and repaired tables are marked with the current MySQL version number. This ensures that
next time you run mysql_upgrade with the same version of the server, it can tell whether there is any
need to check or repair the table again.

mysql_upgrade also saves the MySQL version number in a file named mysql_upgrade_info in the
data directory. This is used to quickly check whether all tables have been checked for this release so that
table-checking can be skipped. To ignore this file and perform the check regardless, use the --force
option.

If you install MySQL from RPM packages on Linux, you must install the server and client RPMs.
mysql_upgrade is included in the server RPM but requires the client RPM because the latter includes
mysqlcheck. (See Section 2.5.1, “Installing MySQL on Linux Using RPM Packages”.)

mysql_upgrade does not upgrade the contents of the help tables. For upgrade instructions, see
Section 5.1.10, “Server-Side Help”.

mysql_upgrade supports the following options, which can be specified on the command line or in the
[mysql_upgrade] and [client] groups of an option file. Other options are passed to mysqlcheck.
For example, it might be necessary to specify the --password=password option. For information
about option files, see Section 4.2.6, “Using Option Files”.

Table 4.4 mysql_upgrade Options

<table>
<thead>
<tr>
<th>Format</th>
<th>Option File</th>
<th>Description</th>
<th>Introduced</th>
</tr>
</thead>
<tbody>
<tr>
<td>--basedir</td>
<td>basedir</td>
<td>Not used; exists only for compatibility with some very old applications</td>
<td></td>
</tr>
<tr>
<td>--character-sets-dir=path</td>
<td>character-sets-dir</td>
<td>Directory where character sets are.</td>
<td></td>
</tr>
<tr>
<td>--compress</td>
<td>compress</td>
<td>Use compression in server/client protocol.</td>
<td></td>
</tr>
<tr>
<td>--datadir=path</td>
<td>datadir</td>
<td>Not used; exists only for compatibility with some very old applications</td>
<td></td>
</tr>
<tr>
<td>--debug[#]</td>
<td>debug</td>
<td>If this is a non-debug version, catch error and exit.</td>
<td></td>
</tr>
<tr>
<td>--debug-check</td>
<td>debug-check</td>
<td>--debug-check Check memory and open file usage at exit.</td>
<td></td>
</tr>
<tr>
<td>--default-auth=plugin</td>
<td>default-auth=plugin</td>
<td>The authentication plugin to use</td>
<td>5.5.10</td>
</tr>
<tr>
<td>--default-character-set=name</td>
<td>default-character-set</td>
<td>Set the default character set.</td>
<td></td>

</tr>
<tr>
<td>--tmpdir=path</td>
<td>tmpdir</td>
<td>Directory for temporary files</td>
<td></td>
</tr>
<tr>
<td>--user=name</td>
<td>user</td>
<td>User for login if not current user.</td>
<td></td>
</tr>
<tr>
<td>--verbose</td>
<td>verbose</td>
<td>Show more information about the process</td>
<td></td>
</tr>
<tr>
<td>--version-check</td>
<td>version-check</td>
<td>Check for proper server version</td>
<td>5.5.32</td>
</tr>
<tr>
<td>--write-binlog</td>
<td>write-binlog</td>
<td>Enables binary logging of all commands including mysqlcheck.</td>
<td></td>
</tr>
</tbody>
</table>

- **--help**
  Display a short help message and exit.

- **--basedir=path**
  The path to the MySQL installation directory. This option is accepted for backward compatibility but ignored. It is removed in MySQL 5.7.

- **--datadir=path**
  The path to the data directory. This option is accepted for backward compatibility but ignored. It is removed in MySQL 5.7.

- **--debug=debug_options, -# debug_options**
  Write a debugging log. A typical `debug_options` string is `d:t:O, file_name`. The default is `d:t:O, /tmp/mysql_upgrade.trace`.

- **--debug-check**
  Print some debugging information when the program exits.

- **--debug-info, -T**
  Print debugging information and memory and CPU usage statistics when the program exits.
• **--default-auth=plugin**
  The client-side authentication plugin to use. See [Section 6.3.6, “Pluggable Authentication”](#).
  This option was added in MySQL 5.5.10.

• **--defaults-extra-file=file_name**
  Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, file_name must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

• **--defaults-file=file_name**
  Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, file_name must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

• **--defaults-group-suffix=str**
  Read not only the usual option groups, but also groups with the usual names and a suffix of str. For example, mysql_upgrade normally reads the [client] and [mysql_upgrade] groups. If the **--defaults-group-suffix=_other** option is given, mysql_upgrade also reads the [client_other] and [mysql_upgrade_other] groups.

• **--force**
  Ignore the mysql_upgrade_info file and force execution of mysqlcheck even if mysql_upgrade has already been executed for the current version of MySQL.

• **--no-defaults**
  Do not read any option files. If program startup fails due to reading unknown options from an option file, **--no-defaults** can be used to prevent them from being read.

• **--plugin-dir=path**
  The directory in which to look for plugins. It may be necessary to specify this option if the --default-auth option is used to specify an authentication plugin but mysql_upgrade does not find it. See [Section 6.3.6, “Pluggable Authentication”](#).
  This option was added in MySQL 5.5.10.

• **--print-defaults**
  Print the program name and all options that it gets from option files.

• **--tmpdir=path, -t path**
  The path name of the directory to use for creating temporary files.

• **--upgrade-system-tables, -s**
  Upgrade only the system tables, do not upgrade data.

• **--user=user_name, -u user_name**
  The MySQL user name to use when connecting to the server. The default user name is root.
MySQL Client Programs

- **--verbose**
  Verbose mode. Print more information about what the program does.

- **--version-check, -k**
  Check the version of the server to which `mysql_upgrade` is connecting to verify that it is the same as the version for which `mysql_upgrade` was built. If not, `mysql_upgrade` exits. This option is enabled by default; to disable the check, use `--skip-version-check`. This option was added in MySQL 5.5.32.

- **--write-binlog**
  Cause binary logging to be enabled while `mysql_upgrade` runs. This is the default behavior; to disable binary logging during the upgrade, use the inverse of this option (that is, start the program with `--skip-write-binlog`).

### 4.5 MySQL Client Programs

This section describes client programs that connect to the MySQL server.

#### 4.5.1 `mysql` — The MySQL Command-Line Tool

`mysql` is a simple SQL shell with input line editing capabilities. It supports interactive and noninteractive use. When used interactively, query results are presented in an ASCII-table format. When used noninteractively (for example, as a filter), the result is presented in tab-separated format. The output format can be changed using command options.

If you have problems due to insufficient memory for large result sets, use the `--quick` option. This forces `mysql` to retrieve results from the server a row at a time rather than retrieving the entire result set and buffering it in memory before displaying it. This is done by returning the result set using the `mysql_use_result()` C API function in the client/server library rather than `mysql_store_result()`.

Using `mysql` is very easy. Invoke it from the prompt of your command interpreter as follows:

```
shell> mysql db_name
```

Or:

```
shell> mysql --user=user_name --password=your_password db_name
```

Then type an SQL statement, end it with `;`, `\g`, or `\G` and press Enter.

Typing `Control+C` causes `mysql` to attempt to kill the current statement. If this cannot be done, or `Control +C` is typed again before the statement is killed, `mysql` exits.

You can execute SQL statements in a script file (batch file) like this:

```
shell> mysql db_name < script.sql > output.tab
```

On Unix, the `mysql` client logs statements executed interactively to a history file. See Section 4.5.1.3, "mysql Logging".

#### 4.5.1.1 `mysql` Options
mysql supports the following options, which can be specified on the command line or in the [mysql] and [client] groups of an option file. For information about option files, see Section 4.2.6, “Using Option Files”.

**Table 4.5 mysql Options**

<table>
<thead>
<tr>
<th>Format</th>
<th>Option File</th>
<th>Description</th>
<th>Introduced</th>
<th>Removed</th>
</tr>
</thead>
<tbody>
<tr>
<td>--auto-rehash</td>
<td>auto-rehash</td>
<td>Enable automatic rehashing</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--auto-vertical-output</td>
<td>auto-vertical-output</td>
<td>Enable automatic vertical result set display</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--batch</td>
<td>batch</td>
<td>Don’t use history file</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--character-sets-dir=path</td>
<td>character-sets-dir</td>
<td>Set the default character set</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--column-names</td>
<td>column-names</td>
<td>Write column names in results</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--column-type-info</td>
<td>column-type-info</td>
<td>Display result set metadata</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--comments</td>
<td>comments</td>
<td>Whether to retain or strip comments in statements sent to the server</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--compress</td>
<td>compress</td>
<td>Compress all information sent between the client and the server</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--connect_timeout</td>
<td>connect_timeout=value</td>
<td>The number of seconds before connection timeout</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--database=dbname</td>
<td>database</td>
<td>The database to use</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--debug [=debug_options]</td>
<td>debug</td>
<td>Write a debugging log</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--debug-check</td>
<td>debug-check</td>
<td>Print debugging information when the program exits</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--debug-info</td>
<td>debug-info</td>
<td>Print debugging information, memory and CPU statistics when the program exits</td>
<td></td>
<td></td>

<td>force</td>
<td>Continue even if an SQL error occurs</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--help</td>
<td></td>
<td>Display help message and exit</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--host=host_name</td>
<td>host</td>
<td>Connect to the MySQL server on the given host</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--html</td>
<td>html</td>
<td>Produce HTML output</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--ignore-spaces</td>
<td>ignore-spaces</td>
<td>Ignore spaces after function names</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--init-command=str</td>
<td>init-command</td>
<td>SQL statement to execute after connecting</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--line-numbers</td>
<td>line-numbers</td>
<td>Write line numbers for errors</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--local-infile=[0</td>
<td>1]</td>
<td>local-infile</td>
<td>Enable or disable for LOCAL capability for LOAD DATA INFILE</td>
<td></td>
</tr>
<tr>
<td>--max_allowed_packet=value</td>
<td>max_allowed_packet=value</td>
<td>The maximum packet length to send to or receive from the server</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--max_join_size=value</td>
<td>max_join_size</td>
<td>The automatic limit for rows in a join when using --safe-updates</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--named-commands</td>
<td>named-commands</td>
<td>Enable named mysql commands</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--net_buffer_length=value</td>
<td>net_buffer_length=value</td>
<td>The buffer size for TCP/IP and socket communication</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--no-auto-rehash</td>
<td></td>
<td>Disable automatic rehashing</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--no-beep</td>
<td>no-beep</td>
<td>Do not beep when errors occur</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--no-defaults</td>
<td></td>
<td>Do not read any option files</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--no-named-commands</td>
<td>no-named-commands</td>
<td>Disable named mysql commands</td>
<td>5.5.3</td>
<td></td>
</tr>
<tr>

</tbody>
</table>
Format | Option File | Description | Introduced | Removed
--- | --- | --- | --- | ---
--tee=file_name | tee | Append a copy of output to the given file | | |
--unbuffered | unbuffered | Flush the buffer after each query | | |
--user=user_name | user | MySQL user name to use when connecting to server | | |
--verbose | | Verbose mode | | |
--version | | Display version information and exit | | |
--vertical | vertical | Print query output rows vertically (one line per column value) | | |
--wait | wait | If the connection cannot be established, wait and retry instead of aborting | | |
--xml | xml | Produce XML output | | |

- --help, -?

Display a help message and exit.

- --auto-rehash

Enable automatic rehashing. This option is on by default, which enables database, table, and column name completion. Use --disable-auto-rehash to disable rehashing. That causes mysql to start faster, but you must issue the `rehash` command or its `#` shortcut if you want to use name completion.

To complete a name, enter the first part and press Tab. If the name is unambiguous, mysql completes it. Otherwise, you can press Tab again to see the possible names that begin with what you have typed so far. Completion does not occur if there is no default database.

**Note**

This feature requires a MySQL client that is compiled with the `readline` library. Typically, the `readline` library is not available on Windows.

- --auto-vertical-output

Cause result sets to be displayed vertically if they are too wide for the current window, and using normal tabular format otherwise. (This applies to statements terminated by `;` or `\G`.) This option was added in MySQL 5.5.3.

- --batch, -B

Print results using tab as the column separator, with each row on a new line. With this option, mysql does not use the history file.

Batch mode results in nontabular output format and escaping of special characters. Escaping may be disabled by using raw mode; see the description for the --raw option.

- --bind-address=ip_address

On a computer having multiple network interfaces, this option can be used to select which interface is employed when connecting to the MySQL server.

This option is supported only in the version of the mysql client that is supplied with MySQL Cluster. It is not available in standard MySQL Server 5.5 releases.
• **--character-sets-dir=path**
The directory where character sets are installed. See Section 10.5, "Character Set Configuration".

• **--column-names**
Write column names in results.

• **--column-type-info,-m**
Display result set metadata.

• **--comments,-c**
Whether to preserve comments in statements sent to the server. The default is --skip-comments (discard comments), enable with --comments (preserve comments).

• **--compress,-C**
Compress all information sent between the client and the server if both support compression.

• **--database=db_name,-D db_name**
The database to use. This is useful primarily in an option file.

• **--debug[=debug_options],-# [debug_options]**
Write a debugging log. A typical debug_options string is d:t:o, file_name. The default is d:t:o, /tmp/mysql.trace.

• **--debug-check**
Print some debugging information when the program exits.

• **--debug-info,-T**
Print debugging information and memory and CPU usage statistics when the program exits.

• **--default-auth=plugin**
The client-side authentication plugin to use. See Section 6.3.6, "Pluggable Authentication". This option was added in MySQL 5.5.7.

• **--default-character-set=charset_name**
Use charset_name as the default character set for the client and connection.

A common issue that can occur when the operating system uses utf8 or another multi-byte character set is that output from the mysql client is formatted incorrectly, due to the fact that the MySQL client uses the latin1 character set by default. You can usually fix such issues by using this option to force the client to use the system character set instead.

See Section 10.5, "Character Set Configuration", for more information.

• **--defaults-extra-file=file_name**
Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, file_name must be the full
path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- **--defaults-file=file_name**
  Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, `file_name` must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- **--defaults-group-suffix=str**
  Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysql` normally reads the `[client]` and `[mysql]` groups. If the `--defaults-group-suffix=_other` option is given, `mysql` also reads the `[client_other]` and `[mysql_other]` groups.

- **--delimiter=str**
  Set the statement delimiter. The default is the semicolon character (";").

- **--disable-named-commands**
  Disable named commands. Use the `\*` form only, or use named commands only at the beginning of a line ending with a semicolon (";`). `mysql` starts with this option enabled by default. However, even with this option, long-format commands still work from the first line. See Section 4.5.1.2, "mysql Commands".

- **--enable-cleartext-plugin**
  Enable the `mysql_clear_password` cleartext authentication plugin. (See Section 6.3.7.5, "The Cleartext Client-Side Authentication Plugin".) This option was added in MySQL 5.5.27.

- **--execute=statement, -e statement**
  Execute the statement and quit. The default output format is like that produced with `--batch`. See Section 4.2.4, "Using Options on the Command Line", for some examples. With this option, `mysql` does not use the history file.

- **--force,-f**
  Continue even if an SQL error occurs.

- **--host=host_name, -h host_name**
  Connect to the MySQL server on the given host.

- **--html,-H**
  Produce HTML output.

- **--ignore-spaces,-i**
  Ignore spaces after function names. The effect of this is described in the discussion for the `IGNORE_SPACE` SQL mode (see Section 5.1.7, "Server SQL Modes").

- **--init-command=str**
  SQL statement to execute after connecting to the server. If auto-reconnect is enabled, the statement is executed again after reconnection occurs.
• **--line-numbers**

Write line numbers for errors. Disable this with **--skip-line-numbers**.

• **--local-infile[={0|1}]**

Enable or disable LOCAL capability for LOAD DATA INFILE. With no value, the option enables LOCAL. The option may be given as **--local-infile=0** or **--local-infile=1** to explicitly disable or enable LOCAL. Enabling LOCAL has no effect if the server does not also support it.

• **--named-commands, -G**

Enable named mysql commands. Long-format commands are permitted, not just short-format commands. For example, quit and \q both are recognized. Use **--skip-named-commands** to disable named commands. See Section 4.5.1.2, “mysql Commands”.

• **--no-auto-rehash, -A**

This has the same effect as **--skip-auto-rehash**. See the description for **--auto-rehash**.

• **--no-beep, -b**

Do not beep when errors occur.

• **--no-defaults**

Do not read any option files. If program startup fails due to reading unknown options from an option file, **--no-defaults** can be used to prevent them from being read.

• **--no-named-commands, -g**

Deprecated, use **--disable-named-commands** instead. **--no-named-commands** was removed in MySQL 5.5.3.

• **--no-pager**

Deprecated form of **--skip-pager**. See the **--pager** option. **--no-pager** was removed in MySQL 5.5.3.

• **--no-tee**

Deprecated form of **--skip-tee**. See the **--tee** option. **--no-tee** is removed in MySQL 5.5.3.

• **--one-database, -o**

Ignore statements except those that occur while the default database is the one named on the command line. This option is rudimentary and should be used with care. Statement filtering is based only on USE statements.

Initially, mysql executes statements in the input because specifying a database *db_name* on the command line is equivalent to inserting USE *db_name* at the beginning of the input. Then, for each USE statement encountered, mysql accepts or rejects following statements depending on whether the database named is the one on the command line. The content of the statements is immaterial.

Suppose that mysql is invoked to process this set of statements:

```
DELETE FROM db2.t2;
USE db2;
```
DROP TABLE db1.t1;
CREATE TABLE db1.t1 (i INT);
USE db1;
INSERT INTO t1 (i) VALUES(1);
CREATE TABLE db2.t1 (j INT);

If the command line is `mysql --force --one-database db1`, `mysql` handles the input as follows:

- The `DELETE` statement is executed because the default database is `db1`, even though the statement names a table in a different database.
- The `DROP TABLE` and `CREATE TABLE` statements are not executed because the default database is not `db1`, even though the statements name a table in `db1`.
- The `INSERT` and `CREATE TABLE` statements are executed because the default database is `db1`, even though the `CREATE TABLE` statement names a table in a different database.

- `--pager[=command]`
  Use the given command for paging query output. If the command is omitted, the default pager is the value of your `PAGER` environment variable. Valid pagers are `less`, `more`, `cat` `[> filename]`, and so forth. This option works only on Unix and only in interactive mode. To disable paging, use `--skip-pager`. Section 4.5.1.2, "mysql Commands", discusses output paging further.

- `--password[=password], -p[password]`
  The password to use when connecting to the server. If you use the short option form `(-p)`, you cannot have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysql` prompts for one.

Specifying a password on the command line should be considered insecure. See Section 6.1.2.1, "End-User Guidelines for Password Security". You can use an option file to avoid giving the password on the command line.

- `--pipe, -W`
  On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=path`
  The directory in which to look for plugins. It may be necessary to specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysql` does not find it. See Section 6.3.6, "Pluggable Authentication".

This option was added in MySQL 5.5.7.

- `--port=port_num, -P port_num`
  The TCP/IP port number to use for the connection.

- `--print-defaults`
  Print the program name and all options that it gets from option files.

- `--prompt=format_str`
  Set the prompt to the specified format. The default is `mysql>`. The special sequences that the prompt can contain are described in Section 4.5.1.2, "mysql Commands".

307
•  **--protocol={TCP|SOCKET|PIPE|MEMORY}**

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see Section 4.2.2, “Connecting to the MySQL Server”.

•  **--quick,-q**

Do not cache each query result, print each row as it is received. This may slow down the server if the output is suspended. With this option, `mysql` does not use the history file.

•  **--raw,-r**

For tabular output, the “boxing” around columns enables one column value to be distinguished from another. For nontabular output (such as is produced in batch mode or when the `--batch` or `--silent` option is given), special characters are escaped in the output so they can be identified easily. Newline, tab, NUL, and backslash are written as \n, \t, \0, and \\. The **--raw** option disables this character escaping.

The following example demonstrates tabular versus nontabular output and the use of raw mode to disable escaping:

```sql
% mysql
mysql> SELECT CHAR(92);
+----------+
| CHAR(92) |
+----------+
| \        |
+----------+
% mysql -s
mysql> SELECT CHAR(92);
CHAR(92)
\
% mysql -s -r
mysql> SELECT CHAR(92);
CHAR(92)
\`

•  **--reconnect**

If the connection to the server is lost, automatically try to reconnect. A single reconnect attempt is made each time the connection is lost. To suppress reconnection behavior, use `--skip-reconnect`.

•  **--safe-updates,--i-am-a-dummy,-U**

Permit only those `UPDATE` and `DELETE` statements that specify which rows to modify by using key values. If you have set this option in an option file, you can override it by using `--safe-updates` on the command line. See Section 4.5.1.6, “mysql Tips”, for more information about this option.

•  **--secure-auth**

Do not send passwords to the server in old (pre-4.1) format. This prevents connections except for servers that use the newer password format.
Note

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided.

- `--show-warnings`
  Cause warnings to be shown after each statement if there are any. This option applies to interactive and batch mode.

- `--sigint-ignore`
  Ignore SIGINT signals (typically the result of typing Control+C).

- `--silent, -s`
  Silent mode. Produce less output. This option can be given multiple times to produce less and less output.

  This option results in nontabular output format and escaping of special characters. Escaping may be disabled by using raw mode; see the description for the `--raw` option.

- `--skip-column-names, -N`
  Do not write column names in results.

- `--skip-line-numbers, -L`
  Do not write line numbers for errors. Useful when you want to compare result files that include error messages.

- `--socket=path, -S path`
  For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`
  Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See Section 6.3.9.4, “SSL Command Options”.

- `--table, -t`
  Display output in table format. This is the default for interactive use, but can be used to produce table output in batch mode.

- `--tee=file_name`
  Append a copy of output to the given file. This option works only in interactive mode. Section 4.5.1.2, “mysql Commands”, discusses tee files further.

- `--unbuffered, -n`
  Flush the buffer after each query.

- `--user=user_name, -u user_name`
  The MySQL user name to use when connecting to the server.
• `--verbose, -v`

Verbose mode. Produce more output about what the program does. This option can be given multiple times to produce more and more output. (For example, `-v -v -v` produces table output format even in batch mode.)

• `--version, -V`

Display version information and exit.

• `--vertical, -E`

Print query output rows vertically (one line per column value). Without this option, you can specify vertical output for individual statements by terminating them with `\G`.

• `--wait, -w`

If the connection cannot be established, wait and retry instead of aborting.

• `--xml, -X`

Produce XML output.

```xml
<field name="column_name">NULL</field>
```

The output when `--xml` is used with `mysql` matches that of `mysqldump --xml`. See Section 4.5.4, “mysqldump — A Database Backup Program” for details.

The XML output also uses an XML namespace, as shown here:

```xml
shell> mysql --xml -uroot -e "SHOW VARIABLES LIKE 'version\%'"
<?xml version="1.0"?>
<resultset statement="SHOW VARIABLES LIKE 'version\%'" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <row>
    <field name="Variable_name">version</field>
    <field name="Value">5.0.40-debug</field>
  </row>
  <row>
    <field name="Variable_name">version_comment</field>
    <field name="Value">Source distribution</field>
  </row>
  <row>
    <field name="Variable_name">version_compile_machine</field>
    <field name="Value">i686</field>
  </row>
  <row>
    <field name="Variable_name">version_compile_os</field>
    <field name="Value">suse-linux-gnu</field>
  </row>
</resultset>
```

(See Bug #25946.)

You can also set the following variables by using `--var_name=value`. The `--set-variable` format is deprecated and was removed in MySQL 5.5.3.

• `connect_timeout`
The number of seconds before connection timeout. (Default value is 0.)

- **max_allowed_packet**
  
  The maximum size of the buffer for client/server communication. The default is 16MB, the maximum is 1GB.

- **max_join_size**
  
  The automatic limit for rows in a join when using --safe-updates. (Default value is 1,000,000.)

- **net_buffer_length**
  
  The buffer size for TCP/IP and socket communication. (Default value is 16KB.)

- **select_limit**
  
  The automatic limit for SELECT statements when using --safe-updates. (Default value is 1,000.)

### 4.5.1.2 mysql Commands

mysql sends each SQL statement that you issue to the server to be executed. There is also a set of commands that mysql itself interprets. For a list of these commands, type help or \h at the mysql> prompt:

```sql
mysql> help

List of all MySQL commands:
Note that all text commands must be first on line and end with ';
?
(\?) Synonym for 'help'.
clear (\c) Clear command.
connect (\r) Reconnect to the server. Optional arguments are db and host.
delimiter (\d) Set statement delimiter.
edit (\e) Edit command with $EDITOR.
eg (\G) Send command to mysql server, display result vertically.
exit (\q) Exit mysql. Same as quit.
go (\g) Send command to mysql server.
help (\h) Display this help.
nopager (\n) Disable pager, print to stdout.
note (\t) Don't write into outfile.
pager (\P) Set PAGER [to_pager]. Print the query results via PAGER.
print (\p) Print current command.
prompt (\R) Change your mysql prompt.
quit (\q) Quit mysql.
rehash (\#) Rebuild completion hash.
source (\.) Execute an SQL script file. Takes a file name as an argument.
status (\a) Get status information from the server.
system (\!) Execute a system shell command.
tee (\T) Set outfile [to_outfile]. Append everything into given outfile.
use (\u) Use another database. Takes database name as argument.
charset (\C) Switch to another charset. Might be needed for processing binlog with multi-byte charsets.
warnings (\W) Show warnings after every statement.
nowarning (\w) Don't show warnings after every statement.
```

For server side help, type 'help contents'

Each command has both a long and short form. The long form is not case sensitive; the short form is. The long form can be followed by an optional semicolon terminator, but the short form should not.

The use of short-form commands within multi-line /* ... */ comments is not supported.
• `help [arg], \h [arg], \? [arg], \? [arg]`

Display a help message listing the available `mysql` commands.

If you provide an argument to the `help` command, `mysql` uses it as a search string to access server-side help from the contents of the MySQL Reference Manual. For more information, see Section 4.5.1.4, “mysql Server-Side Help”.

• `charset charset_name, \C charset_name`

Change the default character set and issue a SET NAMES statement. This enables the character set to remain synchronized on the client and server if `mysql` is run with auto-reconnect enabled (which is not recommended), because the specified character set is used for reconnects.

• `clear, \c`

Clear the current input. Use this if you change your mind about executing the statement that you are entering.

• `connect [db_name host_name], \r [db_name host_name]`

Reconnect to the server. The optional database name and host name arguments may be given to specify the default database or the host where the server is running. If omitted, the current values are used.

• `delimiter str, \d str`

Change the string that `mysql` interprets as the separator between SQL statements. The default is the semicolon character (“;”).

The delimiter string can be specified as an unquoted or quoted argument on the `delimiter` command line. Quoting can be done with either single quote (‘), double quote ("), or backtick (‘) characters. To include a quote within a quoted string, either quote the string with a different quote character or escape the quote with a backslash ("\") character. Backslash should be avoided outside of quoted strings because it is the escape character for MySQL. For an unquoted argument, the delimiter is read up to the first space or end of line. For a quoted argument, the delimiter is read up to the matching quote on the line.

`mysql` interprets instances of the delimiter string as a statement delimiter anywhere it occurs, except within quoted strings. Be careful about defining a delimiter that might occur within other words. For example, if you define the delimiter as X, you will be unable to use the word INDEX in statements. `mysql` interprets this as INDE followed by the delimiter X.

When the delimiter recognized by `mysql` is set to something other than the default of “;”, instances of that character are sent to the server without interpretation. However, the server itself still interprets “;” as a statement delimiter and processes statements accordingly. This behavior on the server side comes into play for multiple-statement execution (see Section 23.8.17, “C API Support for Multiple Statement Execution”), and for parsing the body of stored procedures and functions, triggers, and events (see Section 20.1, “Defining Stored Programs”).

• `edit, \e`

Edit the current input statement. `mysql` checks the values of the EDITOR and VISUAL environment variables to determine which editor to use. The default editor is vi if neither variable is set.

The edit command works only in Unix.
Send the current statement to the server to be executed and display the result using vertical format.

Send the current statement to the server to be executed.

Disable output paging. See the description for pager.

The nopager command works only in Unix.

Disable output copying to the tee file. See the description for tee.

Disable display of warnings after each statement.

Enable output paging. By using the --pager option when you invoke mysql, it is possible to browse or search query results in interactive mode with Unix programs such as less, more, or any other similar program. If you specify no value for the option, mysql checks the value of the PAGER environment variable and sets the pager to that. Pager functionality works only in interactive mode.

Output paging can be enabled interactively with the pager command and disabled with nopager. The command takes an optional argument; if given, the paging program is set to that. With no argument, the pager is set to the pager that was set on the command line, or stdout if no pager was specified.

Output paging works only in Unix because it uses the popen() function, which does not exist on Windows. For Windows, the tee option can be used instead to save query output, although it is not as convenient as pager for browsing output in some situations.

Print the current input statement without executing it.

Reconfigure the mysql prompt to the given string. The special character sequences that can be used in the prompt are described later in this section.

If you specify the prompt command with no argument, mysql resets the prompt to the default of mysql>.

Exit mysql.

Rehash,
Rebuild the completion hash that enables database, table, and column name completion while you are entering statements. (See the description for the `--auto-rehash` option.)

- `source file_name, \. file_name`

Read the named file and executes the statements contained therein. On Windows, you can specify path name separators as `/` or `\`.

- `status, \s`

Provide status information about the connection and the server you are using. If you are running in `--safe-updates` mode, `status` also prints the values for the `mysql` variables that affect your queries.

- `system command, \! command`

Execute the given command using your default command interpreter.

The `system` command works only in Unix.

- `tee [file_name], \T [file_name]`

By using the `--tee` option when you invoke `mysql`, you can log statements and their output. All the data displayed on the screen is appended into a given file. This can be very useful for debugging purposes also. `mysql` flushes results to the file after each statement, just before it prints its next prompt. Tee functionality works only in interactive mode.

You can enable this feature interactively with the `tee` command. Without a parameter, the previous file is used. The `tee` file can be disabled with the `notee` command. Executing `tee` again re-enables logging.

- `use db_name, \u db_name`

Use `db_name` as the default database.

- `warnings, \W`

Enable display of warnings after each statement (if there are any).

Here are a few tips about the `pager` command:

- You can use it to write to a file and the results go only to the file:

  ```
  mysql> pager cat > /tmp/log.txt
  ```

  You can also pass any options for the program that you want to use as your pager:

  ```
  mysql> pager less -n -i -S
  ```

  In the preceding example, note the `-S` option. You may find it very useful for browsing wide query results. Sometimes a very wide result set is difficult to read on the screen. The `-S` option to `less` can make the result set much more readable because you can scroll it horizontally using the left-arrow and right-arrow keys. You can also use `-S` interactively within `less` to switch the horizontal-browse mode on and off. For more information, read the `less` manual page:

  ```
  shell> man less
  ```
• The `-F` and `-X` options may be used with `less` to cause it to exit if output fits on one screen, which is convenient when no scrolling is necessary:

```
mysql> pager less -n -i -S -F -X
```

• You can specify very complex pager commands for handling query output:

```
mysql> pager cat | tee /dr1/tmp/res.txt \ |
| tee /dr2/tmp/res2.txt | less -n -i -S
```

In this example, the command would send query results to two files in two different directories on two different file systems mounted on `/dr1` and `/dr2`, yet still display the results onscreen using `less`.

You can also combine the `tee` and `pager` functions. Have a `tee` file enabled and `pager` set to `less`, and you are able to browse the results using the `less` program and still have everything appended into a file the same time. The difference between the Unix `tee` used with the `pager` command and the `mysql` built-in `tee` command is that the built-in `tee` works even if you do not have the Unix `tee` available. The built-in `tee` also logs everything that is printed on the screen, whereas the Unix `tee` used with `pager` does not log quite that much. Additionally, `tee` file logging can be turned on and off interactively from within `mysql`. This is useful when you want to log some queries to a file, but not others.

The `prompt` command reconfigures the default `mysql>` prompt. The string for defining the prompt can contain the following special sequences.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>\c</code></td>
<td>A counter that increments for each statement you issue</td>
</tr>
<tr>
<td><code>\D</code></td>
<td>The full current date</td>
</tr>
<tr>
<td><code>\d</code></td>
<td>The default database</td>
</tr>
<tr>
<td><code>\h</code></td>
<td>The server host</td>
</tr>
<tr>
<td><code>\l</code></td>
<td>The current delimiter</td>
</tr>
<tr>
<td><code>\m</code></td>
<td>Minutes of the current time</td>
</tr>
<tr>
<td><code>\n</code></td>
<td>A newline character</td>
</tr>
<tr>
<td><code>\O</code></td>
<td>The current month in three-letter format (Jan, Feb, …)</td>
</tr>
<tr>
<td><code>\o</code></td>
<td>The current month in numeric format</td>
</tr>
<tr>
<td><code>\P</code></td>
<td>am/pm</td>
</tr>
<tr>
<td><code>\p</code></td>
<td>The current TCP/IP port or socket file</td>
</tr>
<tr>
<td><code>\R</code></td>
<td>The current time, in 24-hour military time (0–23)</td>
</tr>
<tr>
<td><code>\r</code></td>
<td>The current time, standard 12-hour time (1–12)</td>
</tr>
<tr>
<td><code>\S</code></td>
<td>Semicolon</td>
</tr>
<tr>
<td><code>\s</code></td>
<td>Seconds of the current time</td>
</tr>
<tr>
<td><code>\t</code></td>
<td>A tab character</td>
</tr>
<tr>
<td><code>\U</code></td>
<td>Your full <code>user_name@host_name</code> account name</td>
</tr>
<tr>
<td><code>\u</code></td>
<td>Your user name</td>
</tr>
<tr>
<td><code>\v</code></td>
<td>The server version</td>
</tr>
<tr>
<td><code>\w</code></td>
<td>The current day of the week in three-letter format (Mon, Tue, …)</td>
</tr>
<tr>
<td><code>\Y</code></td>
<td>The current year, four digits</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
<tr>
<td>\y</td>
<td>The current year, two digits</td>
</tr>
<tr>
<td>_</td>
<td>A space</td>
</tr>
<tr>
<td>\</td>
<td>A space (a space follows the backslash)</td>
</tr>
<tr>
<td>'</td>
<td>Single quote</td>
</tr>
<tr>
<td>&quot;</td>
<td>Double quote</td>
</tr>
<tr>
<td>\</td>
<td>A literal &quot;&quot; backslash character</td>
</tr>
<tr>
<td>\x</td>
<td>, for any “x” not listed above</td>
</tr>
</tbody>
</table>

You can set the prompt in several ways:

- **Use an environment variable.** You can set the `MYSQL_PS1` environment variable to a prompt string. For example:

  ```shell```
  export MYSQL_PS1="(\u@\h) [\d]> "
  ```shell```

- **Use a command-line option.** You can set the `--prompt` option on the command line to `mysql`. For example:

  ```shell```
  mysql --prompt="(\u@\h) [\d]> " (user@host) [database]>
  ```shell```

- **Use an option file.** You can set the `prompt` option in the `[mysql]` group of any MySQL option file, such as `/etc/my.cnf` or the `.my.cnf` file in your home directory. For example:

  ```ini```
  [mysql]
  prompt="(\\u\\@\\h) [\\d\\]\\>\\_"
  ```ini```

  In this example, note that the backslashes are doubled. If you set the prompt using the `prompt` option in an option file, it is advisable to double the backslashes when using the special prompt options. There is some overlap in the set of permissible prompt options and the set of special escape sequences that are recognized in option files. (The rules for escape sequences in option files are listed in Section 4.2.6, “Using Option Files”.) The overlap may cause you problems if you use single backslashes. For example, \s is interpreted as a space rather than as the current seconds value. The following example shows how to define a prompt within an option file to include the current time in `HH:MM:SS>` format:

  ```ini```
  [mysql]
  prompt="\r:\m:\s> "
  ```ini```

- **Set the prompt interactively.** You can change your prompt interactively by using the `prompt` (or `\R`) command. For example:

  ```mysql```
  prompt "(\u@\h) [\d]\>\_" 
  PROMPT set to '"(\u@\h) [\d]\>\_"' 
  (user@host) [database]>
  (user@host) [database]> prompt
  Returning to default PROMPT of mysql>
  mysql>
  ```mysql```

### 4.5.1.3 `mysql` Logging
On Unix, the mysql client logs statements executed interactively to a history file. By default, this file is named .mysql_history in your home directory. To specify a different file, set the value of the MYSQL_HISTFILE environment variable.

### How Logging Occurs

Statement logging occurs as follows:

- Statements are logged only when executed interactively. Statements are noninteractive, for example, when read from a file or a pipe. It is also possible to suppress statement logging by using the --batch or --execute option.

- mysql logs each nonempty statement line individually.

- If a statement spans multiple lines (not including the terminating delimiter), mysql concatenates the lines to form the complete statement, maps newlines to spaces, and logs the result, plus a delimiter.

Consequently, an input statement that spans multiple lines can be logged twice. Consider this input:

```sql
mysql> SELECT 'Today is', CONCAT(), ;
```

In this case, mysql logs the “SELECT”, “Today is”, “”, “CONCAT()”, and “;” lines as it reads them. It also logs the complete statement, after mapping `SELECT\n'Today is'\n,\nCURDATE()` to `SELECT 'Today is' , CURDATE()`, plus a delimiter. Thus, these lines appear in logged output:

```
SELECT 'Today is'
,
CURDATE()
;
SELECT 'Today is' , CURDATE();
```

### Controlling the History File

The .mysql_history file should be protected with a restrictive access mode because sensitive information might be written to it, such as the text of SQL statements that contain passwords. See Section 6.1.2.1, “End-User Guidelines for Password Security”.

If you do not want to maintain a history file, first remove .mysql_history if it exists. Then use either of the following techniques to prevent it from being created again:

- Set the MYSQL_HISTFILE environment variable to /dev/null. To cause this setting to take effect each time you log in, put it in one of your shell's startup files.

- Create .mysql_history as a symbolic link to /dev/null; this need be done only once:

  ```
  shell> ln -s /dev/null $HOME/.mysql_history
  ```

### 4.5.1.4 mysql Server-Side Help

mysql> help search_string

If you provide an argument to the help command, mysql uses it as a search string to access server-side help from the contents of the MySQL Reference Manual. The proper operation of this command requires
that the help tables in the `mysql` database be initialized with help topic information (see Section 5.1.10, “Server-Side Help”).

If there is no match for the search string, the search fails:

```sql
mysql> help me
Nothing found
Please try to run 'help contents' for a list of all accessible topics
```

Use `help contents` to see a list of the help categories:

```sql
mysql> help contents
You asked for help about help category: "Contents"
For more information, type 'help <item>', where <item> is one of the following categories:
  Account Management
  Administration
  Data Definition
  Data Manipulation
  Data Types
  Functions
  Functions and Modifiers for Use with GROUP BY
  Geographic Features
  Language Structure
  Plugins
  Storage Engines
  Stored Routines
  Table Maintenance
  Transactions
  Triggers
```

If the search string matches multiple items, `mysql` shows a list of matching topics:

```sql
mysql> help logs
Many help items for your request exist.
To make a more specific request, please type 'help <item>', where <item> is one of the following topics:
  SHOW
  SHOW BINARY LOGS
  SHOW ENGINE
  SHOW LOGS
```

Use a topic as the search string to see the help entry for that topic:

```sql
mysql> help show binary logs
Name: 'SHOW BINARY LOGS'
Description:
Syntax:
  SHOW BINARY LOGS
  SHOW MASTER LOGS
Lists the binary log files on the server. This statement is used as part of the procedure described in [purge-binary-logs], that shows how to determine which logs can be purged.

mysql> SHOW BINARY LOGS;
+---------------+-----------+
| Log_name      | File_size |
+---------------+-----------+
| binlog.000015 | 724935    |
| binlog.000016 | 733481    |
```
The search string can contain the wildcard characters “%” and “_”. These have the same meaning as for pattern-matching operations performed with the LIKE operator. For example, HELP rep% returns a list of topics that begin with rep:

```
mysql> HELP rep%
Many help items for your request exist. To make a more specific request, please type 'help <item>', where <item> is one of the following topics:
   REPAIR TABLE
   REPEAT FUNCTION
   REPLACE LOOP
   REPLACE
   REPLACE FUNCTION
```

### 4.5.1.5 Executing SQL Statements from a Text File

The mysql client typically is used interactively, like this:

```
shell> mysql db_name
```

However, it is also possible to put your SQL statements in a file and then tell mysql to read its input from that file. To do so, create a text file text_file that contains the statements you wish to execute. Then invoke mysql as shown here:

```
shell> mysql db_name < text_file
```

If you place a USE db_name statement as the first statement in the file, it is unnecessary to specify the database name on the command line:

```
shell> mysql < text_file
```

If you are already running mysql, you can execute an SQL script file using the source command or \. command:

```
mysql> source file_name
mysql> \ source file_name
```

Sometimes you may want your script to display progress information to the user. For this you can insert statements like this:

```
SELECT '<info_to_display>' AS ' ';
```

The statement shown outputs <info_to_display>.

You can also invoke mysql with the --verbose option, which causes each statement to be displayed before the result that it produces.

mysql ignores Unicode byte order mark (BOM) characters at the beginning of input files. Previously, it read them and sent them to the server, resulting in a syntax error. Presence of a BOM does not cause mysql to change its default character set. To do that, invoke mysql with an option such as --default-character-set=utf8.

For more information about batch mode, see Section 3.5, "Using mysql in Batch Mode".
4.5.1.6 mysql Tips

This section describes some techniques that can help you use mysql more effectively.

Input-Line Editing

mysql supports input-line editing, which enables you to modify the current input line in place or recall previous input lines. For example, the left-arrow and right-arrow keys move horizontally within the current input line, and the up-arrow and down-arrow keys move up and down through the set of previously entered lines. Backspace deletes the character before the cursor and typing new characters enters them at the cursor position. To enter the line, press Enter.

On Windows, the editing key sequences are the same as supported for command editing in console windows. On Unix, the key sequences depend on the input library used to build mysql (for example, the libedit or readline library).

Documentation for the libedit and readline libraries is available online. To change the set of key sequences permitted by a given input library, define key bindings in the library startup file. This is a file in your home directory: .editrc for libedit and .inputrc for readline.

For example, in libedit, Control+W deletes everything before the current cursor position and Control+U deletes the entire line. In readline, Control+W deletes the word before the cursor and Control+U deletes everything before the current cursor position. If mysql was built using libedit, a user who prefers the readline behavior for these two keys can put the following lines in the .editrc file (creating the file if necessary):

bind "^W" ed-delete-prev-word
bind "^U" vi-kill-line-prev

To see the current set of key bindings, temporarily put a line that says only bind at the end of .editrc. mysql will show the bindings when it starts.

Displaying Query Results Vertically

Some query results are much more readable when displayed vertically, instead of in the usual horizontal table format. Queries can be displayed vertically by terminating the query with \G instead of a semicolon. For example, longer text values that include newlines often are much easier to read with vertical output:

```sql
mysql> SELECT * FROM mails WHERE LENGTH(txt) < 300 LIMIT 300,1\G
*************************** 1. row ***************************
msg_nro: 3068
date: 2000-03-01 23:29:50
time_zone: +0200
mail_from: Monty
reply: monty@no.spam.com
mail_to: "Thimble Smith" <tim@no.spam.com>
subj: UTF-8
txt: >>>>> "Thimble" == Thimble Smith writes:
Thimble> Hi. I think this is a good idea. Is anyone familiar with UTF-8 or Unicode? Otherwise, I'll put this on my TODO list and see what happens.

Yes, please do that.

Regards,
Monty

file: inbox-jani-1
hash: 190402944
1 row in set (0.09 sec)
```
Using the **--safe-updates** Option

For beginners, a useful startup option is **--safe-updates** (or **--i-am-a-dummy**, which has the same effect). It is helpful for cases when you might have issued a `DELETE FROM tbl_name` statement but forgotten the `WHERE` clause. Normally, such a statement deletes all rows from the table. With **--safe-updates**, you can delete rows only by specifying the key values that identify them. This helps prevent accidents.

When you use the **--safe-updates** option, `mysql` issues the following statement when it connects to the MySQL server:

```
SET sql_safe_updates=1, sql_select_limit=1000, sql_max_join_size=1000000;
```

See Section 5.1.4, “Server System Variables”.

The `SET` statement has the following effects:

- You are not permitted to execute an `UPDATE` or `DELETE` statement unless you specify a key constraint in the `WHERE` clause or provide a `LIMIT` clause (or both). For example:

  ```
  UPDATE tbl_name SET not_key_column=val WHERE key_column=val;
  UPDATE tbl_name SET not_key_column=val LIMIT 1;
  ```

- The server limits all large `SELECT` results to 1,000 rows unless the statement includes a `LIMIT` clause.

- The server aborts multiple-table `SELECT` statements that probably need to examine more than 1,000,000 row combinations.

To specify limits different from 1,000 and 1,000,000, you can override the defaults by using the **--select_limit** and **--max_join_size** options:

```
shell> mysql --safe-updates --select_limit=500 --max_join_size=10000
```

Disabling `mysql` Auto-Reconnect

If the `mysql` client loses its connection to the server while sending a statement, it immediately and automatically tries to reconnect once to the server and send the statement again. However, even if `mysql` succeeds in reconnecting, your first connection has ended and all your previous session objects and settings are lost: temporary tables, the autocommit mode, and user-defined and session variables. Also, any current transaction rolls back. This behavior may be dangerous for you, as in the following example where the server was shut down and restarted between the first and second statements without you knowing it:

```
mysql> SET @a=1;
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO t VALUES(@a);
ERROR 2006: MySQL server has gone away
No connection. Trying to reconnect...
Connection id:    1
Current database: test
Query OK, 1 row affected (1.30 sec)

mysql> SELECT * FROM t;
---
| a |
```
The `@a` user variable has been lost with the connection, and after the reconnection it is undefined. If it is important to have `mysql` terminate with an error if the connection has been lost, you can start the `mysql` client with the `--skip-reconnect` option.

For more information about auto-reconnect and its effect on state information when a reconnection occurs, see Section 23.8.16, “Controlling Automatic Reconnection Behavior”.

### 4.5.2 `mysqladmin` — Client for Administering a MySQL Server

`mysqladmin` is a client for performing administrative operations. You can use it to check the server’s configuration and current status, to create and drop databases, and more.

Invoke `mysqladmin` like this:

```shell
shell> mysqladmin [options] command [command-arg] [command [command-arg]] ...
```

`mysqladmin` supports the following commands. Some of the commands take an argument following the command name.

- **create `db_name`**
  Create a new database named `db_name`.

- **debug**
  Tell the server to write debug information to the error log. Format and content of this information is subject to change.
  This includes information about the Event Scheduler. See Section 20.4.5, “Event Scheduler Status”.

- **drop `db_name`**
  Delete the database named `db_name` and all its tables.

- **extended-status**
  Display the server status variables and their values.

- **flush-hosts**
  Flush all information in the host cache.

- **flush-logs**
  Flush all logs.

- **flush-privileges**
  Reload the grant tables (same as `reload`).

- **flush-status**
  Clear status variables.

- **flush-tables**
Flush all tables.

• **flush-threads**

  Flush the thread cache.

• **kill id, id,…**

  Kill server threads. If multiple thread ID values are given, there must be no spaces in the list.

• **old-password new-password**

  This is like the `password` command but stores the password using the old (pre-4.1) password-hashing format. (See Section 6.1.2.4, “Password Hashing in MySQL”.)

• **password new-password**

  Set a new password. This changes the password to `new-password` for the account that you use with `mysqladmin` for connecting to the server. Thus, the next time you invoke `mysqladmin` (or any other client program) using the same account, you will need to specify the new password.

If the `new-password` value contains spaces or other characters that are special to your command interpreter, you need to enclose it within quotation marks. On Windows, be sure to use double quotation marks rather than single quotation marks; single quotation marks are not stripped from the password, but rather are interpreted as part of the password. For example:

```
shell> mysqladmin password "my new password"
```

As of MySQL 5.5.3, the new password can be omitted following the `password` command. In this case, `mysqladmin` prompts for the password value, which enables you to avoid specifying the password on the command line. Omitting the password value should be done only if `password` is the final command on the `mysqladmin` command line. Otherwise, the next argument is taken as the password.

**Caution**

Do not use this command used if the server was started with the `--skip-grant-tables` option. No password change will be applied. This is true even if you precede the `password` command with `flush-privileges` on the same command line to re-enable the grant tables because the flush operation occurs after you connect. However, you can use `mysqladmin flush-privileges` to re-enable the grant table and then use a separate `mysqladmin password` command to change the password.

• **ping**

  Check whether the server is available. The return status from `mysqladmin` is 0 if the server is running, 1 if it is not. This is 0 even in case of an error such as `Access denied`, because this means that the server is running but refused the connection, which is different from the server not running.

• **processlist**

  Show a list of active server threads. This is like the output of the `SHOW PROCESSLIST` statement. If the `--verbose` option is given, the output is like that of `SHOW FULL PROCESSLIST`. (See Section 13.7.5.30, “SHOW PROCESSLIST Syntax”.)

• **reload**
Reload the grant tables.

- **refresh**
  Flush all tables and close and open log files.

- **shutdown**
  Stop the server.

- **start-slave**
  Start replication on a slave server.

- **status**
  Display a short server status message.

- **stop-slave**
  Stop replication on a slave server.

- **variables**
  Display the server system variables and their values.

- **version**
  Display version information from the server.

All commands can be shortened to any unique prefix. For example:

```bash
shell> mysqladmin proc stat
```

<table>
<thead>
<tr>
<th>Id</th>
<th>User</th>
<th>Host</th>
<th>db</th>
<th>Command</th>
<th>Time</th>
<th>State</th>
<th>Info</th>
</tr>
</thead>
<tbody>
<tr>
<td>51</td>
<td>monty</td>
<td>localhost</td>
<td></td>
<td>Query</td>
<td>0</td>
<td></td>
<td>show processlist</td>
</tr>
</tbody>
</table>

Uptime: 1473624  Threads: 1  Questions: 39487
Slow queries: 0  Opens: 541  Flush tables: 1
Open tables: 19  Queries per second avg: 0.0268

The `mysqladmin status` command result displays the following values:

- **Uptime**
  The number of seconds the MySQL server has been running.

- **Threads**
  The number of active threads (clients).

- **Questions**
  The number of questions (queries) from clients since the server was started.

- **Slow queries**
  The number of queries that have taken more than `long_query_time` seconds. See Section 5.2.5, “The Slow Query Log”.
mysqladmin — Client for Administering a MySQL Server

- **Opens**
  The number of tables the server has opened.

- **Flush tables**
  The number of `flush-*`, `refresh`, and `reload` commands the server has executed.

- **Open tables**
  The number of tables that currently are open.

- **Memory in use**
  The amount of memory allocated directly by `mysql`. This value is displayed only when MySQL has been compiled with `safemalloc`, which is available only before MySQL 5.5.6.

- **Maximum memory used**
  The maximum amount of memory allocated directly by `mysql`. This value is displayed only when MySQL has been compiled with `safemalloc`, which is available only before MySQL 5.5.6.

If you execute `mysqladmin shutdown` when connecting to a local server using a Unix socket file, `mysqladmin` waits until the server's process ID file has been removed, to ensure that the server has stopped properly.

`mysqladmin` supports the following options, which can be specified on the command line or in the `[mysqladmin]` and `[client]` groups of an option file. For information about option files, see Section 4.2.6, *“Using Option Files”*.

**Table 4.6 mysqladmin Options**

<table>
<thead>
<tr>
<th>Format</th>
<th>Option File</th>
<th>Description</th>

### mysqladmin — Client for Administering a MySQL Server

#### Option File

<table>
<thead>
<tr>
<th>Format</th>
<th>Description</th>
<th>Introduced</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>--vertical</strong></td>
<td>vertical Print query output rows vertically (one line per column value)</td>
<td></td>
</tr>
<tr>
<td><strong>--wait</strong></td>
<td>wait If the connection cannot be established, wait and retry instead of aborting</td>
<td></td>
</tr>
</tbody>
</table>

- **--help, --?**
  Display a help message and exit.

- **--bind-address=ip_address**
  On a computer having multiple network interfaces, this option can be used to select which interface is employed when connecting to the MySQL server.

  This option is supported only in the version of mysqladmin that is supplied with MySQL Cluster. It is not available in standard MySQL Server 5.5 releases.

- **--character-sets-dir=path**
  The directory where character sets are installed. See Section 10.5, “Character Set Configuration”.

- **--compress, --C**
  Compress all information sent between the client and the server if both support compression.

- **--count=N, --c N**
  The number of iterations to make for repeated command execution if the **--sleep** option is given.

- **--debug=[debug_options], --# [debug_options]**
  Write a debugging log. A typical debug_options string is d:t:o, file_name. The default is d:t:o, /tmp/mysqladmin.trace.

- **--debug-check**
  Print some debugging information when the program exits.

- **--debug-info**
  Print debugging information and memory and CPU usage statistics when the program exits.

- **--default-auth=plugin**
  The client-side authentication plugin to use. See Section 6.3.6, “Pluggable Authentication”.

  This option was added in MySQL 5.5.9.

- **--default-character-set=charset_name**
  Use charset_name as the default character set. See Section 10.5, “Character Set Configuration”.

- **--defaults-extra-file=file_name**
  Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, file_name must be the full
path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- **--defaults-file=file_name**

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, *file_name* must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- **--defaults-group-suffix=str**

Read not only the usual option groups, but also groups with the usual names and a suffix of *str*. For example, *mysqladmin* normally reads the [client] and [mysqladmin] groups. If the --defaults-group-suffix=_other option is given, *mysqladmin* also reads the [client_other] and [mysqladmin_other] groups.

- **--enable-cleartext-plugin**

Enable the *mysql_clear_password* cleartext authentication plugin. (See Section 6.3.7.5, “The Cleartext Client-Side Authentication Plugin”. This option was added in MySQL 5.5.27.

- **--force, -f**

Do not ask for confirmation for the *drop db_name* command. With multiple commands, continue even if an error occurs.

- **--host=host_name, -h host_name**

Connect to the MySQL server on the given host.

- **--no-beep, -b**

Suppress the warning beep that is emitted by default for errors such as a failure to connect to the server.

- **--no-defaults**

Do not read any option files. If program startup fails due to reading unknown options from an option file, **--no-defaults** can be used to prevent them from being read.

- **--password[=password], -p[password]**

The password to use when connecting to the server. If you use the short option form (-p), you cannot have a space between the option and the password. If you omit the *password* value following the --password or -p option on the command line, *mysqladmin* prompts for one.

Specifying a password on the command line should be considered insecure. See Section 6.1.2.1, “End-User Guidelines for Password Security”. You can use an option file to avoid giving the password on the command line.

- **--pipe, -W**

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- **--plugin-dir=path**

The directory in which to look for plugins. It may be necessary to specify this option if the --default-auth option is used to specify an authentication plugin but *mysqladmin* does not find it. See Section 6.3.6, “Pluggable Authentication”.
This option was added in MySQL 5.5.9.

• `--port=port_num, -P port_num`
  The TCP/IP port number to use for the connection.

• `--print-defaults`
  Print the program name and all options that it gets from option files.

• `--protocol={TCP|SOCKET|PIPE|MEMORY}`
  The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see Section 4.2.2, “Connecting to the MySQL Server”.

• `--relative, -r`
  Show the difference between the current and previous values when used with the `--sleep` option. This option works only with the `extended-status` command.

• `--silent, -s`
  Exit silently if a connection to the server cannot be established.

• `--sleep=delay, -i delay`
  Execute commands repeatedly, sleeping for `delay` seconds in between. The `--count` option determines the number of iterations. If `--count` is not given, `mysqladmin` executes commands indefinitely until interrupted.

• `--socket=path, -S path`
  For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

• `--ssl*`
  Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See Section 6.3.9.4, “SSL Command Options”.

• `--user=user_name, -u user_name`
  The MySQL user name to use when connecting to the server.

• `--verbose, -v`
  Verbose mode. Print more information about what the program does.

• `--version, -V`
  Display version information and exit.

• `--vertical, -E`
  Print output vertically. This is similar to `--relative`, but prints output vertically.

• `--wait[=count], -w[count]`
If the connection cannot be established, wait and retry instead of aborting. If a `count` value is given, it indicates the number of times to retry. The default is one time.

You can also set the following variables by using `--var_name=value`. The `--set-variable` format is deprecated and was removed in MySQL 5.5.3. syntax:

- `connect_timeout`
  The maximum number of seconds before connection timeout. The default value is 43200 (12 hours).
- `shutdown_timeout`
  The maximum number of seconds to wait for server shutdown. The default value is 3600 (1 hour).

### 4.5.3 `mysqlcheck` — A Table Maintenance Program

The `mysqlcheck` client performs table maintenance: It checks, repairs, optimizes, or analyzes tables.

Each table is locked and therefore unavailable to other sessions while it is being processed, although for check operations, the table is locked with a `READ` lock only (see Section 13.3.5, “Lock Tables and Unlock Tables Syntax”, for more information about `READ` and `WRITE` locks). Table maintenance operations can be time-consuming, particularly for large tables. If you use the `--databases` or `--all-databases` option to process all tables in one or more databases, an invocation of `mysqlcheck` might take a long time. (This is also true for `mysql_upgrade` because that program invokes `mysqlcheck` to check all tables and repair them if necessary.)

`mysqlcheck` is similar in function to `myisamchk`, but works differently. The main operational difference is that `mysqlcheck` must be used when the `mysqld` server is running, whereas `myisamchk` should be used when it is not. The benefit of using `mysqlcheck` is that you do not have to stop the server to perform table maintenance.

`mysqlcheck` uses the SQL statements `CHECK TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, and `OPTIMIZE TABLE` in a convenient way for the user. It determines which statements to use for the operation you want to perform, and then sends the statements to the server to be executed. For details about which storage engines each statement works with, see the descriptions for those statements in Section 13.7.2, “Table Maintenance Statements”.

The MyISAM storage engine supports all four maintenance operations, so `mysqlcheck` can be used to perform any of them on MyISAM tables. Other storage engines do not necessarily support all operations. In such cases, an error message is displayed. For example, if `test.t` is a `MEMORY` table, an attempt to check it produces this result:

```shell
$ mysqlcheck test t
test.t: The storage engine for the table doesn't support check
```

If `mysqlcheck` is unable to repair a table, see Section 2.11.4, “Rebuilding or Repairing Tables or Indexes” for manual table repair strategies. This will be the case, for example, for InnoDB tables, which can be checked with `CHECK TABLE`, but not repaired with `REPAIR TABLE`.

**Caution**

It is best to make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors.

There are three general ways to invoke `mysqlcheck`:
mysqlcheck — A Table Maintenance Program

shell> mysqlcheck [options] db_name [tbl_name ...]
shell> mysqlcheck [options] --databases db_name ...
shell> mysqlcheck [options] --all-databases

If you do not name any tables following db_name or if you use the --databases or --all-databases option, entire databases are checked.

mysqlcheck has a special feature compared to other client programs. The default behavior of checking tables (--check) can be changed by renaming the binary. If you want to have a tool that repairs tables by default, you should just make a copy of mysqlcheck named mysqlrepair, or make a symbolic link to mysqlcheck named mysqlrepair. If you invoke mysqlrepair, it repairs tables.

The names shown in the following table can be used to change mysqlcheck default behavior.

<table>
<thead>
<tr>
<th>Command</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>mysqlrepair</td>
<td>The default option is --repair</td>
</tr>
<tr>
<td>mysqlanalyze</td>
<td>The default option is --analyze</td>
</tr>
<tr>
<td>mysqloptimize</td>
<td>The default option is --optimize</td>
</tr>
</tbody>
</table>

mysqlcheck supports the following options, which can be specified on the command line or in the [mysqlcheck] and [client] groups of an option file. For information about option files, see Section 4.2.6, “Using Option Files”.

Table 4.7 mysqlcheck Options

<table>
<thead>
<tr>
<th>Format</th>
<th>Option File</th>
<th>Description</th>
<th>Introduced</th>
</tr>
</thead>
<tbody>
<tr>
<td>--all-databases</td>
<td>all-databases</td>
<td>Check all tables in all databases</td>
<td></td>
</tr>
<tr>
<td>--all-in-1</td>
<td>all-in-1</td>
<td>Execute a single statement for each database that names all the tables from that database</td>
<td></td>
</tr>
<tr>
<td>--analyze</td>
<td>analyze</td>
<td>Analyze the tables</td>
<td></td>
</tr>
<tr>
<td>--auto-repair</td>
<td>auto-repair</td>
<td>If a checked table is corrupted, automatically fix it</td>
<td></td>
</tr>
<tr>
<td>--character-sets-dir=path</td>
<td>character-sets-dir</td>
<td>The directory where character sets are installed</td>
<td></td>
</tr>
<tr>
<td>--check</td>
<td>check</td>
<td>Check the tables for errors</td>
<td></td>
</tr>
<tr>
<td>--check-only-changed</td>
<td>check-only-changed</td>
<td>Check only tables that have changed since the last check</td>
<td></td>
</tr>
<tr>
<td>--check-upgrade</td>
<td>check-upgrade</td>
<td>Invoke CHECK TABLE with the FOR UPGRADE option</td>
<td></td>
</tr>
<tr>
<td>--compress</td>
<td>compress</td>
<td>Compress all information sent between the client and the server</td>
<td></td>
</tr>
<tr>
<td>--databases</td>
<td>databases</td>
<td>Process all tables in the named databases</td>
<td></td>
</tr>
<tr>
<td>--debug[=debug_options]</td>
<td>debug</td>
<td>Write a debugging log</td>
<td></td>
</tr>
<tr>
<td>--debug-check</td>
<td>debug-check</td>
<td>Print debugging information when the program exits</td>
<td></td>
</tr>
<tr>
<td>--debug-info</td>
<td>debug-info</td>
<td>Print debugging information, memory and CPU statistics when the program exits</td>
<td></td>
</tr>
<tr>
<td>--default-auth=plugin</td>
<td>default-auth=plugin</td>
<td>The authentication plugin to use</td>
<td>5.5.10</td>
</tr>
<tr>
<td>Format</td>
<td>Option File</td>
<td>Description</td>
<td>Introduced</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------</td>
</tr>
<tr>
<td>--default-character-set=charset_name</td>
<td>default-character-set</td>
<td>Use charset_name as the default character set</td>
<td></td>

<tr>
<td>--defaults-extra-file=file_name</td>
<td></td>
<td>Read option file in addition to the usual option files</td>
<td></td>
</tr>
<tr>
<td>--defaults-file=file_name</td>
<td></td>
<td>Read only the given option file</td>
<td></td>
</tr>
<tr>
<td>--defaults-group-suffix=str</td>
<td></td>
<td>Option group suffix value</td>
<td></td>
</tr>
<tr>
<td>--extended</td>
<td>extended</td>
<td>Check and repair tables</td>
<td></td>
</tr>
<tr>
<td>--fast</td>
<td>fast</td>
<td>Check only tables that have not been closed properly</td>
<td></td>
</tr>
<tr>
<td>--fix-db-names</td>
<td>fix-db-names</td>
<td>Convert database names to 5.1 format</td>
<td></td>
</tr>
<tr>
<td>--fix-table-names</td>
<td>fix-table-names</td>
<td>Convert table names to 5.1 format</td>
<td></td>
</tr>
<tr>
<td>--force</td>
<td>force</td>
<td>Continue even if an SQL error occurs</td>
<td></td>
</tr>
<tr>
<td>--help</td>
<td></td>
<td>Display help message and exit</td>
<td></td>
</tr>
<tr>
<td>--host=host_name</td>
<td>host</td>
<td>Connect to the MySQL server on the given host</td>
<td></td>
</tr>
<tr>
<td>--medium-check</td>
<td>medium-check</td>
<td>Do a check that is faster than an --extended operation</td>
<td></td>
</tr>
<tr>
<td>--no-defaults</td>
<td></td>
<td>Do not read any option files</td>
<td></td>
</tr>
<tr>
<td>--optimize</td>
<td>optimize</td>
<td>Optimize the tables</td>
<td></td>
</tr>
<tr>
<td>--password[=password]</td>
<td>password</td>
<td>The password to use when connecting to the server</td>
<td></td>
</tr>
<tr>
<td>--pipe</td>
<td></td>
<td>On Windows, connect to server using a named pipe</td>
<td></td>
</tr>
<tr>
<td>--plugin-dir=path</td>
<td>plugin-dir=path</td>
<td>The directory where plugins are located</td>
<td>5.5.10</td>
</tr>
<tr>
<td>--port=port_num</td>
<td>port</td>
<td>The TCP/IP port number to use for the connection</td>
<td></td>
</tr>
<tr>
<td>--print-defaults</td>
<td></td>
<td>Print defaults</td>
<td></td>
</tr>
<tr>
<td>--protocol=type</td>
<td>protocol</td>
<td>The connection protocol to use</td>
<td></td>
</tr>
<tr>
<td>--quick</td>
<td>quick</td>
<td>The fastest method of checking</td>
<td></td>
</tr>
<tr>
<td>--repair</td>
<td>repair</td>
<td>Perform a repair that can fix almost anything except unique keys that are not unique</td>
<td></td>
</tr>
<tr>
<td>--silent</td>
<td>silent</td>
<td>Silent mode</td>
<td></td>
</tr>
<tr>
<td>--socket=path</td>
<td>socket</td>
<td>For connections to localhost</td>
<td></td>
</tr>
<tr>
<td>--ssl-ca=file_name</td>
<td>ssl-ca</td>
<td>The path to a file that contains a list of trusted SSL CAs</td>
<td></td>
</tr>
<tr>
<td>--ssl-capath=dir_name</td>
<td>ssl-capath</td>
<td>The path to a directory that contains trusted SSL CA certificates in PEM format</td>
<td></td>
</tr>
<tr>
<td>--ssl-cert=file_name</td>
<td>ssl-cert</td>
<td>The name of the SSL certificate file to use for establishing a secure connection</td>
<td></td>
</tr>
<tr>
<td>--ssl-cipher=cipher_list</td>
<td>ssl-cipher</td>
<td>A list of allowable ciphers to use for SSL encryption</td>
<td></td>
</tr>
</tbody>

<td>Log ANALYZE, OPTIMIZE, REPAIR statements to binary log. --skip-write-binlog adds NO_WRITE_TO_BINLOG to these statements.</td>
<td></td>
</tr>
</tbody>
</table>

- **--help, -?**
  Display a help message and exit.

- **--all-databases, -A**
  Check all tables in all databases. This is the same as using the `--databases` option and naming all the databases on the command line, except that the INFORMATION_SCHEMA and performance_schema databases are not dumped. They can be dumped by explicitly naming them with the `--databases` option.

- **--all-in-1, -1**
  Instead of issuing a statement for each table, execute a single statement for each database that names all the tables from that database to be processed.

- **--analyze, -a**
  Analyze the tables.

- **--auto-repair**
  If a checked table is corrupted, automatically fix it. Any necessary repairs are done after all tables have been checked.

- **--bind-address=ip_address**
  On a computer having multiple network interfaces, this option can be used to select which interface is employed when connecting to the MySQL server.

  This option is supported only in the version of `mysqlcheck` that is supplied with MySQL Cluster. It is not available in standard MySQL Server 5.5 releases.

- **--character-sets-dir=path**
  The directory where character sets are installed. See Section 10.5, “Character Set Configuration”.

- **--check, -c**
Check the tables for errors. This is the default operation.

- **--check-only-changed, -C**

Check only tables that have changed since the last check or that have not been closed properly.

- **--check-upgrade, -g**

Invoke CHECK TABLE with the FOR UPGRADE option to check tables for incompatibilities with the current version of the server. This option automatically enables the --fix-db-names and --fix-table-names options.

- **--compress**

Compress all information sent between the client and the server if both support compression.

- **--databases, -B**

Process all tables in the named databases. Normally, mysqlcheck treats the first name argument on the command line as a database name and following names as table names. With this option, it treats all name arguments as database names.

This option may be used to dump the INFORMATION_SCHEMA and performance_schema databases, which normally are not dumped even with the --all-databases option. (Also use the --skip-lock-tables option.)

- **--debug[=debug_options], -# [debug_options]**

Write a debugging log. A typical debug_options string is d:t:o, file_name. The default is d:t:o.

- **--debug-check**

Print some debugging information when the program exits.

- **--debug-info**

Print debugging information and memory and CPU usage statistics when the program exits.

- **--default-character-set=charset_name**

Use charset_name as the default character set. See Section 10.5, “Character Set Configuration”.

- **--defaults-extra-file=file_name**

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, file_name must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- **--defaults-file=file_name**

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, file_name must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- **--defaults-group-suffix=str**
Read not only the usual option groups, but also groups with the usual names and a suffix of \texttt{str}. For example, \texttt{mysqlcheck} normally reads the \texttt{[client]} and \texttt{[mysqlcheck]} groups. If the \texttt{--defaults-group-suffix=_other} option is given, \texttt{mysqlcheck} also reads the \texttt{[client_other]} and \texttt{[mysqlcheck_other]} groups.

• \texttt{--extended,-e}

If you are using this option to check tables, it ensures that they are 100\% consistent but takes a long time.

If you are using this option to repair tables, it runs an extended repair that may not only take a long time to execute, but may produce a lot of garbage rows also!

• \texttt{--default-auth=plugin}

The client-side authentication plugin to use. See \texttt{Section 6.3.6, “Pluggable Authentication”}. This option was added in MySQL 5.5.10.

• \texttt{--fast,-F}

Check only tables that have not been closed properly.

• \texttt{--fix-db-names}

Convert database names to 5.1 format. Only database names that contain special characters are affected.

• \texttt{--fix-table-names}

Convert table names to 5.1 format. Only table names that contain special characters are affected. This option also applies to views.

• \texttt{--force,-f}

Continue even if an SQL error occurs.

• \texttt{--host=host_name,-h host_name}

Connect to the MySQL server on the given host.

• \texttt{--medium-check,-m}

Do a check that is faster than an \texttt{--extended} operation. This finds only 99.99\% of all errors, which should be good enough in most cases.

• \texttt{--no-defaults}

Do not read any option files. If program startup fails due to reading unknown options from an option file, \texttt{--no-defaults} can be used to prevent them from being read.

• \texttt{--optimize,-o}

Optimize the tables.

• \texttt{--password[=password],-p[password]}
The password to use when connecting to the server. If you use the short option form (-p), you cannot have a space between the option and the password. If you omit the password value following the --password or -p option on the command line, mysqlcheck prompts for one.

Specifying a password on the command line should be considered insecure. See Section 6.1.2.1, “End-User Guidelines for Password Security”. You can use an option file to avoid giving the password on the command line.

- --pipe, -W

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- --plugin-dir=path

The directory in which to look for plugins. It may be necessary to specify this option if the --default-auth option is used to specify an authentication plugin but mysqlcheck does not find it. See Section 6.3.6, “Pluggable Authentication”.

This option was added in MySQL 5.5.10.

- --port=port_num, -P port_num

The TCP/IP port number to use for the connection.

- --print-defaults

Print the program name and all options that it gets from option files.

- --protocol={TCP|SOCKET|PIPE|MEMORY}

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see Section 4.2.2, “Connecting to the MySQL Server”.

- --quick, -q

If you are using this option to check tables, it prevents the check from scanning the rows to check for incorrect links. This is the fastest check method.

If you are using this option to repair tables, it tries to repair only the index tree. This is the fastest repair method.

- --repair, -r

Perform a repair that can fix almost anything except unique keys that are not unique.

- --silent, -s

Silent mode. Print only error messages.

- --socket=path, -S path

For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- --ssl*
Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See Section 6.3.9.4, “SSL Command Options”.

- `--tables`
  Override the `--databases` or `-B` option. All name arguments following the option are regarded as table names.

- `--use frm`
  For repair operations on MyISAM tables, get the table structure from the `.frm` file so that the table can be repaired even if the `.MYI` header is corrupted.

- `--user=user_name`, `-u user_name`
  The MySQL user name to use when connecting to the server.

- `--verbose`, `-v`
  Verbose mode. Print information about the various stages of program operation.

- `--version`, `-V`
  Display version information and exit.

- `--write-binlog`
  This option is enabled by default, so that `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements generated by `mysqlcheck` are written to the binary log. Use `--skip-write-binlog` to cause NO_WRITE_TO_BINLOG to be added to the statements so that they are not logged. Use the `--skip-write-binlog` when these statements should not be sent to replication slaves or run when using the binary logs for recovery from backup.

4.5.4 `mysqldump` — A Database Backup Program

The `mysqldump` client is a utility that performs logical backups, producing a set of SQL statements that can be run to reproduce the original schema objects, table data, or both. It dumps one or more MySQL database for backup or transfer to another SQL server. The `mysqldump` command can also generate output in CSV, other delimited text, or XML format.

`mysqldump` requires at least the `SELECT` privilege for dumped tables, `SHOW VIEW` for dumped views, `TRIGGER` for dumped triggers, and `LOCK TABLES` if the `--single-transaction` option is not used. Certain options might require other privileges as noted in the option descriptions.

To reload a dump file, you must have the same privileges needed to create each of the dumped objects by issuing `CREATE` statements manually.

`mysqldump` output can include `ALTER DATABASE` statements that change the database collation. These may be used when dumping stored programs to preserve their character encodings. To reload a dump file containing such statements, the `ALTER` privilege for the affected database is required.

If you are performing a backup on the server and your tables all are MyISAM tables, you can also use `mysqlhotcopy` for this purpose.

Performance and Scalability Considerations

`mysqldump` advantages include the convenience and flexibility of viewing or even editing the output before restoring. You can clone databases for development and DBA work, or produce slight variations of an
existing database for testing. It is not intended as a fast or scalable solution for backing up substantial amounts of data. With large data sizes, even if the backup step takes a reasonable time, restoring the data can be very slow because replaying the SQL statements involves disk I/O for insertion, index creation, and so on.

For large-scale backup and restore, a **physical** backup is more appropriate, to copy the data files in their original format that can be restored quickly:

- If your tables are primarily **InnoDB** tables, or if you have a mix of **InnoDB** and **MyISAM** tables, consider using the `mysqlbackup` command of the MySQL Enterprise Backup product. (Available as part of the Enterprise subscription.) It provides the best performance for **InnoDB** backups with minimal disruption; it can also back up tables from **MyISAM** and other storage engines; and it provides a number of convenient options to accommodate different backup scenarios. See Section 25.2, "MySQL Enterprise Backup".

- If your tables are primarily **MyISAM** tables, consider using the `mysqlhotcopy` instead, for better performance than `mysqldump` of backup and restore operations. See Section 4.6.9, "mysqlhotcopy — A Database Backup Program".

`mysqldump` can retrieve and dump table contents row by row, or it can retrieve the entire content from a table and buffer it in memory before dumping it. Buffering in memory can be a problem if you are dumping large tables. To dump tables row by row, use the `--quick` option (or `--opt`, which enables `--quick`). The `--opt` option (and hence `--quick`) is enabled by default, so to enable memory buffering, use `--skip-quick`.

If you are using a recent version of `mysqldump` to generate a dump to be reloaded into a very old MySQL server, use the `--skip-opt` option instead of the `--opt` or `--extended-insert` option.

For additional information about `mysqldump`, see Section 7.4, "Using `mysqldump` for Backups".

### Syntax

There are in general three ways to use `mysqldump`—in order to dump a set of one or more tables, a set of one or more complete databases, or an entire MySQL server—as shown here:

```
shell> mysqldump [options] db_name [tbl_name ...]
shell> mysqldump [options] --databases db_name ...
shell> mysqldump [options] --all-databases
```

To dump entire databases, do not name any tables following `db_name`, or use the `--databases` or `--all-databases` option.

`mysqldump` does not dump the **INFORMATION_SCHEMA** or **performance_schema** database by default. To dump either of these, name it explicitly on the command line and also use the `--skip-lock-tables` option. You can also name them with the `--databases` option. Before MySQL 5.5 `mysqldump` silently ignores **INFORMATION_SCHEMA** even if you name it explicitly on the command line.

`mysqldump` does not dump the **performance_schema** database.

Before MySQL 5.5.25, `mysqldump` does not dump the **general_log** or **slow_query_log** tables for dumps of the **mysql** database. As of 5.5.25, the dump includes statements to recreate those tables so that they are not missing after reloading the dump file. Log table contents are not dumped.

`mysqldump` also does not dump the MySQL Cluster **ndbinfo** information database.

To see a list of the options your version of `mysqldump` supports, execute `mysqldump --help`.

Some `mysqldump` options are shorthand for groups of other options:
mysqldump — A Database Backup Program

• Use of --opt is the same as specifying --add-drop-table, --add-locks, --create-options, --disable-keys, --extended-insert, --lock-tables, --quick, and --set-charset. All of the options that --opt stands for also are on by default because --opt is on by default.

• Use of --compact is the same as specifying --skip-add-drop-table, --skip-add-locks, --skip-comments, --skip-disable-keys, and --skip-set_charset options.

To reverse the effect of a group option, uses its --skip-xxx form (--skip-opt or --skip-compact). It is also possible to select only part of the effect of a group option by following it with options that enable or disable specific features. Here are some examples:

• To select the effect of --opt except for some features, use the --skip option for each feature. To disable extended inserts and memory buffering, use --opt --skip-extended-insert --skip-quick. (Actually, --skip-extended-insert --skip-quick is sufficient because --opt is on by default.)

• To reverse --opt for all features except index disabling and table locking, use --skip-opt --disable-keys --lock-tables.

When you selectively enable or disable the effect of a group option, order is important because options are processed first to last. For example, --disable-keys --lock-tables --skip-opt would not have the intended effect; it is the same as --skip-opt by itself.

mysqldump can retrieve and dump table contents row by row, or it can retrieve the entire content from a table and buffer it in memory before dumping it. Buffering in memory can be a problem if you are dumping large tables. To dump tables row by row, use the --quick option (or --opt, which enables --quick). The --opt option (and hence --quick) is enabled by default, so to enable memory buffering, use --skip-quick.

If you are using a recent version of mysqldump to generate a dump to be reloaded into a very old MySQL server, you should not use the --opt or --extended-insert option. Use --skip-opt instead.

For additional information about mysqldump, see Section 7.4, “Using mysqldump for Backups”.

mysqldump supports the following options, which can be specified on the command line or in the [mysqldump] and [client] groups of an option file. For information about option files, see Section 4.2.6, “Using Option Files”.

Table 4.8 mysqldump Options

<td>--xml</td>
<td>xml</td>
<td>Produce XML output</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- `--help, -?`
Display a help message and exit.

- **--add-drop-database**

Add a `DROP DATABASE` statement before each `CREATE DATABASE` statement. This option is typically used in conjunction with the `--all-databases` or `--databases` option because no `CREATE DATABASE` statements are written unless one of those options is specified.

- **--add-drop-table**

Add a `DROP TABLE` statement before each `CREATE TABLE` statement.

- **--add-drop-trigger**

Add a `DROP TRIGGER` statement before each `CREATE TRIGGER` statement.

**Note**

This option is supported only by `mysqldump` as supplied with MySQL Cluster. It is not available when using MySQL Server 5.5.

- **--add-locks**

Surround each table dump with `LOCK TABLES` and `UNLOCK TABLES` statements. This results in faster inserts when the dump file is reloaded. See Section 8.2.2.1, “Speed of INSERT Statements”.

- **--all-databases, -A**

Dump all tables in all databases. This is the same as using the `--databases` option and naming all the databases on the command line.

- **--all-tablespaces, -Y**

Adds to a table dump all SQL statements needed to create any tablespaces used by an `NDBCLUSTER` table. This information is not otherwise included in the output from `mysqldump`. This option is currently relevant only to MySQL Cluster tables.

- **--allow-keywords**

Permit creation of column names that are keywords. This works by prefixing each column name with the table name.

- **--apply-slave-statements**

For a slave dump produced with the `--dump-slave` option, add a `STOP SLAVE` statement before the `CHANGE MASTER TO` statement and a `START SLAVE` statement at the end of the output. This option was added in MySQL 5.5.3.

- **--bind-address=ip_address**

On a computer having multiple network interfaces, this option can be used to select which interface is employed when connecting to the MySQL server.

This option is supported only in the version of `mysqldump` that is supplied with MySQL Cluster. It is not available in standard MySQL Server 5.5 releases.

- **--character-sets-dir=path**
The directory where character sets are installed. See Section 10.5, “Character Set Configuration”.

- **--comments, -i**

Write additional information in the dump file such as program version, server version, and host. This option is enabled by default. To suppress this additional information, use **--skip-comments**.

- **--compact**

Produce more compact output. This option enables the **--skip-add-drop-table, --skip-add-locks, --skip-comments, --skip-disable-keys, and --skip-set-charset** options.

- **--compatible=name**

Produce output that is more compatible with other database systems or with older MySQL servers. The value of **name** can be **ansi, mysql323, mysql40, postgresql, oracle, mssql, db2, maxdb, no_key_options, no_table_options, or no_field_options**. To use several values, separate them by commas. These values have the same meaning as the corresponding options for setting the server SQL mode. See Section 5.1.7, “Server SQL Modes”.

This option does not guarantee compatibility with other servers. It only enables those SQL mode values that are currently available for making dump output more compatible. For example, **--compatible=oracle** does not map data types to Oracle types or use Oracle comment syntax.

*This option requires a server version of 4.1.0 or higher.* With older servers, it does nothing.

- **--complete-insert, -c**

Use complete **INSERT** statements that include column names.

- **--compress, -C**

Compress all information sent between the client and the server if both support compression.

- **--create-options**

Include all MySQL-specific table options in the **CREATE TABLE** statements.

- **--databases, -B**

Dump several databases. Normally, **mysqldump** treats the first name argument on the command line as a database name and following names as table names. With this option, it treats all name arguments as database names. **CREATE DATABASE** and **USE** statements are included in the output before each new database.

- **--debug[=debug_options], -# [debug_options]**

Write a debugging log. A typical **debug_options** string is **d:t:o, file_name**. The default value is **d:t:o,/tmp/mysqldump.trace**.

- **--debug-check**

Print some debugging information when the program exits.

- **--debug-info**

Print debugging information and memory and CPU usage statistics when the program exits.
• **--default-auth=plugin**

The client-side authentication plugin to use. See Section 6.3.6, “Pluggable Authentication”.

This option was added in MySQL 5.5.9.

• **--default-character-set=charset_name**

Use `charset_name` as the default character set. See Section 10.5, “Character Set Configuration”. If no character set is specified, mysqldump uses utf8, and earlier versions use latin1.

• **--defaults-extra-file=file_name**

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, `file_name` must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

• **--defaults-file=file_name**

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, `file_name` must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

• **--defaults-group-suffix=**

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, mysqldump normally reads the [client] and [mysqldump] groups. If the `--defaults-group-suffix=_other` option is given, mysqldump also reads the [client_other] and [mysqldump_other] groups.

• **--delayed-insert**

Write `INSERT DELAYED` statements rather than `INSERT` statements.

• **--delete-master-logs**

On a master replication server, delete the binary logs by sending a `PURGE BINARY LOGS` statement to the server after performing the dump operation. This option automatically enables `--master-data`.

• **--disable-keys, -K**

For each table, surround the `INSERT` statements with `/*!40000 ALTER TABLE tbl_name DISABLE KEYS */;` and `/*!40000 ALTER TABLE tbl_name ENABLE KEYS */;` statements. This makes loading the dump file faster because the indexes are created after all rows are inserted. This option is effective only for nonunique indexes of MyISAM tables. It has no effect for other tables.

• **--dump-date**

If the `--comments` option is given, mysqldump produces a comment at the end of the dump of the following form:

```
-- Dump completed on DATE
```

However, the date causes dump files taken at different times to appear to be different, even if the data are otherwise identical. `--dump-date` and `--skip-dump-date` control whether the date is added to the comment. The default is `--dump-date` (include the date in the comment). `--skip-dump-date` suppresses date printing.
• `--dump-slave[=value]`

This option is similar to `--master-data` except that it is used to dump a replication slave server to produce a dump file that can be used to set up another server as a slave that has the same master as the dumped server. It causes the dump output to include a `CHANGE MASTER TO` statement that indicates the binary log coordinates (file name and position) of the dumped slave’s master. These are the master server coordinates from which the slave should start replicating.

`--dump-slave` causes the coordinates from the master to be used rather than those of the dumped server, as is done by the `--master-data` option. In addition, specifying this option causes the `--master-data` option to be overridden, if used, and effectively ignored.

The option value is handled the same way as for `--master-data` (setting no value or 1 causes a `CHANGE MASTER TO` statement to be written to the dump, setting 2 causes the statement to be written but encased in SQL comments) and has the same effect as `--master-data` in terms of enabling or disabling other options and in how locking is handled.

This option causes `mysqldump` to stop the slave SQL thread before the dump and restart it again after.

In conjunction with `--dump-slave`, the `--apply-slave-statements` and `--include-master-host-port` options can also be used.

This option was added in MySQL 5.5.3.

• `--events, -E`

Include Event Scheduler events for the dumped databases in the output.

• `--extended-insert, -e`

Use multiple-row `INSERT` syntax that include several `VALUES` lists. This results in a smaller dump file and speeds up inserts when the file is reloaded.

• `--fields-terminated-by=...`, `--fields-enclosed-by=...`, `--fields-optionally-enclosed-by=...`, `--fields-escaped-by=...`

These options are used with the `--tab` option and have the same meaning as the corresponding `FIELDS` clauses for `LOAD DATA INFILE`. See Section 13.2.6, “LOAD DATA INFILE Syntax”.

• `--first-slave`

Deprecated. Use `--lock-all-tables` instead. `--first-slave` was removed in MySQL 5.5.3.

• `--flush-logs, -F`

Flush the MySQL server log files before starting the dump. This option requires the `RELOAD` privilege. If you use this option in combination with the `--all-databases` option, the logs are flushed for each database dumped. The exception is when using `--lock-all-tables, --master-data, or (as of MySQL 5.5.21) --single-transaction`: In this case, the logs are flushed only once, corresponding to the moment that all tables are locked. If you want your dump and the log flush to happen at exactly the same moment, you should use `--flush-logs` together with `--lock-all-tables, --master-data, or --single-transaction`.

• `--flush-privileges`

Add a `FLUSH PRIVILEGES` statement to the dump output after dumping the `mysql` database. This option should be used any time the dump contains the `mysql` database and any other database that depends on the data in the `mysql` database for proper restoration.
• **--force, -f**

Continue even if an SQL error occurs during a table dump.

One use for this option is to cause `mysqldump` to continue executing even when it encounters a view that has become invalid because the definition refers to a table that has been dropped. Without `--force`, `mysqldump` exits with an error message. With `--force`, `mysqldump` prints the error message, but it also writes an SQL comment containing the view definition to the dump output and continues executing.

• **--host=host_name, -h host_name**

Dump data from the MySQL server on the given host. The default host is `localhost`.

• **--hex-blob**

Dump binary columns using hexadecimal notation (for example, `'abc'` becomes `0x616263`). The affected data types are `BINARY`, `VARBINARY`, the `BLOB` types, and `BIT`.

• **--include-master-host-port**

For the `CHANGE MASTER TO` statement in a slave dump produced with the `--dump-slave` option, add `MASTER_HOST` and `MASTER_PORT` options for the host name and TCP/IP port number of the slave's master. This option was added in MySQL 5.5.3.

• **--ignore-table=db_name.tbl_name**

Do not dump the given table, which must be specified using both the database and table names. To ignore multiple tables, use this option multiple times. This option also can be used to ignore views.

• **--insert-ignore**

Write `INSERT IGNORE` statements rather than `INSERT` statements.

• **--lines-terminated-by=...**

This option is used with the `--tab` option and has the same meaning as the corresponding `LINES` clause for `LOAD DATA INFILE`. See Section 13.2.6, "LOAD DATA INFILE Syntax".

• **--lock-all-tables, -x**

Lock all tables across all databases. This is achieved by acquiring a global read lock for the duration of the whole dump. This option automatically turns off `--single-transaction` and `--lock-tables`.

• **--lock-tables, -l**

For each dumped database, lock all tables to be dumped before dumping them. The tables are locked with `READ LOCAL` to permit concurrent inserts in the case of `MyISAM` tables. For transactional tables such as `InnoDB`, `--single-transaction` is a much better option than `--lock-tables` because it does not need to lock the tables at all.

Because `--lock-tables` locks tables for each database separately, this option does not guarantee that the tables in the dump file are logically consistent between databases. Tables in different databases may be dumped in completely different states.

• **--log-error=file_name**

Log warnings and errors by appending them to the named file. The default is to do no logging.
• **--master-data[=value]**

Use this option to dump a master replication server to produce a dump file that can be used to set up another server as a slave of the master. It causes the dump output to include a `CHANGE MASTER TO` statement that indicates the binary log coordinates (file name and position) of the dumped server. These are the master server coordinates from which the slave should start replicating after you load the dump file into the slave.

If the option value is 2, the `CHANGE MASTER TO` statement is written as an SQL comment, and thus is informative only; it has no effect when the dump file is reloaded. If the option value is 1, the statement is not written as a comment and takes effect when the dump file is reloaded. If no option value is specified, the default value is 1.

This option requires the `RELOAD` privilege and the binary log must be enabled.

The `--master-data` option automatically turns off `--lock-tables`. It also turns on `--lock-all-tables`, unless `--single-transaction` also is specified, in which case, a global read lock is acquired only for a short time at the beginning of the dump (see the description for `--single-transaction`). In all cases, any action on logs happens at the exact moment of the dump.

It is also possible to set up a slave by dumping an existing slave of the master. In MySQL 5.5.3 and later, you can create such a dump using the `--dump-slave` option, which overrides `--master-data` and causes it to be ignored if both options are used.

In MySQL 5.2.2 and earlier, use the following procedure on the existing slave:

1. Stop the slave's SQL thread and get its current status:

   ```
   mysql> STOP SLAVE SQL_THREAD;
   mysql> SHOW SLAVE STATUS;
   ```

2. From the output of the `SHOW SLAVE STATUS` statement, the binary log coordinates of the master server from which the new slave should start replicating are the values of the `Relay_Master_Log_File` and `Exec_Master_Log_Pos` fields. Denote those values as `file_name` and `file_pos`.

3. Dump the slave server:

   ```
   shell> mysqldump --master-data=2 --all-databases > dumpfile
   ```

   Using `--master-data=2` works only if binary logging has been enabled on the slave. Otherwise, `mysqldump` fails with the error `Binlogging on server not active`. In this case you must handle any locking issues in another manner, using one or more of `--add-locks`, `--lock-tables`, `--lock-all-tables`, or `--single-transaction`, as required by your application and environment.

4. Restart the slave:

   ```
   mysql> START SLAVE;
   ```

5. On the new slave, load the dump file:

   ```
   shell> mysql < dumpfile
   ```
6. On the new slave, set the replication coordinates to those of the master server obtained earlier:

```sql
mysql> CHANGE MASTER TO
    -> MASTER_LOG_FILE = 'file_name', MASTER_LOG_POS = file_pos;
```

The `CHANGE MASTER TO` statement might also need other parameters, such as `MASTER_HOST` to point the slave to the correct master server host. Add any such parameters as necessary.

- **--no-autocommit**

Enclose the `INSERT` statements for each dumped table within `SET autocommit = 0` and `COMMIT` statements.

- **--no-create-db, -n**

This option suppresses the `CREATE DATABASE` statements that are otherwise included in the output if the `--databases` or `--all-databases` option is given.

- **--no-create-info, -t**

Do not write `CREATE TABLE` statements that re-create each dumped table.

### Note

This option does not not exclude statements creating log file groups or tablespaces from `mysqldump` output; however, you can use the `--no-tablespaces` option for this purpose.

- **--no-data, -d**

Do not write any table row information (that is, do not dump table contents). This is useful if you want to dump only the `CREATE TABLE` statement for the table (for example, to create an empty copy of the table by loading the dump file).

- **--no-defaults**

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

- **--no-set-names, -N**

This has the same effect as `--skip-set-charset`.

- **--no-tablespaces, -y**

This option suppresses all `CREATE LOGFILE GROUP` and `CREATE TABLESPACE` statements in the output of `mysqldump`.

- **--opt**

This option is shorthand. It is the same as specifying `--add-drop-table --add-locks --create-options --disable-keys --extended-insert --lock-tables --quick --set-charset`. It should give you a fast dump operation and produce a dump file that can be reloaded into a MySQL server quickly.
The **--opt** option is enabled by default. Use **--skip-opt** to disable it. See the discussion at the beginning of this section for information about selectively enabling or disabling a subset of the options affected by **--opt**.

- **--order-by-primary**

Dump each table's rows sorted by its primary key, or by its first unique index, if such an index exists. This is useful when dumping a MyISAM table to be loaded into an InnoDB table, but will make the dump operation take considerably longer.

- **--password[=password], -p[password]**

The password to use when connecting to the server. If you use the short option form (**-p**), you cannot have a space between the option and the password. If you omit the password value following the **--password** or **-p** option on the command line, mysqldump prompts for one.

Specifying a password on the command line should be considered insecure. See Section 6.1.2.1, “End-User Guidelines for Password Security”. You can use an option file to avoid giving the password on the command line.

- **--pipe, -W**

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- **--plugin-dir=path**

The directory in which to look for plugins. It may be necessary to specify this option if the **--default-auth** option is used to specify an authentication plugin but mysqldump does not find it. See Section 6.3.6, “Pluggable Authentication”.

This option was added in MySQL 5.5.9.

- **--port=port_num, -P port_num**

The TCP/IP port number to use for the connection.

- **--print-defaults**

Print the program name and all options that it gets from option files.

- **--protocol={TCP|SOCKET|PIPE|MEMORY}**

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see Section 4.2.2, “Connecting to the MySQL Server”.

- **--quick, -q**

This option is useful for dumping large tables. It forces mysqldump to retrieve rows for a table from the server a row at a time rather than retrieving the entire row set and buffering it in memory before writing it out.

- **--quote-names, -Q**

Quote identifiers (such as database, table, and column names) within “"" characters. If the **ANSI_QUOTES** SQL mode is enabled, identifiers are quoted within “"" characters. This option is enabled
mysqldump — A Database Backup Program

by default. It can be disabled with --skip-quote-names, but this option should be given after any option such as --compatible that may enable --quote-names.

• --replace

Write REPLACE statements rather than INSERT statements.

• --result-file=file_name, -r file_name

Direct output to a given file. This option should be used on Windows to prevent newline “\n” characters from being converted to “\r\n” carriage return/newline sequences. The result file is created and its previous contents overwritten, even if an error occurs while generating the dump.

• --routines, -R

Include stored routines (procedures and functions) for the dumped databases in the output. Use of this option requires the SELECT privilege for the mysql.proc table. The output generated by using --routines contains CREATE PROCEDURE and CREATE FUNCTION statements to re-create the routines. However, these statements do not include attributes such as the routine creation and modification timestamps. This means that when the routines are reloaded, they will be created with the timestamps equal to the reload time.

If you require routines to be re-created with their original timestamp attributes, do not use --routines. Instead, dump and reload the contents of the mysql.proc table directly, using a MySQL account that has appropriate privileges for the mysql database.

Prior to MySQL 5.5.21, this option had no effect when used together with the --xml option. (Bug #11760384, Bug #52792)

• --set-charset

Add SET NAMES default_character_set to the output. This option is enabled by default. To suppress the SET NAMES statement, use --skip-set-charset.

• --single-transaction

This option sets the transaction isolation mode to REPEATABLE READ and sends a START TRANSACTION SQL statement to the server before dumping data. It is useful only with transactional tables such as InnoDB, because then it dumps the consistent state of the database at the time when START TRANSACTION was issued without blocking any applications.

When using this option, you should keep in mind that only InnoDB tables are dumped in a consistent state. For example, any MyISAM or MEMORY tables dumped while using this option may still change state.

While a --single-transaction dump is in process, to ensure a valid dump file (correct table contents and binary log coordinates), no other connection should use the following statements: ALTER TABLE, CREATE TABLE, DROP TABLE, RENAME TABLE, TRUNCATE TABLE. A consistent read is not isolated from those statements, so use of them on a table to be dumped can cause the SELECT that is performed by mysqldump to retrieve the table contents to obtain incorrect contents or fail.

The --single-transaction option and the --lock-tables option are mutually exclusive because LOCK TABLES causes any pending transactions to be committed implicitly.

This option is not supported for MySQL Cluster tables; the results cannot be guaranteed to be consistent due to the fact that the NDBCLUSTER storage engine supports only the READ_COMMITTED transaction isolation level. You should always use NDB backup and restore instead.
To dump large tables, combine the `--single-transaction` option with the `--quick` option.

- `--skip-comments`

  See the description for the `--comments` option.

- `--skip-opt`

  See the description for the `--opt` option.

- `--socket=path`, `-S path`

  For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

  Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See Section 6.3.9.4, “SSL Command Options”.

- `--tab=path`, `-T path`

  Produce tab-separated text-format data files. For each dumped table, `mysqldump` creates a `tbl_name.sql` file that contains the `CREATE TABLE` statement that creates the table, and the server writes a `tbl_name.txt` file that contains its data. The option value is the directory in which to write the files.

  **Note**

  This option should be used only when `mysqldump` is run on the same machine as the `mysqld` server. You must have the `FILE` privilege, and the server must have permission to write files in the directory that you specify.

  By default, the `.txt` data files are formatted using tab characters between column values and a newline at the end of each line. The format can be specified explicitly using the `--fields-xxx` and `--lines-terminated-by` options.

  Column values are converted to the character set specified by the `--default-character-set` option.

- `--tables`

  Override the `--databases` or `-B` option. `mysqldump` regards all name arguments following the option as table names.

- `--triggers`

  Include triggers for each dumped table in the output. This option is enabled by default; disable it with `--skip-triggers`.

- `--tz-utc`

  This option enables `TIMESTAMP` columns to be dumped and reloaded between servers in different time zones. `mysqldump` sets its connection time zone to UTC and adds `SET TIME_ZONE='+00:00'` to the dump file. Without this option, `TIMESTAMP` columns are dumped and reloaded in the time zones local to the source and destination servers, which can cause the values to change if the servers are in different
time zones. \texttt{--tz-utc} also protects against changes due to daylight saving time. \texttt{--tz-utc} is enabled by default. To disable it, use \texttt{--skip-tz-utc}.

\begin{itemize}
  \item \texttt{--user=user\_name, -u user\_name}
  
  The MySQL user name to use when connecting to the server.
  \item \texttt{--verbose, -v}
  
  Verbose mode. Print more information about what the program does.
  \item \texttt{--version, -V}
  
  Display version information and exit.
  \item \texttt{--where='where\_condition', -w 'where\_condition'}
  
  Dump only rows selected by the given WHERE condition. Quotes around the condition are mandatory if it contains spaces or other characters that are special to your command interpreter.

  \textbf{Examples:}

  \begin{verbatim}
  --where="user='jimf'"
  -w"userid>1"
  -w"userid<1"
  \end{verbatim}

  \item \texttt{--xml, -X}
  
  Write dump output as well-formed XML.
\end{itemize}

\textbf{NULL, 'NULL', and Empty Values:} For a column named \texttt{column\_name}, the NULL value, an empty string, and the string value 'NULL' are distinguished from one another in the output generated by this option as follows.

\begin{table}[h]
\centering
\begin{tabular}{|l|l|}
\hline
\textbf{Value:} & \textbf{XML Representation:} \\
\hline
NULL (unknown value) & <field name="column\_name" xsi:nil="true" /> \\
' ' (empty string) & <field name="column\_name"></field> \\
'NULL' (string value) & <field name="column\_name">NULL</field> \\
\hline
\end{tabular}
\end{table}

The output from the mysql client when run using the --xml option also follows the preceding rules. (See Section 4.5.1.1, "mysql Options").

XML output from \texttt{mysqldump} includes the XML namespace, as shown here:

\begin{verbatim}
shell> mysqldump --xml -u root world City
<?xml version="1.0"?>
<mysqldump xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<database name="world">
<table_structure name="City">
  <field Field="ID" Type="int(11)" Null="NO" Key="PRI" Extra="auto_increment" />
  <field Field="Name" Type="char(35)" Null="NO" Key="" Default="" Extra="" />
  <field Field="CountryCode" Type="char(3)" Null="NO" Key="" Default="" Extra="" />
  <field Field="District" Type="char(20)" Null="NO" Key="" Default="" Extra="" />
  <field Field="Population" Type="int(11)" Null="NO" Key="" Default="0" Extra="" />
  <key Table="City" Non_unique="0" Key_name="PRIMARY" Seq_in_index="1" Column_name="ID">
\end{verbatim}
Prior to MySQL 5.5.21, this option prevented the `--routines` option from working correctly—that is, no stored routines, triggers, or events could be dumped in XML format. (Bug #11760384, Bug #52792)

You can also set the following variables by using `--var_name=value` syntax:

- **max_allowed_packet**
  
  The maximum size of the buffer for client/server communication. The default is 24MB, the maximum is 1GB.

- **net_buffer_length**
  
  The initial size of the buffer for client/server communication. When creating multiple-row `INSERT` statements (as with the `--extended-insert` or `--opt` option), `mysqldump` creates rows up to `net_buffer_length` length. If you increase this variable, you should also ensure that the `net_buffer_length` variable in the MySQL server is at least this large.

  Some options, such as `--opt`, automatically enable `--lock-tables`. If you want to override this, use `--skip-lock-tables` at the end of the option list.

A common use of `mysqldump` is for making a backup of an entire database:

```
shell> mysqldump db_name > backup-file.sql
```

You can load the dump file back into the server like this:

```
shell> mysql db_name < backup-file.sql
```

Or like this:

```
shell> mysql -e "source /path-to-backup/backup-file.sql" db_name
```
for populating databases by copying data from one MySQL server to another:

```
shell> mysqldump --opt db_name | mysql --host=remote_host -C db_name
```

It is possible to dump several databases with one command:

```
shell> mysqldump --databases db_name1 [db_name2 ...] > my_databases.sql
```

To dump all databases, use the `--all-databases` option:

```
shell> mysqldump --all-databases > all_databases.sql
```

For InnoDB tables, mysqldump provides a way of making an online backup:

```
shell> mysqldump --all-databases --single-transaction > all_databases.sql
```

This backup acquires a global read lock on all tables (using `FLUSH TABLES WITH READ LOCK`) at the beginning of the dump. As soon as this lock has been acquired, the binary log coordinates are read and the lock is released. If long updating statements are running when the `FLUSH` statement is issued, the MySQL server may get stalled until those statements finish. After that, the dump becomes lock free and does not disturb reads and writes on the tables. If the update statements that the MySQL server receives are short (in terms of execution time), the initial lock period should not be noticeable, even with many updates.

For point-in-time recovery (also known as “roll-forward,” when you need to restore an old backup and replay the changes that happened since that backup), it is often useful to rotate the binary log (see Section 5.2.4, “The Binary Log”) or at least know the binary log coordinates to which the dump corresponds:

```
shell> mysqldump --all-databases --master-data=2 > all_databases.sql
```

Or:

```
shell> mysqldump --all-databases --flush-logs --master-data=2 > all_databases.sql
```

The `--master-data` and `--single-transaction` options can be used simultaneously, which provides a convenient way to make an online backup suitable for use prior to point-in-time recovery if tables are stored using the InnoDB storage engine.

For more information on making backups, see Section 7.2, “Database Backup Methods”, and Section 7.3, “Example Backup and Recovery Strategy”.

If you encounter problems backing up views, please read the section that covers restrictions on views which describes a workaround for backing up views when this fails due to insufficient privileges. See Section D.5, “Restrictions on Views”.

### 4.5.5 mysqlimport — A Data Import Program

The `mysqlimport` client provides a command-line interface to the `LOAD DATA INFILE` SQL statement. Most options to `mysqlimport` correspond directly to clauses of `LOAD DATA INFILE` syntax. See Section 13.2.6, “LOAD DATA INFILE Syntax”.

Invoke `mysqlimport` like this:
For each text file named on the command line, `mysqlimport` strips any extension from the file name and uses the result to determine the name of the table into which to import the file's contents. For example, files named `patient.txt`, `patient.text`, and `patient` all would be imported into a table named `patient`.

`mysqlimport` supports the following options, which can be specified on the command line or in the `[mysqlimport]` and `[client]` groups of an option file. For information about option files, see Section 4.2.6, “Using Option Files”.

### Table 4.9 `mysqlimport` Options

<table>
<thead>
<tr>
<th>Format</th>
<th>Option File</th>
<th>Description</th>
<th>Introduced</th>
</tr>
</thead>
<tbody>
<tr>
<td>--columns=column_list</td>
<td>columns</td>
<td>This option takes a comma-separated list of column names as its value</td>
<td></td>
</tr>
<tr>
<td>--compress</td>
<td>compress</td>
<td>Compress all information sent between the client and the server</td>
<td></td>
</tr>
<tr>
<td>--debug[=debug_options]</td>
<td>debug</td>
<td>Write a debugging log</td>
<td></td>

</tbody>
</table>

- **--help, -?**  
  Display a help message and exit.

- **--bind-address=ip_address**
On a computer having multiple network interfaces, this option can be used to select which interface is employed when connecting to the MySQL server.

This option is supported only in the version of **mysqlimport** that is supplied with MySQL Cluster. It is not available in standard MySQL Server 5.5 releases.

- **--character-sets-dir=path**
  
  The directory where character sets are installed. See Section 10.5, “Character Set Configuration”.

- **--columns=column_list, -c column_list**
  
  This option takes a comma-separated list of column names as its value. The order of the column names indicates how to match data file columns with table columns.

- **--compress, -C**
  
  Compress all information sent between the client and the server if both support compression.

- **--debug[=debug_options], -# [debug_options]**
  
  Write a debugging log. A typical `debug_options` string is `d:t:o, file_name`. The default is `d:t:o`.

- **--debug-check**
  
  Print some debugging information when the program exits.

- **--debug-info**
  
  Print debugging information and memory and CPU usage statistics when the program exits.

- **--default-character-set=charset_name**
  
  Use `charset_name` as the default character set. See Section 10.5, “Character Set Configuration”.

- **--default-auth=plugin**
  
  The client-side authentication plugin to use. See Section 6.3.6, “Pluggable Authentication”.

  This option was added in MySQL 5.5.10.

- **--defaults-extra-file=file_name**
  
  Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, `file_name` must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- **--defaults-file=file_name**
  
  Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, `file_name` must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- **--defaults-group-suffix=str**
  
  Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, **mysqlimport** normally reads the [client] and [mysqlimport] groups. If the **--
defaults-group-suffix=_other option is given, mysqlimport also reads the [client_other] and [mysqlimport_other] groups.

- --delete, -D

Empty the table before importing the text file.

- --fields-terminated-by=..., --fields-enclosed-by=..., --fields-optionally-enclosed-by=..., --fields-escaped-by=...

These options have the same meaning as the corresponding clauses for LOAD DATA INFILE. See Section 13.2.6, "LOAD DATA INFILE Syntax".

- --force, -f

Ignore errors. For example, if a table for a text file does not exist, continue processing any remaining files. Without --force, mysqlimport exits if a table does not exist.

- --host=host_name, -h host_name

Import data to the MySQL server on the given host. The default host is localhost.

- --ignore, -i

See the description for the --replace option.

- --ignore-lines=N

Ignore the first N lines of the data file.

- --lines-terminated-by=...

This option has the same meaning as the corresponding clause for LOAD DATA INFILE. For example, to import Windows files that have lines terminated with carriage return/linefeed pairs, use --lines-terminated-by="\r\n". (You might have to double the backslashes, depending on the escaping conventions of your command interpreter.) See Section 13.2.6, "LOAD DATA INFILE Syntax".

- --local, -L

Read input files locally from the client host.

- --lock-tables, -l

Lock all tables for writing before processing any text files. This ensures that all tables are synchronized on the server.

- --low-priority

Use LOW_PRIORITY when loading the table. This affects only storage engines that use only table-level locking (such as MyISAM, MEMORY, and MERGE).

- --no-defaults

Do not read any option files. If program startup fails due to reading unknown options from an option file, --no-defaults can be used to prevent them from being read.

- --password[=password], -p[password]
The password to use when connecting to the server. If you use the short option form (-p), you cannot have a space between the option and the password. If you omit the password value following the --password or -p option on the command line, mysqlimport prompts for one.

Specifying a password on the command line should be considered insecure. See Section 6.1.2.1, “End-User Guidelines for Password Security”. You can use an option file to avoid giving the password on the command line.

• --pipe, -W

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

• --plugin-dir=path

The directory in which to look for plugins. It may be necessary to specify this option if the --default-auth option is used to specify an authentication plugin but mysqlimport does not find it. See Section 6.3.6, “Pluggable Authentication”.

This option was added in MySQL 5.5.10.

• --port=port_num, -P port_num

The TCP/IP port number to use for the connection.

• --print-defaults

Print the program name and all options that it gets from option files.

• --protocol={TCP|SOCKET|PIPE|MEMORY}

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see Section 4.2.2, “Connecting to the MySQL Server”.

• --replace, -r

The --replace and --ignore options control handling of input rows that duplicate existing rows on unique key values. If you specify --replace, new rows replace existing rows that have the same unique key value. If you specify --ignore, input rows that duplicate an existing row on a unique key value are skipped. If you do not specify either option, an error occurs when a duplicate key value is found, and the rest of the text file is ignored.

• --silent, -s

Silent mode. Produce output only when errors occur.

• --socket=path, -S path

For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

• --ssl*

Options that begin with --ssl specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See Section 6.3.9.4, “SSL Command Options”.

• --user=user_name, -u user_name
The MySQL user name to use when connecting to the server.

- **--use-threads=N**
  Load files in parallel using \( N \) threads.

- **--verbose, -v**
  Verbose mode. Print more information about what the program does.

- **--version, -V**
  Display version information and exit.

Here is a sample session that demonstrates use of `mysqlimport`:

```
shell> mysql -e 'CREATE TABLE imptest(id INT, n VARCHAR(30))' test
shell> ed
a
100     Max Sydow
101     Count Dracula
w imptest.txt
32
q
shell> od -c imptest.txt
0000000  1   0   0   \t   M   a   x       S   y   d   o   w  \n   1   0
0000020   1   \t   C   o   u   n   t       D   r   a   c   u   l   a  
0000040
shell> mysqlimport --local test imptest.txt
test.imptest: Records: 2  Deleted: 0  Skipped: 0  Warnings: 0
shell> mysql -e 'SELECT * FROM imptest' test
+------+---------------+
| id   | n             |
|------+---------------|
| 100  | Max Sydow     |
| 101  | Count Dracula |
+------+---------------+
```

### 4.5.6 `mysqlshow` — Display Database, Table, and Column Information

The `mysqlshow` client can be used to quickly see which databases exist, their tables, or a table’s columns or indexes.

`mysqlshow` provides a command-line interface to several SQL `SHOW` statements. See Section 13.7.5, “SHOW Syntax”. The same information can be obtained by using those statements directly. For example, you can issue them from the `mysql` client program.

Invoke `mysqlshow` like this:

```
shell> mysqlshow [options] [db_name [tbl_name [col_name]]]
```

- If no database is given, a list of database names is shown.
- If no table is given, all matching tables in the database are shown.
- If no column is given, all matching columns and column types in the table are shown.

The output displays only the names of those databases, tables, or columns for which you have some privileges.
If the last argument contains shell or SQL wildcard characters ("*", "?", "/", or "_"), only those names that are matched by the wildcard are shown. If a database name contains any underscores, those should be escaped with a backslash (some Unix shells require two) to get a list of the proper tables or columns. "*" and "?" characters are converted into SQL "\%" and "_" wildcard characters. This might cause some confusion when you try to display the columns for a table with a "_" in the name, because in this case, mysqlshow shows you only the table names that match the pattern. This is easily fixed by adding an extra "\%" last on the command line as a separate argument.

mysqlshow supports the following options, which can be specified on the command line or in the [mysqlshow] and [client] groups of an option file. For information about option files, see Section 4.2.6, “Using Option Files”.

**Table 4.10 mysqlshow Options**

<table>

</tbody>
</table>

• --help, -?

Display a help message and exit.

• --bind-address=ip_address

On a computer having multiple network interfaces, this option can be used to select which interface is employed when connecting to the MySQL server.

This option is supported only in the version of mysqlshow that is supplied with MySQL Cluster. It is not available in standard MySQL Server 5.5 releases.

• --character-sets-dir=path

The directory where character sets are installed. See Section 10.5, "Character Set Configuration".

• --compress, -C

Compress all information sent between the client and the server if both support compression.

• --count

Show the number of rows per table. This can be slow for non-MyISAM tables.

• --debug[=debug_options], -# [debug_options]

Write a debugging log. A typical debug_options string is d:t:o, file_name. The default is d:t:o.

• --debug-check
Print some debugging information when the program exits.

- **--debug-info**

  Print debugging information and memory and CPU usage statistics when the program exits.

- **--default-character-set=charset_name**

  Use *charset_name* as the default character set. See [Section 10.5, “Character Set Configuration”](#).

- **--default-auth=plugin**

  The client-side authentication plugin to use. See [Section 6.3.6, “Pluggable Authentication”](#).

This option was added in MySQL 5.5.10.

- **--defaults-extra-file=file_name**

  Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, *file_name* must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- **--defaults-file=file_name**

  Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, *file_name* must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- **--defaults-group-suffix=str**

  Read not only the usual option groups, but also groups with the usual names and a suffix of *str*. For example, `mysqlshow` normally reads the [client] and [mysqlshow] groups. If the **--defaults-group-suffix=_other** option is given, `mysqlshow` also reads the [client_other] and [mysqlshow_other] groups.

- **--host=host_name, -h host_name**

  Connect to the MySQL server on the given host.

- **--keys, -k**

  Show table indexes.

- **--no-defaults**

  Do not read any option files. If program startup fails due to reading unknown options from an option file, **--no-defaults** can be used to prevent them from being read.

- **--password[=password], -p[password]**

  The password to use when connecting to the server. If you use the short option form (-p), you cannot have a space between the option and the password. If you omit the *password* value following the **--password** or -p option on the command line, `mysqlshow` prompts for one.

  Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.
• **--pipe**,**-W**
  On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

• **--plugin-dir**=*path*
  The directory in which to look for plugins. It may be necessary to specify this option if the **--default-auth** option is used to specify an authentication plugin but *mysqlshow* does not find it. See Section 6.3.6, “Pluggable Authentication”.

  This option was added in MySQL 5.5.10.

• **--port**=*port_num*, **-P** *port_num*
  The TCP/IP port number to use for the connection.

• **--print-defaults**
  Print the program name and all options that it gets from option files.

• **--protocol**={TCP|SOCKET|PIPE|MEMORY}
  The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see Section 4.2.2, “Connecting to the MySQL Server”.

• **--show-table-type**, **-t**
  Show a column indicating the table type, as in *SHOW FULL TABLES*. The type is **BASE TABLE** or **VIEW**.

• **--socket**=*path*, **-S** *path*
  For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

• **--ssl**
  Options that begin with **--ssl** specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See Section 6.3.9.4, “SSL Command Options”.

• **--status**, **-i**
  Display extra information about each table.

• **--user**=*user_name*, **-u** *user_name*
  The MySQL user name to use when connecting to the server.

• **--verbose**, **-v**
  Verbos mode. Print more information about what the program does. This option can be used multiple times to increase the amount of information.

• **--version**, **-V**
  Display version information and exit.

4.5.7 mysqlslap — Load Emulation Client
**mysqlslap** is a diagnostic program designed to emulate client load for a MySQL server and to report the timing of each stage. It works as if multiple clients are accessing the server.

Invoke **mysqlslap** like this:

```
shell> mysqlslap [options]
```

Some options such as **--create** or **--query** enable you to specify a string containing an SQL statement or a file containing statements. If you specify a file, by default it must contain one statement per line. (That is, the implicit statement delimiter is the newline character.) Use the **--delimiter** option to specify a different delimiter, which enables you to specify statements that span multiple lines or place multiple statements on a single line. You cannot include comments in a file; **mysqlslap** does not understand them.

**mysqlslap** runs in three stages:

1. Create schema, table, and optionally any stored programs or data to use for the test. This stage uses a single client connection.

2. Run the load test. This stage can use many client connections.

3. Clean up (disconnect, drop table if specified). This stage uses a single client connection.

Examples:

Supply your own create and query SQL statements, with 50 clients querying and 200 selects for each (enter the command on a single line):

```
mysqlslap --delimiter=";"
  --create="CREATE TABLE a (b int);INSERT INTO a VALUES (23)"
  --query="SELECT * FROM a" --concurrency=50 --iterations=200
```

Let **mysqlslap** build the query SQL statement with a table of two INT columns and three VARCHAR columns. Use five clients querying 20 times each. Do not create the table or insert the data (that is, use the previous test's schema and data):

```
mysqlslap --concurrency=5 --iterations=20
  --number-int-cols=2 --number-char-cols=3
  --auto-generate-sql
```

Tell the program to load the create, insert, and query SQL statements from the specified files, where the create.sql file has multiple table creation statements delimited by ';' and multiple insert statements delimited by ';'. The --query file will have multiple queries delimited by ';'. Run all the load statements, then run all the queries in the query file with five clients (five times each):

```
mysqlslap --concurrency=5
  --iterations=5 --query=query.sql --create=create.sql
  --delimiter=";"
```

**mysqlslap** supports the following options, which can be specified on the command line or in the [mysqlslap] and [client] groups of an option file. For information about option files, see Section 4.2.6, “Using Option Files”.

**Table 4.11 mysqlslap Options**

<table>
<thead>
<tr>
<th>Format</th>
<th>Option File</th>
<th>Description</th>
<th>Introduced</th>
</tr>
</thead>

- **--help, -?**
  Display a help message and exit.

- **--auto-generate-sql, -a**
  Generate SQL statements automatically when they are not supplied in files or using command options.

- **--auto-generate-sql-add-autocolumn**
  Add an AUTO_INCREMENT column to automatically generated tables.

- **--auto-generate-sql-execute-number=N**
  Specify how many queries to generate automatically.

- **--auto-generate-sql-guid-primary**
  Add a GUID-based primary key to automatically generated tables.

- **--auto-generate-sql-load-type=type**
  Specify the test load type. The permissible values are read (scan tables), write (insert into tables), key (read primary keys), update (update primary keys), or mixed (half inserts, half scanning selects). The default is mixed.

- **--auto-generate-sql-secondary-indexes=N**
  Specify how many secondary indexes to add to automatically generated tables. By default, none are added.

- **--auto-generate-sql-unique-query-number=N**
How many different queries to generate for automatic tests. For example, if you run a key test that performs 1000 selects, you can use this option with a value of 1000 to run 1000 unique queries, or with a value of 50 to perform 50 different selects. The default is 10.

- `--auto-generate-sql-unique-write-number=N`

  How many different queries to generate for `--auto-generate-sql-write-number`. The default is 10.

- `--auto-generate-sql-write-number=N`

  How many row inserts to perform on each thread. The default is 100.

- `--commit=N`

  How many statements to execute before committing. The default is 0 (no commits are done).

- `--compress,-C`

  Compress all information sent between the client and the server if both support compression.

- `--concurrency=N,-c N`

  The number of clients to simulate when issuing the `SELECT` statement.

- `--create=value`

  The file or string containing the statement to use for creating the table.

- `--create-schema=value`

  The schema in which to run the tests.

  **Note**

  If the `--auto-generate-sql` option is also given, `mysqlslap` drops the schema at the end of the test run. To avoid this, use the `--no-drop` option as well.

- `--csv[=file_name]`

  Generate output in comma-separated values format. The output goes to the named file, or to the standard output if no file is given.

- `--debug[=debug_options],-# [debug_options]`

  Write a debugging log. A typical `debug_options` string is `d:t:o, file_name`. The default is `d:t:o, / tmp/mysqlslap.trace`.

- `--debug-check`

  Print some debugging information when the program exits.

- `--debug-info,-T`

  Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-auth=plugin`
The client-side authentication plugin to use. See Section 6.3.6, “Pluggable Authentication”.

This option was added in MySQL 5.5.10.

• **--defaults-extra-file=** *file_name*

  Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, *file_name* must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

• **--defaults-file=** *file_name*

  Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, *file_name* must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

• **--defaults-group-suffix=** *str*

  Read not only the usual option groups, but also groups with the usual names and a suffix of *str*. For example, *mysqlslap* normally reads the [client] and [mysqlslap] groups. If the **--defaults-group-suffix=_other** option is given, *mysqlslap* also reads the [client_other] and [mysqlslap_other] groups.

• **--delimiter=** *str*, **-F** *str*

  The delimiter to use in SQL statements supplied in files or using command options.

• **--detach=N**

  Detach (close and reopen) each connection after each *N* statements. The default is 0 (connections are not detached).

• **--enable-cleartext-plugin**

  Enable the *mysql_clear_password* cleartext authentication plugin. (See Section 6.3.7.5, “The Cleartext Client-Side Authentication Plugin”.) This option was added in MySQL 5.5.27.

• **--engine=** *engine_name*, **-e** *engine_name*

  The storage engine to use for creating tables.

• **--host=** *host_name*, **-h** *host_name*

  Connect to the MySQL server on the given host.

• **--iterations=** *N*, **-i** *N*

  The number of times to run the tests.

• **--no-drop**

  Prevent *mysqlslap* from dropping any schema it creates during the test run. This option was added in MySQL 5.5.12.

• **--no-defaults**
Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

- `--number-char-cols=N, -x N`
  The number of VARCHAR columns to use if `--auto-generate-sql` is specified.

- `--number-int-cols=N, -y N`
  The number of INT columns to use if `--auto-generate-sql` is specified.

- `--number-of-queries=N`
  Limit each client to approximately this many queries. Query counting takes into account the statement delimiter. For example, if you invoke `mysqlslap` as follows, the `;` delimiter is recognized so that each instance of the query string counts as two queries. As a result, 5 rows (not 10) are inserted.

  ```bash
  shell> mysqlslap --delimiter=";" --number-of-queries=10
  --query="use test;insert into t values(null)"
  ```

- `--only-print`
  Do not connect to databases. `mysqlslap` only prints what it would have done.

- `--password[=password], -p[password]`
  The password to use when connecting to the server. If you use the short option form (`-p`), you cannot have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysqlslap` prompts for one.

  Specifying a password on the command line should be considered insecure. See Section 6.1.2.1, “End-User Guidelines for Password Security”. You can use an option file to avoid giving the password on the command line.

- `--pipe, -W`
  On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=path`
  The directory in which to look for plugins. It may be necessary to specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlslap` does not find it. See Section 6.3.6, “Pluggable Authentication”.

  This option was added in MySQL 5.5.10.

- `--port=port_num, -P port_num`
  The TCP/IP port number to use for the connection.

- `--post-query=value`
  The file or string containing the statement to execute after the tests have completed. This execution is not counted for timing purposes.

- `--post-system=str`
The string to execute using `system()` after the tests have completed. This execution is not counted for timing purposes.

- `--pre-query=value`

  The file or string containing the statement to execute before running the tests. This execution is not counted for timing purposes.

- `--pre-system=string`

  The string to execute using `system()` before running the tests. This execution is not counted for timing purposes.

- `--print-defaults`

  Print the program name and all options that it gets from option files.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

  The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see Section 4.2.2, “Connecting to the MySQL Server”.

- `--query=value, -q value`

  The file or string containing the `SELECT` statement to use for retrieving data.

- `--shared-memory-base-name=name`

  On Windows, the shared-memory name to use, for connections made using shared memory to a local server. This option applies only if the server supports shared-memory connections.

- `--silent, -s`

  Silent mode. No output.

- `--socket=path, -S path`

  For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

  Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See Section 6.3.9.4, “SSL Command Options”.

- `--user=user_name, -u user_name`

  The MySQL user name to use when connecting to the server.

- `--verbose, -v`

  Verbose mode. Print more information about what the program does. This option can be used multiple times to increase the amount of information.

- `--version, -V`

  Display version information and exit.
4.6 MySQL Administrative and Utility Programs

This section describes administrative programs and programs that perform miscellaneous utility operations.

4.6.1 **innochecksum** — Offline InnoDB File Checksum Utility

`innochecksum` prints checksums for InnoDB files. This tool reads an InnoDB tablespace file, calculates the checksum for each page, compares the calculated checksum to the stored checksum, and reports mismatches, which indicate damaged pages. It was originally developed to speed up verifying the integrity of tablespace files after power outages but can also be used after file copies. Because checksum mismatches will cause InnoDB to deliberately shut down a running server, it can be preferable to use this tool rather than waiting for a server in production usage to encounter the damaged pages. `innochecksum` supports files up to 2GB in size.

`innochecksum` cannot be used on tablespace files that the server already has open. For such files, you should use `CHECK TABLE` to check tables within the tablespace.

If checksum mismatches are found, you would normally restore the tablespace from backup or start the server and attempt to use `mysqldump` to make a backup of the tables within the tablespace.

Invoke `innochecksum` like this:

```
shell> innochecksum [options] file_name
```

`innochecksum` supports the following options. For options that refer to page numbers, the numbers are zero-based.

- `-c`
  
  Print a count of the number of pages in the file.

- `-d`
  
  Debug mode; prints checksums for each page.

- `-e num`
  
  End at this page number.

- `-p num`
  
  Check only this page number.

- `-s num`
  
  Start at this page number.

- `-v`
  
  Verbose mode; print a progress indicator every five seconds.

4.6.2 **myisam_ftdump** — Display Full-Text Index information

`myisam_ftdump` displays information about FULLTEXT indexes in MyISAM tables. It reads the MyISAM index file directly, so it must be run on the server host where the table is located. Before using `myisam_ftdump`, be sure to issue a `FLUSH TABLES` statement first if the server is running.
myisam_ftdump scans and dumps the entire index, which is not particularly fast. On the other hand, the distribution of words changes infrequently, so it need not be run often.

Invoke myisam_ftdump like this:

```
shell> myisam_ftdump [options] tbl_name index_num
```

The `tbl_name` argument should be the name of a MyISAM table. You can also specify a table by naming its index file (the file with the `.MYI` suffix). If you do not invoke `myisam_ftdump` in the directory where the table files are located, the table or index file name must be preceded by the path name to the table's database directory. Index numbers begin with 0.

Example: Suppose that the test database contains a table named `mytexttable` that has the following definition:

```sql
CREATE TABLE mytexttable
(
    id   INT NOT NULL,
    txt  TEXT NOT NULL,
    PRIMARY KEY (id),
    FULLTEXT (txt)
) ENGINE=MyISAM;
```

The index on `id` is index 0 and the `FULLTEXT` index on `txt` is index 1. If your working directory is the `test` database directory, invoke `myisam_ftdump` as follows:

```
shell> myisam_ftdump mytexttable 1
```

If the path name to the `test` database directory is `/usr/local/mysql/data/test`, you can also specify the table name argument using that path name. This is useful if you do not invoke `myisam_ftdump` in the database directory:

```
shell> myisam_ftdump /usr/local/mysql/data/test/mytexttable 1
```

You can use `myisam_ftdump` to generate a list of index entries in order of frequency of occurrence like this:

```
shell> myisam_ftdump --count mytexttable 1 | sort -r
```

`myisam_ftdump` supports the following options:

- `--help, -h -?`
  Display a help message and exit.
- `--count, -c`
  Calculate per-word statistics (counts and global weights).
- `--dump, -d`
  Dump the index, including data offsets and word weights.
- `--length, -l`
  Report the length distribution.
- `--stats, -s`
Report global index statistics. This is the default operation if no other operation is specified.

- **--verbose, -v**
  
  Verbose mode. Print more output about what the program does.

### 4.6.3 `myisamchk` — MyISAM Table-Maintenance Utility

The `myisamchk` utility gets information about your database tables or checks, repairs, or optimizes them. `myisamchk` works with MyISAM tables (tables that have `.MYD` and `.MYI` files for storing data and indexes).

You can also use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair MyISAM tables. See [Section 13.7.2.2, “CHECK TABLE Syntax”](#), and [Section 13.7.2.5, “REPAIR TABLE Syntax”](#).

The use of `myisamchk` with partitioned tables is not supported.

**Caution**

It is best to make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors.

Invoke `myisamchk` like this:

```
shell> myisamchk [options] tbl_name ...
```

The `options` specify what you want `myisamchk` to do. They are described in the following sections. You can also get a list of options by invoking `myisamchk --help`.

With no options, `myisamchk` simply checks your table as the default operation. To get more information or to tell `myisamchk` to take corrective action, specify options as described in the following discussion.

`tbl_name` is the database table you want to check or repair. If you run `myisamchk` somewhere other than in the database directory, you must specify the path to the database directory, because `myisamchk` has no idea where the database is located. In fact, `myisamchk` does not actually care whether the files you are working on are located in a database directory. You can copy the files that correspond to a database table into some other location and perform recovery operations on them there.

You can name several tables on the `myisamchk` command line if you wish. You can also specify a table by naming its index file (the file with the `.MYI` suffix). This enables you to specify all tables in a directory by using the pattern `*.MYI`. For example, if you are in a database directory, you can check all the MyISAM tables in that directory like this:

```
shell> myisamchk *.MYI
```

If you are not in the database directory, you can check all the tables there by specifying the path to the directory:

```
shell> myisamchk /path/to/database_dir/*/*.MYI
```

You can even check all tables in all databases by specifying a wildcard with the path to the MySQL data directory:

```
shell> myisamchk /path/to/datadir/*//*.MYI
```
The recommended way to quickly check all MyISAM tables is:

```
shell> myisamchk --silent --fast /path/to/datadir/*/*.MYI
```

If you want to check all MyISAM tables and repair any that are corrupted, you can use the following command:

```
shell> myisamchk --silent --force --fast --update-state --key_buffer_size=64M --myisam_sort_buffer_size=64M --read_buffer_size=1M --write_buffer_size=1M /path/to/datadir/*/*.MYI
```

This command assumes that you have more than 64MB free. For more information about memory allocation with myisamchk, see Section 4.6.3.6, "myisamchk Memory Usage".

For additional information about using myisamchk, see Section 7.6, "MyISAM Table Maintenance and Crash Recovery".

**Important**

You must ensure that no other program is using the tables while you are running myisamchk. The most effective means of doing so is to shut down the MySQL server while running myisamchk, or to lock all tables that myisamchk is being used on.

Otherwise, when you run myisamchk, it may display the following error message:

```
warning: clients are using or haven't closed the table properly
```

This means that you are trying to check a table that has been updated by another program (such as the mysqld server) that hasn't yet closed the file or that has died without closing the file properly, which can sometimes lead to the corruption of one or more MyISAM tables.

If mysqld is running, you must force it to flush any table modifications that are still buffered in memory by using FLUSH TABLES. You should then ensure that no one is using the tables while you are running myisamchk.

However, the easiest way to avoid this problem is to use CHECK TABLE instead of myisamchk to check tables. See Section 13.7.2.2, "CHECK TABLE Syntax".

myisamchk supports the following options, which can be specified on the command line or in the [myisamchk] group of an option file. For information about option files, see Section 4.2.6, "Using Option Files".

**Table 4.12 myisamchk Options**

### 4.6.3.1 myisamchk General Options

The options described in this section can be used for any type of table maintenance operation performed by *myisamchk*. The sections following this one describe options that pertain only to specific operations, such as table checking or repairing.

- **--help, -?**
  
  Display a help message and exit. Options are grouped by type of operation.

- **--HELP, -H**
  
  Display a help message and exit. Options are presented in a single list.

- **--debug=debug_options, -# debug_options**
  
  Write a debugging log. A typical `debug_options` string is `d:t:o, file_name`. The default is `d:t:o, /tmp/myisamchk.trace`.

- **--defaults-extra-file=filename**
  
  Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, `filename` must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- **--defaults-file=filename**
  
  Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, `filename` must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- **--defaults-group-suffix=string**
  
  Read not only the usual option groups, but also groups with the usual names and a suffix of `string`. For example, *myisamchk* normally reads the `[myisamchk]` group. If the `--defaults-group-suffix=_other` option is given, *myisamchk* also reads the `[myisamchk_other]` group.

- **--no-defaults**
  
  Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

- **--print-defaults**
  
  Print the program name and all options that it gets from option files.

- **--silent, -s**
Silent mode. Write output only when errors occur. You can use \texttt{-s} twice (\texttt{-ss}) to make \texttt{myisamchk} very silent.

- \texttt{--verbose}, \texttt{-v}
  Verbose mode. Print more information about what the program does. This can be used with \texttt{--d} and \texttt{--e}. Use \texttt{-v} multiple times (\texttt{-vv}, \texttt{-vvv}) for even more output.

- \texttt{--version}, \texttt{-V}
  Display version information and exit.

- \texttt{--wait}, \texttt{-w}
  Instead of terminating with an error if the table is locked, wait until the table is unlocked before continuing. If you are running \texttt{mysqld} with external locking disabled, the table can be locked only by another \texttt{myisamchk} command.

You can also set the following variables by using \texttt{--var_name=value} syntax:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{decode_bits}</td>
<td>9</td>
</tr>
<tr>
<td>\texttt{ft_max_word_len}</td>
<td>version-dependent</td>
</tr>
<tr>
<td>\texttt{ft_min_word_len}</td>
<td>4</td>
</tr>
<tr>
<td>\texttt{ft_stopword_file}</td>
<td>built-in list</td>
</tr>
<tr>
<td>\texttt{key_buffer_size}</td>
<td>523264</td>
</tr>
<tr>
<td>\texttt{myisam_block_size}</td>
<td>1024</td>
</tr>
<tr>
<td>\texttt{myisam_sort_key_blocks}</td>
<td>16</td>
</tr>
<tr>
<td>\texttt{read_buffer_size}</td>
<td>262136</td>
</tr>
<tr>
<td>\texttt{sort_buffer_size}</td>
<td>2097144</td>
</tr>
<tr>
<td>\texttt{sort_key_blocks}</td>
<td>16</td>
</tr>
<tr>
<td>\texttt{stats_method}</td>
<td>nulls_unequal</td>
</tr>
<tr>
<td>\texttt{write_buffer_size}</td>
<td>262136</td>
</tr>
</tbody>
</table>

The possible \texttt{myisamchk} variables and their default values can be examined with \texttt{myisamchk --help}:

\texttt{sort_buffer_size} is used when the keys are repaired by sorting keys, which is the normal case when you use \texttt{--recover}. As of MySQL 5.5.29, \texttt{myisam_sort_buffer_size} is available as an alternative name to \texttt{sort_buffer_size}. \texttt{myisam_sort_buffer_size} is preferable to \texttt{sort_buffer_size} because its name corresponds to the \texttt{myisam_sort_buffer_size} server system variable that has a similar meaning. \texttt{sort_buffer_size} should be considered deprecated.

\texttt{key_buffer_size} is used when you are checking the table with \texttt{--extend-check} or when the keys are repaired by inserting keys row by row into the table (like when doing normal inserts). Repairing through the key buffer is used in the following cases:

- You use \texttt{--safe-recover}.

- The temporary files needed to sort the keys would be more than twice as big as when creating the key file directly. This is often the case when you have large key values for \texttt{CHAR}, \texttt{VARCHAR}, or \texttt{TEXT} columns, because the sort operation needs to store the complete key values as it proceeds. If you have
lots of temporary space and you can force `myisamchk` to repair by sorting, you can use the `--sort-recover` option.

Repairing through the key buffer takes much less disk space than using sorting, but is also much slower.

If you want a faster repair, set the `key_buffer_size` and `myisam_sort_buffer_size` variables to about 25% of your available memory. You can set both variables to large values, because only one of them is used at a time.

`myisam_block_size` is the size used for index blocks.

`stats_method` influences how NULL values are treated for index statistics collection when the `--analyze` option is given. It acts like the `myisam_stats_method` system variable. For more information, see the description of `myisam_stats_method` in Section 5.1.4, “Server System Variables”, and Section 8.3.7, “InnoDB and MyISAM Index Statistics Collection”.

`ft_min_word_len` and `ft_max_word_len` indicate the minimum and maximum word length for FULLTEXT indexes. `ft_stopword_file` names the stopword file. These need to be set under the following circumstances.

If you use `myisamchk` to perform an operation that modifies table indexes (such as repair or analyze), the FULLTEXT indexes are rebuilt using the default full-text parameter values for minimum and maximum word length and the stopword file unless you specify otherwise. This can result in queries failing.

The problem occurs because these parameters are known only by the server. They are not stored in MyISAM index files. To avoid the problem if you have modified the minimum or maximum word length or the stopword file in the server, specify the same `ft_min_word_len`, `ft_max_word_len`, and `ft_stopword_file` values to `myisamchk` that you use for `mysqld`. For example, if you have set the minimum word length to 3, you can repair a table with `myisamchk` like this:

```
shell> myisamchk --recover --ft_min_word_len=3 tbl_name.MYI
```

To ensure that `myisamchk` and the server use the same values for full-text parameters, you can place each one in both the `[mysqld]` and `[myisamchk]` sections of an option file:

```
[mysqld]
ft_min_word_len=3

[myisamchk]
ft_min_word_len=3
```

An alternative to using `myisamchk` is to use the `REPAIR TABLE, ANALYZE TABLE, OPTIMIZE TABLE, or ALTER TABLE`. These statements are performed by the server, which knows the proper full-text parameter values to use.

### 4.6.3.2 `myisamchk` Check Options

`myisamchk` supports the following options for table checking operations:

- `--check, -c`  
  Check the table for errors. This is the default operation if you specify no option that selects an operation type explicitly.

- `--check-only-changed, -C`  
  Check only tables that have changed since the last check.

- `--extend-check, -e`
myisamchk — MyISAM Table-Maintenance Utility

Check the table very thoroughly. This is quite slow if the table has many indexes. This option should only be used in extreme cases. Normally, myisamchk or myisamchk --medium-check should be able to determine whether there are any errors in the table.

If you are using --extend-check and have plenty of memory, setting the key_buffer_size variable to a large value helps the repair operation run faster.

See also the description of this option under table repair options.

For a description of the output format, see Section 4.6.3.5, "Obtaining Table Information with myisamchk".

• --fast, -F
  Check only tables that haven't been closed properly.

• --force, -f
  Do a repair operation automatically if myisamchk finds any errors in the table. The repair type is the same as that specified with the --recover or -r option.

• --information, -i
  Print informational statistics about the table that is checked.

• --medium-check, -m
  Do a check that is faster than an --extend-check operation. This finds only 99.99% of all errors, which should be good enough in most cases.

• --read-only, -T
  Do not mark the table as checked. This is useful if you use myisamchk to check a table that is in use by some other application that does not use locking, such as mysqld when run with external locking disabled.

• --update-state, -U
  Store information in the .MYI file to indicate when the table was checked and whether the table crashed. This should be used to get full benefit of the --check-only-changed option, but you shouldn't use this option if the mysqld server is using the table and you are running it with external locking disabled.

4.6.3.3 myisamchk Repair Options

myisamchk supports the following options for table repair operations (operations performed when an option such as --recover or --safe-recover is given):

• --backup, -B
  Make a backup of the .MYD file as file_name-time.BAK

• --character-sets-dir=path
  The directory where character sets are installed. See Section 10.5, "Character Set Configuration".

• --correct-checksum
  Correct the checksum information for the table.
• **--data-file-length=len, -D len**

The maximum length of the data file (when re-creating data file when it is “full”).

• **--extend-check, -e**

Do a repair that tries to recover every possible row from the data file. Normally, this also finds a lot of garbage rows. Do not use this option unless you are desperate.

See also the description of this option under table checking options.

For a description of the output format, see Section 4.6.3.5, “Obtaining Table Information with myisamchk”.

• **--force, -f**

Overwrite old intermediate files (files with names like `tbl_name.TMD`) instead of aborting.

• **--keys-used=val, -k val**

For myisamchk, the option value is a bit-value that indicates which indexes to update. Each binary bit of the option value corresponds to a table index, where the first index is bit 0. An option value of 0 disables updates to all indexes, which can be used to get faster inserts. Deactivated indexes can be reactivated by using `myisamchk -r`.

• **--no-symlinks, -l**

Do not follow symbolic links. Normally myisamchk repairs the table that a symlink points to. This option does not exist as of MySQL 4.0 because versions from 4.0 on do not remove symlinks during repair operations.

• **--max-record-length=len**

Skip rows larger than the given length if myisamchk cannot allocate memory to hold them.

• **--parallel-recover, -p**

Use the same technique as `--r` and `--n`, but create all the keys in parallel, using different threads. This is beta-quality code. Use at your own risk!

• **--quick, -q**

Achieve a faster repair by modifying only the index file, not the data file. You can specify this option twice to force myisamchk to modify the original data file in case of duplicate keys.

• **--recover, -r**

Do a repair that can fix almost any problem except unique keys that are not unique (which is an extremely unlikely error with MyISAM tables). If you want to recover a table, this is the option to try first. You should try `--safe-recover` only if myisamchk reports that the table cannot be recovered using `--recover`. (In the unlikely case that `--recover` fails, the data file remains intact.)

If you have lots of memory, you should increase the value of `myisam_sort_buffer_size`.

• **--safe-recover, -o**

Do a repair using an old recovery method that reads through all rows in order and updates all index trees based on the rows found. This is an order of magnitude slower than `--recover`, but can handle
a couple of very unlikely cases that --recover cannot. This recovery method also uses much less disk space than --recover. Normally, you should repair first using --recover, and then with --safe-recover only if --recover fails.

If you have lots of memory, you should increase the value of key_buffer_size.

• --set-character-set=name
  Change the character set used by the table indexes. This option was replaced by --set-collation in MySQL 5.0.3.

• --set-collation=name
  Specify the collation to use for sorting table indexes. The character set name is implied by the first part of the collation name.

• --sort-recover, -n
  Force myisamchk to use sorting to resolve the keys even if the temporary files would be very large.

• --tmpdir=path, -t path
  The path of the directory to be used for storing temporary files. If this is not set, myisamchk uses the value of the TMPDIR environment variable. --tmpdir can be set to a list of directory paths that are used successively in round-robin fashion for creating temporary files. The separator character between directory names is the colon (":") on Unix and the semicolon (";") on Windows.

• --unpack, -u
  Unpack a table that was packed with myisampack.

### 4.6.3.4 Other myisamchk Options

myisamchk supports the following options for actions other than table checks and repairs:

• --analyze, -a
  Analyze the distribution of key values. This improves join performance by enabling the join optimizer to better choose the order in which to join the tables and which indexes it should use. To obtain information about the key distribution, use a myisamchk --description --verbose tbl_name command or the SHOW INDEX FROM tbl_name statement.

• --block-search=offset, -b offset
  Find the record that a block at the given offset belongs to.

• --description, -d
  Print some descriptive information about the table. Specifying the --verbose option once or twice produces additional information. See Section 4.6.3.5, “Obtaining Table Information with myisamchk”.

• --set-auto-increment[=value], -A[=value]
  Force AUTO_INCREMENT numbering for new records to start at the given value (or higher, if there are existing records with AUTO_INCREMENT values this large). If value is not specified, AUTO_INCREMENT numbers for new records begin with the largest value currently in the table, plus one.

• --sort-index, -S
Sort the index tree blocks in high-low order. This optimizes seeks and makes table scans that use indexes faster.

- `--sort-records=N, -R N`

Sort records according to a particular index. This makes your data much more localized and may speed up range-based `SELECT` and `ORDER BY` operations that use this index. (The first time you use this option to sort a table, it may be very slow.) To determine a table's index numbers, use `SHOW INDEX`, which displays a table's indexes in the same order that `myisamchk` sees them. Indexes are numbered beginning with 1.

If keys are not packed (`PACK_KEYS=0`), they have the same length, so when `myisamchk` sorts and moves records, it just overwrites record offsets in the index. If keys are packed (`PACK_KEYS=1`), `myisamchk` must unpack key blocks first, then re-create indexes and pack the key blocks again. (In this case, re-creating indexes is faster than updating offsets for each index.)

### 4.6.3.5 Obtaining Table Information with `myisamchk`

To obtain a description of a `MyISAM` table or statistics about it, use the commands shown here. The output from these commands is explained later in this section.

- **`myisamchk -d tbl_name`**

  Runs `myisamchk` in “describe mode” to produce a description of your table. If you start the MySQL server with external locking disabled, `myisamchk` may report an error for a table that is updated while it runs. However, because `myisamchk` does not change the table in describe mode, there is no risk of destroying data.

- **`myisamchk -dv tbl_name`**

  Adding `-v` runs `myisamchk` in verbose mode so that it produces more information about the table. Adding `-v` a second time produces even more information.

- **`myisamchk -eis tbl_name`**

  Shows only the most important information from a table. This operation is slow because it must read the entire table.

- **`myisamchk -eiv tbl_name`**

  This is like `-eis`, but tells you what is being done.

The `tbl_name` argument can be either the name of a `MyISAM` table or the name of its index file, as described in Section 4.6.3, “`myisamchk` — MyISAM Table-Maintenance Utility”. Multiple `tbl_name` arguments can be given.

Suppose that a table named `person` has the following structure. (The `MAX_ROWS` table option is included so that in the example output from `myisamchk` shown later, some values are smaller and fit the output format more easily.)

```sql
CREATE TABLE person
(
    id INT NOT NULL AUTO_INCREMENT,
    last_name VARCHAR(20) NOT NULL,
    first_name VARCHAR(20) NOT NULL,
    birth DATE,
    death DATE,
    PRIMARY KEY (id),
)`
Suppose also that the table has these data and index file sizes:

<table>
<thead>
<tr>
<th>Mode</th>
<th>User</th>
<th>Group</th>
<th>Size</th>
<th>Date</th>
<th>Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>-rw-rw-</td>
<td>mysql</td>
<td>mysql</td>
<td>9347072</td>
<td>Aug 19</td>
<td>11:47</td>
</tr>
<tr>
<td>-rw-rw-</td>
<td>mysql</td>
<td>mysql</td>
<td>6066176</td>
<td>Aug 19</td>
<td>11:47</td>
</tr>
</tbody>
</table>

Example of `myisamchk -dvv` output:

| MyISAM file: | person |
| Record format: | Packed |
| Character set: | latin1_swedish_ci (8) |
| File-version: | 1 |

<td>2 no zeros</td>
</tr>
</tbody>
</table>

Explanations for the types of information `myisamchk` produces are given here. "Keyfile" refers to the index file. "Record" and "row" are synonymous, as are "field" and "column."

The initial part of the table description contains these values:

- **MyISAM file**
  Name of the **MyISAM** (index) file.

- **Record format**
  The format used to store table rows. The preceding examples use **Fixed length**. Other possible values are **Compressed** and **Packed**. (**Packed** corresponds to what **SHOW TABLE STATUS** reports as **Dynamic**.)

- **Character set**
  The table default character set.

- **File-version**
  Version of **MyISAM** format. Currently always 1.
• **Creation time**
  When the data file was created.

• **Recover time**
  When the index/data file was last reconstructed.

• **Status**
  Table status flags. Possible values are `crashed`, `open`, `changed`, `analyzed`, `optimized keys`, and `sorted index pages`.

• **Auto increment key, Last value**
  The key number associated the table's `AUTO_INCREMENT` column, and the most recently generated value for this column. These fields do not appear if there is no such column.

• **Data records**
  The number of rows in the table.

• **Deleted blocks**
  How many deleted blocks still have reserved space. You can optimize your table to minimize this space. See Section 7.6.4, "MyISAM Table Optimization".

• **Datafile parts**
  For dynamic-row format, this indicates how many data blocks there are. For an optimized table without fragmented rows, this is the same as `Data records`.

• **Deleted data**
  How many bytes of unreclaimed deleted data there are. You can optimize your table to minimize this space. See Section 7.6.4, "MyISAM Table Optimization".

• **Datafile pointer**
  The size of the data file pointer, in bytes. It is usually 2, 3, 4, or 5 bytes. Most tables manage with 2 bytes, but this cannot be controlled from MySQL yet. For fixed tables, this is a row address. For dynamic tables, this is a byte address.

• **Keyfile pointer**
  The size of the index file pointer, in bytes. It is usually 1, 2, or 3 bytes. Most tables manage with 2 bytes, but this is calculated automatically by MySQL. It is always a block address.

• **Max datafile length**
  How long the table data file can become, in bytes.

• **Max keyfile length**
  How long the table index file can become, in bytes.

• **Recordlength**
  How much space each row takes, in bytes.
The table description part of the output includes a list of all keys in the table. For each key, myisamchk displays some low-level information:

- **Key**
  This key’s number. This value is shown only for the first column of the key. If this value is missing, the line corresponds to the second or later column of a multiple-column key. For the table shown in the example, there are two table description lines for the second index. This indicates that it is a multiple-part index with two parts.

- **Start**
  Where in the row this portion of the index starts.

- **Len**
  How long this portion of the index is. For packed numbers, this should always be the full length of the column. For strings, it may be shorter than the full length of the indexed column, because you can index a prefix of a string column. The total length of a multiple-part key is the sum of the Len values for all key parts.

- **Index**
  Whether a key value can exist multiple times in the index. Possible values are unique or multip. (multiple).

- **Type**
  What data type this portion of the index has. This is a MyISAM data type with the possible values packed, stripped, or empty.

- **Root**
  Address of the root index block.

- **Blocksize**
  The size of each index block. By default this is 1024, but the value may be changed at compile time when MySQL is built from source.

- **Rec/key**
  This is a statistical value used by the optimizer. It tells how many rows there are per value for this index. A unique index always has a value of 1. This may be updated after a table is loaded (or greatly changed) with myisamchk -a. If this is not updated at all, a default value of 30 is given.

The last part of the output provides information about each column:

- **Field**
  The column number.

- **Start**
  The byte position of the column within table rows.

- **Length**
  The length of the column in bytes.
• **Nullpos, Nullbit**

For columns that can be NULL, MyISAM stores NULL values as a flag in a byte. Depending on how many nullable columns there are, there can be one or more bytes used for this purpose. The Nullpos and Nullbit values, if nonempty, indicate which byte and bit contains that flag indicating whether the column is NULL.

The position and number of bytes used to store NULL flags is shown in the line for field 1. This is why there are six Field lines for the person table even though it has only five columns.

• **Type**

The data type. The value may contain any of the following descriptors:

• **constant**
  
  All rows have the same value.

• **no endspace**
  
  Do not store endspace.

• **no endspace, not_always**
  
  Do not store endspace and do not do endspace compression for all values.

• **no endspace, no empty**
  
  Do not store endspace. Do not store empty values.

• **table-lookup**
  
  The column was converted to an ENUM.

• **zerofill(N)**
  
  The most significant N bytes in the value are always 0 and are not stored.

• **no zeros**
  
  Do not store zeros.

• **always zero**
  
  Zero values are stored using one bit.

• **Huff tree**
  
  The number of the Huffman tree associated with the column.

• **Bits**
  
  The number of bits used in the Huffman tree.

The Huff tree and Bits fields are displayed if the table has been compressed with myisampack. See Section 4.6.5, "myisampack — Generate Compressed, Read-Only MyISAM Tables", for an example of this information.

Example of myisamchk -eiv output:
Checking MyISAM file: person
Data records: 306688  Deleted blocks: 0
- check file-size
- check record delete-chain
No recordlinks
- check key delete-chain
block_size 1024:
- check index reference
- check data record references index: 1
  Key: 1: Keyblocks used: 98% Packed: 0% Max levels: 3
- check data record references index: 2
  Key: 2: Keyblocks used: 99% Packed: 97% Max levels: 3
- check data record references index: 3
  Key: 3: Keyblocks used: 98% Packed: -14% Max levels: 3
Total: Keyblocks used: 98% Packed: 89%
- check records and index references
  *** LOTS OF ROW NUMBERS DELETED ***

Records: 306688 M.recordlength: 25 Packed: 83%
Recordspace used: 97% Empty space: 2% Blocks/Record: 1.00
Record blocks: 306688 Delete blocks: 0
Record data: 7934464 Deleted data: 0
Lost space: 256512 Linkdata: 1156096

User time 43.08, System time 1.68
Maximum resident set size 0, Integral resident set size 0
Non-physical pagefaults 0, Physical pagefaults 0, Swaps 0
Blocks in 0 out 7, Messages in 0 out 0, Signals 0
Voluntary context switches 0, Involuntary context switches 0
Maximum memory usage: 1046926 bytes (1023k)

myisamchk -eiv output includes the following information:

- **Data records**
  The number of rows in the table.

- **Deleted blocks**
  How many deleted blocks still have reserved space. You can optimize your table to minimize this space. See Section 7.6.4, “MyISAM Table Optimization”.

- **Key**
  The key number.

- **Keyblocks used**
  What percentage of the keyblocks are used. When a table has just been reorganized with myisamchk, the values are very high (very near theoretical maximum).

- **Packed**
  MySQL tries to pack key values that have a common suffix. This can only be used for indexes on CHAR and VARCHAR columns. For long indexed strings that have similar leftmost parts, this can significantly reduce the space used. In the preceding example, the second key is 40 bytes long and a 97% reduction in space is achieved.

- **Max levels**
  How deep the B-tree for this key is. Large tables with long key values get high values.
• **Records**
  How many rows are in the table.

• **M.recordlength**
  The average row length. This is the exact row length for tables with fixed-length rows, because all rows have the same length.

• **Packed**
  MySQL strips spaces from the end of strings. The *Packed* value indicates the percentage of savings achieved by doing this.

• **Recordspace used**
  What percentage of the data file is used.

• **Empty space**
  What percentage of the data file is unused.

• **Blocks/Record**
  Average number of blocks per row (that is, how many links a fragmented row is composed of). This is always 1.0 for fixed-format tables. This value should stay as close to 1.0 as possible. If it gets too large, you can reorganize the table. See Section 7.6.4, "MyISAM Table Optimization".

• **Recordblocks**
  How many blocks (links) are used. For fixed-format tables, this is the same as the number of rows.

• **Deleteblocks**
  How many blocks (links) are deleted.

• **Recorddata**
  How many bytes in the data file are used.

• **Deleted data**
  How many bytes in the data file are deleted (unused).

• **Lost space**
  If a row is updated to a shorter length, some space is lost. This is the sum of all such losses, in bytes.

• **Linkdata**
  When the dynamic table format is used, row fragments are linked with pointers (4 to 7 bytes each). *Linkdata* is the sum of the amount of storage used by all such pointers.

### 4.6.3.6 *myisamchk* Memory Usage

Memory allocation is important when you run *myisamchk*. *myisamchk* uses no more memory than its memory-related variables are set to. If you are going to use *myisamchk* on very large tables, you should first decide how much memory you want it to use. The default is to use only about 3MB to perform repairs. By using larger values, you can get *myisamchk* to operate faster. For example, if you have more than
512MB RAM available, you could use options such as these (in addition to any other options you might specify):

```shell
shell> myisamchk --myisam_sort_buffer_size=256M \\
   --key_buffer_size=512M \\
   --read_buffer_size=64M \\
   --write_buffer_size=64M ...
```

Using `--myisam_sort_buffer_size=16M` is probably enough for most cases.

Be aware that `myisamchk` uses temporary files in `TMPDIR`. If `TMPDIR` points to a memory file system, out of memory errors can easily occur. If this happens, run `myisamchk` with the `--tmpdir=path` option to specify a directory located on a file system that has more space.

When performing repair operations, `myisamchk` also needs a lot of disk space:

- Twice the size of the data file (the original file and a copy). This space is not needed if you do a repair with `--quick`; in this case, only the index file is re-created. This space must be available on the same file system as the original data file, as the copy is created in the same directory as the original.
- Space for the new index file that replaces the old one. The old index file is truncated at the start of the repair operation, so you usually ignore this space. This space must be available on the same file system as the original data file.
- When using `--recover` or `--sort-recover` (but not when using `--safe-recover`), you need space on disk for sorting. This space is allocated in the temporary directory (specified by `TMPDIR` or `--tmpdir=path`). The following formula yields the amount of space required:

\[ (\text{largest_key} + \text{row_pointer_length}) \times \text{number_of_rows} \times 2 \]

You can check the length of the keys and the `row_pointer_length` with `myisamchk -dv tbl_name` (see Section 4.6.3.5, "Obtaining Table Information with `myisamchk`"). The `row_pointer_length` and `number_of_rows` values are the Datafile pointer and Data records values in the table description. To determine the `largest_key` value, check the Key lines in the table description. The `Len` column indicates the number of bytes for each key part. For a multiple-column index, the key size is the sum of the `Len` values for all key parts.

If you have a problem with disk space during repair, you can try `--safe-recover` instead of `--recover`.

### 4.6.4 myisamlog — Display MyISAM Log File Contents

`myisamlog` processes the contents of a MyISAM log file. To create such a file, start the server with a `--log-isam=log_file` option.

Invoke `myisamlog` like this:

```shell
shell> myisamlog [options] [file_name [tbl_name] ...]
```

The default operation is update (`-u`). If a recovery is done (`-r`), all writes and possibly updates and deletes are done and errors are only counted. The default log file name is `myisam.log` if no `log_file` argument is given. If tables are named on the command line, only those tables are updated.

`myisamlog` supports the following options:

- `-?`, `-I`

  Display a help message and exit.
- **-c N**
  Execute only N commands.

- **-f N**
  Specify the maximum number of open files.

- **-i**
  Display extra information before exiting.

- **-o offset**
  Specify the starting offset.

- **-p N**
  Remove N components from path.

- **-r**
  Perform a recovery operation.

- **-R record_pos_file record_pos**
  Specify record position file and record position.

- **-u**
  Perform an update operation.

- **-v**
  Verbose mode. Print more output about what the program does. This option can be given multiple times to produce more and more output.

- **-w write_file**
  Specify the write file.

- **-V**
  Display version information.

### 4.6.5 myisampack — Generate Compressed, Read-Only MyISAM Tables

The **myisampack** utility compresses MyISAM tables. **myisampack** works by compressing each column in the table separately. Usually, **myisampack** packs the data file 40% to 70%.

When the table is used later, the server reads into memory the information needed to decompress columns. This results in much better performance when accessing individual rows, because you only have to decompress exactly one row.

MySQL uses **mmap()** when possible to perform memory mapping on compressed tables. If **mmap()** does not work, MySQL falls back to normal read/write file operations.

Please note the following:
• If the `mysqld` server was invoked with external locking disabled, it is not a good idea to invoke
`myisampack` if the table might be updated by the server during the packing process. It is safest to
compress tables with the server stopped.

• After packing a table, it becomes read only. This is generally intended (such as when accessing packed
tables on a CD).

• `myisampack` does not support partitioned tables.

Invoke `myisampack` like this:

```
shell> myisampack [options] file_name ...
```

Each file name argument should be the name of an index (`.MYI`) file. If you are not in the database
directory, you should specify the path name to the file. It is permissible to omit the `.MYI` extension.

After you compress a table with `myisampack`, you should use `myisamchk` `-rq` to rebuild its indexes.
Section 4.6.3, "myisamchk — MyISAM Table-Maintenance Utility".

`myisampack` supports the following options. It also reads option files and supports the options for
processing them described at Section 4.2.7, "Command-Line Options that Affect Option-File Handling".

• `--help`, `-?`
  Display a help message and exit.

• `--backup`, `-b`
  Make a backup of each table’s data file using the name `tbl_name.OLD`.

• `--character-sets-dir=path`
  The directory where character sets are installed. See Section 10.5, "Character Set Configuration".

• `--debug=[debug_options],-# [debug_options]`
  Write a debugging log. A typical `debug_options` string is `d:t:o`, `file_name`. The default is `d:t:o`.

• `--force`, `-f`
  Produce a packed table even if it becomes larger than the original or if the intermediate file from
an earlier invocation of `myisampack` exists. (`myisampack` creates an intermediate file named
`tbl_name.TMD` in the database directory while it compresses the table. If you kill `myisampack`, the
`.TMD` file might not be deleted.) Normally, `myisampack` exits with an error if it finds that `tbl_name.TMD`
exists. With `--force`, `myisampack` packs the table anyway.

• `--join=big_tbl_name,-j big_tbl_name`
  Join all tables named on the command line into a single packed table `big_tbl_name`. All tables that are
to be combined must have identical structure (same column names and types, same indexes, and so
forth).

  `big_tbl_name` must not exist prior to the join operation. All source tables named on the command line
to be merged into `big_tbl_name` must exist. The source tables are read for the join operation but not
modified. The join operation does not create a `.frm` file for `big_tbl_name`, so after the join operation
finishes, copy the `.frm` file from one of the source tables and name it `big_tbl_name.frm`.

• `--silent`, `-s`
Silent mode. Write output only when errors occur.

- **--test, -t**
  Do not actually pack the table, just test packing it.

- **--tmpdir=path, -T path**
  Use the named directory as the location where *myisampack* creates temporary files.

- **--verbose, -v**
  Verbose mode. Write information about the progress of the packing operation and its result.

- **--version, -V**
  Display version information and exit.

- **--wait, -w**
  Wait and retry if the table is in use. If the *mysqld* server was invoked with external locking disabled, it is not a good idea to invoke *myisampack* if the table might be updated by the server during the packing process.

The following sequence of commands illustrates a typical table compression session:

```bash
shell> ls -l station.*
-rw-rw-r--   1 monty    my         994128 Apr 17 19:00 station.MYD
-rw-rw-r--   1 monty    my          53248 Apr 17 19:00 station.MYI

myisampack displays the following kinds of information:

- **normal**
  
  The number of columns for which no extra packing is used.

- **empty-space**
  
  The number of columns containing values that are only spaces. These occupy one bit.

- **empty-zero**
  
  The number of columns containing values that are only binary zeros. These occupy one bit.

- **empty-fill**
  
  The number of integer columns that do not occupy the full byte range of their type. These are changed to a smaller type. For example, a `BIGINT` column (eight bytes) can be stored as a `TINYINT` column (one byte) if all its values are in the range from $-128$ to $127$.

- **pre-space**
  
  The number of decimal columns that are stored with leading spaces. In this case, each value contains a count for the number of leading spaces.

- **end-space**
  
  The number of columns that have a lot of trailing spaces. In this case, each value contains a count for the number of trailing spaces.

- **table-lookup**
  
  The column had only a small number of different values, which were converted to an `ENUM` before Huffman compression.

- **zero**
  
  The number of columns for which all values are zero.

- **Original trees**
  
  The initial number of Huffman trees.

- **After join**
  
  The number of distinct Huffman trees left after joining trees to save some header space.

After a table has been compressed, the **Field** lines displayed by `myisamchk -dvv` include additional information about each column:

- **Type**
  
  The data type. The value may contain any of the following descriptors:

  - **constant**
All rows have the same value.

- **no endspace**
  Do not store endspace.

- **no endspace, not_always**
  Do not store endspace and do not do endspace compression for all values.

- **no endspace, no empty**
  Do not store endspace. Do not store empty values.

- **table-lookup**
  The column was converted to an **ENUM**.

- **zerofill(\(N\))**
  The most significant \(N\) bytes in the value are always 0 and are not stored.

- **no zeros**
  Do not store zeros.

- **always zero**
  Zero values are stored using one bit.

- **Huff tree**
  The number of the Huffman tree associated with the column.

- **Bits**
  The number of bits used in the Huffman tree.

After you run `myisampack`, you must run `myisamchk` to re-create any indexes. At this time, you can also sort the index blocks and create statistics needed for the MySQL optimizer to work more efficiently:

```
shell> myisamchk -rq --sort-index --analyze tbl_name.MYI
```

After you have installed the packed table into the MySQL database directory, you should execute `mysqladmin flush-tables` to force `mysqld` to start using the new table.

To unpack a packed table, use the `--unpack` option to `myisamchk`.

**4.6.6 mysqlaccess — Client for Checking Access Privileges**

`mysqlaccess` is a diagnostic tool that Yves Carlier has provided for the MySQL distribution. It checks the access privileges for a host name, user name, and database combination. Note that `mysqlaccess` checks access using only the **user**, **db**, and **host** tables. It does not check table, column, or routine privileges specified in the **tables_priv**, **columns_priv**, or **procs_priv** tables.

Invoke `mysqlaccess` like this:
mysqlaccess — Client for Checking Access Privileges

shell> mysqlaccess [host_name [user_name [db_name]]] [options]

mysqlaccess supports the following options.

Table 4.13 mysqlaccess Options

</table>

- **--help, -?**
  
  Display a help message and exit.

- **--brief, -b**
  
  Generate reports in single-line tabular format.

- **--commit**
  
  Copy the new access privileges from the temporary tables to the original grant tables. The grant tables must be flushed for the new privileges to take effect. (For example, execute a `mysqladmin reload` command.)
• --copy
  Reload the temporary grant tables from original ones.

• --db=db_name, -d db_name
  Specify the database name.

• --debug=N
  Specify the debug level. \( N \) can be an integer from 0 to 3.

• --host=host_name, -h host_name
  The host name to use in the access privileges.

• --howto
  Display some examples that show how to use \texttt{mysqlaccess}.

• --old_server
  Assume that the server is an old MySQL server (before MySQL 3.21) that does not yet know how to handle full \texttt{WHERE} clauses.

• --password[=password], -p[password]
  The password to use when connecting to the server. If you omit the \texttt{password} value following the --password or -p option on the command line, \texttt{mysqlaccess} prompts for one.

  Specifying a password on the command line should be considered insecure. See Section 6.1.2.1, “End-User Guidelines for Password Security”.

• --plan
  Display suggestions and ideas for future releases.

• --preview
  Show the privilege differences after making changes to the temporary grant tables.

• --relnotes
  Display the release notes.

• --rhost=host_name, -H host_name
  Connect to the MySQL server on the given host.

• --rollback
  Undo the most recent changes to the temporary grant tables.

• --spassword[=password], -P[password]
  The password to use when connecting to the server as the superuser. If you omit the \texttt{password} value following the --spassword or -P option on the command line, \texttt{mysqlaccess} prompts for one.

  Specifying a password on the command line should be considered insecure. See Section 6.1.2.1, “End-User Guidelines for Password Security”.
• **--superuser=user_name, -U user_name**
  Specify the user name for connecting as the superuser.

• **--table, -t**
  Generate reports in table format.

• **--user=user_name, -u user_name**
  The user name to use in the access privileges.

• **--version, -v**
  Display version information and exit.

If your MySQL distribution is installed in some nonstandard location, you must change the location where `mysqlaccess` expects to find the `mysql` client. Edit the `mysqlaccess` script at approximately line 18. Search for a line that looks like this:

```shell
$MYSQL     = '/usr/local/bin/mysql';    # path to mysql executable
```

Change the path to reflect the location where `mysql` actually is stored on your system. If you do not do this, a **Broken pipe** error will occur when you run `mysqlaccess`.

### 4.6.7 mysqlbinlog — Utility for Processing Binary Log Files

The server's binary log consists of files containing "events" that describe modifications to database contents. The server writes these files in binary format. To display their contents in text format, use the `mysqlbinlog` utility. You can also use `mysqlbinlog` to display the contents of relay log files written by a slave server in a replication setup because relay logs have the same format as binary logs. The binary log and relay log are discussed further in Section 5.2.4, “The Binary Log”, and Section 17.2.2, “Replication Relay and Status Logs”.

Invoke `mysqlbinlog` like this:

```
shell> mysqlbinlog [options] log_file ...
```

For example, to display the contents of the binary log file named `binlog.000003`, use this command:

```
shell> mysqlbinlog binlog.000003
```

The output includes events contained in `binlog.000003`. For statement-based logging, event information includes the SQL statement, the ID of the server on which it was executed, the timestamp when the statement was executed, how much time it took, and so forth. For row-based logging, the event indicates a row change rather than an SQL statement. See Section 17.1.2, “Replication Formats”, for information about logging modes.

Events are preceded by header comments that provide additional information. For example:

```shell
# at 141
#100309  9:28:36 server id 123  end_log_pos 245
Query thread_id=3350  exec_time=11  error_code=0
```

In the first line, the number following `at` indicates the file offset, or starting position, of the event in the binary log file.
The second line starts with a date and time indicating when the statement started on the server where the event originated. For replication, this timestamp is propagated to slave servers. server_id is the server_id value of the server where the event originated. end_log_pos indicates where the next event starts (that is, it is the end position of the current event + 1). thread_id indicates which thread executed the event. exec_time is the time spent executing the event, on a master server. On a slave, it is the difference of the end execution time on the slave minus the beginning execution time on the master. The difference serves as an indicator of how much replication lags behind the master. error_code indicates the result from executing the event. Zero means that no error occurred.

Note

When using event groups, the file offsets of all events are grouped together and the comments of all events are grouped together. For example:

```plaintext
# at 587
# at 630
# at 5662
#140627 13:16:52 server id 1  end_log_pos 630 Table_map: `test`.`t1` mapped to number 41
#140627 13:16:52 server id 1  end_log_pos 5662 Write_rows: table id 41
#140627 13:16:52 server id 1  end_log_pos 10694 Write_rows: table id 41 flags: STMT_END_F
```

The three file offsets do not represent blank events.

The output from mysqlbinlog can be re-executed (for example, by using it as input to mysql) to redo the statements in the log. This is useful for recovery operations after a server crash. For other usage examples, see the discussion later in this section and in Section 7.5, “Point-in-Time (Incremental) Recovery Using the Binary Log”.

Normally, you use mysqlbinlog to read binary log files directly and apply them to the local MySQL server. It is also possible to read binary logs from a remote server by using the --read-from-remote-server option. To read remote binary logs, the connection parameter options can be given to indicate how to connect to the server. These options are --host, --password, --port, --protocol, --socket, and --user; they are ignored except when you also use the --read-from-remote-server option.

mysqlbinlog supports the following options, which can be specified on the command line or in the [mysqlbinlog] and [client] groups of an option file. For information about option files, see Section 4.2.6, “Using Option Files”.

Table 4.14 mysqlbinlog Options

<table>
<thead>
<tr>
<th>Format</th>
<th>Option File</th>
<th>Description</th>
<th>Introduced</th>
<th>Removed</th>

</tr>
<tr>
<td>--to-last-log</td>
<td>to-last-log</td>
<td>Do not stop at the end of requested binary log from a MySQL server, but rather continue printing to end of last binary log</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--user=user_name,</td>
<td>user</td>
<td>MySQL user name to use when connecting to server</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--verbose</td>
<td></td>
<td>Reconstruct row events as SQL statements</td>
<td></td>
<td></td>
</tr>
<tr>
<td>--version</td>
<td></td>
<td>Display version information and exit</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- **--help, --?**
  Display a help message and exit.

- **--base64-output [=value]**
  This option determines when events should be displayed encoded as base-64 strings using BINLOG statements. The option has these permissible values (not case sensitive):

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTO</td>
<td>Displays BINLOG statements automatically when necessary (that is, for format description events and row events). If no --base64-output option is given, the effect is the same as --base64-output=AUTO.</td>
</tr>
<tr>
<td>UNSPEC</td>
<td>Displays BINLOG statements whenever possible. If the --base64-output option is given without a value, the effect is the same as --base64-output=ALWAYS.</td>
</tr>
</tbody>
</table>

**Note**

Automatic BINLOG display is the only safe behavior if you intend to use the output of `mysqlbinlog` to re-execute binary log file contents. The other option values are intended only for debugging or testing purposes because they may produce output that does not include all events in executable form.

**Note**

Changes to replication in MySQL 5.6 make output generated by this option unusable, so ALWAYS is deprecated as of MySQL 5.5.8 and will be an invalid value in MySQL 5.6.
mysqlbinlog — Utility for Processing Binary Log Files

- **NEVER** causes BINLOG statements not to be displayed. mysqlbinlog exits with an error if a row event is found that must be displayed using BINLOG.

- **DECODE-ROWS** specifies to mysqlbinlog that you intend for row events to be decoded and displayed as commented SQL statements by also specifying the --verbose option. Like NEVER, DECODE-ROWS suppresses display of BINLOG statements, but unlike NEVER, it does not exit with an error if a row event is found.

For examples that show the effect of --base64-output and --verbose on row event output, see Section 4.6.7.2, "mysqlbinlog Row Event Display".

- **--bind-address=ip_address**

On a computer having multiple network interfaces, this option can be used to select which interface is employed when connecting to the MySQL server.

This option is supported beginning with MySQL 5.5.8.

- **--character-sets-dir=path**

The directory where character sets are installed. See Section 10.5, “Character Set Configuration”.

- **--database=db_name, -d  db_name**

This option causes mysqlbinlog to output entries from the binary log (local log only) that occur while db_name is been selected as the default database by USE.

The --database option for mysqlbinlog is similar to the --binlog-do-db option for mysqld, but can be used to specify only one database. If --database is given multiple times, only the last instance is used.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of --binlog-do-db depend on whether statement-based or row-based logging is in use.

**Statement-based logging.** The --database option works as follows:

- While db_name is the default database, statements are output whether they modify tables in db_name or a different database.

- Unless db_name is selected as the default database, statements are not output, even if they modify tables in db_name.

- There is an exception for CREATE DATABASE, ALTER DATABASE, and DROP DATABASE. The database being created, altered, or dropped is considered to be the default database when determining whether to output the statement.

Suppose that the binary log was created by executing these statements using statement-based-logging:

```sql
INSERT INTO test.t1 (i) VALUES(100);
INSERT INTO db2.t2 (j) VALUES(200);
USE test;
INSERT INTO test.t1 (i) VALUES(101);
INSERT INTO t1 (i) VALUES(102);
INSERT INTO db2.t2 (j) VALUES(201);
USE db2;
INSERT INTO test.t1 (i) VALUES(103);
```
mysqldb --database=test does not output the first two INSERT statements because there is no default database. It outputs the three INSERT statements following USE test, but not the three INSERT statements following USE db2.

mysqldb --database=db2 does not output the first two INSERT statements because there is no default database. It does not output the three INSERT statements following USE test, but does output the three INSERT statements following USE db2.

Row-based logging. mysqldb outputs only entries that change tables belonging to db_name. The default database has no effect on this. Suppose that the binary log just described was created using row-based logging rather than statement-based logging. mysqldb --database=test outputs only those entries that modify t1 in the test database, regardless of whether USE was issued or what the default database is.

If a server is running with binlog_format set to MIXED and you want it to be possible to use mysqldb with the --database option, you must ensure that tables that are modified are in the database selected by USE. (In particular, no cross-database updates should be used.)

Note
Prior to MySQL Cluster NDB 7.2.2, this option did not work correctly with MySQL Cluster tables unless, unless the binary log was generated using --log-bin-use-v1-row-events=0. (Bug #13067813)

• --debug[=debug_options],-# [debug_options]
Write a debugging log. A typical debug_options string is d:t:o, file_name. The default is d:t:o,/tmp/mysqlbinlog.trace.

• --debug-check
Print some debugging information when the program exits.

• --debug-info
Print debugging information and memory and CPU usage statistics when the program exits.

• --default-auth=plugin
The client-side authentication plugin to use. See Section 6.3.6, “Pluggable Authentication”.

This option was added in MySQL 5.5.10.

• --defaults-extra-file=file_name
Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, file_name must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

• --defaults-file=file_name
Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, file_name must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.
• --defaults-group-suffix=\texttt{str}

Read not only the usual option groups, but also groups with the usual names and a suffix of \texttt{str}. For example, \texttt{mysqlbinlog} normally reads the [client] and [mysqlbinlog] groups. If the \texttt{--defaults-group-suffix=_other} option is given, \texttt{mysqlbinlog} also reads the [client\_other] and [mysqlbinlog\_other] groups.

• --disable-log-bin, -D

Disable binary logging. This is useful for avoiding an endless loop if you use the \texttt{--to-last-log} option and are sending the output to the same MySQL server. This option also is useful when restoring after a crash to avoid duplication of the statements you have logged.

This option requires that you have the \texttt{SUPER} privilege. It causes \texttt{mysqlbinlog} to include a \texttt{SET sql_log_bin = 0} statement in its output to disable binary logging of the remaining output. The \texttt{SET} statement is ineffective unless you have the \texttt{SUPER} privilege.

• --force-if-open, -F

Read binary log files even if they are open or were not closed properly.

• --force-read, -f

With this option, if \texttt{mysqlbinlog} reads a binary log event that it does not recognize, it prints a warning, ignores the event, and continues. Without this option, \texttt{mysqlbinlog} stops if it reads such an event.

• --hexdump, -H

Display a hex dump of the log in comments, as described in Section 4.6.7.1, "\texttt{mysqlbinlog} Hex Dump Format". The hex output can be helpful for replication debugging.

• --host=\texttt{host\_name}, -h \texttt{host\_name}

Get the binary log from the MySQL server on the given host.

• --local-load=\texttt{path}, -l \texttt{path}

Prepare local temporary files for \texttt{LOAD DATA INFILE} in the specified directory.

\begin{center}
\begin{itemize}
  \item \textbf{Important}
  \begin{itemize}
    \item These temporary files are not automatically removed by \texttt{mysqlbinlog} or any other MySQL program.
  \end{itemize}
\end{itemize}
\end{center}

• --no-defaults

Do not read any option files. If program startup fails due to reading unknown options from an option file, \texttt{--no-defaults} can be used to prevent them from being read.

• --offset=\texttt{N}, -o \texttt{N}

Skip the first \texttt{N} entries in the log.

• --password[=\texttt{password}], -p[\texttt{password}]

The password to use when connecting to the server. If you use the short option form (\texttt{-p}), you \texttt{cannot} have a space between the option and the password. If you omit the \texttt{password} value following the \texttt{--password} or \texttt{-p} option on the command line, \texttt{mysqlbinlog} prompts for one.
Specifying a password on the command line should be considered insecure. See Section 6.1.2.1, “End-User Guidelines for Password Security”. You can use an option file to avoid giving the password on the command line.

- **--plugin-dir=path**
  The directory in which to look for plugins. It may be necessary to specify this option if the **--default-auth** option is used to specify an authentication plugin but *mysqlbinlog* does not find it. See Section 6.3.6, “Pluggable Authentication”.

  This option was added in MySQL 5.5.10.

- **--port=port_num, -P port_num**
  The TCP/IP port number to use for connecting to a remote server.

- **--position=N**
  Deprecated. Use **--start-position** instead. **--position** was removed in MySQL 5.5.3.

- **--print-defaults**
  Print the program name and all options that it gets from option files.

- **--protocol={TCP|SOCKET|PIPE|MEMORY}**
  The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see Section 4.2.2, “Connecting to the MySQL Server”.

- **--read-from-remote-server, -R**
  Read the binary log from a MySQL server rather than reading a local log file. Any connection parameter options are ignored unless this option is given as well. These options are **--host**, **--password**, **--port**, **--protocol**, **--socket**, and **--user**.

  This option requires that the remote server be running. It works only for binary log files on the remote server, not relay log files.

- **--result-file=name, -r name**
  Direct output to the given file.

- **--server-id=id**
  Display only those events created by the server having the given server ID.

- **--server-id-bits=N**
  Use only the first *N* bits of the *server_id* to identify the server. If the binary log was written by a *mysqld* with server-id-bits set to less than 32 and user data stored in the most significant bit, running *mysqlbinlog* with **--server-id-bits** set to 32 enables this data to be seen.

  This option is supported only by the versions of *mysqlbinlog* supplied with the MySQL Cluster distribution, or built from the MySQL Cluster sources.

- **--set-charset=charset_name**
mysqlbinlog — Utility for Processing Binary Log Files

Add a `SET NAMES charset_name` statement to the output to specify the character set to be used for processing log files.

- `--short-form, -s`
  Display only the statements contained in the log, without any extra information or row-based events. This is for testing only, and should not be used in production systems.

- `--socket=path, -S path`
  For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--start-datetime=datetime`
  Start reading the binary log at the first event having a timestamp equal to or later than the `datetime` argument. The `datetime` value is relative to the local time zone on the machine where you run `mysqlbinlog`. The value should be in a format accepted for the `DATETIME` or `TIMESTAMP` data types. For example:

  ```shell>
  mysqlbinlog --start-datetime="2005-12-25 11:25:56" binlog.000003
  ```

  This option is useful for point-in-time recovery. See Section 7.3, “Example Backup and Recovery Strategy”.

- `--start-position=N, -j N`
  Start reading the binary log at the first event having a position equal to or greater than `N`. This option applies to the first log file named on the command line.

  This option is useful for point-in-time recovery. See Section 7.3, “Example Backup and Recovery Strategy”.

- `--stop-datetime=datetime`
  Stop reading the binary log at the first event having a timestamp equal to or later than the `datetime` argument. This option is useful for point-in-time recovery. See the description of the `--start-datetime` option for information about the `datetime` value.

  This option is useful for point-in-time recovery. See Section 7.3, “Example Backup and Recovery Strategy”.

- `--stop-position=N`
  Stop reading the binary log at the first event having a position equal to or greater than `N`. This option applies to the last log file named on the command line.

  This option is useful for point-in-time recovery. See Section 7.3, “Example Backup and Recovery Strategy”.

- `--to-last-log, -t`
  Do not stop at the end of the requested binary log from a MySQL server, but rather continue printing until the end of the last binary log. If you send the output to the same MySQL server, this may lead to an endless loop. This option requires `--read-from-remote-server`.

- `--user=user_name, -u user_name`
mysqlbinlog — Utility for Processing Binary Log Files

The MySQL user name to use when connecting to a remote server.

•  **--verbose, -v**

Reconstruct row events and display them as commented SQL statements. If this option is given twice, the output includes comments to indicate column data types and some metadata.

For examples that show the effect of **--base64-output** and **--verbose** on row event output, see Section 4.6.7.2, “mysqlbinlog Row Event Display”.

•  **--version, -V**

Display version information and exit.

In MySQL 5.5, the version number shown for mysqlbinlog is always 3.3.

You can also set the following variable by using **--var_name=value** syntax:

•  **open_files_limit**

Specify the number of open file descriptors to reserve.

You can pipe the output of mysqlbinlog into the mysql client to execute the events contained in the binary log. This technique is used to recover from a crash when you have an old backup (see Section 7.5, “Point-in-Time (Incremental) Recovery Using the Binary Log”). For example:

```
shell> mysqlbinlog binlog.000001 | mysql -u root -p
```

Or:

```
shell> mysqlbinlog binlog.[0-9]* | mysql -u root -p
```

You can also redirect the output of mysqlbinlog to a text file instead, if you need to modify the statement log first (for example, to remove statements that you do not want to execute for some reason). After editing the file, execute the statements that it contains by using it as input to the mysql program:

```
shell> mysqlbinlog binlog.000001 > tmpfile
shell> ... edit tmpfile ...
shell> mysql -u root -p < tmpfile
```

When mysqlbinlog is invoked with the **--start-position** option, it displays only those events with an offset in the binary log greater than or equal to a given position (the given position must match the start of one event). It also has options to stop and start when it sees an event with a given date and time. This enables you to perform point-in-time recovery using the **--stop-datetime** option (to be able to say, for example, “roll forward my databases to how they were today at 10:30 a.m.”).

If you have more than one binary log to execute on the MySQL server, the safe method is to process them all using a single connection to the server. Here is an example that demonstrates what may be unsafe:

```
shell> mysqlbinlog binlog.000001 | mysql -u root -p # DANGER!!
shell> mysqlbinlog binlog.000002 | mysql -u root -p # DANGER!!
```

Processing binary logs this way using multiple connections to the server causes problems if the first log file contains a CREATE TEMPORARY TABLE statement and the second log contains a statement that uses the temporary table. When the first mysql process terminates, the server drops the temporary table. When the second mysql process attempts to use the table, the server reports “unknown table.”
To avoid problems like this, use a single `mysql` process to execute the contents of all binary logs that you want to process. Here is one way to do so:

```
shell> mysqlbinlog binlog.000001 binlog.000002 | mysql -u root -p
```

Another approach is to write all the logs to a single file and then process the file:

```
shell> mysqlbinlog binlog.000001 > /tmp/statements.sql
shell> mysqlbinlog binlog.000002 >> /tmp/statements.sql
shell> mysql -u root -p -e "source /tmp/statements.sql"
```

`mysqlbinlog` can produce output that reproduces a `LOAD DATA INFILE` operation without the original data file. `mysqlbinlog` copies the data to a temporary file and writes a `LOAD DATA LOCAL INFILE` statement that refers to the file. The default location of the directory where these files are written is system-specific. To specify a directory explicitly, use the `--local-load` option.

Because `mysqlbinlog` converts `LOAD DATA INFILE` statements to `LOAD DATA LOCAL INFILE` statements (that is, it adds `LOCAL`), both the client and the server that you use to process the statements must be configured with the `LOCAL` capability enabled. See Section 6.1.6, “Security Issues with `LOAD DATA LOCAL`”.

**Warning**

The temporary files created for `LOAD DATA LOCAL` statements are *not* automatically deleted because they are needed until you actually execute those statements. You should delete the temporary files yourself after you no longer need the statement log. The files can be found in the temporary file directory and have names like `original_file_name-#-#`.

### 4.6.7.1 `mysqlbinlog` Hex Dump Format

The `--hexdump` option causes `mysqlbinlog` to produce a hex dump of the binary log contents:

```
shell> mysqlbinlog --hexdump master-bin.000001
```

The hex output consists of comment lines beginning with `#`, so the output might look like this for the preceding command:

```
/*400019 SET @session.max_insert_delayed_threads=0*/;
/*!50003 SET @OLD_COMPLETION_TYPE=@@COMPLETION_TYPE,COMPLETION_TYPE=0*/;
# at 4
#051024 17:24:13 server id 1 end_log_pos 98
# Position Timestamp Type Master ID Size Master Pos Flags
# 00000004 9d fc 5c 43 0f 01 00 00 00 5e 00 00 00 62 00 00 00 00 00
# 00000017 04 00 35 2e 30 2e 31 35 2d 64 65 62 75 67 2d 6c |..5.0.15.debug.l|
# 00000027 6f 67 00 00 00 00 00 00 00 00 00 00 00 00 00 00 |og..............|
# 00000037 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 |................|
# 00000047 00 00 00 00 9d fc 5c 43 13 38 0d 00 12 00 04 04 04 |.......C.8......|
#       Start: binlog v 4, server v 5.0.15-debug-log created 051024 17:24:13
#       at startup
ROLLBACK;
```

Hex dump output currently contains the elements in the following list. This format is subject to change. (For more information about binary log format, see MySQL Internals: The Binary Log.

- **Position**: The byte position within the log file.
• **Timestamp:** The event timestamp. In the example shown, '9d fc 5c 43' is the representation of '051024 17:24:13' in hexadecimal.

• **Type:** The event type code. In the example shown, '0f' indicates a FORMAT_DESCRIPTION_EVENT. The following table lists the possible type codes.

<table>
<thead>
<tr>
<th>Type Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>00     UNKNOWN_EVENT</td>
<td>This event should never be present in the log.</td>
</tr>
<tr>
<td>01     START_EVENT_V3</td>
<td>This indicates the start of a log file written by MySQL 4 or earlier.</td>
</tr>
<tr>
<td>02     QUERY_EVENT</td>
<td>The most common type of events. These contain statements executed on the master.</td>
</tr>
<tr>
<td>03     STOP_EVENT</td>
<td>Indicates that master has stopped.</td>
</tr>
<tr>
<td>04     ROTATE_EVENT</td>
<td>Written when the master switches to a new log file.</td>
</tr>
<tr>
<td>05     INTVAR_EVENT</td>
<td>Used for AUTO_INCREMENT values or when the LAST_INSERT_ID() function is used in the statement.</td>
</tr>
<tr>
<td>06     LOAD_EVENT</td>
<td>Used for LOAD DATA INFILE in MySQL 3.23.</td>
</tr>
<tr>
<td>07     SLAVE_EVENT</td>
<td>Reserved for future use.</td>
</tr>
<tr>
<td>08     CREATE_FILE_EVENT</td>
<td>Used for LOAD DATA INFILE statements. This indicates the start of execution of such a statement. A temporary file is created on the slave. Used in MySQL 4 only.</td>
</tr>
<tr>
<td>09     APPEND_BLOCK_EVENT</td>
<td>Contains data for use in a LOAD DATA INFILE statement. The data is stored in the temporary file on the slave.</td>
</tr>
<tr>
<td>0a     EXEC_LOAD_EVENT</td>
<td>Used for LOAD DATA INFILE statements. The contents of the temporary file is stored in the table on the slave. Used in MySQL 4 only.</td>
</tr>
<tr>
<td>0b     DELETE_FILE_EVENT</td>
<td>Rollback of a LOAD DATA INFILE statement. The temporary file should be deleted on the slave.</td>
</tr>
<tr>
<td>0c     NEW_LOAD_EVENT</td>
<td>Used for LOAD DATA INFILE in MySQL 4 and earlier.</td>
</tr>
<tr>
<td>0d     RAND_EVENT</td>
<td>Used to send information about random values if the RAND() function is used in the statement.</td>
</tr>
<tr>
<td>0e     USER_VAR_EVENT</td>
<td>Used to replicate user variables.</td>
</tr>
<tr>
<td>0f     FORMAT_DESCRIPTION_EVENT</td>
<td>This indicates the start of a log file written by MySQL 5 or later.</td>
</tr>
<tr>
<td>10     XID_EVENT</td>
<td>Event indicating commit of an XA transaction.</td>
</tr>
<tr>
<td>11     BEGIN_LOAD_QUERY_EVENT</td>
<td>Used for LOAD DATA INFILE statements in MySQL 5 and later.</td>
</tr>
<tr>
<td>12     EXECUTE_LOAD_QUERY_EVENT</td>
<td>Used for LOAD DATA INFILE statements in MySQL 5 and later.</td>
</tr>
<tr>
<td>13     TABLE_MAP_EVENT</td>
<td>Information about a table definition. Used in MySQL 5.1.5 and later.</td>
</tr>
<tr>
<td>14     PRE_GA_WRITE_ROWS_EVENT</td>
<td>Row data for a single table that should be created. Used in MySQL 5.1.5 to 5.1.17.</td>
</tr>
<tr>
<td>15     PRE_GA_UPDATE_ROWS_EVENT</td>
<td>Row data for a single table that needs to be updated. Used in MySQL 5.1.5 to 5.1.17.</td>
</tr>
<tr>
<td>Type</td>
<td>Name</td>
</tr>
<tr>
<td>------</td>
<td>------</td>
</tr>
<tr>
<td>16</td>
<td>PRE_GA_DELETE_ROWS_EVENT</td>
</tr>
<tr>
<td>17</td>
<td>WRITE_ROWS_EVENT</td>
</tr>
<tr>
<td>18</td>
<td>UPDATE_ROWS_EVENT</td>
</tr>
<tr>
<td>19</td>
<td>DELETE_ROWS_EVENT</td>
</tr>
<tr>
<td>1a</td>
<td>INCIDENT_EVENT</td>
</tr>
</tbody>
</table>

- **Master ID**: The server ID of the master that created the event.
- **Size**: The size in bytes of the event.
- **Master Pos**: The position of the next event in the original master log file.
- **Flags**: 16 flags. Currently, the following flags are used. The others are reserved for future use.

<table>
<thead>
<tr>
<th>Flag</th>
<th>Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>01</td>
<td>LOG_EVENT_BINLOG_IN_USE_F</td>
<td>Log file correctly closed. (Used only in FORMAT_DESCRIPTION_EVENT.) If this flag is set (if the flags are, for example, '01 00') in a FORMAT_DESCRIPTION_EVENT, the log file has not been properly closed. Most probably this is because of a master crash (for example, due to power failure).</td>
</tr>
<tr>
<td>02</td>
<td>Reserved for future use.</td>
<td></td>
</tr>
<tr>
<td>04</td>
<td>LOG_EVENT_THREAD_SPECIFIC_F</td>
<td>Set if the event is dependent on the connection it was executed in (for example, '04 00'), for example, if the event uses temporary tables.</td>
</tr>
<tr>
<td>08</td>
<td>LOG_EVENT_SUPPRESS_USE_F</td>
<td>Set in some circumstances when the event is not dependent on the default database.</td>
</tr>
</tbody>
</table>

### 4.6.7.2 mysqlbinlog Row Event Display

The following examples illustrate how mysqlbinlog displays row events that specify data modifications. These correspond to events with the WRITE_ROWS_EVENT, UPDATE_ROWS_EVENT, and DELETE_ROWS_EVENT type codes. The --base64-output=DECODE-ROWS and --verbose options may be used to affect row event output.

Suppose that the server is using row-based binary logging and that you execute the following sequence of statements:

```sql
CREATE TABLE t
(
    id INT NOT NULL,
    name VARCHAR(20) NOT NULL,
    date DATE NULL
) ENGINE = InnoDB;

START TRANSACTION;
```
**mysqlbinlog** — Utility for Processing Binary Log Files

```sql
INSERT INTO t VALUES(1, 'apple', NULL);
UPDATE t SET name = 'pear', date = '2009-01-01' WHERE id = 1;
DELETE FROM t WHERE id = 1;
COMMIT;
```

By default, **mysqlbinlog** displays row events encoded as base-64 strings using **BINLOG** statements. Omitting extraneous lines, the output for the row events produced by the preceding statement sequence looks like this:

```shell
shell> mysqlbinlog log_file
...  
# at 218  
#080828 15:03:08 server id 1  end_log_pos 258   Write_rows: table id 17 flags: STMT_END_F
BINLOG 'fAS3SBMBAALAAAAAoAAAAAAAABHRLc3QAAXQAAwMPCgIUAAQ='
fAS3SBcBAAAABAAAABAAAABHRLc3QAAXQAAwMPCgIUAAQ='
"/*!*/;
...
# at 302  
#080828 15:03:08 server id 1  end_log_pos 356   Update_rows: table id 17 flags: STMT_END_F
BINLOG 'fAS3SBMBAALAAAAAC4BAAAABAAAABHRLc3QAAXQAAwMPCgIUAAQ='
fAS3SBgBAAAANgAAAGQBAAAABAAAABAAAABHRLc3QAAXQAAwMPCgIUAAQ='
"/*!*/;
...
# at 400  
#080828 15:03:08 server id 1  end_log_pos 442   Delete_rows: table id 17 flags: STMT_END_F
BINLOG 'fAS3SBMBAALAAAAA7BAAAABAAAABAAAABHRLc3QAAXQAAwMPCgIUAAQ='
fAS3SBkBAAAANkAAAALoBAAAABAAAABAAAABAAAABHRLc3QAAXQAAwMPCgIUAAQ='
"/*!*/;
```

To see the row events as comments in the form of "pseudo-SQL" statements, run **mysqlbinlog** with the `--verbose` or `-v` option. The output will contain lines beginning with `###`:

```shell
shell> mysqlbinlog -v log_file
...  
# at 218  
#080828 15:03:08 server id 1  end_log_pos 258   Write_rows: table id 17 flags: STMT_END_F
BINLOG 'fAS3SBMBAALAAAAAoAAAAAAAABHRLc3QAAXQAAwMPCgIUAAQ='
fAS3SBcBAAAABAAAABAAAABHRLc3QAAXQAAwMPCgIUAAQ='
"/*!*/;
### INSERT INTO test.t
### SET
###   @1=1
###   @2='apple'
###   @3=NULL
...
# at 302  
#080828 15:03:08 server id 1  end_log_pos 356   Update_rows: table id 17 flags: STMT_END_F
BINLOG 'fAS3SBMBAALAAAAAC4BAAAABAAAABHRLc3QAAXQAAwMPCgIUAAQ='
fAS3SBgBAAAANgAAAGQBAAAABAAAABAAAABHRLc3QAAXQAAwMPCgIUAAQ='
"/*!*/;
### UPDATE test.t
### WHERE
###   @1=1
###   @2='apple'
```

417
### mysqlbinlog — Utility for Processing Binary Log Files

```plaintext
### @3=NULL
### SET
###   @1=1
###   @2='pear'
###   @3='2009:01:01'
...
# at 400
#080828 15:03:08 server id 1  end_log_pos 442   Delete_rows: table id 17 flags: STMT_END_F

BINLOG 'fAS3SBMBAAAALAAAAJABAAAAAABAAAAAABHRlc3QAAwMPCgIUAAQ=
'fAS3SBkBAAAAKAAAAAIBAAAQABEAAAAAAEA=/4AQQAARwZWFyIbIP
'/*!*/;
### DELETE FROM test.t
### WHERE
###   @1=1
###   @2='pear'
###   @3='2009:01:01'

Specify --verbose or -v twice to also display data types and some metadata for each column. The output will contain an additional comment following each column change:

```shell
shell> mysqlbinlog -vv log_file
...
```

```plaintext
# at 218
#080828 15:03:08 server id 1  end_log_pos 258   Write_rows: table id 17 flags: STMT_END_F

BINLOG 'fAS3SBMBAAAALAAAAJABAAAAAABAAAAAABHRlc3QAAwMPCgIUAAQ=
'fAS3SBcBAAAAKAAAAAIBAAAQABEAAAAAAEA=/8AQAAAAVhcHBsZQ==
'/*!*/;
### INSERT INTO test.t
### SET
###   @1=1 /* INT meta=0 nullable=0 is_null=0 */
###   @2='apple' /* VARSTRING(20) meta=20 nullable=0 is_null=0 */
###   @3=NULL /* VARSTRING(20) meta=0 nullable=1 is_null=1 */
...
# at 302
#080828 15:03:08 server id 1  end_log_pos 356   Update_rows: table id 17 flags: STMT_END_F

BINLOG 'fAS3SBMBAAAALAAAAJABAAAAAABAAAAAABHRlc3QAAwMPCgIUAAQ=
'fAS3SBgBAAAANgAAAGQBAAAQABEAAAAAAEA=/8AQAAAAVhcHBsZQ==
'/*!*/;
### UPDATE test.t
### WHERE
###   @1=1 /* INT meta=0 nullable=0 is_null=0 */
###   @2='apple' /* VARSTRING(20) meta=20 nullable=0 is_null=0 */
###   @3=NULL /* VARSTRING(20) meta=0 nullable=1 is_null=1 */
### SET
###   @1=1 /* INT meta=0 nullable=0 is_null=0 */
###   @2='pear' /* VARSTRING(20) meta=20 nullable=0 is_null=0 */
###   @3='2009:01:01' /* DATE meta=0 nullable=1 is_null=0 */
...
# at 400
#080828 15:03:08 server id 1  end_log_pos 442   Delete_rows: table id 17 flags: STMT_END_F

BINLOG 'fAS3SBMBAAAALAAAAJABAAAAAABAAAAAABHRlc3QAAwMPCgIUAAQ=
'fAS3SBkBAAAAKAAAAAIBAAAQABEAAAAAAEA=/4AQQAARwZWFyIbIP
'/*!*/;
### DELETE FROM test.t
### WHERE
###   @1=1 /* INT meta=0 nullable=0 is_null=0 */
###   @2='pear' /* VARSTRING(20) meta=20 nullable=0 is_null=0 */
###   @3='2009:01:01' /* DATE meta=0 nullable=1 is_null=0 */
```
You can tell `mysqlbinlog` to suppress the BINLOG statements for row events by using the `--base64-output=DECODE-ROWS` option. This is similar to `--base64-output=NEVER` but does not exit with an error if a row event is found. The combination of `--base64-output=DECODE-ROWS` and `--verbose` provides a convenient way to see row events only as SQL statements:

```bash
shell> mysqlbinlog -v --base64-output=DECODE-ROWS log_file
...
# at 218
#080828 15:03:08 server id 1  end_log_pos 258   Write_rows: table id 17 flags: STMT_END_F
### INSERT INTO test.t
### SET
###   @1=1
###   @2='apple'
###   @3=NULL
...
# at 302
#080828 15:03:08 server id 1  end_log_pos 356   Update_rows: table id 17 flags: STMT_END_F
### UPDATE test.t
### WHERE
###   @1=1
###   @2='apple'
###   @3=NULL
### SET
###   @1=1
###   @2='pear'
###   @3='2009:01:01'
...
# at 400
#080828 15:03:08 server id 1  end_log_pos 442   Delete_rows: table id 17 flags: STMT_END_F
### DELETE FROM test.t
### WHERE
###   @1=1
###   @2='pear'
###   @3='2009:01:01'
```

**Note**

You should not suppress BINLOG statements if you intend to re-execute `mysqlbinlog` output.

The SQL statements produced by `--verbose` for row events are much more readable than the corresponding BINLOG statements. However, they do not correspond exactly to the original SQL statements that generated the events. The following limitations apply:

- The original column names are lost and replaced by `@N`, where `N` is a column number.
- Character set information is not available in the binary log, which affects string column display:
  - There is no distinction made between corresponding binary and nonbinary string types (BINARY and CHAR, VARBINARY and VARCHAR, BLOB and TEXT). The output uses a data type of STRING for fixed-length strings and VARSTRING for variable-length strings.
  - For multi-byte character sets, the maximum number of bytes per character is not present in the binary log, so the length for string types is displayed in bytes rather than in characters. For example, STRING(4) will be used as the data type for values from either of these column types:
    ```sql
    CHAR(4) CHARACTER SET latin1
    CHAR(2) CHARACTER SET ucs2
    ```
- Due to the storage format for events of type UPDATE_ROWS_EVENT, UPDATE statements are displayed with the WHERE clause preceding the SET clause.
Proper interpretation of row events requires the information from the format description event at the
beginning of the binary log. Because `mysqlbinlog` does not know in advance whether the rest of the log
contains row events, by default it displays the format description event using a `BINLOG` statement in the
initial part of the output.

If the binary log is known not to contain any events requiring a `BINLOG` statement (that is, no row events),
the `--base64-output=NEVER` option can be used to prevent this header from being written.

### 4.6.8 `mysqldumpslow` — Summarize Slow Query Log Files

The MySQL slow query log contains information about queries that take a long time to execute (see
Section 5.2.5, “The Slow Query Log”). `mysqldumpslow` parses MySQL slow query log files and prints a
summary of their contents.

Normally, `mysqldumpslow` groups queries that are similar except for the particular values of number and
string data values. It “abstracts” these values to `N` and `'S'` when displaying summary output. The `--a` and `--n`
options can be used to modify value abstracting behavior.

Invoke `mysqldumpslow` like this:

```shell>
mysqldumpslow [options] [log_file ...]
```

`mysqldumpslow` supports the following options.

<table>
<thead>
<tr>
<th>Format</th>
<th>Option File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-a</td>
<td></td>
<td>Do not abstract all numbers to <code>N</code> and strings to <code>S</code></td>
</tr>
<tr>
<td>-n num</td>
<td></td>
<td>Abstract numbers with at least the specified digits</td>
</tr>
<tr>
<td>--debug</td>
<td>debug</td>
<td>Write debugging information</td>
</tr>
<tr>
<td>-g pattern</td>
<td></td>
<td>Only consider statements that match the pattern</td>
</tr>
<tr>
<td>--help</td>
<td></td>
<td>Display help message and exit</td>
</tr>
<tr>
<td>-h name</td>
<td></td>
<td>Host name of the server in the log file name</td>
</tr>
<tr>
<td>-i name</td>
<td></td>
<td>Name of the server instance</td>
</tr>
<tr>
<td>-l</td>
<td></td>
<td>Do not subtract lock time from total time</td>
</tr>
<tr>
<td>-r</td>
<td></td>
<td>Reverse the sort order</td>
</tr>
<tr>
<td>-s value</td>
<td></td>
<td>How to sort output</td>
</tr>
<tr>
<td>-t num</td>
<td></td>
<td>Display only first num queries</td>
</tr>
<tr>
<td>--verbose</td>
<td>verbose</td>
<td>Verbose mode</td>
</tr>
</tbody>
</table>

- `--help`

  Display a help message and exit.

- `--a`

  Do not abstract all numbers to `N` and strings to `'S'`.

- `--debug,-d`
mysqldumpslow — Summarize Slow Query Log Files

Run in debug mode.

-\texttt{-g \textit{pattern}}

Consider only queries that match the (\texttt{grep}-style) pattern.

-\texttt{-h \textit{host}\_name}

Host name of MySQL server for \texttt{*-slow.log} file name. The value can contain a wildcard. The default is * (match all).

-\texttt{-i \textit{name}}

Name of server instance (if using \texttt{mysql.server} startup script).

-\texttt{-l}

Do not subtract lock time from total time.

-\texttt{-n \textit{N}}

Abstract numbers with at least \textit{N} digits within names.

-\texttt{-r}

Reverse the sort order.

-\texttt{-s \textit{sort\_type}}

How to sort the output. The value of \textit{sort\_type} should be chosen from the following list:

-\texttt{t, at}: Sort by query time or average query time

-\texttt{l, al}: Sort by lock time or average lock time

-\texttt{r, ar}: Sort by rows sent or average rows sent

-\texttt{c}: Sort by count

By default, \texttt{mysqldumpslow} sorts by average query time (equivalent to \texttt{-s at}).

-\texttt{-t \textit{N}}

Display only the first \textit{N} queries in the output.

-\texttt{--verbose, -v}

Verbose mode. Print more information about what the program does.

Example of usage:

\begin{verbatim}
shell> mysqldumpslow
Reading mysql slow query log from /usr/local/mysql/data/mysqld51-apple-slow.log
Count: 1 Time=4.32s (4s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
  insert into t2 select * from t1
Count: 3 Time=2.53s (7s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
\end{verbatim}
4.6.9 mysqlhotcopy — A Database Backup Program

mysqlhotcopy is a Perl script that was originally written and contributed by Tim Bunce. It uses FLUSH TABLES, LOCK TABLES, and cp or scp to make a database backup. It is a fast way to make a backup of the database or single tables, but it can be run only on the same machine where the database directories are located. mysqlhotcopy works only for backing up MyISAM and ARCHIVE tables. It runs on Unix.

To use mysqlhotcopy, you must have read access to the files for the tables that you are backing up, the SELECT privilege for those tables, the RELOAD privilege (to be able to execute FLUSH TABLES), and the LOCK TABLES privilege (to be able to lock the tables).

```
shell> mysqlhotcopy db_name [/path/to/new_directory]
```

```
shell> mysqlhotcopy db_name_1 ... db_name_n /path/to/new_directory
```

Back up tables in the given database that match a regular expression:

```
shell> mysqlhotcopy db_name./regex/
```

The regular expression for the table name can be negated by prefixing it with a tilde (“~ ”):

```
shell> mysqlhotcopy db_name./~regex/
```

mysqlhotcopy supports the following options, which can be specified on the command line or in the [mysqlhotcopy] and [client] groups of an option file. For information about option files, see Section 4.2.6, “Using Option Files”.

<table>
<thead>
<tr>
<th>Format</th>
<th>Option File</th>
<th>Description</th>
<th>Introduced</th>
</tr>
</thead>
<tbody>
<tr>
<td>--addtodest</td>
<td>addtodest</td>
<td>Do not rename target directory (if it exists); merely add files to it</td>
<td></td>
</tr>
<tr>
<td>--allowold</td>
<td>allowold</td>
<td>Do not abort if a target exists; rename it by adding an _old suffix</td>
<td></td>
</tr>
<tr>
<td>--checkpoint=db_name.tbl_name</td>
<td>checkpoint</td>
<td>Insert checkpoint entries</td>
<td></td>
</tr>
<tr>
<td>--chroot=path</td>
<td>chroot</td>
<td>Base directory of the chroot jail in which mysqld operates</td>
<td></td>
</tr>
<tr>

</tr>
</tbody>
</table>

- **--help, -?**
  Display a help message and exit.

- **--addtodest**
  Do not rename target directory (if it exists); merely add files to it.

- **--allowold**
  Do not abort if a target exists; rename it by adding an _old suffix.

- **--checkpoint=\texttt{db\_name.tbl\_name}**
  Insert checkpoint entries into the specified database \texttt{db\_name} and table \texttt{tbl\_name}.

- **--chroot=path**
  Base directory of the chroot jail in which mysqld operates. The \texttt{path} value should match that of the \texttt{--chroot} option given to mysqld.

- **--debug**
  Enable debug output.

- **--dryrun, -n**
  Report actions without performing them.

- **--flushlog**
  Flush logs after all tables are locked.
The host name of the local host to use for making a TCP/IP connection to the local server. By default, the connection is made to localhost using a Unix socket file.

- **--keepold**
  Do not delete previous (renamed) target when done.

- **--method=command**
  The method for copying files (cp or scp). The default is cp.

- **--noindices**
  Do not include full index files for MyISAM tables in the backup. This makes the backup smaller and faster. The indexes for reloaded tables can be reconstructed later with myisamchk -rq.

- **--password=password, -p password**
  The password to use when connecting to the server. The password value is not optional for this option, unlike for other MySQL programs.

  Specifying a password on the command line should be considered insecure. See Section 6.1.2.1, “End-User Guidelines for Password Security”. You can use an option file to avoid giving the password on the command line.

- **--port=port_num, -P port_num**
  The TCP/IP port number to use when connecting to the local server.

- **--old_server**
  As of MySQL 5.5.3, mysqlhotcopy uses FLUSH TABLES tbl_list WITH READ LOCK to flush and lock tables. Use the --old_server option if the server is older than 5.5.3, which is when that statement was introduced. This option was added in MySQL 5.5.3.

- **--quiet, -q**
  Be silent except for errors.

- **--record_log_pos=db_name.tbl_name**
  Record master and slave status in the specified database db_name and table tbl_name.

- **--regexp=expr**
  Copy all databases with names that match the given regular expression.

- **--resetmaster**
  Reset the binary log after locking all the tables.

- **--resetslave**
  Reset the master.info file after locking all the tables.

- **--socket=path, -S path**
  The Unix socket file to use for connections to localhost.
mysql_convert_table_format — Convert Tables to Use a Given Storage Engine

- **--suffix=str**
  The suffix to use for names of copied databases.

- **--tmpdir=path**
  The temporary directory. The default is /tmp.

- **--user=user_name,**
  The MySQL user name to use when connecting to the server.

Use `perldoc` for additional `mysqlhotcopy` documentation, including information about the structure of the tables needed for the `--checkpoint` and `--record_log_pos` options:

```
shell> perldoc mysqlhotcopy
```

### 4.6.10 mysql_convert_table_format — Convert Tables to Use a Given Storage Engine

mysql_convert_table_format converts the tables in a database to use a particular storage engine (MyISAM by default). `mysql_convert_table_format` is written in Perl and requires that the DBI and DBD::mysql Perl modules be installed (see Section 2.13, “Perl Installation Notes”).

Invoke `mysql_convert_table_format` like this:

```
shell> mysql_convert_table_format [options] db_name
```

The `db_name` argument indicates the database containing the tables to be converted.

`mysql_convert_table_format` supports the options described in the following list.

- **--help**
  Display a help message and exit.

- **--force**
  Continue even if errors occur.

- **--host=host_name**
  Connect to the MySQL server on the given host.

- **--password=password**
  The password to use when connecting to the server. Note that the password value is not optional for this option, unlike for other MySQL programs.

  Specifying a password on the command line should be considered insecure. See Section 6.1.2.1, “End-User Guidelines for Password Security”. You can use an option file to avoid giving the password on the command line.

- **--port=port_num**
  The TCP/IP port number to use for the connection.
mysql_find_rows — Extract SQL Statements from Files

- **--socket=path**
  For connections to localhost, the Unix socket file to use.
- **--type=engine_name**
  Specify the storage engine that the tables should be converted to use. The default is MyISAM if this option is not given.
- **--user=user_name**
  The MySQL user name to use when connecting to the server.
- **--verbose**
  Verbose mode. Print more information about what the program does.
- **--version**
  Display version information and exit.

4.6.11 **mysql_find_rows** — Extract SQL Statements from Files

mysql_find_rows reads files containing SQL statements and extracts statements that match a given regular expression or that contain USE db_name or SET statements. The utility expects statements to be terminated with semicolon (;) characters.

Invoke mysql_find_rows like this:

```
shell> mysql_find_rows [options] [file_name ...]
```

Each file_name argument should be the name of file containing SQL statements. If no file names are given, mysql_find_rows reads the standard input.

Examples:

```
mysql_find_rows --regexp=problem_table --rows=20 < update.log
mysql_find_rows --regexp=problem_table update-log.1 update-log.2
```

mysql_find_rows supports the following options:

- **--help,** Information
  Display a help message and exit.
- **--regexp=pattern**
  Display queries that match the pattern.
- **--rows=N**
  Quit after displaying N queries.
- **--skip-use-db**
  Do not include USE db_name statements in the output.
- **--start_row=N**
4.6.12 `mysql_fix_extensions` — Normalize Table File Name Extensions

`mysql_fix_extensions` converts the extensions for MyISAM (or ISAM) table files to their canonical forms. It looks for files with extensions matching any lettercase variant of `.frm`, `.myd`, `.myi`, `.isd`, and `.ism` and renames them to have extensions of `.frm`, `.MYD`, `.MYI`, `.ISD`, and `.ISM`, respectively. This can be useful after transferring the files from a system with case-insensitive file names (such as Windows) to a system with case-sensitive file names.

Invoke `mysql_fix_extensions` like this, where `data_dir` is the path name to the MySQL data directory.

```
shell> mysql_fix_extensions data_dir
```

4.6.13 `mysql_setpermission` — Interactively Set Permissions in Grant Tables

`mysql_setpermission` is a Perl script that was originally written and contributed by Luuk de Boer. It interactively sets permissions in the MySQL grant tables. `mysql_setpermission` is written in Perl and requires that the `DBI` and `DBD::mysql` Perl modules be installed (see Section 2.13, “Perl Installation Notes”).

Invoke `mysql_setpermission` like this:

```
shell> mysql_setpermission [options]
```

`options` should be either `--help` to display the help message, or options that indicate how to connect to the MySQL server. The account used when you connect determines which permissions you have when attempting to modify existing permissions in the grant tables.

`mysql_setpermissions` also reads options from the `[client]` and `[perl]` groups in the `.my.cnf` file in your home directory, if the file exists.

`mysql_setpermission` supports the following options:

- `--help`
  Display a help message and exit.

- `--host=host_name`
  Connect to the MySQL server on the given host.

- `--password=password`
  The password to use when connecting to the server. Note that the password value is not optional for this option, unlike for other MySQL programs.

  Specifying a password on the command line should be considered insecure. See Section 6.1.2.1, “End-User Guidelines for Password Security”. You can use an option file to avoid giving the password on the command line.

- `--port=port_num`
mysql_waitpid — Kill Process and Wait for Its Termination

The TCP/IP port number to use for the connection.

- --socket=path
  For connections to localhost, the Unix socket file to use.

- --user=user_name
  The MySQL user name to use when connecting to the server.

4.6.14 mysql_waitpid — Kill Process and Wait for Its Termination

mysql_waitpid signals a process to terminate and waits for the process to exit. It uses the kill() system call and Unix signals, so it runs on Unix and Unix-like systems.

Invoke mysql_waitpid like this:

shell> mysql_waitpid [options] pid wait_time

mysql_waitpid sends signal 0 to the process identified by pid and waits up to wait_time seconds for the process to terminate. pid and wait_time must be positive integers.

If process termination occurs within the wait time or the process does not exist, mysql_waitpid returns 0. Otherwise, it returns 1.

If the kill() system call cannot handle signal 0, mysql_waitpid() uses signal 1 instead.

mysql_waitpid supports the following options:

- --help,-?,-I
  Display a help message and exit.

- --verbose,-v
  Verbose mode. Display a warning if signal 0 could not be used and signal 1 is used instead.

- --version,-V
  Display version information and exit.

4.6.15 mysql_zap — Kill Processes That Match a Pattern

mysql_zap kills processes that match a pattern. It uses the ps command and Unix signals, so it runs on Unix and Unix-like systems.

Invoke mysql_zap like this:

shell> mysql_zap [-signal] [-?If] pattern

A process matches if its output line from the ps command contains the pattern. By default, mysql_zap asks for confirmation for each process. Respond y to kill the process, or q to exit mysql_zap. For any other response, mysql_zap does not attempt to kill the process.

If the -signal option is given, it specifies the name or number of the signal to send to each process. Otherwise, mysql_zap tries first with TERM (signal 15) and then with KILL (signal 9).
The MySQL Program Development Utilities

mysql_zap supports the following additional options:

- `--help, -? , -I`
  Display a help message and exit.

- `-f`
  Force mode. mysql_zap attempts to kill each process without confirmation.

- `-t`
  Test mode. Display information about each process but do not kill it.

4.7 MySQL Program Development Utilities

This section describes some utilities that you may find useful when developing MySQL programs.

In shell scripts, you can use the `my_print_defaults` program to parse option files and see what options would be used by a given program. The following example shows the output that `my_print_defaults` might produce when asked to show the options found in the [client] and [mysql] groups:

```
shell> my_print_defaults client mysql
--port=3306
--socket=/tmp/mysql.sock
--no-auto-rehash
```

Note for developers: Option file handling is implemented in the C client library simply by processing all options in the appropriate group or groups before any command-line arguments. This works well for programs that use the last instance of an option that is specified multiple times. If you have a C or C++ program that handles multiply specified options this way but that doesn't read option files, you need add only two lines to give it that capability. Check the source code of any of the standard MySQL clients to see how to do this.

Several other language interfaces to MySQL are based on the C client library, and some of them provide a way to access option file contents. These include Perl and Python. For details, see the documentation for your preferred interface.

4.7.1 msql2mysql — Convert mSQL Programs for Use with MySQL

Initially, the MySQL C API was developed to be very similar to that for the mSQL database system. Because of this, mSQL programs often can be converted relatively easily for use with MySQL by changing the names of the C API functions.

The `msql2mysql` utility performs the conversion of mSQL C API function calls to their MySQL equivalents. `msql2mysql` converts the input file in place, so make a copy of the original before converting it. For example, use `msql2mysql` like this:

```
shell> cp client-prog.c client-prog.c.orig
shell> msql2mysql client-prog.c
client-prog.c converted
```

Then examine `client-prog.c` and make any post-conversion revisions that may be necessary.

`msql2mysql` uses the `replace` utility to make the function name substitutions. See Section 4.8.2, "replace — A String-Replacement Utility".
### mysql_config — Display Options for Compiling Clients

mysql_config provides you with useful information for compiling your MySQL client and connecting it to MySQL. It is a shell script, so it is available only on Unix and Unix-like systems.

mysql_config supports the following options.

- **--cflags**
  Compiler flags to find include files and critical compiler flags and defines used when compiling the libmysqlclient library. The options returned are tied to the specific compiler that was used when the library was created and might clash with the settings for your own compiler. Use **--include** for more portable options that contain only include paths.

- **--include**
  Compiler options to find MySQL include files.

- **--libmysqld-libs, --embedded**
  Libraries and options required to link with the MySQL embedded server.

- **--libs**
  Libraries and options required to link with the MySQL client library.

- **--libs_r**
  Libraries and options required to link with the thread-safe MySQL client library. In MySQL 5.5, all client libraries are thread-safe, so this option need not be used. The **--libs** option can be used in all cases.

- **--plugindir**
  The default plugin directory path name, defined when configuring MySQL.

- **--port**
  The default TCP/IP port number, defined when configuring MySQL.

- **--socket**
  The default Unix socket file, defined when configuring MySQL.

- **--version**
  Version number for the MySQL distribution.

If you invoke mysql_config with no options, it displays a list of all options that it supports, and their values:

```
shell> mysql_config
Usage: /usr/local/mysql/bin/mysql_config [options]
Options:
  --cflags         [-I/usr/local/mysql/include/mysql -mcpu=pentiumpro]
  --include        [-I/usr/local/mysql/include/mysql]
  --libs           [-L/usr/local/mysql/lib/mysql -lmysqlclient
                           -lpthread -lrt -lssl -lcrypto -ldl]
  --libs_r         [-L/usr/local/mysql/lib/mysql -lmysqlclient_r
```
my_print_defaults — Display Options from Option Files

You can use `mysql_config` within a command line using backticks to include the output that it produces for a particular option. For example, to compile and link a MySQL client program, use `mysql_config` as follows:

```
shell> gcc -c `mysql_config --cflags` progname.c
shell> gcc -o progname progname.o `mysql_config --libs`
```

4.7.3 my_print_defaults — Display Options from Option Files

my_print_defaults displays the options that are present in option groups of option files. The output indicates what options will be used by programs that read the specified option groups. For example, the mysqlcheck program reads the [mysqlcheck] and [client] option groups. To see what options are present in those groups in the standard option files, invoke my_print_defaults like this:

```
shell> my_print_defaults mysqlcheck client
--user=myusername
--password=secret
--host=localhost
```

The output consists of options, one per line, in the form that they would be specified on the command line.

my_print_defaults supports the following options.

- **--help, -?**  
  Display a help message and exit.

- **--config-file=file_name, --defaults-file=file_name, -c file_name**  
  Read only the given option file.

- **--debug=debug_options, -# debug_options**  
  Write a debugging log. A typical debug_options string is d:t:o, file_name. The default is d:t:o,/tmp/my_print_defaults.trace.

- **--defaults-extra-file=file_name, --extra-file=file_name, -e file_name**  
  Read this option file after the global option file but (on Unix) before the user option file.

- **--defaults-group-suffix=suffix, -g suffix**  
  In addition to the groups named on the command line, read groups that have the given suffix.

- **--no-defaults, -n**  
  Return an empty string.

- **--verbose, -v**  
  Verbose mode. Print more information about what the program does.
resolve_stack_dump — Resolve Numeric Stack Trace Dump to Symbols

- --version, -V
  Display version information and exit.

4.7.4 resolve_stack_dump — Resolve Numeric Stack Trace Dump to Symbols

resolve_stack_dump resolves a numeric stack dump to symbols.

Invoke resolve_stack_dump like this:

```
shell> resolve_stack_dump [options] symbols_file [numeric_dump_file]
```

The symbols file should include the output from the `nm --numeric-sort mysqld` command. The numeric dump file should contain a numeric stack track from `mysqld`. If no numeric dump file is named on the command line, the stack trace is read from the standard input.

resolve_stack_dump supports the following options.

- --help, -h
  Display a help message and exit.

- --numeric-dump-file=file_name, -n file_name
  Read the stack trace from the given file.

- --symbols-file=file_name, -s file_name
  Use the given symbols file.

- --version, -V
  Display version information and exit.

For more information, see Section 24.4.1.5, “Using a Stack Trace”.

4.8 Miscellaneous Programs

4.8.1 perror — Explain Error Codes

For most system errors, MySQL displays, in addition to an internal text message, the system error code in one of the following styles:

```
message ... (errno: #)
message ... (Errcode: #)
```

You can find out what the error code means by examining the documentation for your system or by using the perror utility.

perror prints a description for a system error code or for a storage engine (table handler) error code.

Invoke perror like this:

```
shell> perror [options] errorcode ...
```
Example:

```bash
shell> perror 13 64
OS error code 13: Permission denied
OS error code 64: Machine is not on the network
```

To obtain the error message for a MySQL Cluster error code, invoke `perror` with the `--ndb` option:

```bash
shell> perror --ndb errorcode
```

Note that the meaning of system error messages may be dependent on your operating system. A given error code may mean different things on different operating systems.

`perror` supports the following options.

- **--help, --info, -I, -?**
  Display a help message and exit.

- **--ndb**
  Print the error message for a MySQL Cluster error code.

- **--silent, -s**
  Silent mode. Print only the error message.

- **--verbose, -v**
  Verbose mode. Print error code and message. This is the default behavior.

- **--version, -V**
  Display version information and exit.

### 4.8.2 `replace` — A String-Replacement Utility

The `replace` utility program changes strings in place in files or on the standard input.

Invoke `replace` in one of the following ways:

```bash
shell> replace from to [from to] ... -- file_name [file_name] ... 
shell> replace from to [from to] ... < file_name
```

`from` represents a string to look for and `to` represents its replacement. There can be one or more pairs of strings.

Use the `--` option to indicate where the string-replacement list ends and the file names begin. In this case, any file named on the command line is modified in place, so you may want to make a copy of the original before converting it. `replace` prints a message indicating which of the input files it actually modifies.

If the `--` option is not given, `replace` reads the standard input and writes to the standard output.

`replace` uses a finite state machine to match longer strings first. It can be used to swap strings. For example, the following command swaps `a` and `b` in the given files, `file1` and `file2`:
The `replace` program is used by `msql2mysql`. See Section 4.7.1, "msql2mysql — Convert mSQL Programs for Use with MySQL".

`replace` supports the following options.

- `-?`, `-I`
  Display a help message and exit.

- `--debug_options`
  Enable debugging.

- `-s`
  Silent mode. Print less information what the program does.

- `-v`
  Verbose mode. Print more information about what the program does.

- `--version`, `-V`
  Display version information and exit.

### 4.8.3 `resolveip` — Resolve Host name to IP Address or Vice Versa

The `resolveip` utility resolves host names to IP addresses and vice versa.

Invoke `resolveip` like this:

```
shell> resolveip [options] {host_name|ip-addr} ...
```

`resolveip` supports the following options.

- `--help`, `--info`, `-?`, `-I`
  Display a help message and exit.

- `--silent`, `-s`
  Silent mode. Produce less output.

- `--version`, `-V`
  Display version information and exit.

MySQL Server (**mysql**) is the main program that does most of the work in a MySQL installation. This chapter provides an overview of MySQL Server and covers general server administration:

- Server configuration.
- The server log files.
- Management of multiple servers on a single machine.

For additional information on administrative topics, see also:

- Chapter 6, **Security**
- Chapter 7, **Backup and Recovery**
- Chapter 17, **Replication**

### 5.1 The MySQL Server

**mysql** is the MySQL server. The following discussion covers these MySQL server configuration topics:

- Startup options that the server supports. You can specify these options on the command line, through configuration files, or both.
• Server system variables. These variables reflect the current state and values of the startup options, some of which can be modified while the server is running.

• Server status variables. These variables contain counters and statistics about runtime operation.

• How to set the server SQL mode. This setting modifies certain aspects of SQL syntax and semantics, for example for compatibility with code from other database systems, or to control the error handling for particular situations.

• The server shutdown process. There are performance and reliability considerations depending on the type of table (transactional or nontransactional) and whether you use replication.

Note
Not all storage engines are supported by all MySQL server binaries and configurations. To find out how to determine which storage engines your MySQL server installation supports, see Section 13.7.5.17, "SHOW ENGINES Syntax".

5.1.1 Server Option and Variable Reference

The following table provides a list of all the command line options, server and status variables applicable within mysqld.

The table lists command-line options (Cmd-line), options valid in configuration files (Option file), server system variables (System Var), and status variables (Status var) in one unified list, with notification of where each option/variable is valid. If a server option set on the command line or in an option file differs from the name of the corresponding server system or status variable, the variable name is noted immediately below the corresponding option. For status variables, the scope of the variable is shown (Scope) as either global, session, or both. Please see the corresponding sections for details on setting and using the options and variables. Where appropriate, a direct link to further information on the item as available.

For a version of this table that is specific to MySQL Cluster, see Section 18.3.4.1, "MySQL Cluster mysqld Option and Variable Reference".

Table 5.1 Option/Variable Summary

### 5.1.2 Server Configuration Defaults

The MySQL server has many operating parameters, which you can change at server startup using command-line options or configuration files (option files). It is also possible to change many parameters at runtime. For general instructions on setting parameters at startup or runtime, see Section 5.1.3, “Server Command Options”, and Section 5.1.4, “Server System Variables”.

MySQL provides a number of preconfigured option files that can be used as a basis for tuning the MySQL server. Look for files named `my-small.cnf`, `my-medium.cnf`, `my-large.cnf`, and `my-huge.cnf`, which are sample option files for small, medium, large, and very large systems. On Windows, the extension is `.ini` rather than `.cnf`.

\(^a\)This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

\(^b\)This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.
### 5.1.3 Server Command Options

When you start the `mysqld` server, you can specify program options using any of the methods described in Section 4.2.3, “Specifying Program Options”. The most common methods are to provide options in an option file or on the command line. However, in most cases it is desirable to make sure that the server uses the same options each time it runs. The best way to ensure this is to list them in an option file. See Section 4.2.6, “Using Option Files”.

An embedded MySQL server usually reads options from the `[server]`, `[embedded]`, and `[xxxxx_SERVER]` groups, where `xxxxx` is the name of the application into which the server is embedded.

`mysqld` accepts many command options. For a brief summary, execute `mysqld --help`. To see the full list, use `mysqld --verbose --help`.

The following list shows some of the most common server options. Additional options are described in other sections:

- **Options that affect security**: See Section 6.1.4, “Security-Related `mysqld` Options and Variables”.
- **SSL-related options**: See Section 6.3.9.4, “SSL Command Options”.
- **Binary log control options**: See Section 5.2.4, “The Binary Log”.
- **Replication-related options**: See Section 17.1.3, “Replication and Binary Logging Options and Variables”.
- **Options for loading plugins such as pluggable storage engines**: See Section 5.1.8.1, “Installing and Uninstalling Plugins”.
- **Options specific to particular storage engines**: See Section 14.15, “InnoDB Startup Options and System Variables”, Section 15.3.1, “MyISAM Startup Options”, and Section 18.3.4.2, “MySQL Server Options for MySQL Cluster”.

You can also set the values of server system variables by using variable names as options, as described at the end of this section.

Some options control the size of buffers or caches. For a given buffer, the server might need to allocate internal data structures. These structures typically are allocated from the total memory allocated to the buffer, and the amount of space required might be platform dependent. This means that when you assign a value to an option that controls a buffer size, the amount of space actually available might differ from the value assigned. In some cases, the amount might be less than the value assigned. It is also possible that the server will adjust a value upward. For example, if you assign a value of 0 to an option for which the minimal value is 1024, the server will set the value to 1024.
Server Command Options

Values for buffer sizes, lengths, and stack sizes are given in bytes unless otherwise specified.

Some options take file name values. Unless otherwise specified, the default file location is the data directory if the value is a relative path name. To specify the location explicitly, use an absolute path name. Suppose that the data directory is `/var/mysql/data`. If a file-valued option is given as a relative path name, it will be located under `/var/mysql/data`. If the value is an absolute path name, its location is as given by the path name.

- **--help, -?**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>-?</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>--help</td>
</tr>
</tbody>
</table>

| Option-File Format | help |

Display a short help message and exit. Use both the **--verbose** and **--help** options to see the full message.

- **--allow-suspicious-udfs**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--allow-suspicious-udfs</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>allow-suspicious-udfs</td>
</tr>
</tbody>
</table>

| Option-File Format | allow-suspicious-udfs |

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

This option controls whether user-defined functions that have only an *xxx* symbol for the main function can be loaded. By default, the option is off and only UDFs that have at least one auxiliary symbol can be loaded; this prevents attempts at loading functions from shared object files other than those containing legitimate UDFs. See Section 24.3.2.6, “User-Defined Function Security Precautions”.

- **--ansi**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ansi</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-a</td>
</tr>
</tbody>
</table>

| Option-File Format | ansi   |

Use standard (ANSI) SQL syntax instead of MySQL syntax. For more precise control over the server SQL mode, use the **--sql-mode** option instead. See Section 1.8, “MySQL Standards Compliance”, and Section 5.1.7, “Server SQL Modes”.

- **--basedir=path, -b path**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--basedir=path</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-b</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Option-File Format</th>
<th>basedir</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable Name</td>
<td>basedir</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

| Permitted Values |
Server Command Options

<table>
<thead>
<tr>
<th>Type</th>
<th>directory name</th>
</tr>
</thead>
</table>

The path to the MySQL installation directory. All paths are usually resolved relative to this directory.

- **--big-tables**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--big-tables</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>big-tables</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>big_tables</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Default</td>
</tr>
</tbody>
</table>

Enable large result sets by saving all temporary sets in files. This option prevents most “table full” errors, but also slows down queries for which in-memory tables would suffice. Since MySQL 3.23.2, the server is able to handle large result sets automatically by using memory for small temporary tables and switching to disk tables where necessary.

- **--bind-address=addr**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--bind-address=addr</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>bind-address</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>bind_address</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Default</td>
</tr>
</tbody>
</table>

The MySQL server listens on a single network socket for TCP/IP connections. This socket is bound to a single address, but it is possible for an address to map onto multiple network interfaces. The default address is 0.0.0.0. To specify an address explicitly, use the --bind-address=addr option at server startup, where addr is an IPv4 or IPv6 address or a host name. (IPv6 addresses are not supported before MySQL 5.5.3.) If addr is a host name, the server resolves the name to an IP address and binds to that address.

The server treats different types of addresses as follows:

- If the address is 0.0.0.0, the server accepts TCP/IP connections on all server host IPv4 interfaces.
- If the address is ::, the server accepts TCP/IP connections on all server host IPv4 and IPv6 interfaces. Use this address to permit both IPv4 and IPv6 connections on all server interfaces.
- If the address is an IPv4-mapped address, the server accepts TCP/IP connections for that address, in either IPv4 or IPv6 format. For example, if the server is bound to ::ffff:127.0.0.1, clients can connect using --host=127.0.0.1 or --host=::ffff:127.0.0.1.
• If the address is a “regular” IPv4 or IPv6 address (such as 127.0.0.1 or ::1), the server accepts TCP/IP connections only for that IPv4 or IPv6 address.

If you intend to bind the server to a specific address, be sure that the mysql.user grant table contains an account with administrative privileges that you can use to connect to that address. Otherwise, you will not be able to shut down the server. For example, if you bind the server to ::, you can connect to it using all existing accounts. But if you bind the server to ::1, it accepts connections only on that address. In that case, first make sure that the 'root'@'::1' account is present in the mysql.user table so you can still connect to the server to shut it down.

• --binlog-format={ROW|STATEMENT|MIXED}

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--binlog-format=format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>binlog-format</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>binlog_format</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>enumeration</td>
</tr>
<tr>
<td>Default</td>
<td>STATEMENT</td>
</tr>
<tr>
<td>Valid Values</td>
<td>ROW</td>
</tr>
<tr>
<td></td>
<td>STATEMENT</td>
</tr>
<tr>
<td></td>
<td>MIXED</td>
</tr>
</tbody>
</table>

Specify whether to use row-based, statement-based, or mixed replication. Statement-based is the default in MySQL 5.5. This is also true for MySQL Cluster NDB 7.2.1 and later. See Section 17.1.2, “Replication Formats”.

Under some conditions, changing this variable at runtime is not possible, or causes replication to fail. See Section 5.2.4.2, “Setting The Binary Log Format”, for more information.

Prior to MySQL 5.5, setting the binary logging format without enabling binary logging prevented the MySQL server from starting. In MySQL 5.5, the server starts in such cases, the binlog_format global system variable is set, and a warning is logged instead of an error. (Bug #42928)

• --bootstrap

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--bootstrap</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>bootstrap</td>
</tr>
</tbody>
</table>

This option is used by the mysql_install_db script to create the MySQL privilege tables without having to start a full MySQL server.

• --character-sets-dir=path

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--character-sets-dir=path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>character-sets-dir</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>character_sets_dir</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
</tbody>
</table>
Dynamic Variable | No
---|---
Permitted Values | directory name
Type | directory name

The directory where character sets are installed. See Section 10.5, “Character Set Configuration”.

- **--character-set-client-handshake**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--character-set-client-handshake</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>character-set-client-handshake</td>
</tr>
</tbody>
</table>

| Permitted Values | boolean
|------------------|---
| Type             | boolean
| Default          | TRUE

Do not ignore character set information sent by the client. To ignore client information and use the default server character set, use **--skip-character-set-client-handshake**; this makes MySQL behave like MySQL 4.0.

- **--character-set-filesystem=charset_name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--character-set-filesystem=charset_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>character-set-filesystem</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>character_set_filesystem</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

| Permitted Values | string
|------------------|---
| Type             | string
| Default          | binary

The file system character set. This option sets the character_set_filesystem system variable.

- **--character-set-server=charset_name, -C charset_name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--character-set-server</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>character-set-server</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>character_set_server</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

| Permitted Values | string
|------------------|---
| Type             | string
| Default          | latin1

Use charset_name as the default server character set. See Section 10.5, “Character Set Configuration”. If you use this option to specify a nondefault character set, you should also use **--collation-server** to specify the collation.

- **--chroot=path, -r path**

470
Put the `mysqld` server in a closed environment during startup by using the `chroot()` system call. This is a recommended security measure. Note that use of this option somewhat limits `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE`.

- **--collation-server=collation_name**

Use `collation_name` as the default server collation. See Section 10.5, “Character Set Configuration”.

- **--console**

(Windows only.) Write error log messages to `stderr` and `stdout`. `mysqld` does not close the console window if this option is used.

As of MySQL 5.5.3, if both `--log-error` and `--console` are specified, `--log-error` takes precedence. The server writes to the log file, but not to the console. Before 5.5.3, whichever option is given last takes precedence.

- **--core-file**

Write a core file if `mysqld` dies. The name and location of the core file is system dependent. On Linux, a core file named `core.pid` is written to the current working directory of the process, which for `mysqld` is the data directory. `pid` represents the process ID of the server process. On Mac OS X, a core file named
core.pid is written to the /cores directory. On Solaris, use the coreadm command to specify where to write the core file and how to name it.

For some systems, to get a core file you must also specify the --core-file-size option to mysqld_safe. See Section 4.3.2, "mysqld_safe — MySQL Server Startup Script". On some systems, such as Solaris, you do not get a core file if you are also using the --user option. There might be additional restrictions or limitations. For example, it might be necessary to execute ulimit -c unlimited before starting the server. Consult your system documentation.

- --datadir=path, -h path

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--datadir=path</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-h</td>
</tr>
</tbody>
</table>

**Option-File Format**

datadir

**System Variable Name**
datadir

**Variable Scope**
Global

**Dynamic Variable**
No

**Permitted Values**
Type directory name

The path to the data directory.

- --debug[=debug_options], -# [debug_options]

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--debug[=debug_options]</th>
</tr>
</thead>
</table>

**Option-File Format**
debg

**System Variable Name**
debg

**Variable Scope**
Global, Session

**Dynamic Variable**
Yes

**Permitted Values**

<table>
<thead>
<tr>
<th>Type (Unix)</th>
<th>string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>d:t:i:o,/tmp/mysqld.trace</td>
</tr>
</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th>Type (Windows)</th>
<th>string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>d:t:i:o,\mysqld.trace</td>
</tr>
</tbody>
</table>

If MySQL is configured with -DWITH_DEBUG=1, you can use this option to get a trace file of what mysqld is doing. A typical debug_options string is d:t:o, file_name. The default is d:t:i:o,/ tmp/mysqld.trace on Unix and d:t:i:o,\mysqld.trace on Windows.

Using -DWITH_DEBUG=1 to configure MySQL with debugging support enables you to use the --debug="d,parser_debug" option when you start the server. This causes the Bison parser that is used to process SQL statements to dump a parser trace to the server's standard error output. Typically, this output is written to the error log.
This option may be given multiple times. Values that begin with + or – are added to or subtracted from the previous value. For example, `--debug=T --debug=+P` sets the value to `P:T`.

For more information, see Section 24.4.3, “The DEBUG Package”.

• `--debug-sync-timeout [=N]`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--debug-sync-timeout[=#]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>debug-sync-timeout</td>
</tr>
</tbody>
</table>

Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>numeric</td>
</tr>
</tbody>
</table>

Controls whether the Debug Sync facility for testing and debugging is enabled. Use of Debug Sync requires that MySQL be configured with the `-DENABLE_DEBUG_SYNC=1` option (see Section 2.9.4, “MySQL Source-Configuration Options”). If Debug Sync is not compiled in, this option is not available. The option value is a timeout in seconds. The default value is 0, which disables Debug Sync. To enable it, specify a value greater than 0; this value also becomes the default timeout for individual synchronization points. If the option is given without a value, the timeout is set to 300 seconds.

For a description of the Debug Sync facility and how to use synchronization points, see MySQL Internals: Test Synchronization.

• `--default-character-set=charset_name`

<table>
<thead>
<tr>
<th>Deprecated</th>
<th>5.0.0</th>
</tr>
</thead>
</table>

Command-Line Format `--default-character-set=name`

<table>
<thead>
<tr>
<th>Option-File Format</th>
<th>-C name</th>
</tr>
</thead>
</table>

Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
</tr>
</tbody>
</table>

Use `charset_name` as the default character set. This option is deprecated in favor of `--character-set-server`. See Section 10.5, “Character Set Configuration”. `--default-character-set` was removed in MySQL 5.5.3.

• `--default-collation=collation_name`

<table>
<thead>
<tr>
<th>Deprecated</th>
<th>4.1.3</th>
</tr>
</thead>
</table>

Command-Line Format `--default-collation=name`

<table>
<thead>
<tr>
<th>Option-File Format</th>
<th>default-collation</th>
</tr>
</thead>
</table>

Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
</tr>
</tbody>
</table>

Use `collation_name` as the default collation. This option is deprecated in favor of `--collation-server`. See Section 10.5, “Character Set Configuration”. `--default-collation` was removed in MySQL 5.5.3.

• `--default-storage-engine=type`

Command-Line Format `--default-storage-engine=name`
Set the default storage engine (table type) for tables. See Chapter 15, Alternative Storage Engines.

If you disable the default storage engine at server startup, you must set the default engine to a different engine or the server will not start.

- `--default-time-zone=timezon Name`

Set the default server time zone. This option sets the global `time_zone` system variable. If this option is not given, the default time zone is the same as the system time zone (given by the value of the `system_time_zone` system variable).

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, `file_name` must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, `file_name` must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqld` normally reads the `[mysqld]` group. If the `--defaults-group-suffix=_other` option is given, `mysqld` also reads the `[mysqld_other]` group.

- `--delay-key-write[=(OFF|ON|ALL)]`

<table>
<thead>
<tr>
<th>Option-File Format</th>
<th>default-storage-engine</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable Name</td>
<td>default_storage_engine</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values (&lt;= 5.5.4)</td>
<td>Type: enumeration</td>
</tr>
<tr>
<td></td>
<td>Default: MyISAM</td>
</tr>
<tr>
<td>Permitted Values (&gt;= 5.5.5)</td>
<td>Type: enumeration</td>
</tr>
<tr>
<td></td>
<td>Default: InnoDB</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--default-time-zone=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td></td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type: string</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--delay-key-write[=name]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>delay-key-write</td>
</tr>
</tbody>
</table>
### Server Command Options

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>delay_key_write</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>enumeration</td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td>ON</td>
</tr>
<tr>
<td><strong>Valid Values</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>ON</td>
</tr>
<tr>
<td></td>
<td>OFF</td>
</tr>
<tr>
<td></td>
<td>ALL</td>
</tr>
</tbody>
</table>

Specify how to use delayed key writes. Delayed key writing causes key buffers not to be flushed between writes for `MyISAM` tables. `OFF` disables delayed key writes. `ON` enables delayed key writes for those tables that were created with the `DELAY_KEY_WRITE` option. `ALL` delays key writes for all `MyISAM` tables. See Section 8.11.2, "Tuning Server Parameters", and Section 15.3.1, "MyISAM Startup Options".

**Note**

If you set this variable to `ALL`, you should not use `MyISAM` tables from within another program (such as another MySQL server or `myisamchk`) when the tables are in use. Doing so leads to index corruption.

- **--des-key-file=file_name**

  **Command-Line Format** --des-key-file=file_name
  **Option-File Format** des-key-file

  Read the default DES keys from this file. These keys are used by the `DES_ENCRYPT()` and `DES_DECRYPT()` functions.

- **--enable-locking**

  This option is deprecated and was removed in MySQL 5.5.3. Use `--external-locking` instead.

- **--enable-named-pipe**

  **Command-Line Format** --enable-named-pipe
  **Option-File Format** enable-named-pipe
  **Platform Specific** Windows

  Enable support for named pipes. This option applies only on Windows.

- **--enable-pstack**

  **Command-Line Format** --enable-pstack
  **Option-File Format** enable-pstack

  **Permitted Values**
  **Type** boolean
Default | FALSE

This option is nonfunctional before MySQL 5.5.7 and removed in 5.5.7.

• **--engine-condition-pushdown={ON|OFF}**

<table>
<thead>
<tr>
<th>Deprecated</th>
<th>5.5.3, by optimizer_switch</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--engine-condition-pushdown</td>
</tr>
<tr>
<td>Option-File Format</td>
<td>engine-condition-pushdown</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>engine_condition_pushdown</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Sets the `engine_condition_pushdown` system variable. For more information, see Section 8.2.1.5, "Engine Condition Pushdown Optimization".

• **--event-scheduler[=value]**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--event-scheduler[=value]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>event-scheduler</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>event_scheduler</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Enable or disable, and start or stop, the event scheduler.

For detailed information, see The `--event-scheduler` Option [2618].

• **--exit-info[=flags], -T [flags]**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--exit-info[=flags]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>exit-info</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Default</td>
</tr>
<tr>
<td>Valid Values</td>
</tr>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Default</td>
</tr>
<tr>
<td>Valid Values</td>
</tr>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Default</td>
</tr>
</tbody>
</table>
This is a bit mask of different flags that you can use for debugging the `mysqld` server. Do not use this option unless you know exactly what it does!

- `--external-locking`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--external-locking</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>external-locking</code></td>
</tr>
</tbody>
</table>

Enable external locking (system locking), which is disabled by default as of MySQL 4.0. Note that if you use this option on a system on which `lockd` does not fully work (such as Linux), it is easy for `mysqld` to deadlock.

To disable external locking explicitly, use `--skip-external-locking`.

External locking affects only `MyISAM` table access. For more information, including conditions under which it can and cannot be used, see Section 8.10.5, “External Locking”.

- `--flush`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--flush</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>flush</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>flush</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Flush (synchronize) all changes to disk after each SQL statement. Normally, MySQL does a write of all changes to disk only after each SQL statement and lets the operating system handle the synchronizing to disk. See Section B.5.4.2, “What to Do If MySQL Keeps Crashing”.

- `--gdb`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--gdb</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>gdb</code></td>
</tr>
</tbody>
</table>

Install an interrupt handler for `SIGINT` (needed to stop `mysqld` with `^C` to set breakpoints) and disable stack tracing and core file handling. See Section 24.4, “Debugging and Porting MySQL”.

- `--general-log=[0|1]`
### Server Command Options

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--general-log</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>general-log</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>general_log</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Specify the initial general query log state. With no argument or an argument of 1, the `--general-log` option enables the log. If omitted or given with an argument of 0, the option disables the log.

- **--init-file=** file_name

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--init-file=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>init-file</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>init_file</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>file name</td>
</tr>
</tbody>
</table>

Read SQL statements from this file at startup. Each statement must be on a single line and should not include comments.

- **--innodb-** xxx

Set an option for the InnoDB storage engine. The InnoDB options are listed in Section 14.15, "InnoDB Startup Options and System Variables".

- **--install** [service_name]

(Windows only) Install the server as a Windows service that starts automatically during Windows startup. The default service name is MySQL if no service_name value is given. For more information, see Section 2.3.7.7, “Starting MySQL as a Windows Service”.

- **--install-manual** [service_name]

```
Note
If the server is started with the --defaults-file and --install options, --install must be first.
```
(Windows only) Install the server as a Windows service that must be started manually. It does not start automatically during Windows startup. The default service name is MySQL if no service_name value is given. For more information, see Section 2.3.7.7, “Starting MySQL as a Windows Service”.

Note

If the server is started with the --defaults-file and --install-manual options, --install-manual must be first.

- --language=lang_name, -L lang_name

| Deprecated | 5.5.0, by lc-messages-dir |
| Command-Line Format | --language=name |
| Option-File Format | language |
| System Variable Name | language |
| Variable Scope | Global |
| Dynamic Variable | No |
| Permitted Values |
| **Type** | directory name |
| **Default** | /usr/local/mysql/share/mysql/english/ |

The language to use for error messages. lang_name can be given as the language name or as the full path name to the directory where the language files are installed. See Section 10.2, “Setting the Error Message Language”.

As of MySQL 5.5, --lc-messages-dir and --lc-messages should be used rather than --language, which is deprecated and handled as an alias for --lc-messages-dir.

- --large-pages

| Command-Line Format | --large-pages |
| Option-File Format | large-pages |
| System Variable Name | large_pages |
| Variable Scope | Global |
| Dynamic Variable | No |
| Platform Specific | Linux |
| Permitted Values |
| **Type** | boolean |
| **Default** | FALSE |

Some hardware/operating system architectures support memory pages greater than the default (usually 4KB). The actual implementation of this support depends on the underlying hardware and operating system. Applications that perform a lot of memory accesses may obtain performance improvements by using large pages due to reduced Translation Lookaside Buffer (TLB) misses.
MySQL 5.5 supports the Linux implementation of large page support (which is called HugeTLB in Linux). See Section 8.11.4.2, “Enabling Large Page Support”. For Solaris support of large pages, see the description of the `--super-large-pages` option.

`--large-pages` is disabled by default.

- `--lc-messages=locale_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--lc-messages=name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>lc-messages</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>lc_messages</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>string</td>
</tr>
</tbody>
</table>

The locale to use for error messages. The server converts the argument to a language name and combines it with the value of the `--lc-messages-dir` to produce the location for the error message file. See Section 10.2, “Setting the Error Message Language”.

- `--lc-messages-dir=path`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--lc-messages-dir=path</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>lc-messages-dir</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>lc_messages_dir</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>directory name</td>
</tr>
</tbody>
</table>

The directory where error messages are located. The value is used together with the value of `--lc-messages` to produce the location for the error message file. See Section 10.2, “Setting the Error Message Language”.

- `--local-service`

(Command only) A `--local-service` option following the service name causes the server to run using the `LocalService` Windows account that has limited system privileges. This account is available only for Windows XP or newer. If both `--defaults-file` and `--local-service` are given following the service name, they can be in any order. See Section 2.3.7.7, “Starting MySQL as a Windows Service”.

- `--log[=file_name],-l [file_name]`

<table>
<thead>
<tr>
<th>Deprecated</th>
<th>5.1.29, by <code>general-log</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--log[=name]</code></td>
</tr>
<tr>
<td></td>
<td><code>-l</code></td>
</tr>
</tbody>
</table>
This option enables logging to the general query log, which contains entries that record client connections and SQL statements received from clients. The log output destination can be selected with the `--log-output` option. If you omit the file name, MySQL uses `host_name.log` as the file name. See Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”, and Section 5.2.3, “The General Query Log”.

The `--log` option is deprecated and is removed (along with the `log` system variable) in MySQL 5.6. Instead, use the `--general_log` option to enable the general query log and the `--general_log_file=file_name` option to set the general query log file name.

- `--log-error[=file_name]`

Log errors and startup messages to this file. See Section 5.2.2, “The Error Log”. If you omit the file name, MySQL uses `host_name.err`. If the file name has no extension, the server adds an extension of `.err`.

- `--log-isam[=file_name]`

Log all MyISAM changes to this file (used only when debugging MyISAM).

- `--log-long-format`
Log extra information to the binary log and slow query log, if they have been activated. For example, the user name and timestamp are logged for all queries. This option is deprecated, as it now represents the default logging behavior. (See the description for \(--log-short-format\).) The \(--log-queries-not-using-indexes\) option is available for the purpose of logging queries that do not use indexes to the slow query log. \(--log-long-format\) was removed in MySQL 5.5.3.

- \(--\text{log-output}=value,\ldots\)

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>(--\text{log-output}=name)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>log-output</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>log_output</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permit Values</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>set</td>
</tr>
<tr>
<td>Default</td>
<td>FILE</td>
</tr>
<tr>
<td>Valid Values</td>
<td>TABLE, FILE, NONE</td>
</tr>
</tbody>
</table>

This option determines the destination for general query log and slow query log output. The option value can be given as one or more of the words TABLE, FILE, or NONE. TABLE select logging to the general_log and slow_log tables in the mysql database as a destination. FILE selects logging to log files as a destination. NONE disables logging. If NONE is present in the option value, it takes precedence over any other words that are present. TABLE and FILE can both be given to select to both log output destinations.

This option selects log output destinations, but does not enable log output. To do that, use the \(--\text{general_log}\) and \(--\text{slow_query_log}\) options. For FILE logging, the \(--\text{general_log_file}\) and \(--\text{slow_query_log_file}\) options determine the log file location. For more information, see Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”.

- \(--\text{log-queries-not-using-indexes}\)

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>(--\text{log-queries-not-using-indexes})</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>log-queries-not-using-indexes</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>log_queries_not_using_indexes</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permit Values</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>OFF</td>
</tr>
</tbody>
</table>

If you are using this option with the slow query log enabled, queries that are expected to retrieve all rows are logged. See Section 5.2.5, “The Slow Query Log”. This option does not necessarily mean that no index is used. For example, a query that uses a full index scan uses an index but would be logged because the index would not limit the number of rows.
Server Command Options

- **--log-short-format**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--log-short-format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>log-short-format</td>
</tr>
</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Log less information to the binary log and slow query log, if they have been activated.

- **--log-slow-admin-statements**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--log-slow-admin-statements</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>log-slow-admin-statements</td>
</tr>
</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Include slow administrative statements in the statements written to the slow query log. Administrative statements include ALTER TABLE, ANALYZE TABLE, CHECK TABLE, CREATE INDEX, DROP INDEX, OPTIMIZE TABLE, and REPAIR TABLE.

- **--log-slow-queries [=file_name]**

| Deprecated | 5.1.29, by slow-query-log |
| Command-Line Format | --log-slow-queries [=name] |
| Option-File Format   | log-slow-queries          |
| System Variable Name | log_slow_queries          |
| Variable Scope       | Global                     |
| Dynamic Variable     | Yes                        |

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>boolean</th>
</tr>
</thead>
</table>

This option enables logging to the slow query log, which contains entries for all queries that have taken more than long_query_time seconds to execute. See the descriptions of the --log-long-format and --log-short-format options for details. The log output destination can be selected with the --log-output option. If you omit the file name, MySQL uses host_name-slow.log as the file name. See Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”, and Section 5.2.5, “The Slow Query Log”.

The --log-slow-queries option is deprecated and is removed (along with the log_slow_queries system variable) in MySQL 5.6. Instead, use the --slow_query_log option to enable the slow query log and the --slow_query_log_file=file_name option to set the slow query log file name.

- **--log-tc= file_name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--log-tc=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>log-tc</td>
</tr>
</tbody>
</table>
The name of the memory-mapped transaction coordinator log file (for XA transactions that affect multiple storage engines when the binary log is disabled). The default name is `tc.log`. The file is created under the data directory if not given as a full path name. Currently, this option is unused.

- `--log-tc-size=size`

The size in bytes of the memory-mapped transaction coordinator log. The default size is 24KB.

- `--log-warnings[=level],-W [level]`
Print out warnings such as *Aborted connection...* to the error log. This option is enabled (1) by default. To disable it, use `--log-warnings=0`. Specifying the option without a *level* value increments the current value by 1. Enabling this option by setting it greater than 0 is recommended, for example, if you use replication (you get more information about what is happening, such as messages about network failures and reconnections). If the value is greater than 1, aborted connections are written to the error log, and access-denied errors for new connection attempts are written. See Section B.5.2.11, “Communication Errors and Aborted Connections”.

If a slave server was started with `--log-warnings` enabled, the slave prints messages to the error log to provide information about its status, such as the binary log and relay log coordinates where it starts its job, when it is switching to another relay log, when it reconnects after a disconnect, and so forth. The server logs messages about statements that are unsafe for statement-based logging if `--log-warnings` is greater than 0.

- **--low-priority-updates**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--low-priority-updates</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>low-priority-updates</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>low_priority_updates</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

  Give table-modifying operations (*INSERT*, *REPLACE*, *DELETE*, *UPDATE*) lower priority than selects. This can also be done using `{INSERT | REPLACE | DELETE | UPDATE} LOW_PRIORITY ...` to lower the priority of only one query, or by `SET LOW_PRIORITY_UPDATES=1` to change the priority in one thread. This affects only storage engines that use only table-level locking (*MyISAM*, *MEMORY*, *MERGE*). See Section 8.10.2, “Table Locking Issues”.

- **--min-examined-row-limit=number**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--min-examined-row-limit=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>min-examined-row-limit</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>min_examined_row_limit</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Platform</td>
<td></td>
</tr>
<tr>
<td>Bit Size</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td></td>
</tr>
</tbody>
</table>
When this option is set, queries which examine fewer than \textit{number} rows are not written to the slow query log. The default is 0.

- \texttt{--memlock}

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>\texttt{--memlock}</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>\texttt{memlock}</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>\texttt{locked_in_memory}</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

- \textbf{Permitted Values}
  - \textbf{Type}: boolean
  - \textbf{Default}: FALSE

Lock the \texttt{mysqld} process in memory. This option might help if you have a problem where the operating system is causing \texttt{mysqld} to swap to disk.

\texttt{--memlock} works on systems that support the \texttt{mlockall()} system call; this includes Solaris, most Linux distributions that use a 2.4 or newer kernel, and perhaps other Unix systems. On Linux systems, you can tell whether or not \texttt{mlockall()} (and thus this option) is supported by checking to see whether or not it is defined in the system \texttt{mman.h} file, like this:

\begin{verbatim}
shell> grep mlockall /usr/include/sys/mman.h
\end{verbatim}

If \texttt{mlockall()} is supported, you should see in the output of the previous command something like the following:

\begin{verbatim}
extern int mlockall (int __flags) __THROW;
\end{verbatim}

\textbf{Important}

Use of this option may require you to run the server as \texttt{root}, which, for reasons of security, is normally not a good idea. See Section 6.1.5, “How to Run MySQL as a Normal User”.

On Linux and perhaps other systems, you can avoid the need to run the server as \texttt{root} by changing the \texttt{limits.conf} file. See the notes regarding the memlock limit in Section 8.11.4.2, “Enabling Large Page Support”.
You must not try to use this option on a system that does not support the `mlockall()` system call; if you do so, `mysqld` will very likely crash as soon as you try to start it.

- `--myisam-block-size=N`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--myisam-block-size=</code>#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>myisam-block-size</code></td>
</tr>
</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>1024</td>
</tr>
<tr>
<td>Range</td>
<td>1024 .. 16384</td>
</tr>
</tbody>
</table>

The block size to be used for MyISAM index pages.

- `--myisam-recover[=option[,option]...]`

This option is renamed as of MySQL 5.5.3 to `--myisam-recover-options`. See the description of that option for more information.

- `--myisam-recover-options[=option[,option]...]`

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.5.3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--myisam-recover-options[=name]</code></td>
</tr>
<tr>
<td>Option-File Format</td>
<td><code>myisam-recover-options</code></td>
</tr>
</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>enumeration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>OFF</td>
</tr>
<tr>
<td>Valid Values</td>
<td>OFF, DEFAULT, BACKUP, FORCE, QUICK</td>
</tr>
</tbody>
</table>

Set the MyISAM storage engine recovery mode. The option value is any combination of the values of OFF, DEFAULT, BACKUP, FORCE, or QUICK. If you specify multiple values, separate them by commas. Specifying the option with no argument is the same as specifying DEFAULT, and specifying with an explicit value of "" disables recovery (same as a value of OFF). If recovery is enabled, each time mysqld opens a MyISAM table, it checks whether the table is marked as crashed or was not closed properly. (The last option works only if you are running with external locking disabled.) If this is the case, mysqld runs a check on the table. If the table was corrupted, mysqld attempts to repair it.

The following options affect how the repair works.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFF</td>
<td>No recovery.</td>
</tr>
<tr>
<td>DEFAULT</td>
<td>Recovery without backup, forcing, or quick checking.</td>
</tr>
</tbody>
</table>
Server Command Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BACKUP</td>
<td>If the data file was changed during recovery, save a backup of the <code>tbl_name.MYD</code> file as <code>tbl_name-datetime.BAK</code>.</td>
</tr>
<tr>
<td>FORCE</td>
<td>Run recovery even if we would lose more than one row from the <code>.MYD</code> file.</td>
</tr>
<tr>
<td>QUICK</td>
<td>Do not check the rows in the table if there are not any delete blocks.</td>
</tr>
</tbody>
</table>

Before the server automatically repairs a table, it writes a note about the repair to the error log. If you want to be able to recover from most problems without user intervention, you should use the options `BACKUP, FORCE`. This forces a repair of a table even if some rows would be deleted, but it keeps the old data file as a backup so that you can later examine what happened.

This option was named `--myisam-recover`, before MySQL 5.5.3. The old option name still works because it is recognized as an unambiguous prefix of the new name, `--myisam-recover-options`.

(Option prefix recognition occurs as described in Section 4.2.3, “Specifying Program Options”.)

The option value `OFF` is available as of MySQL 5.5.3.

See Section 15.3.1, “MyISAM Startup Options”.

- `--no-defaults`
  Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

- `--old-alter-table`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--old-alter-table</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>old-alter-table</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>old_alter_table</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

When this option is given, the server does not use the optimized method of processing an `ALTER TABLE` operation. It reverts to using a temporary table, copying over the data, and then renaming the temporary table to the original, as used by MySQL 5.0 and earlier. For more information on the operation of `ALTER TABLE`, see Section 13.1.7, “ALTER TABLE Syntax”.

- `--old-style-user-limits`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--old-style-user-limits</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>old-style-user-limits</code></td>
</tr>
</tbody>
</table>

When this option is given, the server does not use the optimized method of processing an `ALTER TABLE` operation. It reverts to using a temporary table, copying over the data, and then renaming the temporary table to the original, as used by MySQL 5.0 and earlier. For more information on the operation of `ALTER TABLE`, see Section 13.1.7, “ALTER TABLE Syntax”.

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Default</td>
</tr>
</tbody>
</table>
Server Command Options

Enable old-style user limits. (Before MySQL 5.0.3, account resource limits were counted separately for each host from which a user connected rather than per account row in the `user` table.) See Section 6.3.4, “Setting Account Resource Limits”.

• **--one-thread**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--one-thread</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>one-thread</td>
</tr>
</tbody>
</table>

Only use one thread (for debugging under Linux). This option is available only if the server is built with debugging enabled. See Section 24.4, “Debugging and Porting MySQL”.

This option is deprecated and is removed in MySQL 5.6. Use `--thread_handling=no-threads` instead.

• **--open-files-limit=count**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--open-files-limit=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>open-files-limit</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>open_files_limit</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 .. platform dependent</td>
</tr>
</tbody>
</table>

Changes the number of file descriptors available to `mysqld`. You should try increasing the value of this option if `mysqld` gives you the error `Too many open files`. `mysqld` uses the option value to reserve descriptors with `setrlimit()`.

Internally, the maximum value for this option is the maximum unsigned integer value, but the actual maximum is platform dependent. If the requested number of file descriptors cannot be allocated, `mysqld` writes a warning to the error log.

`mysqld` may attempt to allocate more than the requested number of descriptors (if they are available), using the values of `max_connections` and `table_open_cache` to estimate whether more descriptors will be needed.

On Unix, the value cannot be set less than `ulimit -n`.

• **--partition[=value]**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--partition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>partition</td>
</tr>
<tr>
<td>Disabled by</td>
<td>skip-partition</td>
</tr>
</tbody>
</table>

Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>ON</td>
</tr>
</tbody>
</table>

Enables or disables user-defined partitioning support in the MySQL Server.
• **--pid-file=path**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--pid-file=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>pid-file</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>pid_file</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>file name</td>
</tr>
</tbody>
</table>

The path name of the process ID file. The server creates the file in the data directory unless an absolute path name is given to specify a different directory. This file is used by other programs such as mysqld_safe to determine the server's process ID.

• **--plugin-xxx**

Specifies an option that pertains to a server plugin. For example, many storage engines can be built as plugins, and for such engines, options for them can be specified with a **--plugin** prefix. Thus, the **--innodb_file_per_table** option for InnoDB can be specified as **--plugin-innodb_file_per_table**.

For boolean options that can be enabled or disabled, the **--skip** prefix and other alternative formats are supported as well (see Section 4.2.5, "Program Option Modifiers"). For example, **--skip-plugin-innodb_file_per_table** disables **innodb_file_per_table**.

The rationale for the **--plugin** prefix is that it enables plugin options to be specified unambiguously if there is a name conflict with a built-in server option. For example, were a plugin writer to name a plugin "sql" and implement a "mode" option, the option name might be **--sql-mode**, which would conflict with the built-in option of the same name. In such cases, references to the conflicting name are resolved in favor of the built-in option. To avoid the ambiguity, users can specify the plugin option as **--plugin-sql-mode**. Use of the **--plugin** prefix for plugin options is recommended to avoid any question of ambiguity.

• **--plugin-load=plugin_list**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--plugin-load=plugin_list</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>plugin-load</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>string</td>
</tr>
</tbody>
</table>

This option tells the server to load the named plugins at startup. The option value is a semicolon-separated list of **name=plugin_library** pairs. Each **name** is the name of the plugin, and **plugin_library** is the name of the shared library that contains the plugin code. Each library file must be located in the directory named by the **plugin_dir** system variable. For example, if plugins named myplug1 and myplug2 have library files myplug1.so and myplug2.so, use this option to load them at startup:

```
shell> mysqld --plugin-load="myplug1=myplug1.so;myplug2=myplug2.so"
```

Quotes are used around the argument value here because semicolon (;) is interpreted as a special character by some command interpreters. (Unix shells treat it as a command terminator, for example.)
All plugins to load must be named in the same `--plugin-load` option. If multiple `--plugin-load` options are given, only the last one is used.

If a plugin library is named without any preceding plugin name, the server loads all plugins in the library.

Each plugin is loaded for a single invocation of `mysqld` only. After a restart, the plugin is not loaded unless `--plugin-load` is used again. This is in contrast to `INSTALL PLUGIN`, which adds an entry to the `mysql.plugins` table to cause the plugin to be loaded for every normal server startup.

Under normal startup, the server determines which plugins to load by reading the `mysql.plugins` system table. If the server is started with the `--skip-grant-tables` option, it does not consult the `mysql.plugins` table and does not load plugins listed there. `--plugin-load` enables plugins to be loaded even when `--skip-grant-tables` is given. `--plugin-load` also enables plugins to be loaded at startup under configurations when plugins cannot be loaded at runtime.

For additional information about plugin loading, see Section 5.1.8.1, “Installing and Uninstalling Plugins”.

- `--port=port_num, -P port_num`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--port=</code>#</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><code>-P</code></td>
</tr>
</tbody>
</table>

| Option-File Format | `port`                          |

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th><code>port</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Default</td>
</tr>
<tr>
<td>Range</td>
</tr>
</tbody>
</table>

The port number to use when listening for TCP/IP connections. The port number must be 1024 or higher unless the server is started by the `root` system user.

- `--port-open-timeout=num`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--port-open-timeout=</code>#</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><code>port-open-timeout</code></td>
</tr>
</tbody>
</table>

| Option-File Format | `port-open-timeout`     |

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Default</td>
</tr>
</tbody>
</table>

On some systems, when the server is stopped, the TCP/IP port might not become available immediately. If the server is restarted quickly afterward, its attempt to reopen the port can fail. This option indicates how many seconds the server should wait for the TCP/IP port to become free if it cannot be opened. The default is not to wait.

- `--print-defaults`

Print the program name and all options that it gets from option files.
Server Command Options

- **--remove [service_name]**

  Command-Line Format
  
  --remove [service_name]

  (Windows only) Remove a MySQL Windows service. The default service name is `MySQL` if no `service_name` value is given. For more information, see Section 2.3.7.7, “Starting MySQL as a Windows Service”.

- **--safe-mode**

<table>
<thead>
<tr>
<th>Deprecated</th>
<th>5.5.26</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--safe-mode</td>
</tr>
<tr>
<td>Option-File Format</td>
<td>safe-mode</td>
</tr>
</tbody>
</table>

  Skip some optimization stages. This option is deprecated and is removed in MySQL 5.6.

- **--safe-show-database**

<table>
<thead>
<tr>
<th>Deprecated</th>
<th>4.0.2</th>
<th>Removed</th>
<th>5.5.3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--safe-show-database</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Option-File Format</td>
<td>safe-show-database</td>
<td></td>
<td></td>
</tr>
<tr>
<td>System Variable Name</td>
<td>safe_show_database</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

  This option is deprecated and does not do anything because there is a `SHOW DATABASES` privilege that can be used to control access to database names on a per-account basis. See Section 6.2.1, “Privileges Provided by MySQL”. `--safe-show-database` was removed in MySQL 5.5.3.

- **--safe-user-create**

  | Command-Line Format | --safe-user-create |
  | Option-File Format | safe-user-create |
  | Permitted Values |
  | Type | boolean |
  | Default | FALSE |

  If this option is enabled, a user cannot create new MySQL users by using the `GRANT` statement unless the user has the `INSERT` privilege for the `mysql.user` table or any column in the table. If you want a user to have the ability to create new users that have those privileges that the user has the right to grant, you should grant the user the following privilege:

  ```sql
  GRANT INSERT(user) ON mysql.user TO 'user_name'@'host_name';
  ```

  This ensures that the user cannot change any privilege columns directly, but has to use the `GRANT` statement to give privileges to other users.
Server Command Options

• **--secure-auth**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--secure-auth</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>secure-auth</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>secure_auth</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>OFF</td>
</tr>
</tbody>
</table>

This option causes the server to block connections by clients that attempt to use accounts that have passwords stored in the old (pre-4.1) format. Use it to prevent all use of passwords employing the old format (and hence insecure communication over the network).

Server startup fails with an error if this option is enabled and the privilege tables are in pre-4.1 format. See Section B.5.2.4, "Client does not support authentication protocol".

The mysql client also has a **--secure-auth** option, which prevents connections to a server if the server requires a password in old format for the client account.

---

**Note**

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided.

• **--secure-file-priv=path**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--secure-file-priv=path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>secure-file-priv</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>secure_file_priv</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>string</td>
</tr>
</tbody>
</table>

This option limits the effect of the LOAD_FILE() function and the LOAD DATA and SELECT ... INTO OUTFILE statements to work only with files in the specified directory.

• **--shared-memory**

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>shared_memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
</tbody>
</table>

Enable shared-memory connections by local clients. This option is available only on Windows.

• **--shared-memory-base-name=name**
The name of shared memory to use for shared-memory connections. This option is available only on Windows. The default name is `MYSQL`. The name is case sensitive.

- **--skip-concurrent-insert**

  Turn off the ability to select and insert at the same time on MyISAM tables. (This is to be used only if you think you have found a bug in this feature.) See Section 8.10.3, “Concurrent Inserts”.

- **--skip-event-scheduler**

  Turns the Event Scheduler OFF. This is not the same as disabling the Event Scheduler, which requires setting `--event-scheduler=DISABLED`; see The `--event-scheduler` Option [2618], for more information.

- **--skip-grant-tables**

  This option causes the server to start without using the privilege system at all, which gives anyone with access to the server unrestricted access to all databases. You can cause a running server to start using the grant tables again by executing `mysqladmin flush-privileges` or `mysqladmin reload` command from a system shell, or by issuing a MySQL `FLUSH PRIVILEGES` statement after connecting to the server. This option also suppresses loading of plugins that were installed with the `INSTALL PLUGIN` statement, user-defined functions (UDFs), and scheduled events. To cause plugins to be loaded anyway, use the `--plugin-load` option.

  Note that `FLUSH PRIVILEGES` might be executed implicitly by other actions performed after startup. For example, `mysql_upgrade` flushes the privileges during the upgrade procedure.

- **--skip-host-cache**

  Disable use of the internal host cache for faster name-to-IP resolution. In this case, the server performs a DNS lookup every time a client connects. See Section 8.11.5.2, “DNS Lookup Optimization and the Host Cache”.

- **--skip-innodb**

  Disable the InnoDB storage engine. In this case, if the default storage engine is InnoDB, the server will not start unless you also use `--default-storage-engine` to set the default to some other engine.

- **--skip-name-resolve**

  Do not resolve host names when checking client connections. Use only IP addresses. If you use this option, all Host column values in the grant tables must be IP addresses or `localhost`. See Section 8.11.5.2, “DNS Lookup Optimization and the Host Cache”.

---

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>shared_memory_base_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
</tbody>
</table>
Depending on the network configuration of your system and the Host values for your accounts, clients may need to connect using an explicit --host option, such as --host=localhost, --host=127.0.0.1, or --host=:1.

- **--skip-networking**

Do not listen for TCP/IP connections at all. All interaction with mysql must be made using named pipes or shared memory (on Windows) or Unix socket files (on Unix). This option is highly recommended for systems where only local clients are permitted. See Section 8.11.5.2, “DNS Lookup Optimization and the Host Cache”.

- **--skip-partition**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--skip-partition</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>--disable-partition</td>
</tr>
</tbody>
</table>

Disables user-defined partitioning. Partitioned tables can be seen using SHOW TABLES or by querying the INFORMATION_SCHEMA.TABLES table, but cannot be created or modified, nor can data in such tables be accessed. All partition-specific columns in the INFORMATION_SCHEMA.PARTITIONS table display NULL.

Since DROP TABLE removes table definition (.frm) files, this statement works on partitioned tables even when partitioning is disabled using the option. The statement, however, does not remove .par files associated with partitioned tables in such cases. For this reason, you should avoid dropping partitioned tables with partitioning disabled, or take action to remove the orphaned .par files manually.

- **--ssl**

Options that begin with --ssl specify whether to permit clients to connect using SSL and indicate where to find SSL keys and certificates. See Section 6.3.9.4, “SSL Command Options”.

- **--standalone**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--standalone</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>standalone</td>
</tr>
</tbody>
</table>

Available on Windows only; instructs the MySQL server not to run as a service.

- **--super-large-pages**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.5.3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--super-large-pages</td>
</tr>
<tr>
<td>Option-File Format</td>
<td>super-large-pages</td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Solaris</td>
</tr>
</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>FALSE</td>
</tr>
</tbody>
</table>
Standard use of large pages in MySQL attempts to use the largest size supported, up to 4MB. Under Solaris, a “super large pages” feature enables uses of pages up to 256MB. This feature is available for recent SPARC platforms. It can be enabled or disabled by using the `--super-large-pages` or `--skip-super-large-pages` option.

- `--symbolic-links,--skip-symbolic-links`

Enable or disable symbolic link support. This option has different effects on Windows and Unix:

- On Windows, enabling symbolic links enables you to establish a symbolic link to a database directory by creating a `db_name.sym` file that contains the path to the real directory. See Using Symbolic Links for Databases on Windows.

- On Unix, enabling symbolic links means that you can link a MyISAM index file or data file to another directory with the `INDEX DIRECTORY` or `DATA DIRECTORY` options of the `CREATE TABLE` statement. If you delete or rename the table, the files that its symbolic links point to also are deleted or renamed. See Using Symbolic Links for MyISAM Tables on Unix.

- `--skip-safemalloc`

Previously, if MySQL was configured with full debugging support, all MySQL programs check for memory overruns during each memory allocation and memory freeing operation. This checking is very slow, so for the server you can avoid it when you do not need it by using the `--skip-safemalloc` option. `safemalloc`, along with this option, was removed in MySQL 5.5.6.

- `--skip-show-database`

This option sets the `skip_show_database` system variable that controls who is permitted to use the `SHOW DATABASES` statement. See Section 5.1.4, “Server System Variables”.

- `--skip-stack-trace`
Do not write stack traces. This option is useful when you are running `mysqld` under a debugger. On some systems, you also must use this option to get a core file. See Section 24.4, “Debugging and Porting MySQL”.

- `--skip-thread-priority`

<table>
<thead>
<tr>
<th>Deprecated</th>
<th>5.1.29</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--skip-thread-priority</code></td>
</tr>
<tr>
<td>Option-File Format</td>
<td><code>skip-thread-priority</code></td>
</tr>
</tbody>
</table>

Disable using thread priorities for faster response time. This option is deprecated and is removed in MySQL 5.6.

- `--slow-query-log={0|1}`

| Command-Line Format | `--slow-query-log` |
| Option-File Format | `slow-query-log` |
| System Variable Name | `slow_query_log` |
| Variable Scope | Global |
| Dynamic Variable | Yes |
| Permitted Values | Type: boolean; Default: OFF |

Specify the initial slow query log state. With no argument or an argument of 1, the `--slow-query-log` option enables the log. If omitted or given with an argument of 0, the option disables the log.

- `--slow-start-timeout=timeout`

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.5.20</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slow-start-timeout=#</code></td>
</tr>
<tr>
<td>Option-File Format</td>
<td><code>slow-start-timeout</code></td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type: numeric; Default: 15000</td>
</tr>
</tbody>
</table>

This option controls the Windows service control manager's service start timeout. The value is the maximum number of milliseconds that the service control manager waits before trying to kill the windows service during startup. The default value is 15000 (15 seconds). If the MySQL service takes too long to start, you may need to increase this value. A value of 0 means there is no timeout.

- `--socket=path`

| Command-Line Format | `--socket=name` |
| Option-File Format | `socket` |
| System Variable Name | `socket` |
On Unix, this option specifies the Unix socket file to use when listening for local connections. The default value is `/tmp/mysql.sock`. If this option is given, the server creates the file in the data directory unless an absolute path name is given to specify a different directory. On Windows, the option specifies the pipe name to use when listening for local connections that use a named pipe. The default value is `MySQL` (not case sensitive).

- `--sql-mode=value[,value[,value...]]`

### Server Command Options

<table>
<thead>
<tr>
<th>Variable Scope</th>
<th>Global</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>

</table>
Server Command Options

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--sysdate-is-now</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>sysdate-is-now</td>
</tr>
</tbody>
</table>

Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

SYSDATE() by default returns the time at which it executes, not the time at which the statement in which it occurs begins executing. This differs from the behavior of NOW(). This option causes SYSDATE() to be an alias for NOW(). For information about the implications for binary logging and replication, see the description for SYSDATE() in Section 12.7, “Date and Time Functions” and for SET TIMESTAMP in Section 5.1.4, “Server System Variables”.

• --tc-heuristic-recover={COMMIT|ROLLBACK}

Command-Line Format       --tc-heuristic-recover=name
Option-File Format         tc-heuristic-recover

Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>enumeration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>COMMIT</td>
</tr>
<tr>
<td>Valid Values</td>
<td>COMMIT</td>
</tr>
</tbody>
</table>

The type of decision to use in the heuristic recovery process. Currently, this option is unused.

• --temp-pool

Command-Line Format       --temp-pool
Option-File Format         temp-pool

Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

This option causes most temporary files created by the server to use a small set of names, rather than a unique name for each new file. This works around a problem in the Linux kernel dealing with creating many new files with different names. With the old behavior, Linux seems to “leak” memory, because it is...
being allocated to the directory entry cache rather than to the disk cache. This option is ignored except on Linux.

- **--transaction-isolation=level**

```
<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--transaction-isolation=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>transaction-isolation</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type: enumeration</td>
</tr>
<tr>
<td>Default: REPEATABLE-READ</td>
</tr>
<tr>
<td>Valid Values</td>
</tr>
<tr>
<td>REPEATABLE-READ</td>
</tr>
<tr>
<td>READ-COMMITTED</td>
</tr>
<tr>
<td>REPEATABLE-READ</td>
</tr>
<tr>
<td>SERIALIZABLE</td>
</tr>
</tbody>
</table>
```

Sets the default transaction isolation level. The `level` value can be `READ-UNCOMMITTED`, `READ-COMMITTED`, `REPEATABLE-READ`, or `SERIALIZABLE`. See Section 13.3.6, “SET TRANSACTION Syntax”.

The default transaction isolation level can also be set at runtime using the `SET TRANSACTION` statement or by setting the `tx_isolation` system variable.

- **--tmpdir=path, -t path**

```
<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--tmpdir=path</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-t</td>
</tr>
</tbody>
</table>

| System Variable Name | tmpdir        |
| Variable Scope       | Global        |
| Dynamic Variable     | No            |

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type: directory name</td>
</tr>
</tbody>
</table>
```

The path of the directory to use for creating temporary files. It might be useful if your default `/tmp` directory resides on a partition that is too small to hold temporary tables. This option accepts several paths that are used in round-robin fashion. Paths should be separated by colon characters (";") on Unix and semicolon characters (";") on Windows. If the MySQL server is acting as a replication slave, you should not set `--tmpdir` to point to a directory on a memory-based file system or to a directory that is cleared when the server host restarts. For more information about the storage location of temporary files, see Section B.5.4.4, “Where MySQL Stores Temporary Files”. A replication slave needs some of its temporary files to survive a machine restart so that it can replicate temporary tables or `LOAD DATA INFILE` operations. If files in the temporary file directory are lost when the server restarts, replication fails.

- **--user={user_name|user_id}, -u {user_name|user_id}**

```
<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--user=name</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-u name</td>
</tr>
</tbody>
</table>
```

Option-File Format

<table>
<thead>
<tr>
<th>Permit Values</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>user</td>
<td>string</td>
</tr>
</tbody>
</table>

Run the mysqld server as the user having the name user_name or the numeric user ID user_id. (“User” in this context refers to a system login account, not a MySQL user listed in the grant tables.)

This option is **mandatory** when starting mysqld as root. The server changes its user ID during its startup sequence, causing it to run as that particular user rather than as root. See Section 6.1.1, “Security Guidelines”.

To avoid a possible security hole where a user adds a --user=root option to a my.cnf file (thus causing the server to run as root), mysqld uses only the first --user option specified and produces a warning if there are multiple --user options. Options in /etc/my.cnf and $MYSQL_HOME/my.cnf are processed before command-line options, so it is recommended that you put a --user option in /etc/my.cnf and specify a value other than root. The option in /etc/my.cnf is found before any other --user options, which ensures that the server runs as a user other than root, and that a warning results if any other --user option is found.

- **--verbose, -v**
  Use this option with the --help option for detailed help.

- **--version, -V**
  Display version information and exit.

You can assign a value to a server system variable by using an option of the form --var_name=value. For example, --key_buffer_size=32M sets the key_buffer_size variable to a value of 32MB.

Note that when you assign a value to a variable, MySQL might automatically correct the value to stay within a given range, or adjust the value to the closest permissible value if only certain values are permitted.

If you want to restrict the maximum value to which a variable can be set at runtime with SET, you can define this by using the --maximum-var_name=value command-line option.

You can change the values of most system variables for a running server with the SET statement. See Section 13.7.4, “SET Syntax”.

Section 5.1.4, “Server System Variables”, provides a full description for all variables, and additional information for setting them at server startup and runtime. Section 8.11.2, “Tuning Server Parameters”, includes information on optimizing the server by tuning system variables.

### 5.1.4 Server System Variables

The MySQL server maintains many system variables that indicate how it is configured. Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. Most of them can be changed dynamically while the server is running by means of the SET statement, which enables you to modify operation of the server without having to stop and restart it. You can refer to system variable values in expressions.

There are several ways to see the names and values of system variables:

- To see the values that a server will use based on its compiled-in defaults and any option files that it reads, use this command:
MySQL --verbose --help

- To see the values that a server will use based on its compiled-in defaults, ignoring the settings in any option files, use this command:

MySQL --no-defaults --verbose --help

- To see the current values used by a running server, use the SHOW VARIABLES statement.

This section provides a description of each system variable. Variables with no version indicated are present in all MySQL 5.5 releases. For historical information concerning their implementation, please see http://dev.mysql.com/doc/refman/5.0/en/ and http://dev.mysql.com/doc/refman/4.1/en/.

The following table lists all available system variables.

### Table 5.2 System Variable Summary

a) This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

b) This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

For additional system variable information, see these sections:

- Section 5.1.5, “Using System Variables”, discusses the syntax for setting and displaying system variable values.
- Section 5.1.5.2, “Dynamic System Variables”, lists the variables that can be set at runtime.
- Information on tuning system variables can be found in Section 8.11.2, “Tuning Server Parameters”.
- Section 14.15, “InnoDB Startup Options and System Variables”, lists InnoDB system variables.
- Section 18.3.4.3, “MySQL Cluster System Variables”, lists system variables which are specific to MySQL Cluster.
- For information on server system variables specific to replication, see Section 17.1.3, “Replication and Binary Logging Options and Variables”.

515
Some system variables control the size of buffers or caches. For a given buffer, the server might need to allocate internal data structures. These structures typically are allocated from the total memory allocated to the buffer, and the amount of space required might be platform dependent. This means that when you assign a value to a system variable that controls a buffer size, the amount of space actually available might differ from the value assigned. In some cases, the amount might be less than the value assigned. It is also possible that the server will adjust a value upward. For example, if you assign a value of 0 to a variable for which the minimal value is 1024, the server will set the value to 1024.

Values for buffer sizes, lengths, and stack sizes are given in bytes unless otherwise specified.

Some system variables take file name values. Unless otherwise specified, the default file location is the data directory if the value is a relative path name. To specify the location explicitly, use an absolute path name. Suppose that the data directory is /var/mysql/data. If a file-valued variable is given as a relative path name, it will be located under /var/mysql/data. If the value is an absolute path name, its location is as given by the path name.

This variable is available only if the **authentication_windows** Windows authentication plugin is enabled and debugging code is enabled. See Section 6.3.7.4, “The Windows Native Authentication Plugin”.

This variable sets the logging level for the Windows authentication plugin. The following table shows the permitted values.

<tr>
<td>2</td>
<td>Log level 1 messages and warning messages</td>
</tr>
<tr>
<td>3</td>
<td>Log level 2 messages and information notes</td>
</tr>
<tr>
<td>4</td>
<td>Log level 3 messages and debug messages</td>
</tr>
</tbody>
</table>
This variable was added in MySQL 5.5.16.

- **authentication_windows_use_principal_name**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.5.16</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Command-Line Format</strong></td>
<td><code>--authentication_windows_use_principal_name</code></td>
</tr>
<tr>
<td><strong>Option-File Format</strong></td>
<td><code>authentication_windows_use_principal_name</code></td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>boolean</td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td>ON</td>
</tr>
</tbody>
</table>

This variable is available only if the `authentication_windows` Windows authentication plugin is enabled. See Section 6.3.7.4, “The Windows Native Authentication Plugin”.

A client that authenticates using the `InitSecurityContext()` function should provide a string identifying the service to which it connects (`targetName`). MySQL uses the principal name (UPN) of the account under which the server is running. The UPN has the form `user_id@computer_name` and need not be registered anywhere to be used. This UPN is sent by the server at the beginning of authentication handshake.

This variable controls whether the server sends the UPN in the initial challenge. By default, the variable is enabled. For security reasons, it can be disabled to avoid sending the server's account name to a client in clear text. If the variable is disabled, the server always sends a `0x00` byte in the first challenge, the client does not specify `targetName`, and as a result, NTLM authentication is used.

If the server fails to obtain its UPN (which will happen primarily in environments that do not support Kerberos authentication), the UPN is not sent by the server and NTLM authentication is used.

This variable was added in MySQL 5.5.16.

- **autocommit**

| **Command-Line Format** | `--autocommit[=#]` from 5.5.8 |
| **Option-File Format** | `autocommit` from 5.5.8 |
| **System Variable Name** | `autocommit` |
| **Variable Scope** | Global, Session |
| **Dynamic Variable** | Yes |

| **Permitted Values** | |
| **Type** | boolean |
| **Default** | ON |

The autocommit mode. If set to 1, all changes to a table take effect immediately. If set to 0, you must use `COMMIT` to accept a transaction or `ROLLBACK` to cancel it. If `autocommit` is 0 and you change it to 1, MySQL performs an automatic `COMMIT` of any open transaction. Another way to begin a transaction is to use a `START TRANSACTION` or `BEGIN` statement. See Section 13.3.1, "START TRANSACTION, COMMIT, and ROLLBACK Syntax".
By default, client connections begin with `autocommit` set to 1. To cause clients to begin with a default of 0, set the global `autocommit` value by starting the server with the `--autocommit=0` option. To set the variable using an option file, include these lines:

```
[mysqld]
atomsmit=0
```

Before MySQL 5.5.8, the global `autocommit` value cannot be set at startup. As a workaround, set the `init_connect` system variable:

```
SET GLOBAL init_connect='SET autocommit=0';
```

The `init_connect` variable can also be set on the command line or in an option file. To set the variable as just shown using an option file, include these lines:

```
[mysqld]
init_connect='SET autocommit=0'
```

The content of `init_connect` is not executed for users that have the `SUPER` privilege (unlike the effect of setting the global `autocommit` value at startup).

- `automatic_sp_privileges`

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>automatic_sp_privileges</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

When this variable has a value of 1 (the default), the server automatically grants the `EXECUTE` and `ALTER ROUTINE` privileges to the creator of a stored routine, if the user cannot already execute and alter or drop the routine. (The `ALTER ROUTINE` privilege is required to drop the routine.) The server also automatically drops those privileges from the creator when the routine is dropped. If `automatic_sp_privileges` is 0, the server does not automatically add or drop these privileges.

The creator of a routine is the account used to execute the `CREATE` statement for it. This might not be the same as the account named as the `DEFINER` in the routine definition.

See also Section 20.2.2, “Stored Routines and MySQL Privileges”.

- `back_log`

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>back_log</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>50</td>
</tr>
</tbody>
</table>
The number of outstanding connection requests MySQL can have. This comes into play when the main MySQL thread gets very many connection requests in a very short time. It then takes some time (although very little) for the main thread to check the connection and start a new thread. The `back_log` value indicates how many requests can be stacked during this short time before MySQL momentarily stops answering new requests. You need to increase this only if you expect a large number of connections in a short period of time.

In other words, this value is the size of the listen queue for incoming TCP/IP connections. Your operating system has its own limit on the size of this queue. The manual page for the Unix `listen()` system call should have more details. Check your OS documentation for the maximum value for this variable. `back_log` cannot be set higher than your operating system limit.

- basedir

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--basedir=path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>basedir</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>basedir</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>directory name</td>
</tr>
</tbody>
</table>

The MySQL installation base directory. This variable can be set with the `--basedir` option. Relative path names for other variables usually are resolved relative to the base directory.

- big_tables

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--big-tables</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>big-tables</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>big_tables</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>OFF</td>
</tr>
</tbody>
</table>

If set to 1, all temporary tables are stored on disk rather than in memory. This is a little slower, but the error `The table tbl_name is full` does not occur for `SELECT` operations that require a large temporary table. The default value for a new connection is 0 (use in-memory temporary tables). Normally, you should never need to set this variable, because in-memory tables are automatically converted to disk-based tables as required.

**Note**

This variable was formerly named `sql_big_tables`. 

519
• **bulk_insert_buffer_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--bulk_insert_buffer_size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>bulk_insert_buffer_size</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>bulk_insert_buffer_size</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Platform</td>
<td></td>
</tr>
<tr>
<td>Bit Size</td>
<td>32</td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>8388608</td>
</tr>
<tr>
<td>Range</td>
<td>0 .. 4294967295</td>
</tr>
</tbody>
</table>

| Permitted Values    |                             |
| Platform            | 64                          |
| Bit Size            |                             |
| Type                | numeric                     |
| Default             | 8388608                     |
| Range               | 0 .. 18446744073709547520  |

MyISAM uses a special tree-like cache to make bulk inserts faster for `INSERT ... SELECT`, `INSERT ... VALUES (...)`, `...`, `...`, and `LOAD DATA INFILE` when adding data to nonempty tables. This variable limits the size of the cache tree in bytes per thread. Setting it to 0 disables this optimization. The default value is 8MB.

• **character_set_client**

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>character_set_client</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>string</td>
</tr>
</tbody>
</table>

The character set for statements that arrive from the client. The session value of this variable is set using the character set requested by the client when the client connects to the server. (Many clients support a **--default-character-set** option to enable this character set to be specified explicitly. See also [Section 10.1.4, "Connection Character Sets and Collations"]) The global value of the variable is used to set the session value in cases when the client-requested value is unknown or not available, or the server is configured to ignore client requests:

• The client is from a version of MySQL older than MySQL 4.1, and thus does not request a character set.

• The client requests a character set not known to the server. For example, a Japanese-enabled client requests `sjis` when connecting to a server not configured with `sjis` support.
Server System Variables

- `mysqld` was started with the `--skip-character-set-client-handshake` option, which causes it to ignore client character set configuration. This reproduces MySQL 4.0 behavior and is useful should you wish to upgrade the server without upgrading all the clients.

`ucs2`, `utf16`, and `utf32` cannot be used as a client character set, which means that they also do not work for `SET NAMES` or `SET CHARACTER SET`.

- `character_set_connection`

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>character_set_connection</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>string</td>
</tr>
</tbody>
</table>

  The character set used for literals that do not have a character set introducer and for number-to-string conversion.

- `character_set_database`

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>character_set_database</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Footnote</td>
<td>This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>string</td>
</tr>
</tbody>
</table>

  The character set used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as `character_set_server`.

- `character_set_filesystem`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--character-set-filesystem=name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>character-set-filesystem</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>character_set_filesystem</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td><code>binary</code></td>
</tr>
</tbody>
</table>

  The file system character set. This variable is used to interpret string literals that refer to file names, such as in the `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` function. Such file names are converted from `character_set_client` to `character_set_filesystem` before the file opening attempt occurs. The default value is `binary`, which means that no conversion occurs. For systems on which multi-byte file names are permitted, a
different value may be more appropriate. For example, if the system represents file names using UTF-8, set `character_set_filesystem` to 'utf8'.

- **character_set_results**

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>character_set_results</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

The character set used for returning query results such as result sets or error messages to the client.

- **character_set_server**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--character-set-server</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>character-set-server</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>character_set_server</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

The server's default character set.

- **character_set_system**

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>character_set_system</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

The character set used by the server for storing identifiers. The value is always utf8.

- **character_sets_dir**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--character-sets-dir=path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>character-sets-dir</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>character_sets_dir</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

The directory containing the system character sets.
The directory where character sets are installed.

- **collation_connection**

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>collation_connection</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>string</td>
</tr>
</tbody>
</table>

The collation of the connection character set.

- **collation_database**

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>collation_database</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>Footnote</strong></td>
<td>This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.</td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>string</td>
</tr>
</tbody>
</table>

The collation used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as **collation_server**.

- **collation_server**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--collation-server</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>collation-server</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>collation_server</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>string</td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td>latin1_swedish_ci</td>
</tr>
</tbody>
</table>

The server's default collation.

- **completion_type**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--completion_type=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>completion_type</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>completion_type</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td></td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Variable Name</th>
<th>Type</th>
<th>Default</th>
<th>Valid Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>concurrent_insert</td>
<td>numeric</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

**Permitted Values (>= 5.5.3)**

<table>
<thead>
<tr>
<th>Type</th>
<th>Default</th>
<th>Valid Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>enumeration</td>
<td>NO_CHAIN</td>
<td>NO_CHAIN, CHAIN, RELEASE, 0, 1, 2</td>
</tr>
</tbody>
</table>

The transaction completion type. This variable can take the values shown in the following table. As of MySQL 5.5.3, the variable can be assigned using either the name values or corresponding integer values. Before 5.5.3, only the integer values can be used.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NO_CHAIN</td>
<td>COMMIT and ROLLBACK are unaffected. This is the default value. (or 0)</td>
</tr>
<tr>
<td>CHAIN</td>
<td>COMMIT and ROLLBACK are equivalent to COMMIT AND CHAIN and ROLLBACK AND CHAIN, respectively. (A new transaction starts immediately with the same isolation level as the just-terminated transaction.) (or 1)</td>
</tr>
<tr>
<td>RELEASE</td>
<td>COMMIT and ROLLBACK are equivalent to COMMIT RELEASE and ROLLBACK RELEASE, respectively. (The server disconnects after terminating the transaction.) (or 2)</td>
</tr>
</tbody>
</table>

completion_type affects transactions that begin with START TRANSACTION or BEGIN and end with COMMIT or ROLLBACK. It does not apply to implicit commits resulting from execution of the statements listed in Section 13.3.3, “Statements That Cause an Implicit Commit”. It also does not apply for XA COMMIT, XA ROLLBACK, or when autocommit=1.

- concurrent_insert
### Server System Variables

**Permitted Values (≥ 5.5.3)**

<table>
<thead>
<tr>
<th>Type</th>
<th>enumeration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>AUTO</td>
</tr>
<tr>
<td>Valid Values</td>
<td>NEVER, AUTO, ALWAYS, 0, 1, 2</td>
</tr>
</tbody>
</table>

If `AUTO` (the default), MySQL permits `INSERT` and `SELECT` statements to run concurrently for MyISAM tables that have no free blocks in the middle of the data file. If you start `mysqld` with `--skip-new`, this variable is set to `NEVER`.

This variable can take the values shown in the following table. As of MySQL 5.5.3, the variable can be assigned using either the name values or corresponding integer values. Before 5.5.3, only the integer values can be used.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NEVER (or 0)</td>
<td>Disables concurrent inserts</td>
</tr>
<tr>
<td>AUTO (or 1)</td>
<td>(Default) Enables concurrent insert for MyISAM tables that do not have holes</td>
</tr>
<tr>
<td>ALWAYS (or 2)</td>
<td>Enables concurrent inserts for all MyISAM tables, even those that have holes. For a table with a hole, new rows are inserted at the end of the table if it is in use by another thread. Otherwise, MySQL acquires a normal write lock and inserts the row into the hole.</td>
</tr>
</tbody>
</table>

See also Section 8.10.3, "Concurrent Inserts".

- `connect_timeout`

**Command-Line Format**

`--connect_timeout=#`

**Option-File Format**

`connect_timeout`

**System Variable Name**

`connect_timeout`

**Variable Scope**

Global

**Dynamic Variable**

Yes

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>10</td>
</tr>
<tr>
<td>Range</td>
<td>2 .. 31536000</td>
</tr>
</tbody>
</table>

The number of seconds that the `mysqld` server waits for a connect packet before responding with `Bad handshake`. The default value is 10 seconds.
Increasing the `connect_timeout` value might help if clients frequently encounter errors of the form
Lost connection to MySQL server at 'XXX', system error: *errno*.

- **datadir**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--datadir=path</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-h</td>
</tr>
<tr>
<td>Option-File Format</td>
<td>datadir</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>datadir</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

**Permitted Values**

**Type** directory name

The MySQL data directory. This variable can be set with the `--datadir` option.

- **date_format**

  This variable is unused.

- **datetime_format**

  This variable is unused.

- **debug**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--debug[=debug_options]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>debug</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>debug</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Permitted Values**

**Type** (Unix)

<table>
<thead>
<tr>
<th>Type (Unix)</th>
<th>string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>d:t:i:o,/tmp/mysqld.trace</td>
</tr>
</tbody>
</table>

**Type** (Windows)

<table>
<thead>
<tr>
<th>Type (Windows)</th>
<th>string</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>d:t:i:0,\mysqld.trace</td>
</tr>
</tbody>
</table>

This variable indicates the current debugging settings. It is available only for servers built with debugging support. The initial value comes from the value of instances of the `--debug` option given at server startup. The global and session values may be set at runtime; the `SUPER` privilege is required, even for the session value.

Assigning a value that begins with + or - cause the value to added to or subtracted from the current value:
Server System Variables

mysql> SET debug = 'T';
mysql> SELECT @@debug;
+---------+
| @@debug |
+---------+
| T       |
+---------+

mysql> SET debug = '+P';
mysql> SELECT @@debug;
+---------+
| @@debug |
+---------+
| P:T     |
+---------+

mysql> SET debug = '-P';
mysql> SELECT @@debug;
+---------+
| @@debug |
+---------+
| T       |
+---------+

For more information, see Section 24.4.3, "The DBUG Package".

- debug_sync

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>debug_sync</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>string</td>
</tr>
</tbody>
</table>

This variable is the user interface to the Debug Sync facility. Use of Debug Sync requires that MySQL be configured with the `-DENABLE_DEBUG_SYNC=1` option (see Section 2.9.4, "MySQL Source-Configuration Options"). If Debug Sync is not compiled in, this system variable is not available.

The global variable value is read only and indicates whether the facility is enabled. By default, Debug Sync is disabled and the value of `debug_sync` is `OFF`. If the server is started with `--debug-sync-timeout=N`, where `N` is a timeout value greater than 0, Debug Sync is enabled and the value of `debug_sync` is `ON - current signal` followed by the signal name. Also, `N` becomes the default timeout for individual synchronization points.

The session value can be read by any user and will have the same value as the global variable. The session value can be set by users that have the `SUPER` privilege to control synchronization points.

For a description of the Debug Sync facility and how to use synchronization points, see MySQL Internals: Test Synchronization.

- default_storage_engine

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--default-storage-engine=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>default-storage-engine</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>default_storage_engine</td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th>Variable Scope</th>
<th>Global, Session</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Permitted Values (<= 5.5.4)**

<table>
<thead>
<tr>
<th>Type</th>
<th>enumeration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>MyISAM</td>
</tr>
</tbody>
</table>

**Permitted Values (>= 5.5.5)**

<table>
<thead>
<tr>
<th>Type</th>
<th>enumeration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>InnoDB</td>
</tr>
</tbody>
</table>

The default storage engine. To set the storage engine at server startup, use the `--default-storage-engine` option. See Section 5.1.3, "Server Command Options".

To see which storage engines are available and enabled, use the `SHOW ENGINES` statement or query the `INFORMATION_SCHEMA.ENGINES` table.

If you disable the default storage engine at server startup, you must set the default engine to a different engine or the server will not start.

This variable was added in MySQL 5.5.3 to be used in preference to `storage_engine`, which is now deprecated.

- **default_week_format**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--default_week_format=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>default_week_format</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>default_week_format</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 .. 7</td>
</tr>
</tbody>
</table>

The default mode value to use for the `WEEK()` function. See Section 12.7, “Date and Time Functions”.

- **delay_key_write**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--delay-key-write [=name]</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>delay-key-write</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>delay_key_write</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>enumeration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>ON</td>
</tr>
</tbody>
</table>
This option applies only to MyISAM tables. It can have one of the following values to affect handling of the DELAY_KEY_WRITE table option that can be used in CREATE TABLE statements.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFF</td>
<td>DELAY_KEY_WRITE is ignored.</td>
</tr>
<tr>
<td>ON</td>
<td>MySQL honors any DELAY_KEY_WRITE option specified in CREATE TABLE statements. This is the default value.</td>
</tr>
<tr>
<td>ALL</td>
<td>All new opened tables are treated as if they were created with the DELAY_KEY_WRITE option enabled.</td>
</tr>
</tbody>
</table>

If DELAY_KEY_WRITE is enabled for a table, the key buffer is not flushed for the table on every index update, but only when the table is closed. This speeds up writes on keys a lot, but if you use this feature, you should add automatic checking of all MyISAM tables by starting the server with the --myisam-recover-options option (for example, --myisam-recover-options=BACKUP,FORCE). See Section 5.1.3, “Server Command Options”, and Section 15.3.1, “MyISAM Startup Options”.

**Warning**

If you enable external locking with --external-locking, there is no protection against index corruption for tables that use delayed key writes.

- delayed_insert_limit
After inserting `delayed_insert_limit` delayed rows, the `INSERT DELAYED` handler thread checks whether there are any `SELECT` statements pending. If so, it permits them to execute before continuing to insert delayed rows.

- **delayed_insert_timeout**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--delayed_insert_timeout=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>delayed_insert_timeout</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>delayed_insert_timeout</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>300</td>
</tr>
</tbody>
</table>

How many seconds an `INSERT DELAYED` handler thread should wait for `INSERT` statements before terminating.

- **delayed_queue_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--delayed_queue_size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>delayed_queue_size</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>delayed_queue_size</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Platform Bit Size</td>
<td>32</td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>1000</td>
</tr>
<tr>
<td>Range</td>
<td>1 .. 4294967295</td>
</tr>
</tbody>
</table>

This is a per-table limit on the number of rows to queue when handling `INSERT DELAYED` statements. If the queue becomes full, any client that issues an `INSERT DELAYED` statement waits until there is room in the queue again.

- **div_precision_increment**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--div_precision_increment=#</code></th>
</tr>
</thead>
</table>
**Server System Variables**

<table>
<thead>
<tr>
<th>Option-File Format</th>
<th><code>div_precision_increment</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable Name</td>
<td><code>div_precision_increment</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>4</td>
</tr>
<tr>
<td>Range</td>
<td>0 .. 30</td>
</tr>
</tbody>
</table>

This variable indicates the number of digits by which to increase the scale of the result of division operations performed with the `/` operator. The default value is 4. The minimum and maximum values are 0 and 30, respectively. The following example illustrates the effect of increasing the default value.

```
mysql> SELECT 1/7;
+--------+
| 1/7    |
+--------+
| 0.1429 |
+--------+
mysql> SET div_precision_increment = 12;
mysql> SELECT 1/7;
+----------------+
| 1/7            |
+----------------+
| 0.142857142857 |
+----------------+
```

- **engine_condition_pushdown**

<table>
<thead>
<tr>
<th>Deprecated</th>
<th>5.5.3, by <a href="#">optimizer_switch</a></th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--engine-condition-pushdown</code></td>
</tr>
<tr>
<td>Option-File Format</td>
<td><code>engine-condition-pushdown</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>engine_condition_pushdown</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>ON</td>
</tr>
</tbody>
</table>

The engine condition pushdown optimization enables processing for certain comparisons to be "pushed down" to the storage engine level for more efficient execution. For more information, see [Section 8.2.1.5, "Engine Condition Pushdown Optimization"](#).

Engine condition pushdown is used only by the [NDBCLUSTER](#) storage engine. Enabling this optimization on a MySQL Server acting as a MySQL Cluster SQL node causes `WHERE` conditions on unindexed columns to be evaluated on the cluster's data nodes and only the rows that match to be sent back to the SQL node that issued the query. This greatly reduces the amount of cluster data that must be sent over the network, increasing the efficiency with which results are returned.
Server System Variables

The `engine_condition_pushdown` variable controls whether engine condition pushdown is enabled. By default, this variable is `ON` (1). Setting it to `OFF` (0) disables pushdown.

This variable is deprecated as of MySQL 5.5.3 and is removed in MySQL 5.6. Use the `engine_condition_pushdown` flag of the `optimizer_switch` variable instead. See Section 8.8.5.2, “Controlling Switchable Optimizations”.

- **error_count**

  The number of errors that resulted from the last statement that generated messages. This variable is read only. See Section 13.7.5.18, “SHOW ERRORS Syntax”.

- **event_scheduler**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--event-scheduler [=value]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>event-scheduler</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>event_scheduler</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Default</td>
</tr>
<tr>
<td>Valid Values</td>
</tr>
</tbody>
</table>

  This variable indicates the status of the Event Scheduler; possible values are ON, OFF, and DISABLED, with the default being OFF. This variable and its effects on the Event Scheduler’s operation are discussed in greater detail in the Overview section of the Events chapter [2618].

- **expire_logs_days**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--expire_logs_days= #</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>expire_logs_days</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>expire_logs_days</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Default</td>
</tr>
<tr>
<td>Range</td>
</tr>
</tbody>
</table>

  The number of days for automatic binary log file removal. The default is 0, which means “no automatic removal.” Possible removals happen at startup and when the binary log is flushed. Log flushing occurs as indicated in Section 5.2, “MySQL Server Logs”.

532
To remove binary log files manually, use the `PURGE BINARY LOGS` statement. See Section 13.4.1.1, "PURGE BINARY LOGS Syntax".

- **external_user**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.5.7</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable Name</td>
<td><code>external_user</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>string</td>
</tr>
</tbody>
</table>

The external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this variable is `NULL`. See Section 6.3.8, "Proxy Users".

This variable was added in MySQL 5.5.7.

- **flush**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--flush</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>flush</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>flush</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>OFF</td>
</tr>
</tbody>
</table>

If `ON`, the server flushes (synchronizes) all changes to disk after each SQL statement. Normally, MySQL does a write of all changes to disk only after each SQL statement and lets the operating system handle the synchronizing to disk. See Section B.5.4.2, “What to Do If MySQL Keeps Crashing”. This variable is set to `ON` if you start `mysqld` with the `--flush` option.

- **flush_time**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--flush_time=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>flush_time</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>flush_time</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Min Value</td>
<td>0</td>
</tr>
</tbody>
</table>
If this is set to a nonzero value, all tables are closed every flush_time seconds to free up resources and synchronize unflushed data to disk. This option is best used only on systems with minimal resources.

- **foreign_key_checks**

If set to 1 (the default), foreign key constraints for InnoDB tables are checked. If set to 0, they are ignored. Disabling foreign key checking can be useful for reloading InnoDB tables in an order different from that required by their parent/child relationships. See Section 14.9.6, “InnoDB and FOREIGN KEY Constraints”.

Setting foreign_key_checks to 0 also affects data definition statements: DROP SCHEMA drops a schema even if it contains tables that have foreign keys that are referred to by tables outside the schema, and DROP TABLE drops tables that have foreign keys that are referred to by other tables.

**Note**

Setting foreign_key_checks to 1 does not trigger a scan of the existing table data. Therefore, rows added to the table while foreign_key_checks = 0 will not be verified for consistency.

- **ft_boolean_syntax**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ft_boolean_syntax=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>ft_boolean_syntax</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>ft_boolean_syntax</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>+ -&gt;&lt;()~*:&quot;&amp;</td>
</tr>
</tbody>
</table>

The list of operators supported by boolean full-text searches performed using IN BOOLEAN MODE. See Section 12.9.2, “Boolean Full-Text Searches”.

The default variable value is '+ -><()~*:"&| '. The rules for changing the value are as follows:

- Operator function is determined by position within the string.
- The replacement value must be 14 characters.
- Each character must be an ASCII nonalphanumeric character.
- Either the first or second character must be a space.
- No duplicates are permitted except the phrase quoting operators in positions 11 and 12. These two characters are not required to be the same, but they are the only two that may be.
- Positions 10, 13, and 14 (which by default are set to “:”, “&”, and “|”) are reserved for future extensions.

- **ft_max_word_len**
### Server System Variables

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ft_max_word_len=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>ft_max_word_len</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>ft_max_word_len</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Min Value</td>
</tr>
</tbody>
</table>

The maximum length of the word to be included in a **FULLTEXT** index.

![Note]

**FULLTEXT** indexes must be rebuilt after changing this variable. Use `REPAIR TABLE tbl_name QUICK`.

- **ft_min_word_len**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ft_min_word_len=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>ft_min_word_len</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>ft_min_word_len</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Default</td>
</tr>
<tr>
<td>Min Value</td>
</tr>
</tbody>
</table>

The minimum length of the word to be included in a **FULLTEXT** index.

![Note]

**FULLTEXT** indexes must be rebuilt after changing this variable. Use `REPAIR TABLE tbl_name QUICK`.

- **ft_query_expansion_limit**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ft_query_expansion_limit=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>ft_query_expansion_limit</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>ft_query_expansion_limit</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th><strong>Variable</strong></th>
<th><strong>Default</strong></th>
<th><strong>Range</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>ft_stopword_file</td>
<td>20</td>
<td>0 .. 1000</td>
</tr>
</tbody>
</table>

The number of top matches to use for full-text searches performed using `WITH QUERY EXPANSION`.

- **ft_stopword_file**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--ft_stopword_file=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>ft_stopword_file</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>ft_stopword_file</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

**Noted**

The file from which to read the list of stopwords for full-text searches. The server looks for the file in the data directory unless an absolute path name is given to specify a different directory. All the words from the file are used; comments are *not* honored. By default, a built-in list of stopwords is used (as defined in the `storage/myisam/ft_static.c` file). Setting this variable to the empty string (`''`) disables stopwords filtering. See also Section 12.9.4, “Full-Text Stopwords”.

- **general_log**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--general-log</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>general-log</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>general_log</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Noted**

Whether the general query log is enabled. The value can be 0 (or `OFF`) to disable the log or 1 (or `ON`) to enable the log. The default value depends on whether the `--general-log` option is given. The destination for log output is controlled by the `log_output` system variable; if that value is `NONE`, no log entries are written even if the log is enabled.

- **general_log_file**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--general-log-file=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>general_log_file</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>general_log_file</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Dynamic Variable</th>
<th>Yes</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Type</strong> file name</td>
<td></td>
</tr>
<tr>
<td><strong>Default</strong> host_name.log</td>
<td></td>
</tr>
</tbody>
</table>

The name of the general query log file. The default value is `host_name.log`, but the initial value can be changed with the `--general_log_file` option.

- **group_concat_max_len**
  
  **Command-Line Format** --group_concat_max_len=#
  
  **Option-File Format**
  
  group_concat_max_len
  
  **System Variable Name**
  
  group_concat_max_len
  
  **Variable Scope**
  
  Global, Session
  
  **Dynamic Variable** Yes
  
  **Permitted Values**
  
  | Platform | 32 |
  | Bit Size |     |
  | **Type** | numeric |
  | **Default** | 1024 |
  | **Range** | 4 .. 4294967295 |

  **Platform**
  
  64
  
  **Bit Size**
  
  numeric
  
  **Default**
  
  1024
  
  **Range**
  
  4 .. 18446744073709547520

  The maximum permitted result length in bytes for the GROUP_CONCAT() function. The default is 1024.

  - **have_compress**
    
    YES if the zlib compression library is available to the server, NO if not. If not, the COMPRESS() and UNCOMPRESS() functions cannot be used.

  - **have_crypt**
    
    YES if the crypt() system call is available to the server, NO if not. If not, the ENCRYPT() function cannot be used.

  - **have_csv**
    
    YES if mysqld supports CSV tables, NO if not.

    This variable is deprecated and is removed in MySQL 5.6. Use SHOW ENGINES instead.

  - **have_dynamic_loading**
    
    YES if mysqld supports dynamic loading of plugins, NO if not.
• **have_geometry**

  YES if the server supports spatial data types, NO if not.

• **have_innodb**

  YES if mysqld supports InnoDB tables. DISABLED if --skip-innodb is used.

  This variable is deprecated and is removed in MySQL 5.6. Use SHOW ENGINES instead.

• **have_openssl**

  This variable is an alias for have_ssl.

• **have_partitioning**

  YES if mysqld supports partitioning.

  This variable is deprecated and is removed in MySQL 5.6. Use SHOW PLUGINS instead. For more information, see Chapter 19, Partitioning.

• **have_profiling**

  YES if statement profiling capability is present, NO if not. If present, the profiling system variable controls whether this capability is enabled or disabled. See Section 13.7.5.32, “SHOW PROFILES Syntax”.

• **have_query_cache**

  YES if mysqld supports the query cache, NO if not.

• **have_rtree_keys**

  YES if RTREE indexes are available, NO if not. (These are used for spatial indexes in MyISAM tables.)

• **have_ssl**

  YES if mysqld supports SSL connections, NO if not. DISABLED indicates that the server was compiled with SSL support, but was not started with the appropriate --ssl-xxx options. For more information, see Section 6.3.9.2, “Configuring MySQL for SSL”.

• **have_symlink**

  YES if symbolic link support is enabled, NO if not. This is required on Unix for support of the DATA DIRECTORY and INDEX DIRECTORY table options, and on Windows for support of data directory symlinks. If the server is started with the --skip-symbolic-links option, the value is DISABLED.

• **hostname**

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>hostname</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>string</td>
</tr>
</tbody>
</table>

The server sets this variable to the server host name at startup.
• **identity**

This variable is a synonym for the `last_insert_id` variable. It exists for compatibility with other database systems. You can read its value with `SELECT @@identity`, and set it using `SET identity`.

• **init_connect**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--init-connect=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>init_connect</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>init_connect</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Permitted Values**

| Type | string |

A string to be executed by the server for each client that connects. The string consists of one or more SQL statements, separated by semicolon characters. For example, each client session begins by default with autocommit mode enabled. For older servers (before MySQL 5.5.8), there is no global `autocommit` system variable to specify that autocommit should be disabled by default, but as a workaround `init_connect` can be used to achieve the same effect:

```
SET GLOBAL init_connect='SET autocommit=0';
```

The `init_connect` variable can also be set on the command line or in an option file. To set the variable as just shown using an option file, include these lines:

```
[mysqld]
init_connect='SET autocommit=0'
```

The content of `init_connect` is not executed for users that have the `SUPER` privilege. This is done so that an erroneous value for `init_connect` does not prevent all clients from connecting. For example, the value might contain a statement that has a syntax error, thus causing client connections to fail. Not executing `init_connect` for users that have the `SUPER` privilege enables them to open a connection and fix the `init_connect` value.

• **init_file**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--init-file=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>init-file</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>init_file</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

**Permitted Values**

| Type | file name |

The name of the file specified with the `--init-file` option when you start the server. This should be a file containing SQL statements that you want the server to execute when it starts. Each statement must be on a single line and should not include comments. No statement terminator such as ;, \g, or \G should be given at the end of each statement.
• **innodb.xxx**

InnoDB system variables are listed in Section 14.15, “InnoDB Startup Options and System Variables”. These variables control many aspects of storage, memory use, and I/O patterns for InnoDB tables, and are especially important now that InnoDB is the default storage engine.

• **insert_id**

The value to be used by the following `INSERT` or `ALTER TABLE` statement when inserting an `AUTO_INCREMENT` value. This is mainly used with the binary log.

• **interactive_timeout**

```
Command-Line Format  --interactive_timeout=#
Option-File Format    interactive_timeout
System Variable Name  interactive_timeout
Variable Scope        Global, Session
Dynamic Variable      Yes

Permitted Values
Type numeric
Default 28800
Min Value 1
```

The number of seconds the server waits for activity on an interactive connection before closing it. An interactive client is defined as a client that uses the `CLIENT_INTERACTIVE` option to `mysql_real_connect()`. See also `wait_timeout`.

• **join_buffer_size**

```
Command-Line Format  --join_buffer_size=#
Option-File Format    join_buffer_size
System Variable Name  join_buffer_size
Variable Scope        Global, Session
Dynamic Variable      Yes

Permitted Values (<= 5.5.2)
Platform Bit Size 32
Type (Other) numeric
Default 131072
Range 8200 .. 4294967295
```

Permitted Values (<= 5.5.2)
Platform Bit Size 64
Type (Other) numeric
Server System Variables

<table>
<thead>
<tr>
<th>Default</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>131072</td>
<td>8228 .. 18446744073709547520</td>
</tr>
</tbody>
</table>

Permitted Values (<= 5.5.2)

<table>
<thead>
<tr>
<th>Platform</th>
<th>Bit Size</th>
<th>Type (Windows)</th>
<th>Default</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>32</td>
<td>numeric</td>
<td>131072</td>
<td>8200 .. 4294967295</td>
</tr>
</tbody>
</table>

Permitted Values (>= 5.5.3)

<table>
<thead>
<tr>
<th>Platform</th>
<th>Bit Size</th>
<th>Type (Other)</th>
<th>Default</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>32</td>
<td>numeric</td>
<td>131072</td>
<td>128 .. 4294967295</td>
</tr>
<tr>
<td></td>
<td>64</td>
<td>numeric</td>
<td>131072</td>
<td>128 .. 18446744073709547520</td>
</tr>
</tbody>
</table>

The minimum size of the buffer that is used for plain index scans, range index scans, and joins that do not use indexes and thus perform full table scans. Normally, the best way to get fast joins is to add indexes. Increase the value of `join_buffer_size` to get a faster full join when adding indexes is not possible. One join buffer is allocated for each full join between two tables. For a complex join between several tables for which indexes are not used, multiple join buffers might be necessary.

There is no gain from setting the buffer larger than required to hold each matching row, and all joins allocate at least the minimum size, so use caution in setting this variable to a large value globally. It is
better to keep the global setting small and change to a larger setting only in sessions that are doing large joins. Memory allocation time can cause substantial performance drops if the global size is larger than needed by most queries that use it.

The maximum permissible setting for `join_buffer_size` is 4GB–1. Larger values are permitted for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB–1 with a warning).

Prior to MySQL 5.5.3, the minimum allowed value for this variable was 8200 for 32-bit platforms and 8228 for 64-bit platforms. In MySQL 5.5.3 and later, the minimum is 128 for all platforms.

For additional information about join buffering, see Section 8.2.1.8, "Nested-Loop Join Algorithms".

- `keep_files_on_create`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--keep_files_on_create=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>keep_files_on_create</td>
</tr>
<tr>

</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>OFF</td>
</tr>
</tbody>
</table>

If a `MyISAM` table is created with no `DATA DIRECTORY` option, the `.MYD` file is created in the database directory. By default, if `MyISAM` finds an existing `.MYD` file in this case, it overwrites it. The same applies to `.MYI` files for tables created with no `INDEX DIRECTORY` option. To suppress this behavior, set the `keep_files_on_create` variable to `ON` (1), in which case `MyISAM` will not overwrite existing files and returns an error instead. The default value is `OFF` (0).

If a `MyISAM` table is created with a `DATA DIRECTORY` or `INDEX DIRECTORY` option and an existing `.MYD` or `.MYI` file is found, `MyISAM` always returns an error. It will not overwrite a file in the specified directory.

- `key_buffer_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--key_buffer_size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>key_buffer_size</td>

</tr>
<tr>
<td>Default</td>
<td>8388608</td>
</tr>
<tr>
<td>Range</td>
<td>8 .. 4294967295</td>
</tr>
</tbody>
</table>

542
Index blocks for MyISAM tables are buffered and are shared by all threads. key_buffer_size is the size of the buffer used for index blocks. The key buffer is also known as the key cache.

The maximum permissible setting for key_buffer_size is 4GB–1 on 32-bit platforms. Larger values are permitted for 64-bit platforms. The effective maximum size might be less, depending on your available physical RAM and per-process RAM limits imposed by your operating system or hardware platform. The value of this variable indicates the amount of memory requested. Internally, the server allocates as much memory as possible up to this amount, but the actual allocation might be less.

You can increase the value to get better index handling for all reads and multiple writes; on a system whose primary function is to run MySQL using the MyISAM storage engine, 25% of the machine’s total memory is an acceptable value for this variable. However, you should be aware that, if you make the value too large (for example, more than 50% of the machine’s total memory), your system might start to page and become extremely slow. This is because MySQL relies on the operating system to perform file system caching for data reads, so you must leave some room for the file system cache. You should also consider the memory requirements of any other storage engines that you may be using in addition to MyISAM.

For even more speed when writing many rows at the same time, use LOCK TABLES. See Section 8.2.2.1, “Speed of INSERT Statements”.

You can check the performance of the key buffer by issuing a SHOW STATUS statement and examining the Key_read_requests, Key_reads, Key_write_requests, and Key_writes status variables. (See Section 13.7.5, “SHOW Syntax”.) The Key_reads/Key_read_requests ratio should normally be less than 0.01. The Key_writes/Key_write_requests ratio is usually near 1 if you are using mostly updates and deletes, but might be much smaller if you tend to do updates that affect many rows at the same time or if you are using the DELAY_KEY_WRITE table option.

The fraction of the key buffer in use can be determined using key_buffer_size in conjunction with the Key_blocks_unused status variable and the buffer block size, which is available from the key_cache_block_size system variable:

\[
1 - \frac{\text{Key_blocks_unused} \times \text{key_cache_block_size}}{\text{key_buffer_size}}
\]

This value is an approximation because some space in the key buffer is allocated internally for administrative structures. Factors that influence the amount of overhead for these structures include block size and pointer size. As block size increases, the percentage of the key buffer lost to overhead tends to decrease. Larger blocks result in a smaller number of read operations (because more keys are obtained per read), but conversely an increase in reads of keys that are not examined (if not all keys in a block are relevant to a query).

It is possible to create multiple MyISAM key caches. The size limit of 4GB applies to each cache individually, not as a group. See Section 8.9.2, “The MyISAM Key Cache”.

- key_cache_age_threshold

Command-Line Format  --key_cache_age_threshold=#
Server System Variables

<table>
<thead>
<tr>
<th>Option-File Format</th>
<th>key_cache_age_threshold</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable Name</td>
<td>key_cache_age_threshold</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Platform</td>
<td>32</td>
</tr>
<tr>
<td>Bit Size</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>300</td>
</tr>
<tr>
<td>Range</td>
<td>100 .. 4294967295</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Option-File Format</th>
<th>key_cache_block_size</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable Name</td>
<td>key_cache_block_size</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Platform</td>
<td>64</td>
</tr>
<tr>
<td>Bit Size</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>300</td>
</tr>
<tr>
<td>Range</td>
<td>100 .. 18446744073709547520</td>
</tr>
</tbody>
</table>

This value controls the demotion of buffers from the hot sublist of a key cache to the warm sublist. Lower values cause demotion to happen more quickly. The minimum value is 100. The default value is 300. See Section 8.9.2, “The MyISAM Key Cache”.

- key_cache_block_size

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--key_cache_block_size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>key_cache_block_size</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>key_cache_block_size</td>

### Server System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>100</td>
</tr>
<tr>
<td>Range</td>
<td>1 .. 100</td>
</tr>
</tbody>
</table>

The division point between the hot and warm sublists of the key cache buffer list. The value is the percentage of the buffer list to use for the warm sublist. Permissible values range from 1 to 100. The default value is 100. See Section 8.9.2, “The MyISAM Key Cache”.

- **language**

  **Deprecated** 5.5.0, by `lc-messages-dir`

  **Command-Line Format**
  
  `--language=name`

  `-L` ______

  **Option-File Format**
  
  `language`

  **System Variable Name**
  
  `language`

  **Variable Scope**
  
  Global

  **Dynamic Variable**
  
  No

  **Permitted Values**

  **Type** directory name

  **Default** `/usr/local/mysql/share/mysql/english/`

  The directory where error messages are located. See Section 10.2, “Setting the Error Message Language”.

  The `language` system variable is removed as of MySQL 5.5.0 (although the `--language` command-line option can still be used). Similar information is available from the `lc_messages_dir` and `lc_messages` variables.

- **large_files_support**

  **System Variable Name**
  
  `large_files_support`

  **Variable Scope**
  
  Global

  **Dynamic Variable**
  
  No

  Whether `mysql` was compiled with options for large file support.

- **large_pages**

  **Command-Line Format**
  
  `--large-pages`

  **Option-File Format**
  
  `large-pages`

  **System Variable Name**
  
  `large_pages`

  **Variable Scope**
  
  Global

  **Dynamic Variable**
  
  No

  **Platform Specific**
  
  Linux

  **Permitted Values**

  **Type** (Linux) boolean
Whether large page support is enabled (via the `--large-pages` option). See Section 8.11.4.2, “Enabling Large Page Support”.

- **large_page_size**

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>large_page_size</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
</tbody>
</table>

If large page support is enabled, this shows the size of memory pages. Currently, large memory pages are supported only on Linux; on other platforms, the value of this variable is always 0. See Section 8.11.4.2, “Enabling Large Page Support”.

- **last_insert_id**

  The value to be returned from `LAST_INSERT_ID()`.

  This is stored in the binary log when you use `LAST_INSERT_ID()` in a statement that updates a table. Setting this variable does not update the value returned by the `mysql_insert_id()` API function.

- **lc_messages**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--lc-messages=name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>lc-messages</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>lc_messages</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>string</td>
</tr>
</tbody>
</table>

  The locale to use for error messages. The server converts the value to a language name and combines it with the value of the `lc_messages_dir` to produce the location for the error message file. See Section 10.2, “Setting the Error Message Language”.

- **lc_messages_dir**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--lc-messages-dir=path</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>lc-messages-dir</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>lc_messages_dir</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>directory name</td>
</tr>
</tbody>
</table>
The directory where error messages are located. The value is used together with the value of `lc_messages` to produce the location for the error message file. See Section 10.2, “Setting the Error Message Language”.

- `lc_time_names`

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>lc_time_names</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>string</td>
</tr>
</tbody>
</table>

This variable specifies the locale that controls the language used to display day and month names and abbreviations. This variable affects the output from the `DATE_FORMAT()`, `DAYNAME()` and `MONTHNAME()` functions. Locale names are POSIX-style values such as 'ja_JP' or 'pt_BR'. The default value is 'en_US' regardless of your system's locale setting. For further information, see Section 10.7, “MySQL Server Locale Support”.

- `license`

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>license</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>GPL</td>
</tr>
</tbody>
</table>

The type of license the server has.

- `local_infile`

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>local_infile</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
</tbody>
</table>

Whether `LOCAL` is supported for `LOAD DATA INFILE` statements. If this variable is disabled, clients cannot use `LOCAL` in `LOAD DATA` statements. See Section 6.1.6, “Security Issues with `LOAD DATA LOCAL`”.

- `lock_wait_timeout`

| Introduced | 5.5.3 |
| Command-Line Format | `--lock_wait_timeout=#` |
| Option-File Format   | `lock_wait_timeout` |
| System Variable Name | `lock_wait_timeout` |
This variable specifies the timeout in seconds for attempts to acquire metadata locks. The permissible values range from 1 to 31536000 (1 year). The default is 31536000.

This timeout applies to all statements that use metadata locks. These include DML and DDL operations on tables, views, stored procedures, and stored functions, as well as `LOCK TABLES`, `FLUSH TABLES WITH READ LOCK`, and `HANDLER` statements.

This timeout does not apply to implicit accesses to system tables in the `mysql` database, such as grant tables modified by `GRANT` or `REVOKE` statements or table logging statements. The timeout does apply to system tables accessed directly, such as with `SELECT` or `UPDATE`.

The timeout value applies separately for each metadata lock attempt. A given statement can require more than one lock, so it is possible for the statement to block for longer than the `lock_wait_timeout` value before reporting a timeout error. When lock timeout occurs, `ER_LOCK_WAIT_TIMEOUT` is reported.

`lock_wait_timeout` does not apply to delayed inserts, which always execute with a timeout of 1 year. This is done to avoid unnecessary timeouts because a session that issues a delayed insert receives no notification of delayed insert timeouts.

This variable was added in MySQL 5.5.3.

- `locked_in_memory`

Whether `mysql` was locked in memory with `--memlock`.

- `log`

Deprecated 5.1.29, by `general-log`

Command-Line Format
```
--log[=name]
-l
```

Option-File Format
`log`

System Variable Name `log`

Variable Scope Global

Dynamic Variable Yes

Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>string</th>
</tr>
</thead>
</table>

Default `OFF`
Server System Variables

Whether logging of all statements to the general query log is enabled. See Section 5.2.3, “The General Query Log”.

This variable is deprecated and is removed in MySQL 5.6. Use general_log instead.

- **log_bin_trust_function_creators**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--log-bin-trust-function-creators</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>log-bin-trust-function-creators</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>log_bin_trust_function_creators</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

This variable applies when binary logging is enabled. It controls whether stored function creators can be trusted not to create stored functions that will cause unsafe events to be written to the binary log. If set to 0 (the default), users are not permitted to create or alter stored functions unless they have the SUPER privilege in addition to the CREATE ROUTINE or ALTER ROUTINE privilege. A setting of 0 also enforces the restriction that a function must be declared with the DETERMINISTIC characteristic, or with the READS SQL DATA or NO SQL characteristic. If the variable is set to 1, MySQL does not enforce these restrictions on stored function creation. This variable also applies to trigger creation. See Section 20.7, “Binary Logging of Stored Programs”.

- **log_error**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--log-error[=name]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>log-error</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>log_error</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>file name</th>
</tr>
</thead>
</table>

The location of the error log, or empty if the server is writing error message to the standard error output. See Section 5.2.2, “The Error Log”.

- **log_output**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--log-output=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>log-output</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>log_output</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Permitted Values
The destination for general query log and slow query log output. The value can be a comma-separated list of one or more of the words `TABLE` (log to tables), `FILE` (log to files), or `NONE` (do not log to tables or files). The default value is `FILE`. If present, takes precedence over any other specifiers. If the value is `NONE` log entries are not written even if the logs are enabled. If the logs are not enabled, no logging occurs even if the value of `log_output` is not `NONE`. For more information, see Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”.

- `log_queries_not_using_indexes`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--log-queries-not-using-indexes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>log-queries-not-using-indexes</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>log_queries_not_using_indexes</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Whether queries that do not use indexes are logged to the slow query log. See Section 5.2.5, “The Slow Query Log”.

- `log_slow_queries`

  | Deprecated          | 5.1.29, by slow-query-log      |
  | Command-Line Format | --log-slow-queries[=name]      |
  | Option-File Format  | log-slow-queries               |
  | System Variable Name| log_slow_queries               |
  | Variable Scope      | Global                         |
  | Dynamic Variable    | Yes                            |
  | **Permitted Values**|                                |
  | Type                | boolean                        |

Whether slow queries should be logged. “Slow” is determined by the value of the `long_query_time` variable. See Section 5.2.5, “The Slow Query Log”.

This variable is deprecated and is removed in MySQL 5.6. Use `slow_query_log` instead.

- `log_warnings`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--log-warnings[=#]</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-W [#]</code></td>
<td>550</td>
</tr>
</tbody>
</table>
### log_warnings

**Option-File Format**

log-warnings[=#]

**System Variable Name**

log_warnings

**Variable Scope**

Global, Session

**Dynamic Variable**

Yes

**Permitted Values**

<table>
<thead>
<tr>
<th>Platform</th>
<th>32</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit Size</td>
<td>32</td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Range</td>
<td>0 .. 4294967295</td>
</tr>
</tbody>
</table>

Whether to produce additional warning messages to the error log. This variable is enabled (1) by default and can be disabled by setting it to 0. The server logs messages about statements that are unsafe for statement-based logging if the value is greater than 0. Aborted connections and access-denied errors for new connection attempts are logged if the value is greater than 1.

- **long_query_time**

**Command-Line Format**

`--long_query_time=#`

**Option-File Format**

long_query_time

**System Variable Name**

long_query_time

**Variable Scope**

Global, Session

**Dynamic Variable**

Yes

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>10</td>
</tr>
<tr>
<td>Min Value</td>
<td>0</td>
</tr>
</tbody>
</table>

If a query takes longer than this many seconds, the server increments the `Slow_queries` status variable. If the slow query log is enabled, the query is logged to the slow query log file. This value is measured in real time, not CPU time, so a query that is under the threshold on a lightly loaded system might be above the threshold on a heavily loaded one. The minimum and default values of `long_query_time` are 0 and 10, respectively. The value can be specified to a resolution of microseconds. For logging to a file, times are written including the microseconds part. For logging to tables, only integer times are written; the microseconds part is ignored. See Section 5.2.5, “The Slow Query Log”:

- **low_priority_updates**
Server System Variables

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--low-priority-updates</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>low-priority-updates</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>low_priority_updates</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Permitted Values**

- **Type**: boolean
- **Default**: FALSE

If set to 1, all INSERT, UPDATE, DELETE, and LOCK TABLE WRITE statements wait until there is no pending SELECT or LOCK TABLE READ on the affected table. This affects only storage engines that use only table-level locking (such as MyISAM, MEMORY, and MERGE). This variable previously was named sql_low_priority_updates.

- **lower_case_file_system**

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>lower_case_file_system</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

**Permitted Values**

- **Type**: boolean

This variable describes the case sensitivity of file names on the file system where the data directory is located. OFF means file names are case sensitive, ON means they are not case sensitive. This variable is read only because it reflects a file system attribute and setting it would have no effect on the file system.

- **lower_case_table_names**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--lower_case_table_names[=#]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>lower_case_table_names</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>lower_case_table_names</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

**Permitted Values**

- **Type**: numeric
- **Default**: 0
- **Range**: 0 .. 2

If set to 0, table names are stored as specified and comparisons are case sensitive. If set to 1, table names are stored in lowercase on disk and comparisons are not case sensitive. If set to 2, table names are stored as given but compared in lowercase. This option also applies to database names and table aliases. For additional information, see Section 9.2.2, “Identifier Case Sensitivity”.

You should *not* set this variable to 0 if you are running MySQL on a system that has case-insensitive file names (such as Windows or Mac OS X). If you set this variable to 0 on such a system and access
MyISAM tablenames using different lettercases, index corruption may result. On Windows the default value is 1. On Mac OS X, the default value is 2.

If you are using InnoDB tables, you should set this variable to 1 on all platforms to force names to be converted to lowercase.

The setting of this variable has no effect on replication filtering options. This is a known issue which is fixed in MySQL 5.6. See Section 17.2.3, “How Servers Evaluate Replication Filtering Rules”, for more information.

You should not use different settings for lower_case_table_names on replication masters and slaves. In particular, you should not do this when the slave uses a case-sensitive file system, as this can cause replication to fail. This is a known issue which is fixed in MySQL 5.6. For more information, see Section 17.4.1.36, “Replication and Variables”.

•  max_allowed_packet

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max_allowed_packet=##</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>max_allowed_packet</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>max_allowed_packet</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>1048576</td>
</tr>
<tr>
<td>Range</td>
<td>1024 .. 1073741824</td>
</tr>
</tbody>
</table>

The maximum size of one packet or any generated/intermediate string.

The packet message buffer is initialized to net_buffer_length bytes, but can grow up to max_allowed_packet bytes when needed. This value by default is small, to catch large (possibly incorrect) packets.

You must increase this value if you are using large BLOB columns or long strings. It should be as big as the largest BLOB you want to use. The protocol limit for max_allowed_packet is 1GB. The value should be a multiple of 1024; nonmultiples are rounded down to the nearest multiple.

When you change the message buffer size by changing the value of the max_allowed_packet variable, you should also change the buffer size on the client side if your client program permits it. The default max_allowed_packet value built in to the client library is 1GB, but individual client programs might override this. For example, mysql and mysqldump have defaults of 16MB and 24MB, respectively. They also enable you to change the client-side value by setting max_allowed_packet on the command line or in an option file.

The session value of this variable is read only.

•  max_connect_errors

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max_connect_errors=##</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>max_connect_errors</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>max_connect_errors</td>
</tr>
</tbody>
</table>
### max_connections

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max_connections=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>max_connections</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>max_connections</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

#### Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>151</td>
</tr>
<tr>
<td>Range</td>
<td>1 .. 100000</td>
</tr>
</tbody>
</table>

The maximum permitted number of simultaneous client connections. By default, this is 151. See Section B.5.2.7, "Too many connections", for more information.

Increasing this value increases the number of file descriptors that `mysqld` requires. See Section 8.4.3.1, "How MySQL Opens and Closes Tables", for comments on file descriptor limits.

### max_delayed_threads

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max_delayed_threads=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>max_delayed_threads</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>max_delayed_threads</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
</tbody>
</table>

#### Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>10</td>
</tr>
<tr>
<td>Range</td>
<td>1 .. 18446744073709547520</td>
</tr>
</tbody>
</table>

If more than this many successive connection requests from a host are interrupted without a successful connection, the server blocks that host from further connections. You can unblock blocked hosts by flushing the host cache. To do so, issue a `FLUSH HOSTS` statement or execute a `mysqladmin flush-hosts` command. If a connection is established successfully within fewer than `max_connect_errors` attempts after a previous connection was interrupted, the error count for the host is cleared to zero. However, once a host is blocked, flushing the host cache is the only way to unblock it.
Server System Variables

<table>
<thead>
<tr>
<th>Dynamic Variable</th>
<th>Yes</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>20</td>
</tr>
<tr>
<td>Range</td>
<td>0 .. 16384</td>
</tr>
</tbody>
</table>

Do not start more than this number of threads to handle `INSERT DELAYED` statements. If you try to insert data into a new table after all `INSERT DELAYED` threads are in use, the row is inserted as if the `DELAYED` attribute was not specified. If you set this to 0, MySQL never creates a thread to handle `DELAYED` rows; in effect, this disables `DELAYED` entirely.

For the `SESSION` value of this variable, the only valid values are 0 or the `GLOBAL` value.

- **max_error_count**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--max_error_count=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>max_error_count</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>max_error_count</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>64</td>
</tr>
<tr>
<td>Range</td>
<td>0 .. 65535</td>
</tr>
</tbody>
</table>

The maximum number of error, warning, and note messages to be stored for display by the `SHOW ERRORS` and `SHOW WARNINGS` statements.

- **max_heap_table_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--max_heap_table_size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>max_heap_table_size</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>max_heap_table_size</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>Platform</strong></td>
<td>32</td>
</tr>
<tr>
<td><strong>Bit Size</strong></td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>16777216</td>
</tr>
<tr>
<td>Range</td>
<td>16384 .. 4294967295</td>
</tr>
<tr>
<td><strong>Platform</strong></td>
<td>64</td>
</tr>
<tr>
<td><strong>Bit Size</strong></td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td></td>
</tr>
<tr>
<td>Range</td>
<td></td>
</tr>
</tbody>
</table>
### Server System Variables

**max_heap_table_size** is not replicated. See Section 17.4.1.21, “Replication and MEMORY Tables”, and Section 17.4.1.36, “Replication and Variables”, for more information.

- **max_insert_delayed_threads**

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>max_insert_delayed_threads</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
</tbody>
</table>

This variable is a synonym for **max_delayed_threads**.

- **max_join_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max_join_size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>max_join_size</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>max_join_size</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>18446744073709551615</td>
</tr>
<tr>
<td>Range</td>
<td>1 .. 18446744073709551615</td>
</tr>
</tbody>
</table>

Do not permit statements that probably need to examine more than **max_join_size** rows (for single-table statements) or row combinations (for multiple-table statements) or that are likely to do more than **max_join_size** disk seeks. By setting this value, you can catch statements where keys are not used properly and that would probably take a long time. Set it if your users tend to perform joins that lack a **WHERE** clause, that take a long time, or that return millions of rows.

Setting this variable to a value other than DEFAULT resets the value of **sql_big_selects** to 0. If you set the **sql_big_selects** value again, the **max_join_size** variable is ignored.

If a query result is in the query cache, no result size check is performed, because the result has previously been computed and it does not burden the server to send it to the client.

This variable previously was named **sql_max_join_size**.
**max_length_for_sort_data**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max_length_for_sort_data=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>max_length_for_sort_data</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>max_length_for_sort_data</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>1024</td>
</tr>
<tr>
<td>Range</td>
<td>4 .. 8388608</td>
</tr>
</tbody>
</table>

The cutoff on the size of index values that determines which *filesort* algorithm to use. See Section 8.2.1.11, "ORDER BY Optimization".

**max_long_data_size**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.5.11</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deprecated</td>
<td>5.5.11</td>
</tr>
<tr>
<td>Command-Line Format</td>
<td>--max_long_data_size=#</td>
</tr>
<tr>
<td>Option-File Format</td>
<td>max_long_data_size</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>max_long_data_size</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>1048576</td>
</tr>
<tr>
<td>Range</td>
<td>1024 .. 4294967295</td>
</tr>
</tbody>
</table>

The maximum size of parameter values that can be sent with the `mysql_stmt_send_long_data()` C API function. If not set at server startup, the default is the value of the `max_allowed_packet` system variable. This variable is deprecated. In MySQL 5.6, it is removed and the maximum parameter size is controlled by `max_allowed_packet`.

**max_prepared_stmt_count**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max_prepared_stmt_count=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>max_prepared_stmt_count</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>max_prepared_stmt_count</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>16382</td>
</tr>
</tbody>
</table>

557
Server System Variables

| Range     | 0 .. 1048576 |

This variable limits the total number of prepared statements in the server. (The sum of the number of prepared statements across all sessions.) It can be used in environments where there is the potential for denial-of-service attacks based on running the server out of memory by preparing huge numbers of statements. If the value is set lower than the current number of prepared statements, existing statements are not affected and can be used, but no new statements can be prepared until the current number drops below the limit. The default value is 16,382. The permissible range of values is from 0 to 1 million. Setting the value to 0 disables prepared statements.

- **max_relay_log_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max_relay_log_size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>max_relay_log_size</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>max_relay_log_size</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>

<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 .. 1073741824</td>
</tr>
</tbody>
</table>

If a write by a replication slave to its relay log causes the current log file size to exceed the value of this variable, the slave rotates the relay logs (closes the current file and opens the next one). If max_relay_log_size is 0, the server uses max_binlog_size for both the binary log and the relay log. If max_relay_log_size is greater than 0, it constrains the size of the relay log, which enables you to have different sizes for the two logs. You must set max_relay_log_size to between 4096 bytes and 1GB (inclusive), or to 0. The default value is 0. See Section 17.2.1, “Replication Implementation Details”.

- **max_seeks_for_key**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max_seeks_for_key=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>max_seeks_for_key</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>max_seeks_for_key</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>

</tr>
<tr>
<td>Default</td>
<td>4294967295</td>
</tr>
<tr>
<td>Range</td>
<td>1 .. 4294967295</td>
</tr>
</tbody>
</table>

Platform Bit Size 64
Server System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>18446744073709547520</td>
</tr>
<tr>
<td>Range</td>
<td>1 .. 18446744073709547520</td>
</tr>
</tbody>
</table>

Limit the assumed maximum number of seeks when looking up rows based on a key. The MySQL optimizer assumes that no more than this number of key seeks are required when searching for matching rows in a table by scanning an index, regardless of the actual cardinality of the index (see Section 13.7.5.23, "SHOW INDEX Syntax"). By setting this to a low value (say, 100), you can force MySQL to prefer indexes instead of table scans.

- **max_sort_length**

  Command-Line Format  
  --max_sort_length=#

  Option-File Format  
  max_sort_length

  System Variable Name  
  max_sort_length

  Variable Scope  
  Global, Session

  Dynamic Variable  
  Yes

  Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>1024</td>
</tr>
<tr>
<td>Range</td>
<td>4 .. 8388608</td>
</tr>
</tbody>
</table>

  The number of bytes to use when sorting data values. Only the first max_sort_length bytes of each value are used; the rest are ignored.

- **max_sp_recursion_depth**

  Command-Line Format  
  --max_sp_recursion_depth[=#]

  Option-File Format  
  max_sp_recursion_depth

  System Variable Name  
  max_sp_recursion_depth

  Variable Scope  
  Global, Session

  Dynamic Variable  
  Yes

  Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Max Value</td>
<td>255</td>
</tr>
</tbody>
</table>

  The number of times that any given stored procedure may be called recursively. The default value for this option is 0, which completely disables recursion in stored procedures. The maximum value is 255.

  Stored procedure recursion increases the demand on thread stack space. If you increase the value of max_sp_recursion_depth, it may be necessary to increase thread stack size by increasing the value of thread_stack at server startup.

- **max_tmp_tables**

  This variable is unused.
Server System Variables

- **max_user_connections**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max_user_connections=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>max_user_connections</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>max_user_connections</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Default</td>
</tr>
<tr>
<td>Range</td>
</tr>
</tbody>
</table>

The maximum number of simultaneous connections permitted to any given MySQL user account. A value of 0 (the default) means "no limit."

This variable has a global value that can be set at server startup or runtime. It also has a read-only session value that indicates the effective simultaneous-connection limit that applies to the account associated with the current session. The session value is initialized as follows:

- If the user account has a nonzero MAX_USER_CONNECTIONS resource limit, the session max_user_connections value is set to that limit.
- Otherwise, the session max_user_connections value is set to the global value.

Account resource limits are specified using the GRANT statement. See Section 6.3.4, "Setting Account Resource Limits", and Section 13.7.1.3, "GRANT Syntax".

- **max_write_lock_count**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max_write_lock_count=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>max_write_lock_count</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>max_write_lock_count</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Default</td>
</tr>
<tr>
<td>Range</td>
</tr>
</tbody>
</table>

The size of the metadata locks cache. The server uses this cache to avoid creation and destruction of synchronization objects. This is particularly helpful on systems where such operations are expensive, such as Windows XP. This variable was added in MySQL 5.5.19.

- **min_examined_row_limit**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--min-examined-row-limit=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>min-examined-row-limit</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>min_examined_row_limit</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>

</tr>
<tr>
<td>Default</td>
</tr>
<tr>
<td>Range</td>
</tr>
</tbody>
</table>

Queries that examine fewer than this number of rows are not logged to the slow query log.

- **myisam_data_pointer_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--myisam_data_pointer_size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>myisam_data_pointer_size</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>myisam_data_pointer_size</td>
</tr>
</tbody>
</table>
The default pointer size in bytes, to be used by `CREATE TABLE` for MyISAM tables when no `MAX_ROWS` option is specified. This variable cannot be less than 2 or larger than 7. The default value is 6. See Section B.5.2.12, "The table is full".

- `myisam_max_sort_file_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--myisam_max_sort_file_size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>myisam_max_sort_file_size</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>myisam_max_sort_file_size</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Variable Scope</th>
<th>Global</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>6</td>
</tr>
<tr>
<td>Range</td>
<td>2 .. 7</td>
</tr>
</tbody>
</table>

The maximum size of the temporary file that MySQL is permitted to use while re-creating a MyISAM index (during `REPAIR TABLE`, `ALTER TABLE`, or `LOAD DATA INFILE`). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

The default value is 2GB. If MyISAM index files exceed this size and disk space is available, increasing the value may help performance. The space must be available in the file system containing the directory where the original index file is located.

- `myisam_mmap_size`

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.5.1</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--myisam_mmap_size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>myisam_mmap_size</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>myisam_mmap_size</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>

<tbody>
<tr>
<td>Platform</td>
</tr>
<tr>
<td>Bit Size</td>
</tr>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Default</td>
</tr>
<tr>
<td>Range</td>
</tr>
</tbody>
</table>

The maximum amount of memory to use for memory mapping compressed MyISAM files. If many compressed MyISAM tables are used, the value can be decreased to reduce the likelihood of memory-swapping problems. This variable was added in MySQL 5.5.1.

- **myisam_recover_options**

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>myisam_recover_options</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

  The value of the `--myisam-recover-options` option. See Section 5.1.3, “Server Command Options”.

- **myisam_repair_threads**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--myisam_repair_threads=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>myisam_repair_threads</td>
</tr>
<tr>

<tbody>
<tr>
<td>Platform</td>
</tr>
<tr>
<td>Bit Size</td>
</tr>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Default</td>
</tr>
<tr>
<td>Range</td>
</tr>
</tbody>
</table>
If this value is greater than 1, *MyISAM* table indexes are created in parallel (each index in its own thread) during the *Repair by sorting* process. The default value is 1.

**Note**
Multi-threaded repair is still *beta-quality* code.

- **myisam_sort_buffer_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--myisam_sort_buffer_size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>myisam_sort_buffer_size</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>myisam_sort_buffer_size</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Platform Bit Size</td>
<td>32</td>
</tr>
<tr>
<td>Type (Other)</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>8388608</td>
</tr>
<tr>
<td>Range</td>
<td>4096 .. 4294967295</td>
</tr>
</tbody>
</table>

The size of the buffer that is allocated when sorting *MyISAM* indexes during a *REPAIR TABLE* or when creating indexes with *CREATE INDEX* or *ALTER TABLE*.

The maximum permissible setting for *myisam_sort_buffer_size* is 4GB–1. Larger values are permitted for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB–1 with a warning).

- **myisam_stats_method**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--myisam_stats_method=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>myisam_stats_method</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>myisam_stats_method</td>
</tr>
</tbody>
</table>

The size of the buffer that is allocated when sorting *MyISAM* indexes during a *REPAIR TABLE* or when creating indexes with *CREATE INDEX* or *ALTER TABLE*.

The maximum permissible setting for *myisam_sort_buffer_size* is 4GB–1. Larger values are permitted for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB–1 with a warning).
Server System Variables

<table>
<thead>
<tr>
<th>Variable Scope</th>
<th>Global, Session</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>enumeration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>nulls_unequal</td>
</tr>
<tr>
<td>Valid Values</td>
<td>nulls_equal</td>
</tr>
<tr>
<td></td>
<td>nulls_unequal</td>
</tr>
<tr>
<td></td>
<td>nulls_ignored</td>
</tr>
</tbody>
</table>

How the server treats NULL values when collecting statistics about the distribution of index values for MyISAM tables. This variable has three possible values, nulls_equal, nulls_unequal, and nulls_ignored. For nulls_equal, all NULL index values are considered equal and form a single value group that has a size equal to the number of NULL values. For nulls_unequal, NULL values are considered unequal, and each NULL forms a distinct value group of size 1. For nulls_ignored, NULL values are ignored.

The method that is used for generating table statistics influences how the optimizer chooses indexes for query execution, as described in Section 8.3.7, “InnoDB and MyISAM Index Statistics Collection”.

- **myisam_use_mmap**

  **Command-Line Format**  
  --myisam_use_mmap

  **Option-File Format**  
  myisam_use_mmap

  **System Variable Name**  
  myisam_use_mmap

  **Variable Scope**  
  Global

  **Dynamic Variable**  
  Yes

  **Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>OFF</td>
</tr>
</tbody>
</table>

  Use memory mapping for reading and writing MyISAM tables.

- **named_pipe**

  **System Variable Name**  
  named_pipe

  **Variable Scope**  
  Global

  **Dynamic Variable**  
  No

  **Platform Specific**  
  Windows

  **Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>OFF</td>
</tr>
</tbody>
</table>

  (Windows only.) Indicates whether the server supports connections over named pipes.

- **net_buffer_length**
Each client thread is associated with a connection buffer and result buffer. Both begin with a size given by `net_buffer_length` but are dynamically enlarged up to `max_allowed_packet` bytes as needed. The result buffer shrinks to `net_buffer_length` after each SQL statement.

This variable should not normally be changed, but if you have very little memory, you can set it to the expected length of statements sent by clients. If statements exceed this length, the connection buffer is automatically enlarged. The maximum value to which `net_buffer_length` can be set is 1MB.

The session value of this variable is read only.

- **net_read_timeout**

  The number of seconds to wait for more data from a connection before aborting the read. When the server is reading from the client, `net_read_timeout` is the timeout value controlling when to abort. When the server is writing to the client, `net_write_timeout` is the timeout value controlling when to abort. See also `slave_net_timeout`.

- **net_retry_count**
If a read or write on a communication port is interrupted, retry this many times before giving up. This value should be set quite high on FreeBSD because internal interrupts are sent to all threads.

- **net_write_timeout**

  **Command-Line Format**  
  --net_write_timeout=#

  **Option-File Format**  
  net_write_timeout

  **System Variable Name**  
  net_write_timeout

  **Variable Scope**  
  Global, Session

  **Dynamic Variable**  
  Yes

  **Permitted Values**

  **Type**  
  numeric

  **Default**  
  60

  **Min Value**  
  1

  The number of seconds to wait for a block to be written to a connection before aborting the write. See also net_read_timeout.

- **new**

  **Command-Line Format**  
  --new

  **Option-File Format**  
  new

  **System Variable Name**  
  new

  **Variable Scope**  
  Global, Session

  **Dynamic Variable**  
  Yes

  **Disabled by**  
  skip-new

  **Permitted Values**

  **Type**  
  boolean

  **Default**  
  FALSE
This variable was used in MySQL 4.0 to turn on some 4.1 behaviors, and is retained for backward compatibility. In MySQL 5.5, its value is always OFF.

- **old**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--old</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>old</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>old</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

**old** is a compatibility variable. It is disabled by default, but can be enabled at startup to revert the server to behaviors present in older versions.

Currently, when **old** is enabled, it changes the default scope of index hints to that used prior to MySQL 5.1.17. That is, index hints with no FOR clause apply only to how indexes are used for row retrieval and not to resolution of ORDER BY or GROUP BY clauses. (See Section 13.2.9.3, “Index Hint Syntax”.) Take care about enabling this in a replication setup. With statement-based binary logging, having different modes for the master and slaves might lead to replication errors.

- **oldAlterTable**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--old-alter-table</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>old-alter-table</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>old_alter_table</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>OFF</td>
</tr>
</tbody>
</table>

When this variable is enabled, the server does not use the optimized method of processing an **ALTER TABLE** operation. It reverts to using a temporary table, copying over the data, and then renaming the temporary table to the original, as used by MySQL 5.0 and earlier. For more information on the operation of **ALTER TABLE**, see Section 13.1.7, “ALTER TABLE Syntax”.

- **oldPasswords**

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>old_passwords</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
</tbody>
</table>

This variable controls the password hashing method used by the **PASSWORD()** function. It also influences password hashing performed by **CREATE USER** and **GRANT** statements that specify a password using an **IDENTIFIED BY** clause.
The following table shows the permitted values of `old_passwords`, the password hashing method for each value, and which authentication plugins use passwords hashed with each method.

<table>
<thead>
<tr>
<th>Value</th>
<th>Password Hashing Method</th>
<th>Associated Authentication Plugin</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 or OFF</td>
<td>MySQL 4.1 native hashing</td>
<td><code>mysql_native_password</code></td>
</tr>
<tr>
<td>1 or ON</td>
<td>Pre-4.1 (&quot;old&quot;) hashing</td>
<td><code>mysql_old_password</code></td>
</tr>
</tbody>
</table>

If `old_passwords=1`, `PASSWORD(str)` returns the same value as `OLD_PASSWORD(str)`. The latter function is not affected by the value of `old_passwords`.

For additional information about authentication plugins and hashing formats, see Section 6.3.6, "Pluggable Authentication", and Section 6.1.2.4, "Password Hashing in MySQL".

**Note**

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided.

- **one_shot**
  
  This is not a variable, but it can be used when setting some variables. It is described in Section 13.7.4, "SET Syntax".

- **open_files_limit**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--open-files-limit=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>open-files-limit</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>open_files_limit</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 .. platform dependent</td>
</tr>
</tbody>
</table>

  The number of files that the operating system permits `mysqld` to open. This is the real value permitted by the system and might be different from the value you gave using the `--open-files-limit` option to `mysqld` or `mysqld_safe`. The value is 0 on systems where MySQL cannot change the number of open files.

- **optimizer_prune_level**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--optimizer_prune_level[=#]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>optimizer_prune_level</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>optimizer_prune_level</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>1</td>
</tr>
</tbody>
</table>

Controls the heuristics applied during query optimization to prune less-promising partial plans from the optimizer search space. A value of 0 disables heuristics so that the optimizer performs an exhaustive search. A value of 1 causes the optimizer to prune plans based on the number of rows retrieved by intermediate plans.

- **optimizer_search_depth**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--optimizer_search_depth[=#]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>optimizer_search_depth</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>optimizer_search_depth</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Default</td>
</tr>
<tr>
<td>Range</td>
</tr>
</tbody>
</table>

The maximum depth of search performed by the query optimizer. Values larger than the number of relations in a query result in better query plans, but take longer to generate an execution plan for a query. Values smaller than the number of relations in a query return an execution plan quicker, but the resulting plan may be far from being optimal. If set to 0, the system automatically picks a reasonable value. If set to 63, the optimizer switches to the algorithm used in MySQL 5.0.0 (and previous versions) for performing searches. The value of 63 is deprecated and will be treated as invalid in a future MySQL release.

- **optimizer_switch**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--optimizer_switch=value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>optimizer_switch</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>optimizer_switch</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values (&lt;= 5.5.2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Valid Values</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values (&gt;= 5.5.3)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Valid Values</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>
The `optimizer_switch` system variable enables control over optimizer behavior. The value of this variable is a set of flags, each of which has a value of `on` or `off` to indicate whether the corresponding optimizer behavior is enabled or disabled. This variable has global and session values and can be changed at runtime. The global default can be set at server startup.

To see the current set of optimizer flags, select the variable value:

```
mysql> SELECT @@optimizer_switch\G
*************************** 1. row ***************************
@@optimizer_switch: index_merge=on,index_merge_union=on, index_merge_sort_union=on, index_merge_intersection=on, engine_condition_pushdown=on
```

For more information about the syntax of this variable and the optimizer behaviors that it controls, see Section 8.8.5.2, “Controlling Switchable Optimizations”.

- `performance_schema_xxx`

Performance Schema system variables are listed in Section 22.9, “Performance Schema System Variables”. These variables may be used to configure Performance Schema operation.

- `pid_file`

```
Command-Line Format   --pid-file=file_name
Option-File Format    pid-file
System Variable Name  pid_file
Variable Scope        Global
Dynamic Variable      No
Permitted Values
Type  file name
```

The path name of the process ID (PID) file. This variable can be set with the `--pid-file` option.

- `plugin_dir`

```
Command-Line Format   --plugin_dir=path
Option-File Format    plugin_dir
System Variable Name  plugin_dir
Variable Scope        Global
Dynamic Variable      No
Permitted Values
Type  directory name
(Windows)
Default  BASEDIR/lib/plugin
```

The path name of the process ID (PID) file. This variable can be set with the `--pid-file` option.
The path name of the plugin directory.

If the plugin directory is writable by the server, it may be possible for a user to write executable code to a file in the directory using `SELECT ... INTO DUMPFILE`. This can be prevented by making `plugin_dir` read only to the server or by setting `--secure-file-priv` to a directory where `SELECT` writes can be made safely.

- **port**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--port=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>-P</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>port</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>3306</td>
</tr>
<tr>
<td>Range</td>
<td>0 .. 65535</td>
</tr>
</tbody>
</table>

The number of the port on which the server listens for TCP/IP connections. This variable can be set with the `--port` option.

- **preload_buffer_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--preload_buffer_size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>preload_buffer_size</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>preload_buffer_size</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>32768</td>
</tr>
<tr>
<td>Range</td>
<td>1024 .. 1073741824</td>
</tr>
</tbody>
</table>

The size of the buffer that is allocated when preloading indexes.
If set to 0 or OFF (the default), statement profiling is disabled. If set to 1 or ON, statement profiling is enabled and the SHOW PROFILE and SHOW PROFILES statements provide access to profiling information. See Section 13.7.5.32, “SHOW PROFILES Syntax”.

- **profiling_history_size**

  The number of statements for which to maintain profiling information if profiling is enabled. The default value is 15. The maximum value is 100. Setting the value to 0 effectively disables profiling. See Section 13.7.5.32, “SHOW PROFILES Syntax”.

- **protocol_version**

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>protocol_version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
</tbody>
</table>

  The version of the client/server protocol used by the MySQL server.

- **proxy_user**

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>proxy_user</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.5.7</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>string</td>
</tr>
</tbody>
</table>

  If the current client is a proxy for another user, this variable is the proxy user account name. Otherwise, this variable is NULL. See Section 6.3.8, “Proxy Users”.

  This variable was added in MySQL 5.5.7.

- **pseudo_slave_mode**

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>pseudo_slave_mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Introduced</td>
<td>5.5.30</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
</tbody>
</table>

  This variable is for internal server use. It was added in MySQL 5.5.30.

- **pseudo_thread_id**

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>pseudo_thread_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Session</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Dynamic Variable</th>
<th>Yes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
</tbody>
</table>

This variable is for internal server use.

- **query_alloc_block_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--query_alloc_block_size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>query_alloc_block_size</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>query_alloc_block_size</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

| Permitted Values |    |
| Platform         | 32 |
| Bit Size         |    |
| Type             | numeric |
| Default          | 8192  |
| Range            | 1024 .. 4294967295 |
| Block Size       | 1024 |

The allocation size of memory blocks that are allocated for objects created during statement parsing and execution. If you have problems with memory fragmentation, it might help to increase this parameter.

- **query_cache_limit**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--query_cache_limit=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>query_cache_limit</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>query_cache_limit</td>

| Type             | numeric |
| Default          | 8192  |
| Range            | 1024 .. 18446744073709547520 |
| Block Size       | 1024 |
Server System Variables

| Default  | 1048576 |
| Range    | 0 .. 4294967295 |

Permitted Values

| Platform | 64 |
| Bit Size |   |

| Type         | numeric |
| Default      | 1048576 |
| Range        | 0 .. 18446744073709547520 |

Do not cache results that are larger than this number of bytes. The default value is 1MB.

- **query_cache_min_res_unit**

  Command-Line Format  
  `--query_cache_min_res_unit=`

  Option-File Format  
  `query_cache_min_res_unit`  

  System Variable Name  
  `query_cache_min_res_unit`  

  Variable Scope  
  Global  

  Dynamic Variable  
  Yes  

  Permitted Values

  | Platform | 32 |
  | Bit Size |   |

  | Type         | numeric |
  | Default      | 4096 |
  | Range        | 512 .. 4294967295 |

  Permitted Values

  | Platform | 64 |
  | Bit Size |   |

  | Type         | numeric |
  | Default      | 4096 |
  | Range        | 512 .. 18446744073709547520 |

  The minimum size (in bytes) for blocks allocated by the query cache. The default value is 4096 (4KB). Tuning information for this variable is given in Section 8.9.3.3, “Query Cache Configuration”.

- **query_cache_size**

  Command-Line Format  
  `--query_cache_size=`

  Option-File Format  
  `query_cache_size`  

  System Variable Name  
  `query_cache_size`  

  Variable Scope  
  Global  

  Dynamic Variable  
  Yes  

  Permitted Values

  | Platform | 32 |
  | Bit Size |   |
### Server System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 .. 4294967295</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Platform</th>
<th>Bit Size</th>
<th>Type</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>0</td>
<td>Range</td>
<td>0 .. 18446744073709547520</td>
</tr>
</tbody>
</table>

The amount of memory allocated for caching query results. The default value is 0, which disables the query cache. To reduce overhead significantly, you should also start the server with `query_cache_type=0` if you will not be using the query cache. The permissible values are multiples of 1024; other values are rounded down to the nearest multiple. Note that `query_cache_size` bytes of memory are allocated even if `query_cache_type` is set to 0. See Section 8.9.3.3, “Query Cache Configuration”, for more information.

The query cache needs a minimum size of about 40KB to allocate its structures. (The exact size depends on system architecture.) If you set the value of `query_cache_size` too small, a warning will occur, as described in Section 8.9.3.3, “Query Cache Configuration”.

- **query_cache_type**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--query_cache_type=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>query_cache_type</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>query_cache_type</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
<th>Type</th>
<th>enumeration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>Valid Values</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>

Set the query cache type. Setting the `GLOBAL` value sets the type for all clients that connect thereafter. Individual clients can set the `SESSION` value to affect their own use of the query cache. Possible values are shown in the following table.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 or OFF</td>
<td>Do not cache results in or retrieve results from the query cache. Note that this does not deallocate the query cache buffer. To do that, you should set <code>query_cache_size</code> to 0.</td>
</tr>
<tr>
<td>1 or ON</td>
<td>Cache all cacheable query results except for those that begin with <code>SELECT SQL_NO_CACHE</code>.</td>
</tr>
<tr>
<td>2 or DEMAND</td>
<td>Cache results only for cacheable queries that begin with <code>SELECT SQL_CACHE</code>.</td>
</tr>
</tbody>
</table>
This variable defaults to `ON`.

If the server is started with `query_cache_type` set to 0, it does not acquire the query cache mutex at all, which means that the query cache cannot be enabled at runtime and there is reduced overhead in query execution.

- `query_cache_wlock_invalidate`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--query_cache_wlock_invalidate</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>query_cache_wlock_invalidate</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>query_cache_wlock_invalidate</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Normally, when one client acquires a `WRITE` lock on a `MyISAM` table, other clients are not blocked from issuing statements that read from the table if the query results are present in the query cache. Setting this variable to 1 causes acquisition of a `WRITE` lock for a table to invalidate any queries in the query cache that refer to the table. This forces other clients that attempt to access the table to wait while the lock is in effect.

- `query_prealloc_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--query_prealloc_size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>query_prealloc_size</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>query_prealloc_size</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Platform Bit Size</td>
<td>32</td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>8192</td>
</tr>
<tr>
<td>Range</td>
<td>8192 . . 4294967295</td>
</tr>
<tr>
<td>Block Size</td>
<td>1024</td>
</tr>
</tbody>
</table>

| Permitted Values    |                          |
| Platform Bit Size   | 64                       |
| Type                | numeric                  |
| Default             | 8192                     |
| Range               | 8192 . . 18446744073709547520 |
The size of the persistent buffer used for statement parsing and execution. This buffer is not freed between statements. If you are running complex queries, a larger `query_prealloc_size` value might be helpful in improving performance, because it can reduce the need for the server to perform memory allocation during query execution operations.

- **rand_seed1**

  The `rand_seed1` and `rand_seed2` variables exist as session variables only, and can be set but not read. The variables—but not their values—are shown in the output of `SHOW VARIABLES`.

  The purpose of these variables is to support replication of the `RAND()` function. For statements that invoke `RAND()`, the master passes two values to the slave, where they are used to seed the random number generator. The slave uses these values to set the session variables `rand_seed1` and `rand_seed2` so that `RAND()` on the slave generates the same value as on the master.

- **rand_seed2**

  See the description for `rand_seed1`.

- **range_alloc_block_size**

  The size of blocks that are allocated when doing range optimization.

- **read_buffer_size**
Server System Variables

Command-Line Format  --read_buffer_size=#
Option-File Format  read_buffer_size
System Variable Name  read_buffer_size
Variable Scope  Global, Session
Dynamic Variable  Yes

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type      numeric</td>
</tr>
<tr>
<td>Default   131072</td>
</tr>
<tr>
<td>Range     8200 .. 2147479552</td>
</tr>
</tbody>
</table>

Each thread that does a sequential scan for a MyISAM table allocates a buffer of this size (in bytes) for each table it scans. If you do many sequential scans, you might want to increase this value, which defaults to 131072. The value of this variable should be a multiple of 4KB. If it is set to a value that is not a multiple of 4KB, its value will be rounded down to the nearest multiple of 4KB.

This option is also used in the following context for all search engines:

- For caching the indexes in a temporary file (not a temporary table), when sorting rows for ORDER BY.
- For bulk insert into partitions.
- For caching results of nested queries.

and in one other storage engine-specific way: to determine the memory block size for MEMORY tables.

The maximum permissible setting for read_buffer_size is 2GB.

For more information about memory use during different operations, see Section 8.11.4.1, “How MySQL Uses Memory”.

- read_only

Command-Line Format  --read-only
Option-File Format  read_only
System Variable Name  read_only
Variable Scope  Global
Dynamic Variable  Yes

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type      boolean</td>
</tr>
<tr>
<td>Default   false</td>
</tr>
</tbody>
</table>

This variable is off by default. When it is enabled, the server permits no updates except from users that have the SUPER privilege or (on a slave server) from updates performed by slave threads. In replication setups, it can be useful to enable read_only on slave servers to ensure that slaves accept updates only from the master server and not from clients.

read_only does not apply to TEMPORARY tables, nor does it prevent the server from inserting rows into the log tables (see Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”).
This variable does not prevent the use of `ANALYZE TABLE` or `OPTIMIZE TABLE` statements because its purpose is to prevent changes to table structure or contents. Analysis and optimization do not qualify as such changes. This means, for example, that consistency checks on read-only slaves can be performed with `mysqlcheck --all-databases --analyze`.

`read_only` exists only as a `GLOBAL` variable, so changes to its value require the `SUPER` privilege. Changes to `read_only` on a master server are not replicated to slave servers. The value can be set on a slave server independent of the setting on the master.

**Important**

In MySQL 5.5, enabling `read_only` prevents the use of the `SET PASSWORD` statement by any user not having the `SUPER` privilege. This is not necessarily the case for all MySQL release series. When replicating from one MySQL release series to another (for example, from a MySQL 5.0 master to a MySQL 5.1 or later slave), you should check the documentation for the versions running on both master and slave to determine whether the behavior of `read_only` in this regard is or is not the same, and, if it is different, whether this has an impact on your applications.

The following conditions apply:

- If you attempt to enable `read_only` while you have any explicit locks (acquired with `LOCK TABLES`) or have a pending transaction, an error occurs.

- If you attempt to enable `read_only` while other clients hold explicit table locks or have pending transactions, the attempt blocks until the locks are released and the transactions end. While the attempt to enable `read_only` is pending, requests by other clients for table locks or to begin transactions also block until `read_only` has been set.

- `read_only` can be enabled while you hold a global read lock (acquired with `FLUSH TABLES WITH READ LOCK`) because that does not involve table locks.

As of MySQL 5.5.3, attempts to set `read_only` block for active transactions that hold metadata locks until those transactions end.

- `read_rnd_buffer_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--read_rnd_buffer_size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>

</tr>
</tbody>
</table>

- **Permitted Values (<= 5.5.2)**
  - **Type**: numeric
  - **Default**: 262144
  - **Range**: 8200 .. 2147483647

- **Permitted Values (>= 5.5.3)**
  - **Type**: numeric
  - **Default**: 262144
When reading rows from a MyISAM table in sorted order following a key-sorting operation, the rows are read through this buffer to avoid disk seeks. See Section 8.2.1.11, “ORDER BY Optimization”. Setting the variable to a large value can improve ORDER BY performance by a lot. However, this is a buffer allocated for each client, so you should not set the global variable to a large value. Instead, change the session variable only from within those clients that need to run large queries.

The maximum permissible setting for `read_rnd_buffer_size` is 2GB.

For more information about memory use during different operations, see Section 8.11.4.1, “How MySQL Uses Memory”.

- `read_rnd_buffer_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>

<td>0 .. 65535</td>
</tr>
</tbody>
</table>

The value of the **--report-port** option.

- **report_user**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--report-user=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>report-user</td>
</tr>
</tbody>
</table>
### Server System Variables

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>report_user</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Variable Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic Variable</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>string</td>
</tr>
</tbody>
</table>

The value of the `--report-user` option. Not the same as the name for the MySQL replication user account.

- `rpl_semi_sync_master_enabled`

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>rpl_semi_sync_master_enabled</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Variable Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic Variable</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>boolean</td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td>OFF</td>
</tr>
</tbody>
</table>

Controls whether semisynchronous replication is enabled on the master. To enable or disable the plugin, set this variable to **ON** or **OFF** (or 1 or 0), respectively. The default is **OFF**.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_master_timeout`

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>rpl_semi_sync_master_timeout</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Variable Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic Variable</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>numeric</td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td>10000</td>
</tr>
</tbody>
</table>

A value in milliseconds that controls how long the master waits on a commit for acknowledgment from a slave before timing out and reverting to asynchronous replication. The default value is 10000 (10 seconds).

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_master_trace_level`

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>rpl_semi_sync_master_trace_level</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Variable Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic Variable</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>numeric</td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td>32</td>
</tr>
</tbody>
</table>
The semisynchronous replication debug trace level on the master. Currently, four levels are defined:

- 1 = general level (for example, time function failures)
- 16 = detail level (more verbose information)
- 32 = net wait level (more information about network waits)
- 64 = function level (information about function entry and exit)

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_master_wait_no_slave`

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>rpl_semi_sync_master_wait_no_slave</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>ON</td>
</tr>
</tbody>
</table>

With semisynchronous replication, for each transaction, the master waits until timeout for acknowledgment of receipt from some semisynchronous slave. If no response occurs during this period, the master reverts to normal replication. This variable controls whether the master waits for the timeout to expire before reverting to normal replication even if the slave count drops to zero during the timeout period.

If the value is **ON** (the default), it is permissible for the slave count to drop to zero during the timeout period (for example, if slaves disconnect). The master still waits for the timeout, so as long as some slave reconnects and acknowledges the transaction within the timeout interval, semisynchronous replication continues.

If the value is **OFF**, the master reverts to normal replication if the slave count drops to zero during the timeout period.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_slave_enabled`

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>rpl_semi_sync_slave_enabled</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Controls whether semisynchronous replication is enabled on the slave. To enable or disable the plugin, set this variable to **ON** or **OFF** (or 1 or 0), respectively. The default is **OFF**.

This variable is available only if the slave-side semisynchronous replication plugin is installed.
• rpl_semi_sync_slave_trace_level

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>rpl_semi_sync_slave_trace_level</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>32</td>
</tr>
</tbody>
</table>

The semisynchronous replication debug trace level on the slave. See rpl_semi_sync_master_trace_level for the permissible values.

This variable is available only if the slave-side semisynchronous replication plugin is installed.

• secure_auth

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--secure-auth</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>secure-auth</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>secure_auth</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>OFF</td>
</tr>
</tbody>
</table>

If this variable is enabled, the server blocks connections by clients that attempt to use accounts that have passwords stored in the old (pre-4.1) format.

Enable this variable to prevent all use of passwords employing the old format (and hence insecure communication over the network).

Server startup fails with an error if this variable is enabled and the privilege tables are in pre-4.1 format. See Section B.5.2.4, "Client does not support authentication protocol".

Note

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided.

• secure_file_priv

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--secure-file-priv=path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>secure-file-priv</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>secure_file_priv</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td></td>
</tr>
</tbody>
</table>
By default, this variable is empty. If set to the name of a directory, it limits the effect of the `LOAD_FILE()` function and the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements to work only with files in that directory.

- **server_id**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--server-id=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>server-id</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>server_id</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Permitted Values**

- **Type**: numeric
- **Default**: 0
- **Range**: 0 .. 4294967295

The server ID, used in replication to give each master and slave a unique identity. This variable is set by the `--server-id` option. For each server participating in replication, you should pick a positive integer in the range from 1 to $2^{32} - 1$ to act as that server's ID.

- **shared_memory**

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>shared_memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
</tbody>
</table>

(Windows only.) Whether the server permits shared-memory connections.

- **shared_memory_base_name**

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>shared_memory_base_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Platform Specific</td>
<td>Windows</td>
</tr>
</tbody>
</table>

(Windows only.) The name of shared memory to use for shared-memory connections. This is useful when running multiple MySQL instances on a single physical machine. The default name is `MYSQL`. The name is case sensitive.

- **skip_external_locking**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--skip-external-locking</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>skip_external_locking</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>skip_external_locking</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>
Server System Variables

**skip_name_resolve**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--skip-name-resolve</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>skip-name-resolve</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>skip_name_resolve</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

This variable is set from the value of the `--skip-name-resolve` option. If it is ON, mysqld resolves host names when checking client connections. If OFF, mysqld uses only IP numbers and all Host column values in the grant tables must be IP addresses or localhost. See Section 8.11.5.2, “DNS Lookup Optimization and the Host Cache”.

This variable was added in MySQL 5.5.5.

**skip_networking**

This is ON if the server permits only local (non-TCP/IP) connections. On Unix, local connections use a Unix socket file. On Windows, local connections use a named pipe or shared memory. This variable can be set to ON with the `--skip-networking` option.

**skip_show_database**

This is ON if mysqld uses external locking (system locking), ON if external locking is disabled. This affects only MyISAM table access.

This variable is set by the `--external-locking` or `--skip-external-locking` option. External locking has been disabled by default as of MySQL 4.0.

External locking affects only MyISAM table access. For more information, including conditions under which it can and cannot be used, see Section 8.10.5, “External Locking”.

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--skip-show-database</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>skip-show-database</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>skip_show_database</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
</tbody>
</table>
Server System Variables

<table>
<thead>
<tr>
<th>Dynamic Variable</th>
<th>No</th>
</tr>
</thead>
</table>

This prevents people from using the `SHOW DATABASES` statement if they do not have the `SHOW DATABASES` privilege. This can improve security if you have concerns about users being able to see databases belonging to other users. Its effect depends on the `SHOW DATABASES` privilege: If the variable value is **ON**, the `SHOW DATABASES` statement is permitted only to users who have the `SHOW DATABASES` privilege, and the statement displays all database names. If the value is **OFF**, `SHOW DATABASES` is permitted to all users, but displays the names of only those databases for which the user has the `SHOW DATABASES` or other privilege. (Note that any global privilege is considered a privilege for the database.)

- **slow_launch_time**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--slow_launch_time=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>slow_launch_time</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>slow_launch_time</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>2</td>
</tr>
</tbody>
</table>

If creating a thread takes longer than this many seconds, the server increments the `Slow_launch_threads` status variable.

- **slow_query_log**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--slow-query-log-log</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>slow-query-log</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>slow_query_log</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Whether the slow query log is enabled. The value can be 0 (or **OFF**) to disable the log or 1 (or **ON**) to enable the log. The default value depends on whether the `--slow_query_log` option is given. The destination for log output is controlled by the `log_output` system variable; if that value is **NONE**, no log entries are written even if the log is enabled.

“Slow” is determined by the value of the `long_query_time` variable. See Section 5.2.5, “The Slow Query Log”.

- **slow_query_log_file**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--slow-query-log-file=file_name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>slow_query_log_file</code></td>
</tr>
</tbody>
</table>
### slow_query_log_file

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>slow_query_log_file</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>file name</td>
</tr>
<tr>
<td>Default</td>
<td>host_name-slow.log</td>
</tr>
</tbody>
</table>

The name of the slow query log file. The default value is `host_name-slow.log`, but the initial value can be changed with the `--slow_query_log_file` option.

#### socket

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--socket=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>socket</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>socket</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>file name</td>
</tr>
<tr>
<td>Default</td>
<td>/tmp/mysql.sock</td>
</tr>
</tbody>
</table>

On Unix platforms, this variable is the name of the socket file that is used for local client connections. The default is `/tmp/mysql.sock`. (For some distribution formats, the directory might be different, such as `/var/lib/mysql` for RPMs.)

On Windows, this variable is the name of the named pipe that is used for local client connections. The default value is MySQL (not case sensitive).

#### sort_buffer_size

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--sort_buffer_size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>sort_buffer_size</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>sort_buffer_size</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td>Platform Bit Size</td>
<td>32</td>
</tr>
<tr>
<td>Type (Other)</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>2097144</td>
</tr>
<tr>
<td>Range</td>
<td>32768 .. 4294967295</td>
</tr>
</tbody>
</table>

| Platform Bit Size       | 64                    |
Each session that needs to do a sort allocates a buffer of this size. `sort_buffer_size` is not specific to any storage engine and applies in a general manner for optimization. See Section 8.2.1.11, "ORDER BY Optimization", for example.

If you see many `Sort_merge_passes` per second in SHOW GLOBAL STATUS output, you can consider increasing the `sort_buffer_size` value to speed up ORDER BY or GROUP BY operations that cannot be improved with query optimization or improved indexing. The entire buffer is allocated even if it is not all needed, so setting it larger than required globally will slow down most queries that sort. It is best to increase it as a session setting, and only for the sessions that need a larger size. On Linux, there are thresholds of 256KB and 2MB where larger values may significantly slow down memory allocation, so you should consider staying below one of those values. Experiment to find the best value for your workload. See Section B.5.4.4, “Where MySQL Stores Temporary Files”.

The maximum permissible setting for `sort_buffer_size` is 4GB–1. Larger values are permitted for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB–1 with a warning).

- `sql_auto_is_null`

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th><code>sql_auto_is_null</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values (&lt; 5.5.2)</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Permitted Values (&gt; 5.5.3)</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
</tbody>
</table>

If this variable is set to 1, then after a statement that successfully inserts an automatically generated AUTO_INCREMENT value, you can find that value by issuing a statement of the following form:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

If the statement returns a row, the value returned is the same as if you invoked the `LAST_INSERT_ID()` function. For details, including the return value after a multiple-row insert, see Section 12.14, “Information Functions”. If no AUTO_INCREMENT value was successfully inserted, the SELECT statement returns no row.
The behavior of retrieving an AUTO_INCREMENT value by using an IS NULL comparison is used by some ODBC programs, such as Access. See Obtaining Auto-Increment Values. This behavior can be disabled by setting sql_auto_is_null to 0.

The default value of sql_auto_is_null is 0 as of MySQL 5.5.3, and 1 for earlier versions.

- sql_big_selects

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>sql_big_selects</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
</tbody>
</table>

If set to 0, MySQL aborts SELECT statements that are likely to take a very long time to execute (that is, statements for which the optimizer estimates that the number of examined rows exceeds the value of max_join_size). This is useful when an inadvisable WHERE statement has been issued. The default value for a new connection is 1, which permits all SELECT statements.

If you set the max_join_size system variable to a value other than DEFAULT, sql_big_selects is set to 0.

- sql_buffer_result

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>sql_buffer_result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
</tbody>
</table>

If set to 1, sql_buffer_result forces results from SELECT statements to be put into temporary tables. This helps MySQL free the table locks early and can be beneficial in cases where it takes a long time to send results to the client. The default value is 0.

- sql_log_bin

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>sql_log_bin</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
</tbody>
</table>

This variable controls whether logging to the binary log is done. The default value is 1 (do logging). To change logging for the current session, change the session value of this variable. The session user must have the SUPER privilege to set this variable.
Beginning with MySQL 5.5.5, it is no longer possible to set `@@session.sql_log_bin` within a transaction or subquery. (Bug #53437)

- **sql_log_off**

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>sql_log_off</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type: boolean, Default: 0</td>
</tr>
</tbody>
</table>

This variable controls whether logging to the general query log is done. The default value is 0 (do logging). To change logging for the current session, change the session value of this variable. The session user must have the `SUPER` privilege to set this option. The default value is 0.

- **sql_log_update**

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>sql_log_update</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type: boolean</td>
</tr>
</tbody>
</table>

This variable is deprecated, and is mapped to `sql_log_bin`. It was removed in MySQL 5.5.3.

- **sql_mode**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--sql-mode=name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>sql-mode</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td>sql_mode</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type: set, Default: ''</td>
</tr>
</tbody>
</table>

**Valid Values**
- ALLOW_INVALIDDATES
- ANSI_QUOTES
- ERROR_FOR_DIVISION_BY_ZERO
- HIGH_NOT_PRECEDENCE
- IGNORE_SPACE
- NO_AUTO_CREATE_USER
Server System Variables

<table>

<tr>
<td>PIPES_AS_CONCAT</td>
</tr>
<tr>
<td>REAL_AS_FLOAT</td>
</tr>
<tr>
<td>STRICT_ALL_TABLES</td>
</tr>
<tr>
<td>STRICT_TRANS_TABLES</td>
</tr>
</tbody>
</table>

The current server SQL mode, which can be set dynamically. See Section 5.1.7, “Server SQL Modes”.

**Note**

MySQL installation programs may configure the SQL mode during the installation process. If the SQL mode differs from the default or from what you expect, check for a setting in an option file that the server reads at startup.

- **sql_notes**

  If set to 1 (the default), warnings of Note level increment warning_count and the server records them. If set to 0, Note warnings do not increment warning_count and the server does not record them. mysqldump includes output to set this variable to 0 so that reloading the dump file does not produce warnings for events that do not affect the integrity of the reload operation.

- **sql_quote_show_create**

  If set to 1 (the default), the server quotes identifiers for SHOW CREATE TABLE and SHOW CREATE DATABASE statements. If set to 0, quoting is disabled. This option is enabled by default so that replication works for identifiers that require quoting. See Section 13.7.5.12, “SHOW CREATE TABLE Syntax”, and Section 13.7.5.8, “SHOW CREATE DATABASE Syntax”.

- **sql_safe_updates**

  If set to 1, MySQL aborts UPDATE or DELETE statements that do not use a key in the WHERE clause or a LIMIT clause. (Specifically, UPDATE statements must have a WHERE clause that uses a key or a LIMIT clause, or both. DELETE statements must have both.) This makes it possible to catch UPDATE or DELETE statements where keys are not used properly and that would probably change or delete a large number of rows. The default value is 0.

- **sql_select_limit**
The maximum number of rows to return from `SELECT` statements. The default value for a new connection is the maximum number of rows that the server permits per table. Typical default values are \(2^{32} - 1\) or \(2^{64} - 1\). If you have changed the limit, the default value can be restored by assigning a value of `DEFAULT`.

If a `SELECT` has a `LIMIT` clause, the `LIMIT` takes precedence over the value of `sql_select_limit`.

- **sql_warnings**

  This variable controls whether single-row `INSERT` statements produce an information string if warnings occur. The default is 0. Set the value to 1 to produce an information string.

- **ssl_ca**

  The path to a file with a list of trusted SSL CAs.

- **ssl_capath**

  The path to a directory that contains trusted SSL CA certificates in PEM format.

- **ssl_cert**
Server System Variables

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>file name</td>
</tr>
</tbody>
</table>

The name of the SSL certificate file to use for establishing a secure connection.

- **ssl_cipher**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--ssl-cipher=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>ssl-cipher</td>
</tr>
<tr>

<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>string</td>
</tr>
</tbody>
</table>

The name of the SSL key file to use for establishing a secure connection.

- **storage_engine**

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>storage_engine</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values (&gt;= 5.5.3, &lt;= 5.5.4)</td>
<td>enumeration</td>
</tr>
<tr>
<td>Default</td>
<td>MyISAM</td>
</tr>
<tr>
<td>Permitted Values (&gt;= 5.5.5)</td>
<td>enumeration</td>
</tr>
<tr>
<td>Default</td>
<td>InnoDB</td>
</tr>
</tbody>
</table>

The default storage engine (table type). To set the storage engine at server startup, use the --default-storage-engine option. See Section 5.1.3, “Server Command Options”.

This variable is deprecated as of MySQL 5.5.3. Use default_storage_engine instead.

- **stored_program_cache**
### introduced

**5.5.21**

### command-line format

```
--stored-program-cache=#
```

### option-file format

```
stored_program_cache
```

### system variable name

```
stored_program_cache
```

### variable scope

**Global**

### dynamic variable

**Yes**

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
</tr>
<tr>
<td>numeric</td>
</tr>
<tr>
<td><strong>Default</strong></td>
</tr>
<tr>
<td>256</td>
</tr>
<tr>
<td><strong>Range</strong></td>
</tr>
<tr>
<td>256 .. 524288</td>
</tr>
</tbody>
</table>

Sets a soft upper limit for the number of cached stored routines per connection. The value of this variable is specified in terms of the number of stored routines held in each of the two caches maintained by the MySQL Server for, respectively, stored procedures and stored functions.

Whenever a stored routine is executed this cache size is checked before the first or top-level statement in the routine is parsed; if the number of routines of the same type (stored procedures or stored functions according to which is being executed) exceeds the limit specified by this variable, the corresponding cache is flushed and memory previously allocated for cached objects is freed. This allows the cache to be flushed safely, even when there are dependencies between stored routines.

- **sync Frm**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--sync-frm</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>sync_frm</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>sync_frm</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
</tr>
<tr>
<td>boolean</td>
</tr>
<tr>
<td><strong>Default</strong></td>
</tr>
<tr>
<td>TRUE</td>
</tr>
</tbody>
</table>

If this variable is set to 1, when any nontemporary table is created its `.frm` file is synchronized to disk (using `fdatasync()`). This is slower but safer in case of a crash. The default is 1.

- **system_time_zone**

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th><code>system_time_zone</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
</tr>
<tr>
<td>string</td>
</tr>
</tbody>
</table>

The server system time zone. When the server begins executing, it inherits a time zone setting from the machine defaults, possibly modified by the environment of the account used for running the server or the startup script. The value is used to set `system_time_zone`. Typically the time zone is specified by the
The `TZ` environment variable. It also can be specified using the `--timezone` option of the `mysqld_safe` script.

The `system_time_zone` variable differs from `time_zone`. Although they might have the same value, the latter variable is used to initialize the time zone for each client that connects. See Section 10.6, “MySQL Server Time Zone Support”.

- `table_definition_cache`

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>table_definition_cache</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>400</td>
</tr>
<tr>
<td>Range</td>
<td>400 .. 524288</td>
</tr>
</tbody>
</table>

The number of table definitions (from `.frm` files) that can be stored in the definition cache. If you use a large number of tables, you can create a large table definition cache to speed up opening of tables. The table definition cache takes less space and does not use file descriptors, unlike the normal table cache. The minimum and default values are both 400.

- `table_lock_wait_timeout`

<table>
<thead>
<tr>
<th>Removed</th>
<th>5.5.3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--table_lock_wait_timeout=#</code></td>
</tr>
<tr>
<td>Option-File Format</td>
<td><code>table_lock_wait_timeout</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td>table_lock_wait_timeout</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>50</td>
</tr>
<tr>
<td>Range</td>
<td>1 .. 1073741824</td>
</tr>
</tbody>
</table>

This variable is unused. It was removed in 5.5.3.

- `table_open_cache`

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>table_open_cache</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>400</td>
</tr>
<tr>
<td>Range</td>
<td>1 .. 524288</td>
</tr>
</tbody>
</table>
The number of open tables for all threads. Increasing this value increases the number of file descriptors that mysqld requires. You can check whether you need to increase the table cache by checking the Opened_tables status variable. See Section 5.1.6, “Server Status Variables”. If the value of Opened_tables is large and you do not use FLUSH TABLES often (which just forces all tables to be closed and reopened), then you should increase the value of the table_open_cache variable. For more information about the table cache, see Section 8.4.3.1, “How MySQL Opens and Closes Tables”.

- **table_type**

  This variable was removed in MySQL 5.5.3. Use storage_engine instead.

- **thread_cache_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--thread_cache_size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>thread_cache_size</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>thread_cache_size</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 .. 16384</td>
</tr>
</tbody>
</table>

  How many threads the server should cache for reuse. When a client disconnects, the client’s threads are put in the cache if there are fewer than thread_cache_size threads there. Requests for threads are satisfied by reusing threads taken from the cache if possible, and only when the cache is empty is a new thread created. This variable can be increased to improve performance if you have a lot of new connections. Normally, this does not provide a notable performance improvement if you have a good thread implementation. However, if your server sees hundreds of connections per second you should normally set thread_cache_size high enough so that most new connections use cached threads. By examining the difference between the Connections and Threads_created status variables, you can see how efficient the thread cache is. For details, see Section 5.1.6, “Server Status Variables”.

- **thread_concurrency**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--thread_concurrency=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>thread_concurrency</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>thread_concurrency</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>10</td>
</tr>
<tr>
<td>Range</td>
<td>1 .. 512</td>
</tr>
</tbody>
</table>

  This variable is specific to Solaris 8 and earlier systems, for which mysqld invokes the thr_setconcurrency() function with the variable value. This function enables applications to give
the threads system a hint about the desired number of threads that should be run at the same time. Current Solaris versions document this as having no effect.

- **thread_handling**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--thread_handling=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>thread_handling</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>thread_handling</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

**Permitted Values (≤ 5.5.13)**

- **Type**: enumeration
- **Default**: one-thread-per-connection
- **Valid Values**:
  - no-threads
  - one-thread-per-connection

**Permitted Values (≥ 5.5.16)**

- **Type**: enumeration
- **Default**: one-thread-per-connection
- **Valid Values**:
  - no-threads
  - one-thread-per-connection
  - dynamically-loaded

The thread-handling model used by the server for connection threads. The permissible user-settable values are **no-threads** (the server uses a single thread to handle one connection) and **one-thread-per-connection** (the server uses one thread to handle each client connection; this is the default). **no-threads** is useful for debugging under Linux; see Section 24.4, “Debugging and Porting MySQL”.

If the thread pool plugin is enabled, the server sets the **thread_handling value to dynamically-loaded**. See Section 8.11.6.1, “Thread Pool Components and Installation”.

- **thread_pool_algorithm**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.5.16</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--thread_pool_algorithm=#</td>
</tr>
<tr>
<td>Option-File Format</td>
<td>thread_pool_algorithm</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>thread_pool_algorithm</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

**Permitted Values**

- **Type**: numeric
- **Default**: 0
- **Range**: 0 .. 1

This variable controls which algorithm the thread pool plugin uses:
- A value of 0 (the default) uses a conservative low-concurrency algorithm which is most well tested and is known to produce very good results.

- A value of 1 increases the concurrency and uses a more aggressive algorithm which at times has been known to perform 5–10% better on optimal thread counts, but has degrading performance as the number of connections increases. Its use should be considered as experimental and not supported.

This variable was added in MySQL 5.5.16. It is available only if the thread pool plugin is enabled. See Section 8.11.6, “The Thread Pool Plugin”

- `thread_pool_high_priority_connection`

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.5.16</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--thread_pool_high_priority_connection=#</code></td>
</tr>
<tr>
<td>Option-File Format</td>
<td><code>thread_pool_high_priority_connection</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>thread_pool_high_priority_connection</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 .. 1</td>
</tr>
</tbody>
</table>

This variable affects queuing of new statements prior to execution. If the value is 0 (false, the default), statement queuing uses both the low-priority and high-priority queues. If the value is 1 (true), queued statements always go to the high-priority queue.

This variable was added in MySQL 5.5.16. It is available only if the thread pool plugin is enabled. See Section 8.11.6, “The Thread Pool Plugin”

- `thread_pool_max_unused_threads`

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.5.16</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--thread_pool_max_unused_threads=#</code></td>
</tr>
<tr>
<td>Option-File Format</td>
<td><code>thread_pool_max_unused_threads</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>thread_pool_max_unused_threads</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 .. 4096</td>
</tr>
</tbody>
</table>

The maximum permitted number of unused threads in the thread pool. This variable makes it possible to limit the amount of memory used by sleeping threads.
A value of 0 (the default) means no limit on the number of sleeping threads. A value of \( N \) where \( N \) is greater than 0 means 1 consumer thread and \( N-1 \) reserve threads. In this case, if a thread is ready to sleep but the number of sleeping threads is already at the maximum, the thread exits rather than going to sleep.

A sleeping thread is either sleeping as a consumer thread or a reserve thread. The thread pool permits one thread to be the consumer thread when sleeping. If a thread goes to sleep and there is no existing consumer thread, it will sleep as a consumer thread. When a thread must be woken up, a consumer thread is selected if there is one. A reserve thread is selected only when there is no consumer thread to wake up.

This variable was added in MySQL 5.5.16. It is available only if the thread pool plugin is enabled. See Section 8.11.6, “The Thread Pool Plugin”

- **thread_pool_prio_kickup_timer**

| Introduced | 5.5.16 |
| Command-Line Format | `--thread_pool_prio_kickup_timer=#` |
| Option-File Format | `thread_pool_prio_kickup_timer` |
| System Variable Name | `thread_pool_prio_kickup_timer` |
| Variable Scope | Global, Session |
| Dynamic Variable | Yes |

| Permitted Values |
| Type | numeric |
| Default | 1000 |
| Range | 0 .. 4294967294 |

This variable affects statements waiting for execution in the low-priority queue. The value is the number of milliseconds before a waiting statement is moved to the high-priority queue. The default is 1000 (1 second). The range of values is 0 to \( 2^{32} - 2 \).

This variable was added in MySQL 5.5.16. It is available only if the thread pool plugin is enabled. See Section 8.11.6, “The Thread Pool Plugin”

- **thread_pool_size**

| Introduced | 5.5.16 |
| Command-Line Format | `--thread_pool_size=#` |
| System Variable Name | `thread_pool_size` |
| Variable Scope | Global |
| Dynamic Variable | No |

| Permitted Values |
| Type | numeric |
| Default | 16 |
| Range | 1 .. 64 |
The number of thread groups in the thread pool. This is the most important parameter controlling thread pool performance. It affects how many statements can execute simultaneously. The default value is 16, with a range from 1 to 64 of permissible values. If a value outside this range is specified, the thread pool plugin does not load and the server writes a message to the error log.

This variable was added in MySQL 5.5.16. It is available only if the thread pool plugin is enabled. See Section 8.11.6, “The Thread Pool Plugin”

- **thread_pool_stall_limit**

```markdown
<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.5.16</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--thread_pool_stall_limit=#</td>
</tr>
<tr>
<td>Option-File Format</td>
<td>thread_pool_stall_limit</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>thread_pool_stall_limit</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>6</td>
</tr>
<tr>
<td>Range</td>
<td>4 .. 600</td>
</tr>
</tbody>
</table>
```

This variable affects executing statements. The value is the amount of time a statement has to finish after starting to execute before it becomes defined as stalled, at which point the thread pool permits the thread group to begin executing another statement. The value is measured in 10 millisecond units, so a value of 6 (the default) means 60ms. The range of values is 4 to 600 (40ms to 6s). Short wait values permit threads to start more quickly. Short values are also better for avoiding deadlock situations. Long wait values are useful for workloads that include long-running statements, to avoid starting too many new statements while the current ones execute.

This variable was added in MySQL 5.5.16. It is available only if the thread pool plugin is enabled. See Section 8.11.6, “The Thread Pool Plugin”

- **thread_stack**

```markdown
<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--thread_stack=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>thread_stack</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>thread_stack</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Platform Bit Size</td>
<td>32</td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>196608</td>
</tr>
<tr>
<td>Range</td>
<td>131072 .. 4294967295</td>
</tr>
</tbody>
</table>
```
The stack size for each thread. Many of the limits detected by the `crash-me` test are dependent on this value. See Section 8.12.2, "The MySQL Benchmark Suite". The default of 192KB (256KB for 64-bit systems) is large enough for normal operation. If the thread stack size is too small, it limits the complexity of the SQL statements that the server can handle, the recursion depth of stored procedures, and other memory-consuming actions.

- **time_format**

  This variable is unused.

- **time_zone**

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>time_zone</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type string</td>
</tr>
</tbody>
</table>

  The current time zone. This variable is used to initialize the time zone for each client that connects. By default, the initial value of this is 'SYSTEM' (which means, "use the value of system_time_zone"). The value can be specified explicitly at server startup with the `--default-time-zone` option. See Section 10.6, "MySQL Server Time Zone Support".

- **timed_mutexes**

  | Deprecated | 5.5.39 |
  | Command-Line Format | `--timed_mutexes` |
  | Option-File Format | `timed_mutexes` |
  | System Variable Name | `timed_mutexes` |
  | Variable Scope | Global |
  | Dynamic Variable | Yes |
  | Permitted Values | Type boolean |
  | Default | OFF |

  In MySQL 5.5, this variable is deprecated; it has no use. It will be removed in a future MySQL release.
Server System Variables

- **timestamp**

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>timestamp</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
</tbody>
</table>

Set the time for this client. This is used to get the original timestamp if you use the binary log to restore rows. `timestamp_value` should be a Unix epoch timestamp (a value like that returned by `UNIX_TIMESTAMP()`, not a value in `'YYYY-MM-DD hh:mm:ss'` format) or `DEFAULT`.

Setting `timestamp` to a constant value causes it to retain that value until it is changed again. Setting `timestamp` to `DEFAULT` causes its value to be the current date and time as of the time it is accessed.

`SET timestamp` affects the value returned by `NOW()` but not by `SYSDATE()`. This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()`. The server can be started with the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`, in which case `SET timestamp` affects both functions.

- **tmp_table_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--tmp_table_size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>tmp_table_size</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>tmp_table_size</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>16777216</td>
</tr>
<tr>
<td>Range</td>
<td>1024 .. 18446744073709551615</td>
</tr>
</tbody>
</table>

The maximum size of internal in-memory temporary tables. (The actual limit is determined as the minimum of `tmp_table_size` and `max_heap_table_size`.) If an in-memory temporary table exceeds the limit, MySQL automatically converts it to an on-disk MyISAM table. Increase the value of `tmp_table_size` (and `max_heap_table_size` if necessary) if you do many advanced `GROUP BY` queries and you have lots of memory. This variable does not apply to user-created MEMORY tables.

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing the values of the `Created_tmp_disk_tables` and `Created_tmp_tables` variables.

See also Section 8.4.4, “How MySQL Uses Internal Temporary Tables”.

- **tmpdir**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--tmpdir=path</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>tmpdir</td>
</tr>
</tbody>
</table>

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing the values of the `Created_tmp_disk_tables` and `Created_tmp_tables` variables.
### tmpdir

<table>
<thead>
<tr>
<th><strong>System Variable Name</strong></th>
<th>tmpdir</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Variable Scope</strong></td>
<td>Global</td>
</tr>
<tr>
<td><strong>Dynamic Variable</strong></td>
<td>No</td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>directory name</td>
</tr>
</tbody>
</table>

The directory used for temporary files and temporary tables. This variable can be set to a list of several paths that are used in round-robin fashion. Paths should be separated by colon characters (":") on Unix and semicolon characters (";") on Windows.

The multiple-directory feature can be used to spread the load between several physical disks. If the MySQL server is acting as a replication slave, you should not set tmpdir to point to a directory on a memory-based file system or to a directory that is cleared when the server host restarts. A replication slave needs some of its temporary files to survive a machine restart so that it can replicate temporary tables or `LOAD DATA INFILE` operations. If files in the temporary file directory are lost when the server restarts, replication fails. You can set the slave's temporary directory using the `slave_load_tmpdir` variable. In that case, the slave will not use the general tmpdir value and you can set tmpdir to a nonpermanent location.

- **transaction_alloc_block_size**

<table>
<thead>
<tr>
<th><strong>Command-Line Format</strong></th>
<th><code>--transaction_alloc_block_size=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Option-File Format</strong></td>
<td><code>transaction_alloc_block_size</code></td>
</tr>
<tr>
<td><strong>System Variable Name</strong></td>
<td><code>transaction_alloc_block_size</code></td>
</tr>
<tr>
<td><strong>Variable Scope</strong></td>
<td>Global, Session</td>
</tr>
<tr>
<td><strong>Dynamic Variable</strong></td>
<td>Yes</td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Platform</strong></td>
<td>32</td>
</tr>
<tr>
<td><strong>Bit Size</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>numeric</td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td>8192</td>
</tr>
<tr>
<td><strong>Range</strong></td>
<td>1024 .. 4294967295</td>
</tr>
<tr>
<td><strong>Block Size</strong></td>
<td>1024</td>
</tr>
</tbody>
</table>

The amount in bytes by which to increase a per-transaction memory pool which needs memory. See the description of `transaction_prealloc_size`.

- **transaction_prealloc_size**
<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--transaction_prealloc_size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>transaction_prealloc_size</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>transaction_prealloc_size</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th>Platform Bit Size</th>
<th>32</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>4096</td>
</tr>
<tr>
<td>Range</td>
<td>1024 .. 4294967295</td>
</tr>
<tr>
<td>Block Size</td>
<td>1024</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Platform Bit Size</th>
<th>64</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>4096</td>
</tr>
<tr>
<td>Range</td>
<td>1024 .. 18446744073709547520</td>
</tr>
<tr>
<td>Block Size</td>
<td>1024</td>
</tr>
</tbody>
</table>

There is a per-transaction memory pool from which various transaction-related allocations take memory. The initial size of the pool in bytes is `transaction_prealloc_size`. For every allocation that cannot be satisfied from the pool because it has insufficient memory available, the pool is increased by `transaction_alloc_block_size` bytes. When the transaction ends, the pool is truncated to `transaction_prealloc_size` bytes.

By making `transaction_prealloc_size` sufficiently large to contain all statements within a single transaction, you can avoid many `malloc()` calls.

- `tx_isolation`

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>tx_isolation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>enumeration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>REPEATABLE-READ</td>
</tr>
<tr>
<td>Valid Values</td>
<td>READ-UNCOMMITTED</td>
</tr>
<tr>
<td></td>
<td>READ-COMMITTED</td>
</tr>
<tr>
<td></td>
<td>REPEATABLE-READ</td>
</tr>
<tr>
<td></td>
<td>SERIALIZABLE</td>
</tr>
</tbody>
</table>
Server System Variables

The default transaction isolation level. Defaults to `REPEATABLE-READ`.

This variable can be set directly, or indirectly using the `SET TRANSACTION` statement. See Section 13.3.6, "SET TRANSACTION Syntax". If you set `tx_isolation` directly to an isolation level name that contains a space, the name should be enclosed within quotation marks, with the space replaced by a dash. For example:

```
SET tx_isolation = 'READ-COMMITTED';
```

Any unique prefix of a valid value may be used to set the value of this variable.

The default transaction isolation level can also be set at startup using the `--transaction-isolation` server option.

- **unique_checks**

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>unique_checks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
</tbody>
</table>

If set to 1 (the default), uniqueness checks for secondary indexes in InnoDB tables are performed. If set to 0, storage engines are permitted to assume that duplicate keys are not present in input data. If you know for certain that your data does not contain uniqueness violations, you can set this to 0 to speed up large table imports to InnoDB.

Note that setting this variable to 0 does not require storage engines to ignore duplicate keys. An engine is still permitted to check for them and issue duplicate-key errors if it detects them.

- **updatable_views_with_limit**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--updatable_views_with_limit=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>updatable_views_with_limit</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>updatable_views_with_limit</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
</tbody>
</table>

This variable controls whether updates to a view can be made when the view does not contain all columns of the primary key defined in the underlying table, if the update statement contains a `LIMIT` clause. (Such updates often are generated by GUI tools.) An update is an `UPDATE` or `DELETE` statement. Primary key here means a `PRIMARY KEY` or a `UNIQUE` index in which no column can contain `NULL`.

The variable can have two values:
Server System Variables

- **1 or YES**: Issue a warning only (not an error message). This is the default value.
- **0 or NO**: Prohibit the update.

**version**

The version number for the server. The value might also include a suffix indicating server build or configuration information. `-log` indicates that one or more of the general log, slow query log, or binary log are enabled. `-debug` indicates that the server was built with debugging support enabled.

**version_comment**

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>string</td>
</tr>
</tbody>
</table>

The CMake configuration program has a `COMPILATION_COMMENT` option that permits a comment to be specified when building MySQL. This variable contains the value of that comment. See Section 2.9.4, “MySQL Source-Configuration Options”.

**version_compile_machine**

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>string</td>
</tr>
</tbody>
</table>

The type of machine or architecture on which MySQL was built.

**version_compile_os**

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>string</td>
</tr>
</tbody>
</table>

The type of operating system on which MySQL was built.

**wait_timeout**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--wait_timeout=#</code></td>
<td></td>
</tr>
<tr>
<td>Option-File Format</td>
<td><code>wait_timeout</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>wait_timeout</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
</tbody>
</table>
Using System Variables

<table>
<thead>
<tr>
<th>Dynamic Variable</th>
<th>Yes</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Type</strong> (Other)</td>
<td>numeric</td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td>28800</td>
</tr>
<tr>
<td><strong>Range</strong></td>
<td>1 .. 31536000</td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Type</strong> (Windows)</td>
<td>numeric</td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td>28800</td>
</tr>
<tr>
<td><strong>Range</strong></td>
<td>1 .. 2147483</td>
</tr>
</tbody>
</table>

The number of seconds the server waits for activity on a noninteractive connection before closing it.

On thread startup, the session `wait_timeout` value is initialized from the global `wait_timeout` value or from the global `interactive_timeout` value, depending on the type of client (as defined by the `CLIENT_INTERACTIVE` connect option to `mysql_real_connect()`). See also `interactive_timeout`.

• `warning_count`

The number of errors, warnings, and notes that resulted from the last statement that generated messages. This variable is read only. See Section 13.7.5.41, "SHOW WARNINGS Syntax".

5.1.5 Using System Variables

The MySQL server maintains many system variables that indicate how it is configured. Section 5.1.4, "Server System Variables", describes the meaning of these variables. Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. Most of them can be changed dynamically while the server is running by means of the `SET` statement, which enables you to modify operation of the server without having to stop and restart it. You can refer to system variable values in expressions.

The server maintains two kinds of system variables. Global variables affect the overall operation of the server. Session variables affect its operation for individual client connections. A given system variable can have both a global and a session value. Global and session system variables are related as follows:

• When the server starts, it initializes all global variables to their default values. These defaults can be changed by options specified on the command line or in an option file. (See Section 4.2.3, “Specifying Program Options”.)

• The server also maintains a set of session variables for each client that connects. The client's session variables are initialized at connect time using the current values of the corresponding global variables. For example, the client's SQL mode is controlled by the session `sql_mode` value, which is initialized when the client connects to the value of the global `sql_mode` value.

System variable values can be set globally at server startup by using options on the command line or in an option file. When you use a startup option to set a variable that takes a numeric value, the value can be given with a suffix of `K`, `M`, or `G` (either uppercase or lowercase) to indicate a multiplier of 1024, 1024² or 1024³; that is, units of kilobytes, megabytes, or gigabytes, respectively. Thus, the following command starts the server with a query cache size of 16 megabytes and a maximum packet size of one gigabyte:
Using System Variables

mysqld --query_cache_size=16M --max_allowed_packet=1G

Within an option file, those variables are set like this:

```
[mysqld]
query_cache_size=16M
max_allowed_packet=1G
```

The lettercase of suffix letters does not matter; 16M and 16m are equivalent, as are 1G and 1g.

If you want to restrict the maximum value to which a system variable can be set at runtime with the SET statement, you can specify this maximum by using an option of the form `--maximum-var_name=value` at server startup. For example, to prevent the value of `query_cache_size` from being increased to more than 32MB at runtime, use the option `--maximum-query_cache_size=32M`.

Many system variables are dynamic and can be changed while the server runs by using the SET statement. For a list, see Section 5.1.5.2, “Dynamic System Variables”. To change a system variable with SET, refer to it as `var_name`, optionally preceded by a modifier:

- To indicate explicitly that a variable is a global variable, precede its name by `GLOBAL` or `@@global`. The `SUPER` privilege is required to set global variables.

- To indicate explicitly that a variable is a session variable, precede its name by `SESSION`, `@@session`, or `@`. Setting a session variable requires no special privilege, but a client can change only its own session variables, not those of any other client.

- `LOCAL` and `@@local` are synonyms for `SESSION` and `@@session`.

- If no modifier is present, SET changes the session variable.

A SET statement can contain multiple variable assignments, separated by commas. If you set several system variables, the most recent `GLOBAL` or `SESSION` modifier in the statement is used for following variables that have no modifier specified.

Examples:

```
SET sort_buffer_size=10000;
SET @@local.sort_buffer_size=10000;
SET GLOBAL sort_buffer_size=1000000, SESSION sort_buffer_size=1000000;
SET @@sort_buffer_size=1000000;
SET @@global.sort_buffer_size=1000000, @@local.sort_buffer_size=1000000;
```

The `@@var_name` syntax for system variables is supported for compatibility with some other database systems.

If you change a session system variable, the value remains in effect until your session ends or until you change the variable to a different value. The change is not visible to other clients.

If you change a global system variable, the value is remembered and used for new connections until the server restarts. (To make a global system variable setting permanent, you should set it in an option file.) The change is visible to any client that accesses that global variable. However, the change affects the corresponding session variable only for clients that connect after the change. The global variable change does not affect the session variable for any client that is currently connected (not even that of the client that issues the `SET GLOBAL` statement).

To prevent incorrect usage, MySQL produces an error if you use `SET GLOBAL` with a variable that can only be used with `SET SESSION` or if you do not specify `GLOBAL` (or `@@global`) when setting a global variable.
To set a `SESSION` variable to the `GLOBAL` value or a `GLOBAL` value to the compiled-in MySQL default value, use the `DEFAULT` keyword. For example, the following two statements are identical in setting the session value of `max_join_size` to the global value:

```sql
SET max_join_size=DEFAULT;
SET @@session.max_join_size=@@global.max_join_size;
```

Not all system variables can be set to `DEFAULT`. In such cases, use of `DEFAULT` results in an error.

You can refer to the values of specific global or session system variables in expressions by using one of the `@@`-modifiers. For example, you can retrieve values in a `SELECT` statement like this:

```sql
SELECT @@global.sql_mode, @@session.sql_mode, @@sql_mode;
```

When you refer to a system variable in an expression as `@@var_name` (that is, when you do not specify `@@global.` or `@@session.`), MySQL returns the session value if it exists and the global value otherwise. (This differs from `SET @@var_name = value`, which always refers to the session value.)

**Note**

Some variables displayed by `SHOW VARIABLES` may not be available using `SELECT @@var_name` syntax; an `Unknown system variable` occurs. As a workaround in such cases, you can use `SHOW VARIABLES LIKE 'var_name'`.

Suffixes for specifying a value multiplier can be used when setting a variable at server startup, but not to set the value with `SET` at runtime. On the other hand, with `SET` you can assign a variable's value using an expression, which is not true when you set a variable at server startup. For example, the first of the following lines is legal at server startup, but the second is not:

```
shell> mysql --max_allowed_packet=16M
shell> mysql --max_allowed_packet=16*1024*1024
```

Conversely, the second of the following lines is legal at runtime, but the first is not:

```
mysql> SET GLOBAL max_allowed_packet=16M;
mysql> SET GLOBAL max_allowed_packet=16*1024*1024;
```

**Note**

Some system variables can be enabled with the `SET` statement by setting them to `ON` or `1`, or disabled by setting them to `OFF` or `0`. However, to set such a variable on the command line or in an option file, you must set it to `1` or `0`; setting it to `ON` or `OFF` will not work. For example, on the command line, `--delay_key_write=1` works but `--delay_key_write=ON` does not.

To display system variable names and values, use the `SHOW VARIABLES` statement:

```
mysql> SHOW VARIABLES;
+-----------------+-------------------+
| Variable_name   | Value             |
+-----------------+-------------------+
| auto_increment_increment | 1                |
| auto_increment_offset      | 1                |
| automatic_sp_privileges    | ON               |
| back_log                 | 50               |
| basedir                 | /home/mysql/    |
+-----------------+-------------------+
```

</tbody>
</table>

With a `LIKE` clause, the statement displays only those variables that match the pattern. To obtain a specific variable name, use a `LIKE` clause as shown:

```
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the "%" wildcard character in a `LIKE` clause:

```
SHOW VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because "_" is a wildcard that matches any single character, you should escape it as "\_" to match it literally. In practice, this is rarely necessary.

For `SHOW VARIABLES`, if you specify neither `GLOBAL` nor `SESSION`, MySQL returns `SESSION` values.

The reason for requiring the `GLOBAL` keyword when setting `GLOBAL`-only variables but not when retrieving them is to prevent problems in the future. If we were to remove a `SESSION` variable that has the same name as a `GLOBAL` variable, a client with the `SUPER` privilege might accidentally change the `GLOBAL` variable rather than just the `SESSION` variable for its own connection. If we add a `SESSION` variable with the same name as a `GLOBAL` variable, a client that intends to change the `GLOBAL` variable might find only its own `SESSION` variable changed.

### 5.1.5.1 Structured System Variables

A structured variable differs from a regular system variable in two respects:

- Its value is a structure with components that specify server parameters considered to be closely related.
- There might be several instances of a given type of structured variable. Each one has a different name and refers to a different resource maintained by the server.
MySQL 5.5 supports one structured variable type, which specifies parameters governing the operation of key caches. A key cache structured variable has these components:

- `key_buffer_size`
- `key_cache_block_size`
- `key_cache_division_limit`
- `key_cache_age_threshold`

This section describes the syntax for referring to structured variables. Key cache variables are used for syntax examples, but specific details about how key caches operate are found elsewhere, in Section 8.9.2, "The MyISAM Key Cache".

To refer to a component of a structured variable instance, you can use a compound name in `instance_name.component_name` format. Examples:

```
hot_cache.key_buffer_size
hot_cache.key_cache_block_size
cold_cache.key_cache_block_size
```

For each structured system variable, an instance with the name of `default` is always predefined. If you refer to a component of a structured variable without any instance name, the `default` instance is used. Thus, `default.key_buffer_size` and `key_buffer_size` both refer to the same system variable.

Structured variable instances and components follow these naming rules:

- For a given type of structured variable, each instance must have a name that is unique within variables of that type. However, instance names need not be unique across structured variable types. For example, each structured variable has an instance named `default`, so `default` is not unique across variable types.

- The names of the components of each structured variable type must be unique across all system variable names. If this were not true (that is, if two different types of structured variables could share component member names), it would not be clear which default structured variable to use for references to member names that are not qualified by an instance name.

- If a structured variable instance name is not legal as an unquoted identifier, refer to it as a quoted identifier using backticks. For example, `hot-cache` is not legal, but ``hot-cache` is.

- `global`, `session`, and `local` are not legal instance names. This avoids a conflict with notation such as `@@global.var_name` for referring to nonstructured system variables.

Currently, the first two rules have no possibility of being violated because the only structured variable type is the one for key caches. These rules will assume greater significance if some other type of structured variable is created in the future.

With one exception, you can refer to structured variable components using compound names in any context where simple variable names can occur. For example, you can assign a value to a structured variable using a command-line option:

```
shell> mysqld --hot_cache.key_buffer_size=64K
```

In an option file, use this syntax:
Using System Variables

If you start the server with this option, it creates a key cache named `hot_cache` with a size of 64KB in addition to the default key cache that has a default size of 8MB.

Suppose that you start the server as follows:

```
shell> mysqld --key_buffer_size=256K
  --extra_cache.key_buffer_size=128K
  --extra_cache.key_cache_block_size=2048
```

In this case, the server sets the size of the default key cache to 256KB. (You could also have written `--default.key_buffer_size=256K`.) In addition, the server creates a second key cache named `extra_cache` that has a size of 128KB, with the size of block buffers for caching table index blocks set to 2048 bytes.

The following example starts the server with three different key caches having sizes in a 3:1:1 ratio:

```
shell> mysqld --key_buffer_size=6M
  --hot_cache.key_buffer_size=2M
  --cold_cache.key_buffer_size=2M
```

Structured variable values may be set and retrieved at runtime as well. For example, to set a key cache named `hot_cache` to a size of 10MB, use either of these statements:

```
mysql> SET GLOBAL hot_cache.key_buffer_size = 10*1024*1024;
mysql> SET @@global.hot_cache.key_buffer_size = 10*1024*1024;
```

To retrieve the cache size, do this:

```
mysql> SELECT @@global.hot_cache.key_buffer_size;
```

However, the following statement does not work. The variable is not interpreted as a compound name, but as a simple string for a LIKE pattern-matching operation:

```
mysql> SHOW GLOBAL VARIABLES LIKE 'hot_cache.key_buffer_size';
```

This is the exception to being able to use structured variable names anywhere a simple variable name may occur.

### 5.1.5.2 Dynamic System Variables

Many server system variables are dynamic and can be set at runtime using SET GLOBAL or SET SESSION. You can also obtain their values using SELECT. See Section 5.1.5, “Using System Variables”.

The following table shows the full list of all dynamic system variables. The last column indicates for each variable whether GLOBAL or SESSION (or both) apply. The table also lists session options that can be set with the SET statement. Section 5.1.4, “Server System Variables”, discusses these options.

Variables that have a type of “string” take a string value. Variables that have a type of “numeric” take a numeric value. Variables that have a type of “boolean” can be set to 0, 1, ON or OFF. (If you set them on the command line or in an option file, use the numeric values.) Variables that are marked as “enumeration” normally should be set to one of the available values for the variable, but can also be set to the number that corresponds to the desired enumeration value. For enumerated system variables, the first enumeration
value corresponds to 0. This differs from **ENUM** columns, for which the first enumeration value corresponds to 1.

5.1.6 Server Status Variables

The server maintains many status variables that provide information about its operation. You can view these variables and their values by using the `SHOW [GLOBAL | SESSION] STATUS` statement (see Section 13.7.5.36, "SHOW STATUS Syntax"). The optional `GLOBAL` keyword aggregates the values over all connections, and `SESSION` shows the values for the current connection.

```
mysql> SHOW GLOBAL STATUS;
+-----------------+----------+
| Variable_name   | Value    |
+-----------------+----------+
| Aborted_clients | 0        |
| Aborted_connects| 0        |
| Bytes_received  | 155372598|
| Bytes_sent      | 1176560426|
| ...             |          |
| Connections     | 30023    |
| Created_tmp_disk_tables | 0    |
| Created_tmp_files | 3      |
| Created_tmp_tables | 2      |
| ...             |          |
| Threads_created | 217      |
```
Server Status Variables

<table>
<thead>
<tr>
<th>Threads_running</th>
<th>88</th>
</tr>
</thead>
<tbody>
<tr>
<td>Uptime</td>
<td>1389872</td>
</tr>
</tbody>
</table>

Many status variables are reset to 0 by the `FLUSH STATUS` statement.

The following table lists all available server status variables:

The status variables have the following meanings. For meanings of status variables specific to MySQL Cluster, see Section 18.3.4.4, “MySQL Cluster Status Variables”.

- **Aborted_clients**
  The number of connections that were aborted because the client died without closing the connection properly. See Section B.5.2.11, “Communication Errors and Aborted Connections”.

- **Aborted_connects**
  The number of failed attempts to connect to the MySQL server. See Section B.5.2.11, “Communication Errors and Aborted Connections”.

- **Binlog_cache_disk_use**
  The number of transactions that used the binary log cache but that exceeded the value of `binlog_cache_size` and used a temporary file to store changes from the transaction.

In MySQL versions 5.5.3 through 5.5.8, this variable also included the number of nontransactional statements that caused the binary log transaction cache to be written to disk. Beginning with MySQL 5.5.9, the number of such nontransactional statements is tracked separately in the `Binlog_stmt_cache_disk_use` status variable.

- **Binlog_cache_use**
  The number of transactions that used the binary log cache.

- **Binlog_stmt_cache_disk_use**
  The number of nontransactional statements that used the binary log statement cache but that exceeded the value of `binlog_stmt_cache_size` and used a temporary file to store those statements.

- **Binlog_stmt_cache_use**
  The number of nontransactional statements that used the binary log statement cache.

- **Bytes_received**
  The number of bytes received from all clients.

- **Bytes_sent**
  The number of bytes sent to all clients.

- **Com_***
  The `Com_***` statement counter variables indicate the number of times each `***` statement has been executed. There is one status variable for each type of statement. For example, `Com_delete` and `Com_update` count `DELETE` and `UPDATE` statements, respectively. `Com_delete_multi` and `Com_update_multi` are similar but apply to `DELETE` and `UPDATE` statements that use multiple-table syntax.

If a query result is returned from query cache, the server increments the `Qcache_hits` status variable, not `Com_select`. See Section 8.9.3.4, “Query Cache Status and Maintenance”.

---

<table>
<thead>
<tr>
<th>Variable Name</th>
<th>Variable Type</th>
<th>Variable Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Uptime_since_flush_status</code></td>
<td>numeric</td>
<td>GLOBAL</td>
</tr>
</tbody>
</table>
All of the `Com_stmt_` variables are increased even if a prepared statement argument is unknown or an error occurred during execution. In other words, their values correspond to the number of requests issued, not to the number of requests successfully completed.

The `Com_stmt_` status variables are as follows:

- `Com_stmt_prepare`
- `Com_stmt_execute`
- `Com_stmt_fetch`
- `Com_stmt_send_long_data`
- `Com_stmt_reset`
- `Com_stmt_close`

Those variables stand for prepared statement commands. Their names refer to the `COM_` command set used in the network layer. In other words, their values increase whenever prepared statement API calls such as `mysql_stmt_prepare()` and `mysql_stmt_execute()`, and so forth are executed. However, `Com_stmt_prepare`, `Com_stmt_execute` and `Com_stmt_close` also increase for `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE`, respectively. Additionally, the values of the older statement counter variables `Com_prepare_sql`, `Com_execute_sql`, and `Com_dealloc_sql` increase for the `PREPARE`, `EXECUTE`, and `DEALLOCATE PREPARE` statements. `Com_stmt_fetch` stands for the total number of network round-trips issued when fetching from cursors.

`Com_stmt_reprepare` indicates the number of times statements were automatically reprepared by the server after metadata changes to tables or views referred to by the statement. A reprepare operation increments `Com_stmt_reprepare`, and also `Com_stmt_prepare`.

- **Compression**
  Whether the client connection uses compression in the client/server protocol.

- **Connections**
  The number of connection attempts (successful or not) to the MySQL server.

- **Created_tmp_disk_tables**
  The number of internal on-disk temporary tables created by the server while executing statements.

  If an internal temporary table is created initially as an in-memory table but becomes too large, MySQL automatically converts it to an on-disk table. The maximum size for in-memory temporary tables is the minimum of the `tmp_table_size` and `max_heap_table_size` values. If `Created_tmp_disk_tables` is large, you may want to increase the `tmp_table_size` or `max_heap_table_size` value to lessen the likelihood that internal temporary tables in memory will be converted to on-disk tables.

  You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing the values of the `Created_tmp_disk_tables` and `Created_tmp_tables` variables.

  See also Section 8.4.4, “How MySQL Uses Internal Temporary Tables”.

- **Created_tmp_files**
Server Status Variables

How many temporary files `mysql` has created.

- **Created_tmp_tables**
  
  The number of internal temporary tables created by the server while executing statements.
  
  You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing the values of the `Created_tmp_disk_tables` and `Created_tmp_tables` variables.
  
  See also Section 8.4.4, “How MySQL Uses Internal Temporary Tables”.
  
  Each invocation of the `SHOW STATUS` statement uses an internal temporary table and increments the global `Created_tmp_tables` value.

- **Delayed_errors**
  
  The number of rows written with `INSERT DELAYED` for which some error occurred (probably duplicate key).

- **Delayed_insert_threads**
  
  The number of `INSERT DELAYED` handler threads in use.

- **Delayed_writes**
  
  The number of `INSERT DELAYED` rows written.

- **Flush_commands**
  
  The number of times the server flushes tables, whether because a user executed a `FLUSH TABLES` statement or due to internal server operation. It is also incremented by receipt of a `COM_REFRESH` packet. This is in contrast to `Com_flush`, which indicates how many `FLUSH` statements have been executed, whether `FLUSH TABLES`, `FLUSH LOGS`, and so forth.

- **Handler_commit**
  
  The number of internal `COMMIT` statements.

- **Handler_delete**
  
  The number of times that rows have been deleted from tables.

- **Handler_prepare**
  
  A counter for the prepare phase of two-phase commit operations.

- **Handler_read_first**
  
  The number of times the first entry in an index was read. If this value is high, it suggests that the server is doing a lot of full index scans; for example, `SELECT col1 FROM foo`, assuming that `col1` is indexed.

- **Handler_read_key**
  
  The number of requests to read a row based on a key. If this value is high, it is a good indication that your tables are properly indexed for your queries.
• **Handler_read_last**

The number of requests to read the last key in an index. With `ORDER BY`, the server will issue a first-key request followed by several next-key requests, whereas with `ORDER BY DESC`, the server will issue a last-key request followed by several previous-key requests. This variable was added in MySQL 5.5.7.

• **Handler_read_next**

The number of requests to read the next row in key order. This value is incremented if you are querying an index column with a range constraint or if you are doing an index scan.

• **Handler_read_prev**

The number of requests to read the previous row in key order. This read method is mainly used to optimize `ORDER BY ... DESC`.

• **Handler_read_rnd**

The number of requests to read a row based on a fixed position. This value is high if you are doing a lot of queries that require sorting of the result. You probably have a lot of queries that require MySQL to scan entire tables or you have joins that do not use keys properly.

• **Handler_read_rnd_next**

The number of requests to read the next row in the data file. This value is high if you are doing a lot of table scans. Generally this suggests that your tables are not properly indexed or that your queries are not written to take advantage of the indexes you have.

• **Handler_rollback**

The number of requests for a storage engine to perform a rollback operation.

• **Handler_savepoint**

The number of requests for a storage engine to place a savepoint.

• **Handler_savepoint_rollback**

The number of requests for a storage engine to roll back to a savepoint.

• **Handler_update**

The number of requests to update a row in a table.

• **Handler_write**

The number of requests to insert a row in a table.

• **Innodb_buffer_pool_bytes_data**

The total number of bytes in the InnoDB buffer pool containing data. The number includes both dirty and clean pages. For more accurate memory usage calculations than with `Innodb_buffer_pool_pages_data`, when compressed tables cause the buffer pool to hold pages of different sizes.

• **Innodb_buffer_pool_pages_data**

The number of pages containing data (dirty or clean).
Server Status Variables

- **Innodb_buffer_pool_bytes_dirty**
  The total current number of bytes held in dirty pages in the InnoDB buffer pool. For more accurate memory usage calculations than with `Innodb_buffer_pool_pages_dirty`, when compressed tables cause the buffer pool to hold pages of different sizes.

- **Innodb_buffer_pool_pages_dirty**
  The number of pages currently dirty.

- **Innodb_buffer_pool_pages_flushed**
  The number of buffer pool page-flush requests.

- **Innodb_buffer_pool_pages_free**
  The number of free pages.

- **Innodb_buffer_pool_pages_latched**
  The number of latched pages in InnoDB buffer pool. These are pages currently being read or written or that cannot be flushed or removed for some other reason. Calculation of this variable is expensive, so it is available only when the `UNIV_DEBUG` system is defined at server build time.

- **Innodb_buffer_pool_pages_misc**
  The number of pages that are busy because they have been allocated for administrative overhead such as row locks or the adaptive hash index. This value can also be calculated as `Innodb_buffer_pool_pages_total - Innodb_buffer_pool_pages_free - Innodb_buffer_pool_pages_data`.

- **Innodb_buffer_pool_pages_total**
  The total size of the buffer pool, in pages.

- **Innodb_buffer_pool_read_ahead**
  The number of pages read into the InnoDB buffer pool by the read-ahead background thread.

- **Innodb_buffer_pool_read_ahead_evicted**
  The number of pages read into the InnoDB buffer pool by the read-ahead background thread that were subsequently evicted without having been accessed by queries.

- **Innodb_buffer_pool_read_requests**
  The number of logical read requests.

- **Innodb_buffer_pool_reads**
  The number of logical reads that InnoDB could not satisfy from the buffer pool, and had to read directly from the disk.

- **Innodb_buffer_pool_wait_free**
  Normally, writes to the InnoDB buffer pool happen in the background. However, if it is necessary to read or create a page and no clean pages are available, it is also necessary to wait for pages to be flushed first. This counter counts instances of these waits. If the buffer pool size has been set properly, this value should be small.
Server Status Variables

- **Innodb_buffer_pool_write_requests**
  The number writes done to the InnoDB buffer pool.

- **Innodb_data_fsyncs**
  The number of `fsync()` operations so far.

- **Innodb_data_pending_fsyncs**
  The current number of pending `fsync()` operations.

- **Innodb_data_pending_reads**
  The current number of pending reads.

- **Innodb_data_pending_writes**
  The current number of pending writes.

- **Innodb_data_read**
  The amount of data read since the server was started.

- **Innodb_data_reads**
  The total number of data reads.

- **Innodb_data_writes**
  The total number of data writes.

- **Innodb_data_written**
  The amount of data written so far, in bytes.

- **Innodb_dblwr_pages_written**
  The number of pages that have been written for doublewrite operations. See Section 14.13.1, “InnoDB Disk I/O”.

- **Innodb_dblwr_writes**
  The number of doublewrite operations that have been performed. See Section 14.13.1, “InnoDB Disk I/O”.

- **Innodb_have_atomic_builtins**
  Indicates whether the server was built with atomic instructions.

- **Innodb_log_waits**
  The number of times that the log buffer was too small and a wait was required for it to be flushed before continuing.

- **Innodb_log_write_requests**
  The number of log write requests.

- **Innodb_log_writes**
The number of physical writes to the log file.

- **Innodb_os_log_fsyncs**
  The number of `fsync()` writes done to the log file.

- **Innodb_os_log_pending_fsyncs**
  The number of pending log file `fsync()` operations.

- **Innodb_os_log_pending_writes**
  The number of pending log file writes.

- **Innodb_os_log_written**
  The number of bytes written to the log file.

- **Innodb_page_size**
  The compiled-in InnoDB page size (default 16KB). Many values are counted in pages; the page size enables them to be easily converted to bytes.

- **Innodb_pages_created**
  The number of pages created.

- **Innodb_pages_read**
  The number of pages read.

- **Innodb_pages_written**
  The number of pages written.

- **Innodb_row_lock_current_waits**
  The number of row locks currently being waited for.

- **Innodb_row_lock_time**
  The total time spent in acquiring row locks, in milliseconds.

- **Innodb_row_lock_time_avg**
  The average time to acquire a row lock, in milliseconds.

- **Innodb_row_lock_time_max**
  The maximum time to acquire a row lock, in milliseconds.

- **Innodb_row_lock_waits**
  The number of times a row lock had to be waited for.

- **Innodb_rows_deleted**
  The number of rows deleted from InnoDB tables.
Server Status Variables

- **Innodb_rows_inserted**
  The number of rows inserted into InnoDB tables.

- **Innodb_rows_read**
  The number of rows read from InnoDB tables.

- **Innodb_rows_updated**
  The number of rows updated in InnoDB tables.

- **Innodb_truncated_status_writes**
  The number of times output from the `SHOW ENGINE INNODB STATUS` is truncated. Monitoring applications that parse the output from this command can test this value before and after issuing the `SHOW ENGINE` command, to confirm if the output is complete or not.

- **Key_blocks_not_flushed**
  The number of key blocks in the key cache that have changed but have not yet been flushed to disk.

- **Key_blocks_unused**
  The number of unused blocks in the key cache. You can use this value to determine how much of the key cache is in use; see the discussion of `key_buffer_size` in Section 5.1.4, “Server System Variables”.

- **Key_blocks_used**
  The number of used blocks in the key cache. This value is a high-water mark that indicates the maximum number of blocks that have ever been in use at one time.

- **Key_read_requests**
  The number of requests to read a key block from the cache.

- **Key_reads**
  The number of physical reads of a key block from disk. If `Key_reads` is large, then your `key_buffer_size` value is probably too small. The cache miss rate can be calculated as `Key_reads/Key_read_requests`.

- **Key_write_requests**
  The number of requests to write a key block to the cache.

- **Key_writes**
  The number of physical writes of a key block to disk.

- **Last_query_cost**
  The total cost of the last compiled query as computed by the query optimizer. This is useful for comparing the cost of different query plans for the same query. The default value of 0 means that no query has been compiled yet. The default value is 0. `Last_query_cost` has session scope.

  The `Last_query_cost` value can be computed accurately only for simple “flat” queries, not complex queries such as those with subqueries or `UNION`. For the latter, the value is set to 0.
Server Status Variables

- **Max_used_connections**
  The maximum number of connections that have been in use simultaneously since the server started.

- **Not_flushed_delayed_rows**
  The number of rows waiting to be written in `INSERT DELAYED` queues.

- **Open_files**
  The number of files that are open. This count includes regular files opened by the server. It does not include other types of files such as sockets or pipes. Also, the count does not include files that storage engines open using their own internal functions rather than asking the server level to do so.

- **Open_streams**
  The number of streams that are open (used mainly for logging).

- **Open_table_definitions**
  The number of cached `.frm` files.

- **Open_tables**
  The number of tables that are open.

- **Opened_files**
  The number of files that have been opened with `my_open()` (a `mysys` library function). Parts of the server that open files without using this function do not increment the count.

- **Opened_table_definitions**
  The number of `.frm` files that have been cached.

- **Opened_tables**
  The number of tables that have been opened. If `Opened_tables` is big, your `table_open_cache` value is probably too small.

- **Performance_schema_**
  Performance Schema status variables are listed in Section 22.10, "Performance Schema Status Variables". These variables provide information about instrumentation that could not be loaded or created due to memory constraints.

- **Prepared_stmt_count**
  The current number of prepared statements. (The maximum number of statements is given by the `max_prepared_stmt_count` system variable.)

- **Qcache_free_blocks**
  The number of free memory blocks in the query cache.

- **Qcache_free_memory**
  The amount of free memory for the query cache.

- **Qcache_hits**
Server Status Variables

The number of query cache hits.

- **Qcache_inserts**
  The number of queries added to the query cache.

- **Qcache_lowmem_prunes**
  The number of queries that were deleted from the query cache because of low memory.

- **Qcache_not_cached**
  The number of noncached queries (not cacheable, or not cached due to the `query_cache_type` setting).

- **Qcache_queries_in_cache**
  The number of queries registered in the query cache.

- **Qcache_total_blocks**
  The total number of blocks in the query cache.

- **Queries**
  The number of statements executed by the server. This variable includes statements executed within stored programs, unlike the `Questions` variable. It does not count `COM_PING` or `COM_STATISTICS` commands.

- **Questions**
  The number of statements executed by the server. This includes only statements sent to the server by clients and not statements executed within stored programs, unlike the `Queries` variable. This variable does not count `COM_PING`, `COM_STATISTICS`, `COM_STMT_PREPARE`, `COM_STMT_CLOSE`, or `COM_STMT_RESET` commands.

- **Rpl_semi_sync_master_clients**
  The number of semisynchronous slaves.
  This variable is available only if the master-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_net_avg_wait_time**
  The average time in microseconds the master waited for a slave reply.
  This variable is available only if the master-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_net_wait_time**
  The total time in microseconds the master waited for slave replies.
  This variable is available only if the master-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_net_waits**
  The total number of times the master waited for slave replies.
  This variable is available only if the master-side semisynchronous replication plugin is installed.
Server Status Variables

- **Rpl_semi_sync_master_no_times**
  The number of times the master turned off semisynchronous replication.
  This variable is available only if the master-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_no_tx**
  The number of commits that were not acknowledged successfully by a slave.
  This variable is available only if the master-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_status**
  Whether semisynchronous replication currently is operational on the master. The value is **ON** if the plugin has been enabled and a commit acknowledgment has occurred. It is **OFF** if the plugin is not enabled or the master has fallen back to asynchronous replication due to commit acknowledgment timeout.
  This variable is available only if the master-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_timefunc_failures**
  The number of times the master failed when calling time functions such as `gettimeofday()`.
  This variable is available only if the master-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_tx_avg_wait_time**
  The average time in microseconds the master waited for each transaction.
  This variable is available only if the master-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_tx_wait_time**
  The total time in microseconds the master waited for transactions.
  This variable is available only if the master-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_tx_waits**
  The total number of times the master waited for transactions.
  This variable is available only if the master-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_wait_pos_backtraverse**
  The total number of times the master waited for an event with binary coordinates lower than events waited for previously. This can occur when the order in which transactions start waiting for a reply is different from the order in which their binary log events are written.
  This variable is available only if the master-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_wait_sessions**
  The number of sessions currently waiting for slave replies.
  This variable is available only if the master-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_master_wait_pos_backtraverse**
  The total number of times the master waited for an event with binary coordinates lower than events waited for previously. This can occur when the order in which transactions start waiting for a reply is different from the order in which their binary log events are written.
  This variable is available only if the master-side semisynchronous replication plugin is installed.
The number of commits that were acknowledged successfully by a slave. This variable is available only if the master-side semisynchronous replication plugin is installed.

- **Rpl_semi_sync_slave_status**
  Whether semisynchronous replication currently is operational on the slave. This is **ON** if the plugin has been enabled and the slave I/O thread is running, **OFF** otherwise.
  This variable is available only if the slave-side semisynchronous replication plugin is installed.

- **Rpl_status**
  The status of fail-safe replication (not implemented). This variable is unused and is removed in MySQL 5.6.

- **Select_full_join**
  The number of joins that perform table scans because they do not use indexes. If this value is not 0, you should carefully check the indexes of your tables.

- **Select_full_range_join**
  The number of joins that used a range search on a reference table.

- **Select_range**
  The number of joins that used ranges on the first table. This is normally not a critical issue even if the value is quite large.

- **Select_range_check**
  The number of joins without keys that check for key usage after each row. If this is not 0, you should carefully check the indexes of your tables.

- **Select_scan**
  The number of joins that did a full scan of the first table.

- **Slave_heartbeat_period**
  Shows the replication heartbeat interval (in seconds) on a replication slave.

- **Slave_open_temp_tables**
  The number of temporary tables that the slave SQL thread currently has open. If the value is greater than zero, it is not safe to shut down the slave; see Section 17.4.1.22, “Replication and Temporary Tables”.

- **Slave_received_heartbeats**
  This counter increments with each replication heartbeat received by a replication slave since the last time that the slave was restarted or reset, or a CHANGE MASTER TO statement was issued.

- **Slave_retried_transactions**
  The total number of times since startup that the replication slave SQL thread has retried transactions.

- **Slave_running**
Server Status Variables

This is **ON** if this server is a replication slave that is connected to a replication master, and both the I/O and SQL threads are running; otherwise, it is **OFF**.

- **Slow_launch_threads**
The number of threads that have taken more than `slow_launch_time` seconds to create.

- **Slow_queries**
The number of queries that have taken more than `long_query_time` seconds. This counter increments regardless of whether the slow query log is enabled. For information about that log, see Section 5.2.5, "The Slow Query Log".

- **Sort_merge_passes**
The number of merge passes that the sort algorithm has had to do. If this value is large, you should consider increasing the value of the `sort_buffer_size` system variable.

- **Sort_range**
The number of sorts that were done using ranges.

- **Sort_rows**
The number of sorted rows.

- **Sort_scan**
The number of sorts that were done by scanning the table.

- **Ssl_accept_renegotiates**
The number of renegotiates needed to establish the connection.

- **Ssl_accepts**
The number of accepted SSL connections.

- **Ssl_callback_cache_hits**
The number of callback cache hits.

- **Ssl_cipher**
The current SSL cipher (empty for non-SSL connections).

- **Ssl_cipher_list**
The list of possible SSL ciphers (empty for non-SSL connections).

- **Ssl_client_connects**
The number of SSL connection attempts to an SSL-enabled master.

- **Ssl_connect_renegotiates**
The number of renegotiates needed to establish the connection to an SSL-enabled master.

- **Ssl_ctx_verify_depth**
The SSL context verification depth (how many certificates in the chain are tested).

- **Ssl_ctx_verify_mode**
  The SSL context verification mode.

- **Ssl_default_timeout**
  The default SSL timeout.

- **Ssl_finished_accepts**
  The number of successful SSL connections to the server.

- **Ssl_finished_connects**
  The number of successful slave connections to an SSL-enabled master.

- **Ssl_session_cache_hits**
  The number of SSL session cache hits.

- **Ssl_session_cache_misses**
  The number of SSL session cache misses.

- **Ssl_session_cache_mode**
  The SSL session cache mode.

- **Ssl_session_cache_overflows**
  The number of SSL session cache overflows.

- **Ssl_session_cache_size**
  The SSL session cache size.

- **Ssl_session_cache_timeouts**
  The number of SSL session cache timeouts.

- **Ssl_sessions_reused**
  How many SSL connections were reused from the cache.

- **Ssl_used_session_cache_entries**
  How many SSL session cache entries were used.

- **Ssl_verify_depth**
  The verification depth for replication SSL connections.

- **Ssl_verify_mode**
  The verification mode for replication SSL connections.

- **Ssl_version**
Server Status Variables

The SSL version number.

- **Table_locks_immediate**
  
The number of times that a request for a table lock could be granted immediately.

- **Table_locks_waited**
  
The number of times that a request for a table lock could not be granted immediately and a wait was needed. If this is high and you have performance problems, you should first optimize your queries, and then either split your table or tables or use replication.

- **Tc_log_max_pages_used**
  
  For the memory-mapped implementation of the log that is used by **mysqld** when it acts as the transaction coordinator for recovery of internal XA transactions, this variable indicates the largest number of pages used for the log since the server started. If the product of **Tc_log_max_pages_used** and **Tc_log_page_size** is always significantly less than the log size, the size is larger than necessary and can be reduced. (The size is set by the **--log-tc-size** option. Currently, this variable is unused: It is unneeded for binary log-based recovery, and the memory-mapped recovery log method is not used unless the number of storage engines capable of two-phase commit is greater than one. (**InnoDB** is the only applicable engine.)

- **Tc_log_page_size**
  
  The page size used for the memory-mapped implementation of the XA recovery log. The default value is determined using **getpagesize()**. Currently, this variable is unused for the same reasons as described for **Tc_log_max_pages_used**.

- **Tc_log_page_waits**
  
  For the memory-mapped implementation of the recovery log, this variable increments each time the server was not able to commit a transaction and had to wait for a free page in the log. If this value is large, you might want to increase the log size (with the **--log-tc-size** option). For binary log-based recovery, this variable increments each time the binary log cannot be closed because there are two-phase commits in progress. (The close operation waits until all such transactions are finished.)

- **Threads_cached**
  
  The number of threads in the thread cache.

- **Threads_connected**
  
  The number of currently open connections.

- **Threads_created**
  
  The number of threads created to handle connections. If **Threads_created** is big, you may want to increase the **thread_cache_size** value. The cache miss rate can be calculated as **Threads_created/Connections**.

- **Threads_running**
  
  The number of threads that are not sleeping.

- **Uptime**
  
  The number of seconds that the server has been up.
• Uptime_since_flush_status
  The number of seconds since the most recent FLUSH STATUS statement.

5.1.7 Server SQL Modes

The MySQL server can operate in different SQL modes, and can apply these modes differently for different clients, depending on the value of the sql_mode system variable. DBAs can set the global SQL mode to match site server operating requirements, and each application can set its session SQL mode to its own requirements.

Modes affect the SQL syntax MySQL supports and the data validation checks it performs. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers.

• Setting the SQL Mode
• The Most Important SQL Modes
• Full List of SQL Modes
• Strict SQL Mode
• Combination SQL Modes

For answers to questions often asked about server SQL modes in MySQL, see Section A.3, “MySQL 5.5 FAQ: Server SQL Mode”.

When working with InnoDB tables, consider also the innodb_strict_mode system variable. It enables additional error checks for InnoDB tables.

Setting the SQL Mode

The default SQL mode is empty (no modes set).

To set the SQL mode at server startup, use the --sql-mode="modes" option on the command line, or sql-mode="modes" in an option file such as my.cnf (Unix operating systems) or my.ini (Windows). modes is a list of different modes separated by commas. To clear the SQL mode explicitly, set it to an empty string using --sql-mode="" on the command line, or sql-mode="" in an option file.

Note
MySQL installation programs may configure the SQL mode during the installation process. If the SQL mode differs from the default or from what you expect, check for a setting in an option file that the server reads at startup.

To change the SQL mode at runtime, set the global or session sql_mode system variable using a SET statement:

```
SET GLOBAL sql_mode = 'modes';
SET SESSION sql_mode = 'modes';
```

Setting the GLOBAL variable requires the SUPER privilege and affects the operation of all clients that connect from that time on. Setting the SESSION variable affects only the current client. Each client can change its session sql_mode value at any time.

To determine the current global or session sql_mode value, use the following statements:
Server SQL Modes

SELECT @@GLOBAL.sql_mode;
SELECT @@SESSION.sql_mode;

Important

SQL mode and user-defined partitioning. Changing the server SQL mode after creating and inserting data into partitioned tables can cause major changes in the behavior of such tables, and could lead to loss or corruption of data. It is strongly recommended that you never change the SQL mode once you have created tables employing user-defined partitioning.

When replicating partitioned tables, differing SQL modes on master and slave can also lead to problems. For best results, you should always use the same server SQL mode on the master and on the slave.

See Section 19.5, “Restrictions and Limitations on Partitioning”, for more information.

The Most Important SQL Modes

The most important sql_mode values are probably these:

• ANSI

  This mode changes syntax and behavior to conform more closely to standard SQL. It is one of the special combination modes listed at the end of this section.

• STRICT_TRANS_TABLES

  If a value could not be inserted as given into a transactional table, abort the statement. For a nontransactional table, abort the statement if the value occurs in a single-row statement or the first row of a multiple-row statement. More details are given later in this section.

• TRADITIONAL

  Make MySQL behave like a “traditional” SQL database system. A simple description of this mode is “give an error instead of a warning” when inserting an incorrect value into a column. It is one of the special combination modes listed at the end of this section.

Note

The INSERT or UPDATE aborts as soon as the error is noticed. This may not be what you want if you are using a nontransactional storage engine, because data changes made prior to the error may not be rolled back, resulting in a “partially done” update.

When this manual refers to “strict mode,” it means a mode with either or both STRICT_TRANS_TABLES or STRICT_ALL_TABLES enabled.

Full List of SQL Modes

The following list describes all supported SQL modes:

• ALLOW_INVALID_DATES

  Do not perform full checking of dates. Check only that the month is in the range from 1 to 12 and the day is in the range from 1 to 31. This is very convenient for Web applications where you obtain year,
month, and day in three different fields and you want to store exactly what the user inserted (without date validation). This mode applies to `DATE` and `DATETIME` columns. It does not apply `TIMESTAMP` columns, which always require a valid date.

The server requires that month and day values be legal, and not merely in the range 1 to 12 and 1 to 31, respectively. With strict mode disabled, invalid dates such as '2004-04-31' are converted to '0000-00-00' and a warning is generated. With strict mode enabled, invalid dates generate an error. To permit such dates, enable `ALLOW_INVALID_DATES`.

- **ANSI_QUOTES**

  Treat "" as an identifier quote character (like the `"` quote character) and not as a string quote character. You can still use "" to quote identifiers with this mode enabled. With `ANSI_QUOTES` enabled, you cannot use double quotation marks to quote literal strings, because it is interpreted as an identifier.

- **ERROR_FOR_DIVISION_BY_ZERO**

  The `ERROR_FOR_DIVISION_BY_ZERO` mode affects handling of division by zero, which includes `MOD(N,0)`. For data-change operations (`INSERT`, `UPDATE`), its effect also depends on whether strict SQL mode is enabled.

  - If this mode is not enabled, division by zero inserts `NULL` and produces no warning.
  - If this mode is enabled, division by zero inserts `NULL` and produces a warning.
  - If this mode and strict mode are enabled, division by zero produces an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, division by zero inserts `NULL` and produces a warning.

  For `SELECT`, division by zero returns `NULL`. Enabling `ERROR_FOR_DIVISION_BY_ZERO` causes a warning to be produced as well, regardless of whether strict mode is enabled.

- **HIGH_NOT_PRECEDENCE**

  The precedence of the `NOT` operator is such that expressions such as `NOT a BETWEEN b AND c` are parsed as `NOT (a BETWEEN b AND c)`. In some older versions of MySQL, the expression was parsed as `(NOT a) BETWEEN b AND c`. The old higher-precedence behavior can be obtained by enabling the `HIGH_NOT_PRECEDENCE` SQL mode.

  ```
  mysql> SET sql_mode = '';
  mysql> SELECT NOT 1 BETWEEN -5 AND 5;
  -> 0
  mysql> SET sql_mode = 'HIGH_NOT_PRECEDENCE';
  mysql> SELECT NOT 1 BETWEEN -5 AND 5;
  -> 1
  ```

- **IGNORE_SPACE**

  Permit spaces between a function name and the " (" character. This causes built-in function names to be treated as reserved words. As a result, identifiers that are the same as function names must be quoted as described in Section 9.2, "Schema Object Names". For example, because there is a `COUNT()` function, the use of `count` as a table name in the following statement causes an error:

  ```
  mysql> CREATE TABLE count (i INT);
  ERROR 1064 (42000): You have an error in your SQL syntax
  ```

  The table name should be quoted:
The **IGNORE_SPACE** SQL mode applies to built-in functions, not to user-defined functions or stored functions. It is always permissible to have spaces after a UDF or stored function name, regardless of whether **IGNORE_SPACE** is enabled.

For further discussion of **IGNORE_SPACE**, see Section 9.2.4, “Function Name Parsing and Resolution”.

- **NO_AUTO_CREATE_USER**

Prevent the **GRANT** statement from automatically creating new users if it would otherwise do so, unless authentication information is specified. The statement must specify a nonempty password using **IDENTIFIED BY** or an authentication plugin using **IDENTIFIED WITH**.

- **NO_AUTO_VALUE_ON_ZERO**

**NO_AUTO_VALUE_ON_ZERO** affects handling of **AUTO_INCREMENT** columns. Normally, you generate the next sequence number for the column by inserting either **NULL** or **0** into it. **NO_AUTO_VALUE_ON_ZERO** suppresses this behavior for **0** so that only **NULL** generates the next sequence number.

This mode can be useful if **0** has been stored in a table’s **AUTO_INCREMENT** column. (Storing **0** is not a recommended practice, by the way.) For example, if you dump the table with **mysqldump** and then reload it, MySQL normally generates new sequence numbers when it encounters the **0** values, resulting in a table with contents different from the one that was dumped. Enabling **NO_AUTO_VALUE_ON_ZERO** before reloading the dump file solves this problem. **mysqldump** now automatically includes in its output a statement that enables **NO_AUTO_VALUE_ON_ZERO**, to avoid this problem.

- **NO_BACKSLASH_ESCAPES**

Disable the use of the backslash character (“\”) as an escape character within strings. With this mode enabled, backslash becomes an ordinary character like any other.

- **NO_DIR_IN_CREATE**

When creating a table, ignore all **INDEX DIRECTORY** and **DATA DIRECTORY** directives. This option is useful on slave replication servers.

- **NO_ENGINE_SUBSTITUTION**

Control automatic substitution of the default storage engine when a statement such as **CREATE TABLE** or **ALTER TABLE** specifies a storage engine that is disabled or not compiled in.

Because storage engines can be pluggable at runtime, unavailable engines are treated the same way:

With **NO_ENGINE_SUBSTITUTION** disabled, for **CREATE TABLE** the default engine is used and a warning occurs if the desired engine is unavailable. For **ALTER TABLE**, a warning occurs and the table is not altered.

With **NO_ENGINE_SUBSTITUTION** enabled, an error occurs and the table is not created or altered if the desired engine is unavailable.

- **NO_FIELD_OPTIONS**

Do not print MySQL-specific column options in the output of **SHOW CREATE TABLE**. This mode is used by **mysqldump** in portability mode.
• **NO_KEY_OPTIONS**

Do not print MySQL-specific index options in the output of `SHOW CREATE TABLE`. This mode is used by `mysqldump` in portability mode.

• **NO_TABLE_OPTIONS**

Do not print MySQL-specific table options (such as `ENGINE`) in the output of `SHOW CREATE TABLE`. This mode is used by `mysqldump` in portability mode.

• **NO_UNSIGNED_SUBTRACTION**

By default, subtraction between integer operands produces an `UNSIGNED` result if any operand is `UNSIGNED`. When `NO_UNSIGNED_SUBTRACTION` is enabled, the subtraction result is signed, even if any operand is unsigned. For example, compare the type of column `c2` in table `t1` with that of column `c2` in table `t2`:

```sql
mysql> SET sql_mode=''
mysql> CREATE TABLE test (c1 BIGINT UNSIGNED NOT NULL);
mysql> CREATE TABLE t1 SELECT c1 - 1 AS c2 FROM test;
mysql> DESCRIBE t1;
+-------+---------------------+------+-----+---------+-------+
| Field | Type                | Null | Key | Default | Extra |
+-------+---------------------+------+-----+---------+-------+
| c2    | bigint(21) unsigned |      |     | 0       |       |
+-------+---------------------+------+-----+---------+-------+
mysql> SET sql_mode='NO_UNSIGNED_SUBTRACTION';
mysql> CREATE TABLE t2 SELECT c1 - 1 AS c2 FROM test;
mysql> DESCRIBE t2;
+-------+------------+------+-----+---------+-------+
| Field | Type       | Null | Key | Default | Extra |
+-------+------------+------+-----+---------+-------+
| c2    | bigint(21) |      |     | 0       |       |
+-------+------------+------+-----+---------+-------+
```

Note that this means that `BIGINT UNSIGNED` is not 100% usable in all contexts. See Section 12.10, “Cast Functions and Operators”.

```sql
mysql> SET sql_mode = '';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+-------------------------+
| CAST(0 AS UNSIGNED) - 1 |
+-------------------------+
| 18446744073709551615    |
+-------------------------+
mysql> SET sql_mode = 'NO_UNSIGNED_SUBTRACTION';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+-------------------------+
| CAST(0 AS UNSIGNED) - 1 |
+-------------------------+
| -1                      |
+-------------------------+
```

• **NO_ZERO_DATE**

The `NO_ZERO_DATE` mode affects whether the server permits `'0000-00-00'` as a valid date. Its effect also depends on whether strict SQL mode is enabled.

• If this mode is not enabled, `'0000-00-00'` is permitted and inserts produce no warning.
Server SQL Modes

- If this mode is enabled, '0000-00-00' is permitted and inserts produce a warning.
- If this mode and strict mode are enabled, '0000-00-00' is not permitted and inserts produce an error, unless IGNORE is given as well. For INSERT IGNORE and UPDATE IGNORE, '0000-00-00' is permitted and inserts produce a warning.

**NO_ZERO_IN_DATE**

The NO_ZERO_IN_DATE mode affects whether the server permits dates in which the year part is nonzero but the month or day part is 0. (This mode affects dates such as '2010-00-01' or '2010-01-00', but not '0000-00-00'. To control whether the server permits '0000-00-00', use the NO_ZERO_DATE mode.) The effect of NO_ZERO_IN_DATE also depends on whether strict SQL mode is enabled.

- If this mode is not enabled, dates with zero parts are permitted and inserts produce no warning.
- If this mode is enabled, dates with zero parts are inserted as '0000-00-00' and produce a warning.
- If this mode and strict mode are enabled, dates with zero parts are not permitted and inserts produce an error, unless IGNORE is given as well. For INSERT IGNORE and UPDATE IGNORE, dates with zero parts are inserted as '0000-00-00' and produce a warning.

**ONLY_FULL_GROUP_BY**

Do not permit queries for which the select list or HAVING list refers to nonaggregated columns that are not named in the GROUP BY clause.

The following queries are invalid with ONLY_FULL_GROUP_BY enabled. The first is invalid because address in the select list is not named in the GROUP BY clause, and the second because max_age in the HAVING clause is not named in the GROUP BY clause:

```sql
mysql> SELECT name, address, MAX(age) FROM t GROUP BY name;
ERROR 1055 (42000): 't.address' isn't in GROUP BY
```

```sql
mysql> SELECT name, address, MAX(age) FROM t GROUP BY name
-> HAVING max_age < 30;
Empty set (0.00 sec)
ERROR 1463 (42000): Non-grouping field 'max_age' is used in HAVING clause
```

In the second example, the query could be rewritten to use HAVING MAX(age) instead, so that the reference is to a column named in an aggregate function. (max_age fails because it is an aggregate function.)

In addition, if a query has aggregate functions and no GROUP BY clause, it cannot have nonaggregated columns in the select list or ORDER BY list:

```sql
mysql> SELECT name, MAX(age) FROM t;
ERROR 1140 (42000): Mixing of GROUP columns (MIN(),MAX(),COUNT(),...)
with no GROUP columns is illegal if there is no GROUP BY clause
```

For more information, see Section 12.16.3, "MySQL Extensions to GROUP BY".

- **PAD_CHAR_TO_FULL_LENGTH**
By default, trailing spaces are trimmed from \texttt{CHAR} column values on retrieval. If \texttt{PAD_CHAR_TO_FULL_LENGTH} is enabled, trimming does not occur and retrieved \texttt{CHAR} values are padded to their full length. This mode does not apply to \texttt{VARCHAR} columns, for which trailing spaces are retained on retrieval.

```
mysql> CREATE TABLE t1 (c1 CHAR(10));
Query OK, 0 rows affected (0.37 sec)

mysql> INSERT INTO t1 (c1) VALUES('xy');
Query OK, 1 row affected (0.01 sec)

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT c1, CHAR_LENGTH(c1) FROM t1;
+------|-----------------+
| c1   | CHAR_LENGTH(c1) |
| xy   | 2               |
+------|-----------------+
1 row in set (0.00 sec)

mysql> SET sql_mode = 'PAD_CHAR_TO_FULL_LENGTH';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT c1, CHAR_LENGTH(c1) FROM t1;
+------------|-----------------+
| c1         | CHAR_LENGTH(c1) |
| xy         | 10              |
+------------|-----------------+
1 row in set (0.00 sec)
```

- \texttt{PIPECES\_AS\_CONCAT}

  Treat \texttt{||} as a string concatenation operator (same as \texttt{CONCAT()}) rather than as a synonym for \texttt{OR}.

- \texttt{REAL\_AS\_FLOAT}

  Treat \texttt{REAL} as a synonym for \texttt{FLOAT}. By default, MySQL treats \texttt{REAL} as a synonym for \texttt{DOUBLE}.

- \texttt{STRICT\_ALL\_TABLES}

  Enable strict mode for all storage engines. Invalid data values are rejected. Additional details follow.

- \texttt{STRICT\_TRANS\_TABLES}

  Enable strict mode for transactional storage engines, and when possible for nontransactional storage engines. Additional details follow.

\textbf{Strict SQL Mode}

Strict mode controls how MySQL handles invalid or missing values in data-change statements such as \texttt{INSERT} or \texttt{UPDATE}. A value can be invalid for several reasons. For example, it might have the wrong data type for the column, or it might be out of range. A value is missing when a new row to be inserted does not contain a value for a non-\texttt{NULL} column that has no explicit \texttt{DEFAULT} clause in its definition. (For a \texttt{NULL} column, \texttt{NULL} is inserted if the value is missing.)
If strict mode is not in effect, MySQL inserts adjusted values for invalid or missing values and produces warnings (see Section 13.7.5.41, "SHOW WARNINGS Syntax"). In strict mode, you can produce this behavior by using `INSERT IGNORE` or `UPDATE IGNORE`.

For statements such as `SELECT` that do not change data, invalid values generate a warning in strict mode, not an error.

Strict mode does not affect whether foreign key constraints are checked. `foreign_key_checks` can be used for that. (See Section 5.1.4, "Server System Variables".)

Strict SQL mode is in effect if either `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` is enabled, although the effects of these modes differ somewhat:

- For transactional tables, an error occurs for invalid or missing values in a data-change statement when either `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` is enabled. The statement is aborted and rolled back.
- For nontransactional tables, the behavior is the same for either mode if the bad value occurs in the first row to be inserted or updated: The statement is aborted and the table remains unchanged. If the statement inserts or modifies multiple rows and the bad value occurs in the second or later row, the result depends on which strict mode is enabled:
  - For `STRICT_ALL_TABLES`, MySQL returns an error and ignores the rest of the rows. However, because the earlier rows have been inserted or updated, the result is a partial update. To avoid this, use single-row statements, which can be aborted without changing the table.
  - For `STRICT_TRANS_TABLES`, MySQL converts an invalid value to the closest valid value for the column and inserts the adjusted value. If a value is missing, MySQL inserts the implicit default value for the column data type. In either case, MySQL generates a warning rather than an error and continues processing the statement. Implicit defaults are described in Section 11.6, "Data Type Default Values".

Strict mode also affects handling of division by zero, zero dates, and zeros in dates, in conjunction with the `ERROR_FOR_DIVISION_BY_ZERO`, `NO_ZERO_DATE`, and `NO_ZERO_IN_DATE` modes. For details, see the descriptions of those modes.

### Combination SQL Modes

The following special modes are provided as shorthand for combinations of mode values from the preceding list.

- **ANSI**
  
  Equivalent to `REAL_AS_FLOAT`, `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`.

  `ANSI` mode also causes the server to return an error for queries where a set function `S` with an outer reference `S(outer_ref)` cannot be aggregated in the outer query against which the outer reference has been resolved. This is such a query:

  ```sql
  SELECT * FROM t1 WHERE t1.a IN (SELECT MAX(t1.b) FROM t2 WHERE ...);
  ```

  Here, `MAX(t1.b)` cannot aggregated in the outer query because it appears in the `WHERE` clause of that query. Standard SQL requires an error in this situation. If `ANSI` mode is not enabled, the server treats `S(outer_ref)` in such queries the same way that it would interpret `S(const)`.

  See Section 1.8, "MySQL Standards Compliance".
5.1.8 Server Plugins

MySQL supports a plugin API that enables creation of server components. Plugins can be loaded at server startup, or loaded and unloaded at runtime without restarting the server. The components supported by this interface include, but are not limited to, storage engines, full-text parser plugins, partitioning support, and server extensions.

5.1.8.1 Installing and Uninstalling Plugins

Server plugins must be loaded into the server before they can be used. MySQL enables you to load a plugin at server startup or at runtime. It is also possible to control the activation of loaded plugins at startup, and to unload them at runtime.

- Installing plugins
- Controlling plugin activation
- Uninstalling plugins
Installing Plugins

Server plugins must be known to the server before they can be used. A plugin can be made known several ways, as described here. In the following descriptions, `plugin_name` stands for a plugin name such as `innodb` or `csv`.

Built-in plugins:

A plugin that is built in to the server is known by the server automatically. Normally, the server enables the plugin at startup, although this can be changed with the `--plugin_name` option.

Plugins registered in the `mysql.plugin` table:

The `mysql.plugin` table serves as a registry of plugins. The server normally enables each plugin listed in the table at startup, although whether a given plugin is enabled can be changed with the `--plugin_name` option. If the server is started with the `--skip-grant-tables` option, it does not consult this table and does not load the plugins listed there.

Plugins named with the `--plugin-load` option:

A plugin that is located in a plugin library file can be loaded at server startup with the `--plugin-load` option. Normally, the server enables the plugin at startup, although this can be changed with the `--plugin_name` option.

The option value is a semicolon-separated list of `name=plugin_library` pairs. Each `name` is the name of the plugin, and `plugin_library` is the name of the shared library that contains the plugin code. If a plugin library is named without any preceding plugin name, the server loads all plugins in the library. Each library file must be located in the directory named by the `plugin_dir` system variable.

This option does not register any plugin in the `mysql.plugin` table. For subsequent restarts, the server loads the plugin again only if `--plugin-load` is given again. That is, this option effects a one-time installation that persists only for one server invocation.

`--plugin-load` enables plugins to be loaded even when `--skip-grant-tables` is given (which causes the server to ignore the `mysql.plugin` table). `--plugin-load` also enables plugins to be loaded at startup under configurations when plugins cannot be loaded at runtime.

Plugins installed with the `INSTALL PLUGIN` statement:

A plugin that is located in a plugin library file can be loaded at runtime with the `INSTALL PLUGIN` statement. The statement also registers the plugin in the `mysql.plugin` table to cause the server to load it on subsequent restarts. For this reason, `INSTALL PLUGIN` requires the `INSERT` privilege for the `mysql.plugin` table.

If a plugin is named both using a `--plugin-load` option and in the `mysql.plugin` table, the server starts but writes these messages to the error log:

```
100310 19:15:44 [ERROR] Function 'plugin_name' already exists
100310 19:15:44 [Warning] Couldn't load plugin named 'plugin_name'
with soname 'plugin_object_file'.
```

Example: The `--plugin-load` option installs a plugin at server startup. To install a plugin named `myplugin` in a plugin library file named `somepluglib.so`, use these lines in a `my.cnf` file:

```
[mysqld]
plugin-load=myplugin=somepluglib.so
```
In this case, the plugin is not registered in `mysql.plugin`. Restarting the server without the `--plugin-load` option causes the plugin not to be loaded at startup.

Alternatively, the `INSTALL PLUGIN` statement causes the server to load the plugin code from the library file at runtime:

```
mysql> INSTALL PLUGIN myplugin SONAME 'somepluglib.so';
```

`INSTALL PLUGIN` also causes “permanent” plugin registration: The server lists the plugin in the `mysql.plugin` table to ensure that it is loaded on subsequent server restarts.

Many plugins can be loaded either at server startup or at runtime. However, if a plugin is designed such that it must be loaded and initialized during server startup, use `--plugin-load` rather than `INSTALL PLUGIN`.

While a plugin is loaded, information about it is available at runtime from several sources, such as the `INFORMATION_SCHEMA.PLUGINS` table and the `SHOW PLUGINS` statement. For more information, see Section 5.1.8.2, “Obtaining Server Plugin Information”.

### Controlling Plugin Activation

If the server knows about a plugin when it starts (for example, because the plugin is named using a `--plugin-load` option or registered in the `mysql.plugin` table), the server loads and enables the plugin by default. It is possible to control activation for such a plugin using a `--plugin_name[=value]` startup option named after the plugin. In the following descriptions, `plugin_name` stands for a plugin name such as `innodb` or `csv`. As with other options, dashes and underscores are interchangeable in option names. For example, `--my_plugin=ON` and `--my-plugin=ON` are equivalent.

- `--plugin_name=OFF`
  
  Tells the server to disable the plugin.

- `--plugin_name[=ON]`
  
  Tells the server to enable the plugin. (Specifying the option as `--plugin_name` without a value has the same effect.) If the plugin fails to initialize, the server runs with the plugin disabled.

- `--plugin_name=FORCE`
  
  Tells the server to enable the plugin, but if plugin initialization fails, the server does not start. In other words, this option forces the server to run with the plugin enabled or not at all.

- `--plugin_name=FORCE_PLUS_PERMANENT`
  
  Like `FORCE`, but in addition prevents the plugin from being unloaded at runtime. If a user attempts to do so with `UNINSTALL PLUGIN`, an error occurs. This value is available as of MySQL 5.5.7.

The values `OFF`, `ON`, `FORCE`, and `FORCE_PLUS_PERMANENT` are not case sensitive.

The activation state for plugins is visible in the `LOAD_OPTION` column of the `INFORMATION_SCHEMA.PLUGINS` table.

Suppose that `CSV`, `BLACKHOLE`, and `ARCHIVE` are built-in pluggable storage engines and that you want the server to load them at startup, subject to these conditions: The server is permitted to run if `CSV` initialization fails, but must require that `BLACKHOLE` initialization succeeds, and `ARCHIVE` should be disabled. To accomplish that, use these lines in an option file:
[mysqld]
csv=ON
blackhole=FORCE
archive=OFF

The `--enable-plugin_name` option format is supported as a synonym for `--plugin_name=ON`. The `--disable-plugin_name` and `--skip-plugin_name` option formats are supported as synonyms for `--plugin_name=OFF`.

Before MySQL 5.1.36, plugin options are boolean options (see Section 4.2.5, “Program Option Modifiers”). That is, any of these options enable the plugin:

```
--plugin_name
--plugin_name=1
--enable-plugin_name
```

And these options disable the plugin:

```
--plugin_name=0
--disable-plugin_name
--skip-plugin_name
```

If you upgrade to MySQL 5.5 from a version older than 5.1.36 and previously used options of the form `--plugin_name=0` or `--plugin_name=1`, the equivalent options are now `--plugin_name=OFF` and `--plugin_name=ON`, respectively. You also have the choice of requiring plugins to start successfully by using `--plugin_name=FORCE` or `--plugin_name=FORCE_PLUS_PERMANENT`.

If a plugin is disabled, either explicitly with `OFF` or implicitly because it was enabled with `ON` but failed to initialize, aspects of server operation that require the plugin will change. For example, if the plugin implements a storage engine, existing tables for the storage engine become inaccessible, and attempts to create new tables for the storage engine result in tables that use the default storage engine unless the `NO_ENGINE_SUBSTITUTION` SQL mode has been enabled to cause an error to occur instead.

Disabling a plugin may require adjustment to other options. For example, if you start the server using `--skip-innodb` to disable InnoDB, other `innodb_xxx` options likely will need to be omitted from the startup command. In addition, because InnoDB is the default storage engine, it will not start unless you specify another available storage engine with `--default-storage-engine`.

### Uninstalling Plugins

A plugin known to the server can be uninstalled to disable it at runtime with the `UNINSTALL PLUGIN` statement. The statement unloads the plugin and removes it from the `mysql.plugin` table if it is registered there. For this reason, `UNINSTALL PLUGIN` statement requires the `DELETE` privilege for the `mysql.plugin` table. With the plugin no longer registered in the table, the server will not load the plugin automatically for subsequent restarts.

`UNINSTALL PLUGIN` can unload plugins regardless of whether they were loaded with `INSTALL PLUGIN` or `--plugin-load`.

`UNINSTALL PLUGIN` is subject to these exceptions:

- It cannot unload plugins that are built in to the server. These can be identified as those that have a library name of `NULL` in the output from `INFORMATION_SCHEMA.PLUGINS` or `SHOW PLUGINS`.

- It cannot unload plugins for which the server was started with `--plugin_name=FORCE_PLUS_PERMANENT`, which prevents plugin unloading at runtime. These can be identified from the `LOAD_OPTION` column of the `INFORMATION_SCHEMA.PLUGINS` table.
5.1.8.2 Obtaining Server Plugin Information

There are several ways to determine which plugins are installed in the server:

- The `INFORMATION_SCHEMA.PLUGINS` table contains a row for each loaded plugin. Any that have a `PLUGIN_LIBRARY` value of `NULL` are built in and cannot be unloaded.

  ```sql
  mysql> SELECT * FROM information_schema.PLUGINS\G
  *************************** 1. row ***************************
  PLUGIN_NAME: binlog
  PLUGIN_VERSION: 1.0
  PLUGIN_STATUS: ACTIVE
  PLUGIN_TYPE: STORAGE ENGINE
  PLUGIN_TYPE_VERSION: 50158.0
  PLUGIN_LIBRARY: NULL
  PLUGIN_LIBRARY_VERSION: NULL
  PLUGIN_AUTHOR: MySQL AB
  PLUGIN_DESCRIPTION: This is a pseudo storage engine to represent the binlog in a transaction
  PLUGIN_LICENSE: GPL
  LOAD_OPTION: FORCE
  ...
  *************************** 10. row ***************************
  PLUGIN_NAME: InnoDB
  PLUGIN_VERSION: 1.0
  PLUGIN_STATUS: ACTIVE
  PLUGIN_TYPE: STORAGE ENGINE
  PLUGIN_TYPE_VERSION: 50158.0
  PLUGIN_LIBRARY: ha_innodb_plugin.so
  PLUGIN_LIBRARY_VERSION: 1.0
  PLUGIN_AUTHOR: Innobase Oy
  PLUGIN_DESCRIPTION: Supports transactions, row-level locking, and foreign keys
  PLUGIN_LICENSE: GPL
  LOAD_OPTION: ON
  ...
  ```

- The `SHOW PLUGINS` statement displays a row for each loaded plugin. Any that have a `Library` value of `NULL` are built in and cannot be unloaded.

  ```sql
  mysql> SHOW PLUGINS\G
  *************************** 1. row ***************************
  Name: binlog
  Status: ACTIVE
  Type: STORAGE ENGINE
  Library: NULL
  License: GPL
  ...
  *************************** 10. row ***************************
  Name: InnoDB
  Status: ACTIVE
  Type: STORAGE ENGINE
  Library: ha_innodb_plugin.so
  License: GPL
  ...
  ```

- The `mysql.plugin` table shows which plugins have been registered with `INSTALL PLUGIN`. The table contains only plugin names and library file names, so it does not provide as much information as the `PLUGINS` table or the `SHOW PLUGINS` statement.

5.1.9 IPv6 Support

As of MySQL 5.5.3, support for IPv6 includes these capabilities:
IPv6 Support

- MySQL Server can accept TCP/IP connections from clients connecting over IPv6. For example, this command connects over IPv6 to the MySQL server on the local host:

  ```shell
  mysql -h ::1
  ```

  To use this capability, two things must be true:

  - Your system must be configured to support IPv6. See Section 5.1.9.1, “Verifying System Support for IPv6”.

  - The default MySQL server configuration permits only IPv4 connections, so the server must be configured for IPv6 connections. To permit IPv6 connections in addition to or instead of IPv4 connections, start the server with an appropriate `--bind-address` option. See Section 5.1.4, “Server System Variables”.

- MySQL account names permit IPv6 addresses to enable DBAs to specify privileges for clients that connect to the server over IPv6. See Section 6.2.3, “Specifying Account Names”. IPv6 addresses can be specified in account names in statements such as `CREATE USER`, `GRANT`, and `REVOKE`. For example:

  ```sql
  mysql> CREATE USER 'bill'@'::1' IDENTIFIED BY 'secret';
  mysql> GRANT SELECT ON mydb.* TO 'bill'@'::1';
  ```

The following sections describe how to set up MySQL so that clients can connect to the server over IPv6.

### 5.1.9.1 Verifying System Support for IPv6

Before MySQL Server can accept IPv6 connections, the operating system on your server host must support IPv6. As a simple test to determine whether that is true, try this command:

```shell
ping6 ::1
```

To produce a description of your system's network interfaces, invoke `ifconfig -a` and look for IPv6 addresses in the output.

If your host does not support IPv6, consult your system documentation for instructions on enabling it. It might be that you need only reconfigure an existing network interface to add an IPv6 address. Or a more extensive change might be needed, such as rebuilding the kernel with IPv6 options enabled.

These links may be helpful in setting up IPv6 on various platforms:

- Windows XP
- Gentoo Linux
- Ubuntu Linux
- Linux (Generic)
- Mac OS X

### 5.1.9.2 Configuring the MySQL Server to Permit IPv6 Connections

The MySQL server listens on a single network socket for TCP/IP connections. This socket is bound to a single address, but it is possible for an address to map onto multiple network interfaces. The default address is `0.0.0.0`. To specify an address explicitly, use the `--bind-address=addr` option at server
IPv6 Support

startup, where $addr$ is an IPv4 or IPv6 address or a host name. (IPv6 addresses are not supported before MySQL 5.5.3.) If $addr$ is a host name, the server resolves the name to an IP address and binds to that address.

The server treats different types of addresses as follows:

- If the address is $0.0.0.0$, the server accepts TCP/IP connections on all server host IPv4 interfaces.
- If the address is $::$, the server accepts TCP/IP connections on all server host IPv4 and IPv6 interfaces. Use this address to permit both IPv4 and IPv6 connections on all server interfaces.
- If the address is an IPv4-mapped address, the server accepts TCP/IP connections for that address, in either IPv4 or IPv6 format. For example, if the server is bound to $::ffff:127.0.0.1$, clients can connect using --host=127.0.0.1 or --host=::ffff:127.0.0.1.
- If the address is a “regular” IPv4 or IPv6 address (such as $127.0.0.1$ or $::1$), the server accepts TCP/IP connections only for that IPv4 or IPv6 address.

If you intend to bind the server to a specific address, be sure that the mysql.user grant table contains an account with administrative privileges that you can use to connect to that address. Otherwise, you will not be able to shut down the server. For example, if you bind the server to $::1$, you can connect to it using all existing accounts. But if you bind the server to $::1$, it accepts connections only on that address. In that case, first make sure that the 'root'@'::1' account is present in the mysql.user table so you can still connect to the server to shut it down.

5.1.9.3 Connecting Using the IPv6 Local Host Address

The following procedure shows how to configure MySQL to permit IPv6 connections by clients that connect to the local server using the $::1$ local host address. The instructions given here assume that your system supports IPv6.

1. Start the MySQL server with an appropriate --bind-address option to permit it to accept IPv6 connections. For example, put the following lines in your server option file and restart the server:

```
[mysqld]
bind-address = ::
```

Alternatively, you can bind the server to $::1$, but that makes the server more restrictive for TCP/IP connections. It accepts only IPv6 connections for that single address and rejects IPv4 connections. For more information, see Section 5.1.9.2, “Configuring the MySQL Server to Permit IPv6 Connections”.

2. As an administrator, connect to the server and create an account for a local user who will connect from the $::1$ local IPv6 host address:

```
mysql> CREATE USER 'ipv6user'@'::1' IDENTIFIED BY 'ipv6pass';
```

For the permitted syntax of IPv6 addresses in account names, see Section 6.2.3, “Specifying Account Names”. In addition to the CREATE USER statement, you can issue GRANT statements that give specific privileges to the account, although that is not necessary for the remaining steps in this procedure.

3. Invoke the mysql client to connect to the server using the new account:

```
shell> mysql -h ::1 -u ipv6user -pipv6pass
```

4. Try some simple statements that show connection information:
IPv6 Support

5.1.9.4 Connecting Using IPv6 Nonlocal Host Addresses

The following procedure shows how to configure MySQL to permit IPv6 connections by remote clients. It is similar to the preceding procedure for local clients, but the server and client hosts are distinct and each has its own nonlocal IPv6 address. The example uses these addresses:

Server host: 2001:db8:0:f101::1
Client host: 2001:db8:0:f101::2

These addresses are chosen from the nonroutable address range recommended by IANA for documentation purposes and suffice for testing on your local network. To accept IPv6 connections from clients outside the local network, the server host must have a public address. If your network provider assigns you an IPv6 address, you can use that. Otherwise, another way to obtain an address is to use an IPv6 broker; see Section 5.1.9.5, "Obtaining an IPv6 Address from a Broker".

1. Start the MySQL server with an appropriate --bind-address option to permit it to accept IPv6 connections. For example, put the following lines in your server option file and restart the server:

   `[mysqld]
   bind-address = ::`

   Alternatively, you can bind the server to 2001:db8:0:f101::1, but that makes the server more restrictive for TCP/IP connections. It accepts only IPv6 connections for that single address and rejects IPv4 connections. For more information, see Section 5.1.9.2, “Configuring the MySQL Server to Permit IPv6 Connections”.

2. On the server host (2001:db8:0:f101::1), create an account for a user who will connect from the client host (2001:db8:0:f101::2):

   `mysql> CREATE USER 'remoteipv6user'@'2001:db8:0:f101::2' IDENTIFIED BY 'remoteipv6pass';`

3. On the client host (2001:db8:0:f101::2), invoke the mysql client to connect to the server using the new account:

   `shell> mysql -h 2001:db8:0:f101::1 -u remoteipv6user -premoteipv6pass`

4. Try some simple statements that show connection information:

   `mysql> STATUS
   ...
   Connection: 2001:db8:0:f101::1 via TCP/IP`
   `mysql> SELECT CURRENT_USER();`

   +----------------+
   | CURRENT_USER() |
   | ipv6user@::1   |
   +----------------+
5.1.9.5 Obtaining an IPv6 Address from a Broker

If you do not have a public IPv6 address that enables your system to communicate over IPv6 outside your local network, you can obtain one from an IPv6 broker. The Wikipedia IPv6 Tunnel Broker page lists several brokers and their features, such as whether they provide static addresses and the supported routing protocols.

After configuring your server host to use a broker-supplied IPv6 address, start the MySQL server with an appropriate `--bind-address` option to permit the server to accept IPv6 connections. For example, put the following lines in the server option file and restart the server:

```
[mysqld]
bind-address = ::
```

Alternatively, you can bind the server to the specific IPv6 address provided by the broker, but that makes the server more restrictive for TCP/IP connections. It accepts only IPv6 connections for that single address and rejects IPv4 connections. For more information, see Section 5.1.9.2, "Configuring the MySQL Server to Permit IPv6 Connections". In addition, if the broker allocates dynamic addresses, the address provided for your system might change the next time you connect to the broker. If so, any accounts you create that name the original address become invalid. To bind to a specific address but avoid this change-of-address problem, you may be able to arrange with the broker for a static IPv6 address.

The following example shows how to use Freenet6 as the broker and the `gogoc` IPv6 client package on Gentoo Linux.

1. Create a account at Freenet6 by visiting this URL and signing up:
   
   http://gogonet.gogo6.com

2. After creating the account, go to this URL, sign in, and create a user ID and password for the IPv6 broker:

   http://gogonet.gogo6.com/page/freenet6-registration

3. As root, install `gogoc`:

   shell> emerge gogoc

4. Edit `/etc/gogoc/gogoc.conf` to set the `userid` and `password` values. For example:

   userid=gogouser
   passwd=gogopass

5. Start `gogoc`:

   shell> /etc/init.d/gogoc start

   To start `gogoc` each time your system boots, execute this command:

   shell> rc-update add gogoc default
6. Use `ping6` to try to ping a host:

```
shell> ping6 ipv6.google.com
```

7. To see your IPv6 address:

```
shell> ifconfig tun
```

### 5.1.10 Server-Side Help

MySQL Server supports a `HELP` statement that returns online information from the MySQL Reference manual (see Section 13.8.3, "HELP Syntax"). The proper operation of this statement requires that the help tables in the `mysql` database be initialized with help topic information, which is done by processing the contents of the `fill_help_tables.sql` script.

If you install MySQL using a binary or source distribution on Unix, help table content initialization occurs when you run `mysql_install_db`. For an RPM distribution on Linux or binary distribution on Windows, content initialization occurs as part of the MySQL installation process.

If you upgrade MySQL using a binary distribution, help table content is not upgraded automatically, but you can upgrade it manually. Locate the `fill_help_tables.sql` file in the `share` or `share/mysql` directory. Change location into that directory and process the file with the `mysql` client as follows:

```
shell> mysql -u root mysql < fill_help_tables.sql
```

You can also obtain the latest `fill_help_tables.sql` at any time to upgrade your help tables. Download the proper file for your version of MySQL from [http://dev.mysql.com/doc/index-other.html](http://dev.mysql.com/doc/index-other.html). After downloading and uncompressing the file, process it with `mysql` as described previously.

If you are working with Bazaar and a MySQL development source tree, you must use a downloaded copy of the `fill_help_tables.sql` file because the source tree contains only a "stub" version.

**Note**

For a server that participates in replication, the help table content upgrade process involves multiple servers. For details, see Section 17.4.1.28, "Replication of Server-Side Help Tables".

### 5.1.11 Server Response to Signals

On Unix, signals can be sent to processes. `mysqld` responds to signals sent to it as follows:

- **SIGTERM** causes the server to shut down.
- **SIGHUP** causes the server to reload the grant tables and to flush tables, logs, the thread cache, and the host cache. These actions are like various forms of the `FLUSH` statement. The server also writes a status report to the error log that has this format:

```
Status information:
Current dir: /var/mysql/data/
Running threads: 0  Stack size: 196608
Current locks:
Key caches: default
```
On some Mac OS X 10.3 versions, `mysqld` ignores `SIGHUP` and `SIGQUIT`.

### 5.1.12 The Shutdown Process

The server shutdown process takes place as follows:

1. **The shutdown process is initiated.**

   This can occur initiated several ways. For example, a user with the `SHUTDOWN` privilege can execute a `mysqladmin shutdown` command. `mysqladmin` can be used on any platform supported by MySQL. Other operating system-specific shutdown initiation methods are possible as well: The server shuts down on Unix when it receives a `SIGTERM` signal. A server running as a service on Windows shuts down when the services manager tells it to.

2. **The server creates a shutdown thread if necessary.**

   Depending on how shutdown was initiated, the server might create a thread to handle the shutdown process. If shutdown was requested by a client, a shutdown thread is created. If shutdown is the result of receiving a `SIGTERM` signal, the signal thread might handle shutdown itself, or it might create a separate thread to do so. If the server tries to create a shutdown thread and cannot (for example, if memory is exhausted), it issues a diagnostic message that appears in the error log:

   ```
   Error: Can't create thread to kill server
   ```

3. **The server stops accepting new connections.**

   To prevent new activity from being initiated during shutdown, the server stops accepting new client connections by closing the handlers for the network interfaces to which it normally listens for connections: the TCP/IP port, the Unix socket file, the Windows named pipe, and shared memory on Windows.
4. The server terminates current activity.

For each thread associated with a client connection, the server breaks the connection to the client and marks the thread as killed. Threads die when they notice that they are so marked. Threads for idle connections die quickly. Threads that currently are processing statements check their state periodically and take longer to die. For additional information about thread termination, see Section 13.7.6.4, “KILL Syntax”, in particular for the instructions about killed REPAIR TABLE or OPTIMIZE TABLE operations on MyISAM tables.

For threads that have an open transaction, the transaction is rolled back. Note that if a thread is updating a nontransactional table, an operation such as a multiple-row UPDATE or INSERT may leave the table partially updated because the operation can terminate before completion.

If the server is a master replication server, it treats threads associated with currently connected slaves like other client threads. That is, each one is marked as killed and exits when it next checks its state.

If the server is a slave replication server, it stops the I/O and SQL threads, if they are active, before marking client threads as killed. The SQL thread is permitted to finish its current statement (to avoid causing replication problems), and then stops. If the SQL thread is in the middle of a transaction at this point, the server waits until the current replication event group (if any) has finished executing, or until the user issues a KILL QUERY or KILL CONNECTION statement. See also Section 13.4.2.6, “STOP SLAVE Syntax”.

If the slave is updating a nontransactional table when it is forcibly killed, the slave’s data may become inconsistent with the master.

5. The server shuts down or closes storage engines.

At this stage, the server flushes the table cache and closes all open tables.

Each storage engine performs any actions necessary for tables that it manages. For example, MyISAM flushes any pending index writes for a table. InnoDB flushes its buffer pool to disk (unless innodb_fast_shutdown is 2), writes the current LSN to the tablespace, and terminates its own internal threads.

6. The server exits.

5.2 MySQL Server Logs

MySQL Server has several logs that can help you find out what activity is taking place.

<table>
<thead>
<tr>
<th>Log Type</th>
<th>Information Written to Log</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error log</td>
<td>Problems encountered starting, running, or stopping mysqld</td>
</tr>
<tr>
<td>General query log</td>
<td>Established client connections and statements received from clients</td>
</tr>
<tr>
<td>Binary log</td>
<td>Statements that change data (also used for replication)</td>
</tr>
<tr>
<td>Relay log</td>
<td>Data changes received from a replication master server</td>
</tr>
<tr>
<td>Slow query log</td>
<td>Queries that took more than long_query_time seconds to execute</td>
</tr>
</tbody>
</table>

By default, no logs are enabled (except the error log on Windows). The following log-specific sections provide information about the server options that enable logging.

By default, the server writes files for all enabled logs in the data directory. You can force the server to close and reopen the log files (or in some cases switch to a new log file) by flushing the logs. Log flushing occurs when you issue a FLUSH LOGS statement; execute mysqladmin with a flush-logs
or refresh argument; or execute mysqldump with a --flush-logs or --master-data option. See Section 13.7.6.3, "FLUSH Syntax", Section 4.5.2, "mysqladmin — Client for Administering a MySQL Server", and Section 4.5.4, "mysqldump — A Database Backup Program". In addition, the binary log is flushed when its size reaches the value of the max_binlog_size system variable.

You can control the general query and slow query logs during runtime. You can enable or disable logging, or change the log file name. You can tell the server to write general query and slow query entries to log tables, log files, or both. For details, see Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”, Section 5.2.3, “The General Query Log”, and Section 5.2.5, “The Slow Query Log”.

The relay log is used only on slave replication servers, to hold data changes from the master server that must also be made on the slave. For discussion of relay log contents and configuration, see Section 17.2.2.1, “The Slave Relay Log”.

For information about log maintenance operations such as expiration of old log files, see Section 5.2.6, “Server Log Maintenance”.

For information about keeping logs secure, see Section 6.1.2.3, “Passwords and Logging”.

5.2.1 Selecting General Query and Slow Query Log Output Destinations

MySQL Server provides flexible control over the destination of output to the general query log and the slow query log, if those logs are enabled. Possible destinations for log entries are log files or the general_log and slow_log tables in the mysql database. Either or both destinations can be selected.

Before MySQL 5.5.7, logging to tables incurs significantly more server overhead than logging to files. If you enable the general log or slow query log and require highest performance, you should use file logging, not table logging.

Log control at server startup. The --log-output option specifies the destination for log output. This option does not in itself enable the logs. Its syntax is --log-output [=value,...]:

- If --log-output is given with a value, the value should be a comma-separated list of one or more of the words TABLE (log to tables), FILE (log to files), or NONE (do not log to tables or files). NONE, if present, takes precedence over any other specifiers.

- If --log-output is omitted, the default logging destination is FILE.

The general_log system variable controls logging to the general query log for the selected log destinations. If specified at server startup, general_log takes an optional argument of 1 or 0 to enable or disable the log. To specify a file name other than the default for file logging, set the general_log_file variable. Similarly, the slow_query_log variable controls logging to the slow query log for the selected destinations and setting slow_query_log_file specifies a file name for file logging. If either log is enabled, the server opens the corresponding log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the FILE log destination is selected.

Examples:

- To write general query log entries to the log table and the log file, use --log-output=TABLE,FILE to select both log destinations and --general_log to enable the general query log.

- To write general and slow query log entries only to the log tables, use --log-output=TABLE to select tables as the log destination and --general_log and --slow_query_log to enable both logs.

- To write slow query log entries only to the log file, use --log-output=FILE to select files as the log destination and --slow_query_log to enable the slow query log. (In this case, because the default log destination is FILE, you could omit the --log-output option.)
Log control at runtime. The system variables associated with log tables and files enable runtime control over logging:

- The global `log_output` system variable indicates the current logging destination. It can be modified at runtime to change the destination.

- The global `general_log` and `slow_query_log` variables indicate whether the general query log and slow query log are enabled (`ON`) or disabled (`OFF`). You can set these variables at runtime to control whether the logs are enabled.

- The global `general_log_file` and `slow_query_log_file` variables indicate the names of the general query log and slow query log files. You can set these variables at server startup or at runtime to change the names of the log files.

- To disable or enable general query logging for the current connection, set the session `sql_log_off` variable to `ON` or `OFF`.

The use of tables for log output offers the following benefits:

- Log entries have a standard format. To display the current structure of the log tables, use these statements:

  ```
  SHOW CREATE TABLE mysql.general_log;
  SHOW CREATE TABLE mysql.slow_log;
  ```

- Log contents are accessible through SQL statements. This enables the use of queries that select only those log entries that satisfy specific criteria. For example, to select log contents associated with a particular client (which can be useful for identifying problematic queries from that client), it is easier to do this using a log table than a log file.

- Logs are accessible remotely through any client that can connect to the server and issue queries (if the client has the appropriate log table privileges). It is not necessary to log in to the server host and directly access the file system.

The log table implementation has the following characteristics:

- In general, the primary purpose of log tables is to provide an interface for users to observe the runtime execution of the server, not to interfere with its runtime execution.

- `CREATE TABLE`, `ALTER TABLE`, and `DROP TABLE` are valid operations on a log table. For `ALTER TABLE` and `DROP TABLE`, the log table cannot be in use and must be disabled, as described later.

- By default, the log tables use the `CSV` storage engine that writes data in comma-separated values format. For users who have access to the `.CSV` files that contain log table data, the files are easy to import into other programs such as spreadsheets that can process CSV input.

The log tables can be altered to use the `MyISAM` storage engine. You cannot use `ALTER TABLE` to alter a log table that is in use. The log must be disabled first. No engines other than `CSV` or `MyISAM` are legal for the log tables.

- To disable logging so that you can alter (or drop) a log table, you can use the following strategy. The example uses the general query log; the procedure for the slow query log is similar but uses the `slow_log` table and `slow_query_log` system variable.

  ```
  SET @old_log_state = @@global.general_log;
  SET GLOBAL general_log = 'OFF';
  ALTER TABLE mysql.general_log ENGINE = MyISAM;
  ```
SET GLOBAL general_log = @old_log_state;

- **TRUNCATE TABLE** is a valid operation on a log table. It can be used to expire log entries.
- **RENAME TABLE** is a valid operation on a log table. You can atomically rename a log table (to perform log rotation, for example) using the following strategy:

```sql
USE mysql;
DROP TABLE IF EXISTS general_log2;
CREATE TABLE general_log2 LIKE general_log;
RENAME TABLE general_log TO general_log_backup, general_log2 TO general_log;
```

- As of MySQL 5.5.7, **CHECK TABLE** is a valid operation on a log table.
- **LOCK TABLES** cannot be used on a log table.
- **INSERT**, **DELETE**, and **UPDATE** cannot be used on a log table. These operations are permitted only internally to the server itself.
- **FLUSH TABLES WITH READ LOCK** and the state of the global `read_only` system variable have no effect on log tables. The server can always write to the log tables.
- Entries written to the log tables are not written to the binary log and thus are not replicated to slave servers.
- To flush the log tables or log files, use **FLUSH TABLES** or **FLUSH LOGS**, respectively.
- Partitioning of log tables is not permitted.
- Before MySQL 5.5.25, **mysqldump** does not dump the `general_log` or `slow_query_log` tables for dumps of the `mysql` database. As of 5.5.25, the dump includes statements to recreate those tables so that they are not missing after reloading the dump file. Log table contents are not dumped.

### 5.2.2 The Error Log

The error log contains information indicating when **mysqld** was started and stopped and also any critical errors that occur while the server is running. If **mysqld** notices a table that needs to be automatically checked or repaired, it writes a message to the error log.

On some operating systems, the error log contains a stack trace if **mysqld** dies. The trace can be used to determine where **mysqld** died. See Section 24.4, “Debugging and Porting MySQL”.

In the following discussion, “console” means `stderr`, the standard error output; this is your terminal or console window unless the standard error output has been redirected. (For example, if invoked with the `--syslog` option, **mysqld_safe** arranges for the server’s `stderr` to be sent to the `syslog` facility, as described later.)

On Windows, the **--log-error** and **--console** options both affect error logging:

- Without **--log-error**, **mysqld** writes error messages to `host_name.err` in the data directory.
- With **--log-error [=file_name]**, **mysqld** writes error messages to an error log file. The server uses the named file if present, creating it in the data directory unless an absolute path name is given to specify a different directory. If no file is named, the default name is `host_name.err` in the data directory.
- If **--console** is given, **mysqld** writes error messages to the console, unless **--log-error** is also given. If both options are present, **--console** is ignored and has no effect. Their order does not matter.
--log-error takes precedence and error messages go to a log file. (Before MySQL 5.5.3, if both options are given, the last one takes precedence.)

In addition, on Windows, events and error messages are written to the Windows Event Log within the Application log. Entries marked as Warning and Note are written to the Event Log, but not informational messages such as information statements from individual storage engines. These log entries have a source of MySQL. You cannot disable writing information to the Windows Event Log.

On Unix and Unix-like systems, mysqld writes error log messages as follows:

- Without --log-error, mysqld writes error messages to the console.
- With --log-error=file_name, mysqld writes error messages to an error log file. The server uses the named file if present, creating it in the data directory unless an absolute path name is given to specify a different directory. If no file is named, the default name is host_name.err in the data directory.

At runtime, log_error system variable indicates the error log file name if error output is written to a file.

If you flush the logs using FLUSH LOGS or mysqladmin flush-logs and mysqld is writing the error log to a file (for example, if it was started with the --log-error option), the effect is version dependent:

- As of MySQL 5.5.7, the server closes and reopens the log file. To rename the file, do so manually before flushing. Then flushing the logs reopens a new file with the original file name. For example, you can rename the file and create a new one using the following commands:

  shell> mv host_name.err host_name.err-old
  shell> mysqladmin flush-logs
  shell> mv host_name.err-old backup-directory

  On Windows, use rename rather than mv.
- Prior to MySQL 5.5.7, the server renames the current log file with the suffix -old, then creates a new empty log file. Be aware that a second log-flushing operation thus causes the original error log file to be lost unless you save it under a different name. On Windows, you cannot rename the error log while the server has it open before MySQL 5.5.7. To avoid a restart, flush the logs first to cause the server to rename the original file and create a new one, then save the renamed file. That also works on Unix, or you can use the commands shown earlier.

No error log renaming occurs when the logs are flushed in any case if the server is not writing to a named file.

If you use mysqld_safe to start mysqld, mysqld_safe arranges for mysqld to write error messages to a log file or to syslog. mysqld_safe has three error-logging options, --syslog, --skip-syslog, and --log-error. The default with no logging options or with --skip-syslog is to use the default log file. To explicitly specify use of an error log file, specify --log-error=file_name to mysqld_safe, and mysqld_safe will arrange for mysqld to write messages to a log file. To use syslog instead, specify the --syslog option.

If you specify --log-error in an option file in a [mysqld], [server], or [mysqld_safe] section, mysqld_safe will find and use the option.

If mysqld_safe is used to start mysqld and mysqld dies unexpectedly, mysqld_safe notices that it needs to restart mysqld and writes a restarted mysqld message to the error log.

The --log-warnings option or log_warnings system variable can be used to control warning logging to the error log. The default value is enabled (1). Warning logging can be disabled using a value of 0. If the
value is greater than 1, aborted connections are written to the error log, and access-denied errors for new connection attempts are written. See Section B.5.2.11, “Communication Errors and Aborted Connections”.

5.2.3 The General Query Log

The general query log is a general record of what mysqld is doing. The server writes information to this log when clients connect or disconnect, and it logs each SQL statement received from clients. The general query log can be very useful when you suspect an error in a client and want to know exactly what the client sent to mysqld.

mysqld writes statements to the query log in the order that it receives them, which might differ from the order in which they are executed. This logging order is in contrast with that of the binary log, for which statements are written after they are executed but before any locks are released. In addition, the query log may contain statements that only select data while such statements are never written to the binary log.

When using statement-based logging all statements are written to the query log, but when using row-based logging, updates are sent as row changes rather than SQL statements, and thus these statements are never written to the query log when binlog_format is ROW. A given update also might not be written to the query log when this variable is set to MIXED, depending on the statement used. See Section 17.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”, for more information.

By default, the general query log is disabled. To specify the initial general query log state explicitly, use --general_log=[{0|1}]. With no argument or an argument of 1, --general_log enables the log. With an argument of 0, this option disables the log. To specify a log file name, use --general_log_file=file_name. To specify the log destination, use --log-output (as described in Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”). The older options to enable the general query log, --log and -l, are deprecated.

If you specify no name for the general query log file, the default name is host_name.log. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

To disable or enable the general query log or change the log file name at runtime, use the global general_log and general_log_file system variables. Set general_log to 0 (or OFF) to disable the log or to 1 (or ON) to enable it. Set general_log_file to specify the name of the log file. If a log file already is open, it is closed and the new file is opened.

When the general query log is enabled, the server writes output to any destinations specified by the --log-output option or log_output system variable. If you enable the log, the server opens the log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the FILE log destination is selected. If the destination is NONE, the server writes no queries even if the general log is enabled. Setting the log file name has no effect on logging if the log destination value does not contain FILE.

Server restarts and log flushing do not cause a new general query log file to be generated (although flushing closes and reopens it). To rename the file and create a new one, use the following commands:

```
shell> mv host_name.log host_name-old.log
shell> mysqladmin flush-logs
shell> mv host_name-old.log backup-directory
```

On Windows, use rename rather than mv.

You can also rename the general query log file at runtime by disabling the log:

```
SET GLOBAL general_log = 'OFF';
```
With the log disabled, rename the log file externally; for example, from the command line. Then enable the log again:

```
SET GLOBAL general_log = 'ON';
```

This method works on any platform and does not require a server restart.

The session `sql_log_off` variable can be set to `ON` or `OFF` to disable or enable general query logging for the current connection.

The general query log should be protected because logged statements might contain passwords. See Section 6.1.2.3, “Passwords and Logging”.

### 5.2.4 The Binary Log

The binary log contains “events” that describe database changes such as table creation operations or changes to table data. It also contains events for statements that potentially could have made changes (for example, a `DELETE` which matched no rows), unless row-based logging is used. The binary log also contains information about how long each statement took that updated data. The binary log has two important purposes:

- For replication, the binary log on a master replication server provides a record of the data changes to be sent to slave servers. The master server sends the events contained in its binary log to its slaves, which execute those events to make the same data changes that were made on the master. See Section 17.2, “Replication Implementation”.

- Certain data recovery operations require use of the binary log. After a backup has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See Section 7.5, “Point-in-Time (Incremental) Recovery Using the Binary Log”.

The binary log is not used for statements such as `SELECT` or `SHOW` that do not modify data. To log all statements (for example, to identify a problem query), use the general query log. See Section 5.2.3, “The General Query Log”.

Running a server with binary logging enabled makes performance slightly slower. However, the benefits of the binary log in enabling you to set up replication and for restore operations generally outweigh this minor performance decrement.

The binary log should be protected because logged statements might contain passwords. See Section 6.1.2.3, “Passwords and Logging”.

The following discussion describes some of the server options and variables that affect the operation of binary logging. For a complete list, see Section 17.1.3.4, “Binary Log Options and Variables”.

To enable the binary log, start the server with the `--log-bin[=base_name]` option. If no `base_name` value is given, the default name is the value of the `pid-file` option (which by default is the name of host machine) followed by `-bin`. If the basename is given, the server writes the file in the data directory unless the basename is given with a leading absolute path name to specify a different directory. It is recommended that you specify a basename explicitly rather than using the default of the host name; see Section B.5.8, “Known Issues in MySQL”, for the reason.

If you supply an extension in the log name (for example, `--log-bin=base_name.extension`), the extension is silently removed and ignored.

`mysqld` appends a numeric extension to the binary log basename to generate binary log file names. The number increases each time the server creates a new log file, thus creating an ordered series of files. The
The server creates a new file in the series each time it starts or flushes the logs. The server also creates a
new binary log file automatically after the current log's size reaches \texttt{max_binlog_size}. A binary log file
may become larger than \texttt{max_binlog_size} if you are using large transactions because a transaction is
written to the file in one piece, never split between files.

To keep track of which binary log files have been used, \texttt{mysqld} also creates a binary log index file
that contains the names of all used binary log files. By default, this has the same basename as the binary log
file, with the extension \texttt{'.index'}. You can change the name of the binary log index file with the \texttt{--log-bin-index=\texttt{file_name}} option. You should not manually edit this file while \texttt{mysqld} is running; doing
so would confuse \texttt{mysqld}.

The term “binary log file” generally denotes an individual numbered file containing database events. The
term “binary log” collectively denotes the set of numbered binary log files plus the index file.

A client that has the \texttt{SUPER} privilege can disable binary logging of its own statements by using a \texttt{SET
sql_log_bin=0} statement. See Section 5.1.4, “Server System Variables”.

The format of the events recorded in the binary log is dependent on the binary logging format. Three format
types are supported, row-based logging, statement-based logging and mixed-base logging. The binary
logging format used depends on the MySQL version. For general descriptions of the logging formats, see
Section 5.2.4.1, “Binary Logging Formats”. For detailed information about the format of the binary log, see
MySQL Internals: The Binary Log.

The server evaluates the \texttt{--binlog-do-db} and \texttt{--binlog-ignore-db} options in the same way as it
does the \texttt{--replicate-do-db} and \texttt{--replicate-ignore-db} options. For information about how this
is done, see Section 17.2.3.1, “Evaluation of Database-Level Replication and Binary Logging Options”.

If you are replicating from a MySQL Cluster to a standalone MySQL Server, you should be aware that
the \texttt{NDB} storage engine uses default values for some binary logging options (including options specific
to \texttt{NDB} such as \texttt{--ndb-log-update-as-write} [2534]) that differ from those used by other storage
engines. If not corrected for, these differences can lead to divergence of the master's and slave's binary
logs. For more information, see Replication from \texttt{NDB} to other storage engines. In particular, if you are
using a nontransactional storage engine such as \texttt{MyISAM} on the slave, see Replication from \texttt{NDB} to a
nontransactional storage engine.

A replication slave server by default does not write to its own binary log any data modifications that are
received from the replication master. To log these modifications, start the slave with the \texttt{--log-slave-updates}
option in addition to the \texttt{--log-bin} option (see Section 17.1.3.3, “Replication Slave Options
and Variables”). This is done when a slave is also to act as a master to other slaves in chained replication.

You can delete all binary log files with the \texttt{RESET MASTER} statement, or a subset of them with \texttt{PURGE
BINARY LOGS}. See Section 13.7.6.6, “RESET Syntax”, and Section 13.4.1.1, “PURGE BINARY LOGS
Syntax”.

If you are using replication, you should not delete old binary log files on the master until you are sure that
no slave still needs to use them. For example, if your slaves never run more than three days behind, once
a day you can execute \texttt{mysqladmin flush-logs} on the master and then remove any logs that are
more than three days old. You can remove the files manually, but it is preferable to use \texttt{PURGE BINARY
LOGS}, which also safely updates the binary log index file for you (and which can take a date argument). See
Section 13.4.1.1, “PURGE BINARY LOGS Syntax”.

You can display the contents of binary log files with the \texttt{mysqlbinlog} utility. This can be useful when you
want to reprocess statements in the log for a recovery operation. For example, you can update a MySQL
server from the binary log as follows:

\begin{verbatim}
shell> mysqlbinlog log_file | mysql -h server_name
\end{verbatim}
MySQL also can be used to display replication slave relay log file contents because they are written using the same format as binary log files. For more information on the `mysqlbinlog` utility and how to use it, see Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”. For more information about the binary log and recovery operations, see Section 7.5, “Point-in-Time (Incremental) Recovery Using the Binary Log”.

Binary logging is done immediately after a statement or transaction completes but before any locks are released or any commit is done. This ensures that the log is logged in commit order.

Updates to nontransactional tables are stored in the binary log immediately after execution.

Within an uncommitted transaction, all updates (UPDATE, DELETE, or INSERT) that change transactional tables such as InnoDB tables are cached until a COMMIT statement is received by the server. At that point, mysqld writes the entire transaction to the binary log before the COMMIT is executed.

Modifications to nontransactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to nontransactional tables, the entire transaction is logged with a ROLLBACK statement at the end to ensure that the modifications to those tables are replicated.

When a thread that handles the transaction starts, it allocates a buffer of `binlog_cache_size` to buffer statements. If a statement is bigger than this, the thread opens a temporary file to store the transaction. The temporary file is deleted when the thread ends.

The `Binlog_cache_use` status variable shows the number of transactions that used this buffer (and possibly a temporary file) for storing statements. The `Binlog_cache_disk_use` status variable shows how many of those transactions actually had to use a temporary file. These two variables can be used for tuning `binlog_cache_size` to a large enough value that avoids the use of temporary files.

The `max_binlog_cache_size` system variable (default 4GB, which is also the maximum) can be used to restrict the total size used to cache a multiple-statement transaction. If a transaction is larger than this many bytes, it fails and rolls back. The minimum value is 4096.

If you are using the binary log and row based logging, concurrent inserts are converted to normal inserts for CREATE ... SELECT or INSERT ... SELECT statements. This is done to ensure that you can re-create an exact copy of your tables by applying the log during a backup operation. If you are using statement-based logging, the original statement is written to the log.

The binary log format has some known limitations that can affect recovery from backups. See Section 17.4.1, “Replication Features and Issues”.

Binary logging for stored programs is done as described in Section 20.7, “Binary Logging of Stored Programs”.

Note that the binary log format differs in MySQL 5.5 from previous versions of MySQL, due to enhancements in replication. See Section 17.4.2, “Replication Compatibility Between MySQL Versions”.

Writes to the binary log file and binary log index file are handled in the same way as writes to MyISAM tables. See Section B.5.4.3, “How MySQL Handles a Full Disk”.

By default, the binary log is not synchronized to disk at each write. So if the operating system or machine (not only the MySQL server) crashes, there is a chance that the last statements of the binary log are lost. To prevent this, you can make the binary log be synchronized to disk after every \( N \) writes to the binary log, with the `sync_binlog` system variable. See Section 5.1.4, “Server System Variables”. 1 is the safest value for `sync_binlog`, but also the slowest. Even with `sync_binlog` set to 1, there is still the chance of an inconsistency between the table content and binary log content in case of a crash. For example, if you are using InnoDB tables and the MySQL server processes a COMMIT statement, it writes the whole transaction to the binary log and then commits this transaction into InnoDB. If the server crashes between
those two operations, the transaction is rolled back by InnoDB at restart but still exists in the binary log. To resolve this, you should set \(--innodb_support_xa\) to 1. Although this option is related to the support of XA transactions in InnoDB, it also ensures that the binary log and InnoDB data files are synchronized.

For this option to provide a greater degree of safety, the MySQL server should also be configured to synchronize the binary log and the InnoDB logs to disk at every transaction. The InnoDB logs are synchronized by default, and \(\text{sync_binlog}=1\) can be used to synchronize the binary log. The effect of this option is that at restart after a crash, after doing a rollback of transactions, the MySQL server cuts rolled back InnoDB transactions from the binary log. This ensures that the binary log reflects the exact data of InnoDB tables, and so, that the slave remains in synchrony with the master (not receiving a statement which has been rolled back).

If the MySQL server discovers at crash recovery that the binary log is shorter than it should have been, it lacks at least one successfully committed InnoDB transaction. This should not happen if \(\text{sync_binlog}=1\) and the disk/file system do an actual sync when they are requested to (some do not), so the server prints an error message The binary log file name is shorter than its expected size. In this case, this binary log is not correct and replication should be restarted from a fresh snapshot of the master’s data.

The session values of the following system variables are written to the binary log and honored by the replication slave when parsing the binary log:

- \(\text{sql_mode}\) (except that the \text{NO_DIR_IN_CREATE} mode is not replicated; see Section 17.4.1.36, “Replication and Variables”)
- \(\text{foreign_key_checks}\)
- \(\text{unique_checks}\)
- \(\text{character_set_client}\)
- \(\text{collation_connection}\)
- \(\text{collation_database}\)
- \(\text{collation_server}\)
- \(\text{sql_auto_is_null}\)

**5.2.4.1 Binary Logging Formats**

The server uses several logging formats to record information in the binary log. The exact format employed depends on the version of MySQL being used. There are three logging formats:

- Replication capabilities in MySQL originally were based on propagation of SQL statements from master to slave. This is called \text{statement-based logging}. You can cause this format to be used by starting the server with \(--\text{binlog-format}=\text{STATEMENT}\).
- In \text{row-based logging}, the master writes events to the binary log that indicate how individual table rows are affected. You can cause the server to use row-based logging by starting it with \(--\text{binlog-format}=\text{ROW}\).
- A third option is also available: \text{mixed logging}. With mixed logging, statement-based logging is used by default, but the logging mode switches automatically to row-based in certain cases as described below. You can cause MySQL to use mixed logging explicitly by starting \text{mysqld} with the option \(--\text{binlog-format}=\text{MIXED}\).

In MySQL 5.5, the default binary logging format is \text{STATEMENT}. 
The logging format can also be set or limited by the storage engine being used. This helps to eliminate issues when replicating certain statements between a master and slave which are using different storage engines.

With statement-based replication, there may be issues with replicating nondeterministic statements. In deciding whether or not a given statement is safe for statement-based replication, MySQL determines whether it can guarantee that the statement can be replicated using statement-based logging. If MySQL cannot make this guarantee, it marks the statement as potentially unreliable and issues the warning, Statement may not be safe to log in statement format.

You can avoid these issues by using MySQL's row-based replication instead.

### 5.2.4.2 Setting The Binary Log Format

You can select the binary logging format explicitly by starting the MySQL server with `--binlog-format=type`. The supported values for `type` are:

- **STATEMENT** causes logging to be statement based.
- **ROW** causes logging to be row based.
- **MIXED** causes logging to use mixed format.

In MySQL 5.5, the default binary logging format is **STATEMENT**. This includes MySQL Cluster NDB 7.2.1 and later MySQL Cluster NDB 7.2 releases, which are based on MySQL 5.5.

The logging format also can be switched at runtime. To specify the format globally for all clients, set the global value of the `binlog_format` system variable:

```sql
mysql> SET GLOBAL binlog_format = 'STATEMENT';
mysql> SET GLOBAL binlog_format = 'ROW';
mysql> SET GLOBAL binlog_format = 'MIXED';
```

An individual client can control the logging format for its own statements by setting the session value of `binlog_format`:

```sql
mysql> SET SESSION binlog_format = 'STATEMENT';
mysql> SET SESSION binlog_format = 'ROW';
mysql> SET SESSION binlog_format = 'MIXED';
```

**Note**

Each MySQL Server can set its own and only its own binary logging format (true whether `binlog_format` is set with global or session scope). This means that changing the logging format on a replication master does not cause a slave to change its logging format to match. (When using **STATEMENT** mode, the `binlog_format` system variable is not replicated; when using **MIXED** or **ROW** logging mode, it is replicated but is ignored by the slave.) Changing the binary logging format on the master while replication is ongoing, or without also changing it on the slave can thus cause unexpected results, or even cause replication to fail altogether.

To change the global or session `binlog_format` value, you must have the **SUPER** privilege.

In addition to switching the logging format manually, a slave server may switch the format **automatically**. This happens when the server is running in either **STATEMENT** or **MIXED** format and encounters an event in the binary log that is written in **ROW** logging format. In that case, the slave switches to row-based replication temporarily for that event, and switches back to the previous format afterward.
There are several reasons why a client might want to set binary logging on a per-session basis:

- A session that makes many small changes to the database might want to use row-based logging.
- A session that performs updates that match many rows in the `WHERE` clause might want to use statement-based logging because it will be more efficient to log a few statements than many rows.
- Some statements require a lot of execution time on the master, but result in just a few rows being modified. It might therefore be beneficial to replicate them using row-based logging.

There are exceptions when you cannot switch the replication format at runtime:

- From within a stored function or a trigger
- If the `NDBCLUSTER` storage engine is enabled
- If the session is currently in row-based replication mode and has open temporary tables

Trying to switch the format in any of these cases results in an error.

If you are using InnoDB tables and the transaction isolation level is `READ COMMITTED` or `READ UNCOMMITTED`, only row-based logging can be used. It is possible to change the logging format to `STATEMENT`, but doing so at runtime leads very rapidly to errors because InnoDB can no longer perform inserts.

Switching the replication format at runtime is not recommended when any temporary tables exist, because temporary tables are logged only when using statement-based replication, whereas with row-based replication they are not logged. With mixed replication, temporary tables are usually logged; exceptions happen with user-defined functions (UDFs) and with the `UUID()` function.

With the binary log format set to `ROW`, many changes are written to the binary log using the row-based format. Some changes, however, still use the statement-based format. Examples include all DDL (data definition language) statements such as `CREATE TABLE`, `ALTER TABLE`, or `DROP TABLE`.

The `--binlog-row-event-max-size` option is available for servers that are capable of row-based replication. Rows are stored into the binary log in chunks having a size in bytes not exceeding the value of this option. The value must be a multiple of 256. The default value is 1024.

**Warning**

When using `statement-based logging` for replication, it is possible for the data on the master and slave to become different if a statement is designed in such a way that the data modification is *nondeterministic*; that is, it is left to the will of the query optimizer. In general, this is not a good practice even outside of replication. For a detailed explanation of this issue, see Section B.5.8, “Known Issues in MySQL”.

### 5.2.4.3 Mixed Binary Logging Format

When running in `MIXED` logging format, the server automatically switches from statement-based to row-based logging under the following conditions:

- When a DML statement updates an `NDBCLUSTER` table.
- When a function contains `UUID()`.
- When one or more tables with `AUTO_INCREMENT` columns are updated and a trigger or stored function is invoked. Like all other unsafe statements, this generates a warning if `binlog_format = STATEMENT`.
For more information, see Section 17.4.1.1, “Replication and AUTO_INCREMENT”.

- When any `INSERT DELAYED` is executed.

- When the body of a view requires row-based replication, the statement creating the view also uses it. For example, this occurs when the statement creating a view uses the `UUID()` function.

- When a call to a UDF is involved.

- If a statement is logged by row and the session that executed the statement has any temporary tables, logging by row is used for all subsequent statements (except for those accessing temporary tables) until all temporary tables in use by that session are dropped.

  This is true whether or not any temporary tables are actually logged.

  Temporary tables cannot be logged using row-based format; thus, once row-based logging is used, all subsequent statements using that table are unsafe. The server approximates this condition by treating all statements executed during the session as unsafe until the session no longer holds any temporary tables.

- When `FOUND_ROWS()` or `ROW_COUNT()` is used. (Bug #12092, Bug #30244)

- When `USER()`, `CURRENT_USER()`, or `CURRENT_USER` is used. (Bug #28086)

- When a statement refers to one or more system variables. (Bug #31168)

  **Exception.** The following system variables, when used with session scope (only), do not cause the logging format to switch:

  - `auto_increment_increment`
  - `auto_increment_offset`
  - `character_set_client`
  - `character_set_connection`
  - `character_set_database`
  - `character_set_server`
  - `collation_connection`
  - `collation_database`
  - `collation_server`
  - `foreign_key_checks`
  - `identity`
  - `last_insert_id`
  - `lc_time_names`
  - `pseudo_thread_id`
  - `sql_auto_is_null`
• time_zone
• timestamp
• unique_checks

For information about determining system variable scope, see Section 5.1.5, "Using System Variables".

For information about how replication treats sql_mode, see Section 17.4.1.36, "Replication and Variables".

• When one of the tables involved is a log table in the mysql database.
• When the LOAD_FILE() function is used. (Bug #39701)

Note

A warning is generated if you try to execute a statement using statement-based logging that should be written using row-based logging. The warning is shown both in the client (in the output of SHOW WARNINGS) and through the mysqld error log. A warning is added to the SHOW WARNINGS table each time such a statement is executed. However, only the first statement that generated the warning for each client session is written to the error log to prevent flooding the log.

In addition to the decisions above, individual engines can also determine the logging format used when information in a table is updated. The logging capabilities of an individual engine can be defined as follows:

• If an engine supports row-based logging, the engine is said to be row-logging capable.
• If an engine supports statement-based logging, the engine is said to be statement-logging capable.

A given storage engine can support either or both logging formats. The following table lists the formats supported by each engine.

<table>
<thead>
<tr>
<th>Storage Engine</th>
<th>Row Logging Supported</th>
<th>Statement Logging Supported</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

In MySQL 5.5.3 and later, whether a statement is to be logged and the logging mode to be used is determined according to the type of statement (safe, unsafe, or binary injected), the binary logging format...
(STATEMENT, ROW, or MIXED), and the logging capabilities of the storage engine (statement capable, row capable, both, or neither). (Binary injection refers to logging a change that must be logged using ROW format.)

Statements may be logged with or without a warning; failed statements are not logged, but generate errors in the log. This is shown in the following decision table, where SLC stands for “statement-logging capable” and RLC stands for “row-logging capable”.

<table>
<thead>
<tr>

</table>
Handling of mixed-format logging in MySQL 5.5.2 and earlier. The decision-making process for binary logging changed in MySQL 5.5.3, due to the fix for Bug #39934. Prior to MySQL 5.5.3, when determining the logging mode to be used, the capabilities of all the tables affected by the event are combined, and the set of affected tables is then marked according to these rules:

- A set of tables is defined as **row-logging restricted** if the tables are row-logging capable but not statement-logging capable.

- A set of tables is defined as **statement-logging restricted** if the tables are statement-logging capable but not row-logging capable.

Once the determination of the possible logging formats required by the statement is complete it is compared to the current `binlog_format` setting. The following table is used in MySQL 5.5.2 and earlier to decide how the information is recorded in the binary log or, if appropriate, whether an error is raised. In the table, a safe operation is defined as one that is deterministic.

In MySQL 5.5.2 and earlier, several rules decide whether the statement is deterministic, as shown in the following table, where `SLR` stands for “statement-logging restricted” and `RLR` stands for “row-logging restricted”. A statement is **statement-logging restricted** if one or more of the tables it accesses is not row-logging capable. Similarly, a statement is **row-logging restricted** if any table accessed by the statement is not statement-logging capable.

In all MySQL 5.5 releases, when a warning is produced by the determination, a standard MySQL warning is produced (and is available using `SHOW WARNINGS`). The information is also written to the `mysqld` error log. Only one error for each error instance per client connection is logged to prevent flooding the log. The log message includes the SQL statement that was attempted.

If a slave server was started with `--log-warnings` enabled, the slave prints messages to the error log to provide information about its status, such as the binary log and relay log coordinates where it starts its job, when it is switching to another relay log, when it reconnects after a disconnect, and so forth.

#### 5.2.4.4 Logging Format for Changes to mysql Database Tables

The contents of the grant tables in the `mysql` database can be modified directly (for example, with `INSERT` or `DELETE`) or indirectly (for example, with `GRANT` or `CREATE USER`). Statements that affect `mysql` database tables are written to the binary log using the following rules:

- Data manipulation statements that change data in `mysql` database tables directly are logged according to the setting of the `binlog_format` system variable. This pertains to statements such as `INSERT`, `UPDATE`, `DELETE`, `REPLACE`, `DO`, `LOAD DATA INFILE`, `SELECT`, and `TRUNCATE TABLE`. 

---

685
• Statements that change the MySQL database indirectly are logged as statements regardless of the value of `binlog_format`. This pertains to statements such as `GRANT`, `REVOKE`, `SET PASSWORD`, `RENAME USER`, `CREATE` (all forms except `CREATE TABLE ... SELECT`), `ALTER` (all forms), and `DROP` (all forms).

`CREATE TABLE ... SELECT` is a combination of data definition and data manipulation. The `CREATE TABLE` part is logged using statement format and the `SELECT` part is logged according to the value of `binlog_format`.

### 5.2.5 The Slow Query Log

The slow query log consists of SQL statements that took more than `long_query_time` seconds to execute and required at least `min_examined_row_limit` rows to be examined. The minimum and default values of `long_query_time` are 0 and 10, respectively. The value can be specified to a resolution of microseconds. For logging to a file, times are written including the microseconds part. For logging to tables, only integer times are written; the microseconds part is ignored.

By default, administrative statements are not logged, nor are queries that do not use indexes for lookups. This behavior can be changed using `--log-slow-admin-statements` and `log_queries_not_using_indexes`, as described later.

The time to acquire the initial locks is not counted as execution time. `mysqld` writes a statement to the slow query log after it has been executed and after all locks have been released, so log order might differ from execution order.

By default, the slow query log is disabled. To specify the initial slow query log state explicitly, use `--slow_query_log={0|1}`. With no argument or an argument of 1, `--slow_query_log` enables the log. With an argument of 0, this option disables the log. To specify a log file name, use `--slow_query_log_file=file_name`. To specify the log destination, use `--log-output` (as described in Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”). The older option to enable the slow query log file, `--log-slow-queries`, is deprecated.

If you specify no name for the slow query log file, the default name is `host_name-slow.log`. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

To disable or enable the slow query log or change the log file name at runtime, use the global `slow_query_log` and `slow_query_log_file` system variables. Set `slow_query_log` to 0 (or `OFF`) to disable the log or to 1 (or `ON`) to enable it. Set `slow_query_log_file` to specify the name of the log file. If a log file already is open, it is closed and the new file is opened.

When the slow query log is enabled, the server writes output to any destinations specified by the `--log-output` option or `log_output` system variable. If you enable the log, the server opens the log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected. If the destination is `NONE`, the server writes no queries even if the slow query log is enabled. Setting the log file name has no effect on logging if the log destination value does not contain `FILE`.

The server writes less information to the slow query log (and binary log) if you use the `--log-short-format` option.

To include slow administrative statements in the statements written to the slow query log, use the `--log-slow-admin-statements` server option. Administrative statements include `ALTER TABLE`, `ANALYZE TABLE`, `CHECK TABLE`, `CREATE INDEX`, `DROP INDEX`, `OPTIMIZE TABLE`, and `REPAIR TABLE`.

To include queries that do not use indexes for row lookups in the statements written to the slow query log, enable the `log_queries_not_using_indexes` system variable. When such queries are logged, the slow query log may grow quickly.
The server uses the controlling parameters in the following order to determine whether to write a query to the slow query log:

1. The query must either not be an administrative statement, or \texttt{--log-slow-admin-statements} must have been specified.

2. The query must have taken at least \texttt{long_query_time} seconds, or \texttt{log_queries_not_using_indexes} must be enabled and the query used no indexes for row lookups.

3. The query must have examined at least \texttt{min_examined_row_limit} rows.

The server does not write queries handled by the query cache to the slow query log, nor queries that would not benefit from the presence of an index because the table has zero rows or one row.

By default, a replication slave does not write replicated queries to the slow query log. To change this, use the \texttt{--log-slow-slave-statements} server option.

The slow query log should be protected because logged statements might contain passwords. See Section 6.1.2.3, “Passwords and Logging”.

The slow query log can be used to find queries that take a long time to execute and are therefore candidates for optimization. However, examining a long slow query log can become a difficult task. To make this easier, you can process a slow query log file using the \texttt{mysqldumpslow} command to summarize the queries that appear in the log. See Section 4.6.8, “\texttt{mysqldumpslow} — Summarize Slow Query Log Files”.

\section*{5.2.6 Server Log Maintenance}

As described in Section 5.2, “MySQL Server Logs”, MySQL Server can create several different log files to help you see what activity is taking place. However, you must clean up these files regularly to ensure that the logs do not take up too much disk space.

When using MySQL with logging enabled, you may want to back up and remove old log files from time to time and tell MySQL to start logging to new files. See Section 7.2, “Database Backup Methods”.

On a Linux (Red Hat) installation, you can use the \texttt{mysql-log-rotate} script for this. If you installed MySQL from an RPM distribution, this script should have been installed automatically. Be careful with this script if you are using the binary log for replication. You should not remove binary logs until you are certain that their contents have been processed by all slaves.

On other systems, you must install a short script yourself that you start from \texttt{cron} (or its equivalent) for handling log files.

For the binary log, you can set the \texttt{expire_logs_days} system variable to expire binary log files automatically after a given number of days (see Section 5.1.4, “Server System Variables”). If you are using replication, you should set the variable no lower than the maximum number of days your slaves might lag behind the master. To remove binary logs on demand, use the \texttt{PURGE BINARY LOGS} statement (see Section 13.4.1.1, “\texttt{PURGE BINARY LOGS} Syntax”).

You can force MySQL to start using new log files by flushing the logs. Log flushing occurs when you issue a \texttt{FLUSH LOGS} statement or execute a \texttt{mysqldump} \texttt{--flush-logs}, \texttt{mysqladmin refresh}, \texttt{mysqldump --flush-logs}, or \texttt{mysqladmin --master-data} command. See Section 13.7.6.3, “\texttt{FLUSH Syntax}”, Section 4.5.2, “\texttt{mysqladmin} — Client for Administering a MySQL Server”, and Section 4.5.4, “\texttt{mysqldump} — A Database Backup Program”. In addition, the binary log is flushed when its size reaches the value of the \texttt{max_binlog_size} system variable.
As of MySQL 5.5.3, `FLUSH LOGS` supports optional modifiers to enable selective flushing of individual logs (for example, `FLUSH BINARY LOGS`).

A log-flushing operation does the following:

- If general query logging or slow query logging to a log file is enabled, the server closes and reopens the general query log file or slow query log file.

- If binary logging is enabled, the server closes the current binary log file and opens a new log file with the next sequence number.

- If the server was started with the `--log-error` option to cause the error log to be written to a file, the result of a log-flushing operation is version dependent:
  - As of MySQL 5.5.7, the server closes and reopens the log file.
  - Prior to MySQL 5.5.7, the server renames the current log file with the suffix `-old`, then creates a new empty log file.

The server creates a new binary log file when you flush the logs. However, it just closes and reopens the general and slow query log files. To cause new files to be created on Unix, rename the current log files before flushing them. At flush time, the server opens new log files with the original names. For example, if the general and slow query log files are named `mysql.log` and `mysql-slow.log`, you can use a series of commands like this:

```shell
shell> cd mysql-data-directory
shell> mv mysql.log mysql.old
shell> mv mysql-slow.log mysql-slow.old
shell> mysqladmin flush-logs
```

On Windows, use `rename` rather than `mv`.

At this point, you can make a backup of `mysql.old` and `mysql-slow.old` and then remove them from disk.

A similar strategy can be used to back up the error log file, if there is one, except that, on Windows, you cannot rename the error log file while the server has it open before MySQL 5.5.7. To rename the error log file, a stop and restart can be avoided by flushing the logs to cause the server to rename the current log file with the suffix `-old` and create a new empty error log file. For further information, see Section 5.2.2, “The Error Log”.

You can rename the general query log or slow query log at runtime by disabling the log:

```sql
SET GLOBAL general_log = 'OFF';
SET GLOBAL slow_query_log = 'OFF';
```

With the logs disabled, rename the log files externally; for example, from the command line. Then enable the logs again:

```sql
SET GLOBAL general_log = 'ON';
SET GLOBAL slow_query_log = 'ON';
```

This method works on any platform and does not require a server restart.

## 5.3 Running Multiple MySQL Instances on One Machine

In some cases, you might want to run multiple instances of MySQL on a single machine. You might want to test a new MySQL release while leaving an existing production setup undisturbed. Or you might want to
give different users access to different `mysql` servers that they manage themselves. (For example, you might be an Internet Service Provider that wants to provide independent MySQL installations for different customers.)

It is possible to use a different MySQL server binary per instance, or use the same binary for multiple instances, or any combination of the two approaches. For example, you might run a server from MySQL 5.1 and one from MySQL 5.5, to see how different versions handle a given workload. Or you might run multiple instances of the current production version, each managing a different set of databases.

Whether or not you use distinct server binaries, each instance that you run must be configured with unique values for several operating parameters. This eliminates the potential for conflict between instances. Parameters can be set on the command line, in option files, or by setting environment variables. See Section 4.2.3, “Specifying Program Options”. To see the values used by a given instance, connect to it and execute a `SHOW VARIABLES` statement.

The primary resource managed by a MySQL instance is the data directory. Each instance should use a different data directory, the location of which is specified using the `--datadir=path` option. For methods of configuring each instance with its own data directory, and warnings about the dangers of failing to do so, see Section 5.3.1, “Setting Up Multiple Data Directories”.

In addition to using different data directories, several other options must have different values for each server instance:

- `--port=port_num`
  
  `--port` controls the port number for TCP/IP connections. Alternatively, if the host has multiple network addresses, you can use `--bind-address` to cause each server to listen to a different address.

- `--socket=path`
  
  `--socket` controls the Unix socket file path on Unix or the named pipe name on Windows. On Windows, it is necessary to specify distinct pipe names only for those servers configured to permit named-pipe connections.

- `--shared-memory-base-name=name`
  
  This option is used only on Windows. It designates the shared-memory name used by a Windows server to permit clients to connect using shared memory. It is necessary to specify distinct shared-memory names only for those servers configured to permit shared-memory connections.

- `--pid-file=file_name`
  
  This option indicates the path name of the file in which the server writes its process ID.

If you use the following log file options, their values must differ for each server:

- `--general_log_file=file_name`
- `--log-bin[]=file_name`
- `--slow_query_log_file=file_name`
- `--log-error[]=file_name`

For further discussion of log file options, see Section 5.2, “MySQL Server Logs”.

To achieve better performance, you can specify the following option differently for each server, to spread the load between several physical disks:
Setting Up Multiple Data Directories

- **--tmpdir=path**

Having different temporary directories also makes it easier to determine which MySQL server created any given temporary file.

If you have multiple MySQL installations in different locations, you can specify the base directory for each installation with the **--basedir=path** option. This causes each instance to automatically use a different data directory, log files, and PID file because the default for each of those parameters is relative to the base directory. In that case, the only other options you need to specify are the **--socket** and **--port** options. Suppose that you install different versions of MySQL using tar file binary distributions. These install in different locations, so you can start the server for each installation using the command `bin/mysqld_safe` under its corresponding base directory. `mysqld_safe` determines the proper **--basedir** option to pass to `mysqld`, and you need specify only the **--socket** and **--port** options to `mysqld_safe`.

As discussed in the following sections, it is possible to start additional servers by specifying appropriate command options or by setting environment variables. However, if you need to run multiple servers on a more permanent basis, it is more convenient to use option files to specify for each server those option values that must be unique to it. The **--defaults-file** option is useful for this purpose.

### 5.3.1 Setting Up Multiple Data Directories

Each MySQL Instance on a machine should have its own data directory. The location is specified using the **--datadir=path** option.

There are different methods of setting up a data directory for a new instance:

- Create a new data directory.
- Copy an existing data directory.

The following discussion provides more detail about each method.

**Warning**

Normally, you should never have two servers that update data in the same databases. This may lead to unpleasant surprises if your operating system does not support fault-free system locking. If (despite this warning) you run multiple servers using the same data directory and they have logging enabled, you must use the appropriate options to specify log file names that are unique to each server. Otherwise, the servers try to log to the same files.

Even when the preceding precautions are observed, this kind of setup works only with MyISAM and MERGE tables, and not with any of the other storage engines. Also, this warning against sharing a data directory among servers always applies in an NFS environment. Permitting multiple MySQL servers to access a common data directory over NFS is a very bad idea. The primary problem is that NFS is the speed bottleneck. It is not meant for such use. Another risk with NFS is that you must devise a way to ensure that two or more servers do not interfere with each other. Usually NFS file locking is handled by the lockd daemon, but at the moment there is no platform that performs locking 100% reliably in every situation.

**Create a New Data Directory**

With this method, the data directory will be in the same state as when you first install MySQL. It will have the default set of MySQL accounts and no user data.
On Unix, initialize the data directory by running `mysql_install_db`. See Section 2.10.1, “Postinstallation Procedures for Unix-like Systems”.

On Windows, the data directory is included in the MySQL distribution:

- MySQL Zip archive distributions for Windows contain an unmodified data directory. You can unpack such a distribution into a temporary location, then copy it to where you are setting up the new instance.

- As of MySQL 5.5.5, Windows MSI package installers create and set up the data directory that the installed server will use, but also create a pristine “template” data directory named `data` under the installation directory. After an installation has been performed using an MSI package, the template data directory can be copied to set up additional MySQL instances.

### Copy an Existing Data Directory

With this method, any MySQL accounts or user data present in the data directory are carried over to the new data directory.

1. Stop the existing MySQL instance using the data directory. This must be a clean shutdown so that the instance flushes any pending changes to disk.

2. Copy the data directory to the location where the new data directory should be.

3. Copy the `my.cnf` or `my.ini` option file used by the existing instance. This serves as a basis for the new instance.

4. Modify the new option file so that any pathnames referring to the original data directory refer to the new data directory. Also, modify any other options that must be unique per instance, such as the TCP/IP port number and the log files. For a list of parameters that must be unique per instance, see Section 5.3, “Running Multiple MySQL Instances on One Machine”.

5. Start the new instance, telling it to use the new option file.

### 5.3.2 Running Multiple MySQL Instances on Windows

You can run multiple servers on Windows by starting them manually from the command line, each with appropriate operating parameters, or by installing several servers as Windows services and running them that way. General instructions for running MySQL from the command line or as a service are given in Section 2.3, “Installing MySQL on Microsoft Windows”. The following sections describe how to start each server with different values for those options that must be unique per server, such as the data directory. These options are listed in Section 5.3, “Running Multiple MySQL Instances on One Machine”.

#### 5.3.2.1 Starting Multiple MySQL Instances at the Windows Command Line

The procedure for starting a single MySQL server manually from the command line is described in Section 2.3.7.5, “Starting MySQL from the Windows Command Line”. To start multiple servers this way, you can specify the appropriate options on the command line or in an option file. It is more convenient to place the options in an option file, but it is necessary to make sure that each server gets its own set of options. To do this, create an option file for each server and tell the server the file name with a `--defaults-file` option when you run it.

Suppose that you want to run `mysqld` on port 3307 with a data directory of `C:\mydata1`, and `mysqld-debug` on port 3308 with a data directory of `C:\mydata2`. Use this procedure:

1. Make sure that each data directory exists, including its own copy of the `mysql` database that contains the grant tables.
2. Create two option files. For example, create one file named `C:\my-opts1.cnf` that looks like this:

```
[mysqld]
datadir = C:/mydata1
port = 3307
```

Create a second file named `C:\my-opts2.cnf` that looks like this:

```
[mysqld]
datadir = C:/mydata2
port = 3308
```

3. Use the `--defaults-file` option to start each server with its own option file:

```
C:\> C:\mysql\bin\mysqld --defaults-file=C:\my-opts1.cnf
C:\> C:\mysql\bin\mysqld-debug --defaults-file=C:\my-opts2.cnf
```

Each server starts in the foreground (no new prompt appears until the server exits later), so you will need to issue those two commands in separate console windows.

To shut down the servers, connect to each using the appropriate port number:

```
C:\> C:\mysql\bin\mysqladmin --port=3307 shutdown
C:\> C:\mysql\bin\mysqladmin --port=3308 shutdown
```

Servers configured as just described permit clients to connect over TCP/IP. If your version of Windows supports named pipes and you also want to permit named-pipe connections, use the `mysqld` or `mysqld-debug` server and specify options that enable the named pipe and specify its name. Each server that supports named-pipe connections must use a unique pipe name. For example, the `C:\my-opts1.cnf` file might be written like this:

```
[mysqld]
datadir = C:/mydata1
port = 3307
enable-named-pipe
socket = mypipe1
```

Modify `C:\my-opts2.cnf` similarly for use by the second server. Then start the servers as described previously.

A similar procedure applies for servers that you want to permit shared-memory connections. Enable such connections with the `--shared-memory` option and specify a unique shared-memory name for each server with the `--shared-memory-base-name` option.

### 5.3.2.2 Starting Multiple MySQL Instances as Windows Services

On Windows, a MySQL server can run as a Windows service. The procedures for installing, controlling, and removing a single MySQL service are described in Section 2.3.7.7, “Starting MySQL as a Windows Service”.

To set up multiple MySQL services, you must make sure that each instance uses a different service name in addition to the other parameters that must be unique per instance.

For the following instructions, suppose that you want to run the `mysqld` server from two different versions of MySQL that are installed at `C:\mysql-5.1.55` and `C:\mysql-5.5.40`, respectively. (This might be the case if you are running 5.1.55 as your production server, but also want to conduct tests using 5.5.40.)
To install MySQL as a Windows service, use the --install or --install-manual option. For information about these options, see Section 2.3.7.7, “Starting MySQL as a Windows Service”.

Based on the preceding information, you have several ways to set up multiple services. The following instructions describe some examples. Before trying any of them, shut down and remove any existing MySQL services.

• **Approach 1:** Specify the options for all services in one of the standard option files. To do this, use a different service name for each server. Suppose that you want to run the 5.1.55 mysqld using the service name of `mysqld1` and the 5.5.40 mysqld using the service name `mysqld2`. In this case, you can use the `[mysqld1]` group for 5.1.55 and the `[mysqld2]` group for 5.5.40. For example, you can set up `C:\my.cnf` like this:

```ini
# options for mysqld1 service
[mysqld1]
basedir = C:/mysql-5.1.55
port = 3307
enable-named-pipe
socket = mypipe1

# options for mysqld2 service
[mysqld2]
basedir = C:/mysql-5.5.40
port = 3308
enable-named-pipe
socket = mypipe2
```

Install the services as follows, using the full server path names to ensure that Windows registers the correct executable program for each service:

```bash
C:\> C:\mysql-5.1.55\bin\mysqld --install mysqld1
C:\> C:\mysql-5.5.40\bin\mysqld --install mysqld2
```

To start the services, use the services manager, or use `NET START` with the appropriate service names:

```bash
C:\> NET START mysqld1
C:\> NET START mysqld2
```

To stop the services, use the services manager, or use `NET STOP` with the appropriate service names:

```bash
C:\> NET STOP mysqld1
C:\> NET STOP mysqld2
```

• **Approach 2:** Specify options for each server in separate files and use `--defaults-file` when you install the services to tell each server what file to use. In this case, each file should list options using a `[mysqld]` group.

With this approach, to specify options for the 5.1.55 mysqld, create a file `C:\my-opts1.cnf` that looks like this:

```ini
[mysqld]
basedir = C:/mysql-5.1.55
port = 3307
enable-named-pipe
socket = mypipe1
```

For the 5.5.40 mysqld, create a file `C:\my-opts2.cnf` that looks like this:
Running Multiple MySQL Instances on Unix

Install the services as follows (enter each command on a single line):

```bash
C:\> C:\mysql-5.1.55\bin\mysqld --install mysqld1
    --defaults-file=C:\my-opts1.cnf
C:\> C:\mysql-5.5.40\bin\mysqld --install mysqld2
    --defaults-file=C:\my-opts2.cnf
```

When you install a MySQL server as a service and use a `--defaults-file` option, the service name must precede the option.

After installing the services, start and stop them the same way as in the preceding example.

To remove multiple services, use `mysqld --remove` for each one, specifying a service name following the `--remove` option. If the service name is the default (MySQL), you can omit it.

5.3.3 Running Multiple MySQL Instances on Unix

One way is to run multiple MySQL instances on Unix is to compile different servers with different default TCP/IP ports and Unix socket files so that each one listens on different network interfaces. Compiling in different base directories for each installation also results automatically in a separate, compiled-in data directory, log file, and PID file location for each server.

Assume that an existing 5.1 server is configured for the default TCP/IP port number (3306) and Unix socket file (`/tmp/mysql.sock`). To configure a new 5.5.40 server to have different operating parameters, use a CMake command something like this:

```bash
shell> cmake . -DMYSQL_TCP_PORT=port_number \
    -DMYSQL_UNIX_ADDR=file_name \
    -DCMAKE_INSTALL_PREFIX=/usr/local/mysql-5.5.40
```

Here, `port_number` and `file_name` must be different from the default TCP/IP port number and Unix socket file path name, and the `CMAKE_INSTALL_PREFIX` value should specify an installation directory different from the one under which the existing MySQL installation is located.

If you have a MySQL server listening on a given port number, you can use the following command to find out what operating parameters it is using for several important configurable variables, including the base directory and Unix socket file name:

```bash
shell> mysqladmin --host=host_name --port=port_number variables
```

With the information displayed by that command, you can tell what option values not to use when configuring an additional server.

If you specify `localhost` as the host name, `mysqladmin` defaults to using a Unix socket file connection rather than TCP/IP. To explicitly specify the connection protocol, use the `--protocol={TCP|SOCKET|PIPE|MEMORY}` option.

You need not compile a new MySQL server just to start with a different Unix socket file and TCP/IP port number. It is also possible to use the same server binary and start each invocation of it with different parameter values at runtime. One way to do so is by using command-line options:
Using Client Programs in a Multiple-Server Environment

To start a second server, provide different --socket and --port option values, and pass a --datadir=path option to mysqld_safe so that the server uses a different data directory.

Alternatively, put the options for each server in a different option file, then start each server using a --defaults-file option that specifies the path to the appropriate option file. For example, if the option files for two server instances are named /usr/local/mysql/my.cnf and /usr/local/mysql/my.cnf2, start the servers like this: command:

```
shell> mysqld_safe --defaults-file=/usr/local/mysql/my.cnf
shell> mysqld_safe --defaults-file=/usr/local/mysql/my.cnf2
```

Another way to achieve a similar effect is to use environment variables to set the Unix socket file name and TCP/IP port number:

```
shell> MYSQL_UNIX_PORT=/tmp/mysqld-new.sock
shell> MYSQL_TCP_PORT=3307
shell> export MYSQL_UNIX_PORT MYSQL_TCP_PORT
shell> mysql_install_db --user=mysql
shell> mysqld_safe --datadir=/path/to/datadir &
```

This is a quick way of starting a second server to use for testing. The nice thing about this method is that the environment variable settings apply to any client programs that you invoke from the same shell. Thus, connections for those clients are automatically directed to the second server.

Section 2.12, “Environment Variables”, includes a list of other environment variables you can use to affect MySQL programs.

On Unix, the `mysqld_multi` script provides another way to start multiple servers. See Section 4.3.4, “mysqld_multi — Manage Multiple MySQL Servers”.

5.3.4 Using Client Programs in a Multiple-Server Environment

To connect with a client program to a MySQL server that is listening to different network interfaces from those compiled into your client, you can use one of the following methods:

- Start the client with `--host=host_name --port=port_number` to connect using TCP/IP to a remote server, with `--host=127.0.0.1 --port=port_number` to connect using TCP/IP to a local server, or with `--host=localhost --socket=file_name` to connect to a local server using a Unix socket file or a Windows named pipe.

- Start the client with `--protocol=TCP` to connect using TCP/IP, `--protocol=SOCKET` to connect using a Unix socket file, `--protocol=PIPE` to connect using a named pipe, or `--protocol=MEMORY` to connect using shared memory. For TCP/IP connections, you may also need to specify `--host` and `--port` options. For the other types of connections, you may need to specify a `--socket` option to specify a Unix socket file or Windows named-pipe name, or a `--shared-memory-base-name` option to specify the shared-memory name. Shared-memory connections are supported only on Windows.

- On Unix, set the `MYSQL_UNIX_PORT` and `MYSQL_TCP_PORT` environment variables to point to the Unix socket file and TCP/IP port number before you start your clients. If you normally use a specific socket file or port number, you can place commands to set these environment variables in your `.login` file so that they apply each time you log in. See Section 2.12, “Environment Variables”.

- Specify the default Unix socket file and TCP/IP port number in the [client] group of an option file. For example, you can use `C:\my.cnf` on Windows, or the `.my.cnf` file in your home directory on Unix. See Section 4.2.6, “Using Option Files”.

695
• In a C program, you can specify the socket file or port number arguments in the `mysql_real_connect()` call. You can also have the program read option files by calling `mysql_options()`. See Section 23.8.7, “C API Function Descriptions”.

• If you are using the Perl `DBD::mysql` module, you can read options from MySQL option files. For example:

```perl
$dsn = "DBI:mysql:test;mysql_read_default_group=client;".
  "mysql_read_default_file=/usr/local/mysql/data/my.cnf";
$dhb = DBI->connect($dsn, $user, $password);
```

See Section 23.10, “MySQL Perl API”.

Other programming interfaces may provide similar capabilities for reading option files.

### 5.4 Tracing `mysql` Using DTrace

The DTrace probes in the MySQL server are designed to provide information about the execution of queries within MySQL and the different areas of the system being utilized during that process. The organization and triggering of the probes means that the execution of an entire query can be monitored with one level of probes (`query-start` and `query-done`) but by monitoring other probes you can get successively more detailed information about the execution of the query in terms of the locks used, sort methods and even row-by-row and storage-engine level execution information.

The DTrace probes are organized so that you can follow the entire query process, from the point of connection from a client, through the query execution, row-level operations, and back out again. You can think of the probes as being fired within a specific sequence during a typical client connect/execute/disconnect sequence, as shown in the following figure.

**Figure 5.1 The MySQL Architecture Using Pluggable Storage Engines**

Global information is provided in the arguments to the DTrace probes at various levels. Global information, that is, the connection ID and user/host and where relevant the query string, is provided at key levels (`connection-start`, `command-start`, `query-start`, and `query-exec-start`). As you go deeper into the probes, it is assumed either you are only interested in the individual executions (row-level probes provide information on the database and table name only), or that you will combine the row-level probes with the notional parent probes to provide the information about a specific query. Examples of this will be given as the format and arguments of each probe are provided.

For more information on DTrace and writing DTrace scripts, read the DTrace User Guide.
MySQL 5.5 includes support for DTrace probes on Solaris 10 Update 5 (Solaris 5/08) on SPARC, x86 and x86_64 platforms. Probes are also supported on Mac OS X 10.4 and higher. Enabling the probes should be automatic on these platforms. To explicitly enable or disable the probes during building, use the 

`-DENABLE_DTRACE=1` or `DENABLE_DTRACE=0` option to CMake.

If a non-Solaris platform includes DTrace support, building mysqld on that platform will include DTrace support.

### 5.4.1 mysqld DTrace Probe Reference

MySQL supports the following static probes, organized into groups of functionality.

#### Table 5.5 MySQL DTrace Probes

<table>
<thead>
<tr>
<th>Group</th>
<th>Probes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connection</td>
<td><code>connection-start, connection-done</code></td>
</tr>
<tr>
<td>Command</td>

<td><code>multi-delete-start, multi-delete-done</code></td>
</tr>
<tr>
<td>Network</td>
<td><code>net-read-start, net-read-done, net-write-start, net-write-done</code></td>
</tr>
<tr>
<td>Keycache</td>
<td><code>keycache-read-start, keycache-read-block, keycache-read-done, keycache-read-hit, keycache-read-miss, keycache-write-start, keycache-write-block, keycache-write-done</code></td>
</tr>
</tbody>
</table>

**Note**

When extracting the argument data from the probes, each argument is available as `argN`, starting with `arg0`. To identify each argument within the definitions they are...
provided with a descriptive name, but you must access the information using the corresponding argN parameter.

### 5.4.1.1 Connection Probes

The `connection-start` and `connection-done` probes enclose a connection from a client, regardless of whether the connection is through a socket or network connection.

<table>
<thead>
<tr>
<th>connection-start(connectionid, user, host)</th>
<th>connection-done(status, connectionid)</th>
</tr>
</thead>
</table>

- **`connection-start`:** Triggered after a connection and successful login/authentication have been completed by a client. The arguments contain the connection information:
  - **`connectionid`:** An unsigned long containing the connection ID. This is the same as the process ID shown as the Id value in the output from `SHOW PROCESSLIST`.
  - **`user`:** The username used when authenticating. The value will be blank for the anonymous user.
  - **`host`:** The host of the client connection. For a connection made using UNIX sockets, the value will be blank.

- **`connection-done`:** Triggered just as the connection to the client has been closed. The arguments are:
  - **`status`:** The status of the connection when it was closed. A logout operation will have a value of 0; any other termination of the connection has a nonzero value.
  - **`connectionid`:** The connection ID of the connection that was closed.

The following D script will quantify and summarize the average duration of individual connections, and provide a count, dumping the information every 60 seconds:

```d
#!/usr/sbin/dtrace -s

mysql*:::connection-start
{
    self->start = timestamp;
}

mysql*:::connection-done
/self->start/
{
    @ = quantize(((timestamp - self->start)/1000000));
    self->start = 0;
}

tick-60s
{
    printa(@);
}
```

When executed on a server with a large number of clients you might see output similar to this:

```
1 57413 :tick-60s
value  ------------- Distribution ------------- count
-1 |                                         0
 0 |@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@ 30011
 1 |                                         59
 2 |                                         5
 4 |                                         20
 8 |                                         29
```

5.4.1.2 Command Probes

The command probes are executed before and after a client command is executed, including any SQL statement that might be executed during that period. Commands include operations such as the initialization of the DB, use of the `COM_CHANGE_USER` operation (supported by the MySQL protocol), and manipulation of prepared statements. Many of these commands are used only by the MySQL client API from various connectors such as PHP and Java.

```
command-start(connectionid, command, user, host)
command-done(status)
```

- `command-start`: Triggered when a command is submitted to the server.
- `connectionid`: The connection ID of the client executing the command.
- `command`: An integer representing the command that was executed. Possible values are shown in the following table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>COM_SLEEP</td>
<td>Internal thread state</td>
</tr>
<tr>
<td>01</td>
<td>COM_QUIT</td>
<td>Close connection</td>
</tr>
<tr>
<td>02</td>
<td>COM_INIT_DB</td>
<td>Select database (USE ...)</td>
</tr>
<tr>
<td>03</td>
<td>COM_QUERY</td>
<td>Execute a query</td>
</tr>
<tr>
<td>04</td>
<td>COM_FIELD_LIST</td>
<td>Get a list of fields</td>
</tr>
<tr>
<td>05</td>
<td>COM_CREATE_DB</td>
<td>Create a database (deprecated)</td>
</tr>
<tr>
<td>06</td>
<td>COM_DROP_DB</td>
<td>Drop a database (deprecated)</td>
</tr>
<tr>
<td>07</td>
<td>COM_REFRESH</td>
<td>Refresh connection</td>
</tr>
<tr>
<td>08</td>
<td>COM_SHUTDOWN</td>
<td>Shutdown server</td>
</tr>
<tr>
<td>09</td>
<td>COM_STATISTICS</td>
<td>Get statistics</td>
</tr>
<tr>
<td>10</td>
<td>COM_PROCESS_INFO</td>
<td>Get processes (SHOW PROCESSLIST)</td>
</tr>
<tr>
<td>11</td>
<td>COM_CONNECT</td>
<td>Initialize connection</td>
</tr>
<tr>
<td>12</td>
<td>COM_PROCESS_KILL</td>
<td>Kill process</td>
</tr>
<tr>
<td>13</td>
<td>COM_DEBUG</td>
<td>Get debug information</td>
</tr>
<tr>
<td>14</td>
<td>COM_PING</td>
<td>Ping</td>
</tr>
<tr>
<td>15</td>
<td>COM_TIME</td>
<td>Internal thread state</td>
</tr>
<tr>
<td>Value</td>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>--------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>16</td>
<td>COM_DELAYED_INSERT</td>
<td>Internal thread state</td>
</tr>
<tr>
<td>17</td>
<td>COM_CHANGE_USER</td>
<td>Change user</td>
</tr>
<tr>
<td>18</td>
<td>COM_BINLOG_DUMP</td>
<td>Used by a replication slave or <code>mysqlbinlog</code> to initiate a binary log read</td>
</tr>
<tr>
<td>19</td>
<td>COM_TABLE_DUMP</td>
<td>Used by a replication slave to get the master table information</td>
</tr>
<tr>
<td>20</td>
<td>COM_CONNECT_OUT</td>
<td>Used by a replication slave to log a connection to the server</td>
</tr>
<tr>
<td>21</td>
<td>COM_REGISTER_SLAVE</td>
<td>Used by a replication slave during registration</td>
</tr>
<tr>
<td>22</td>
<td>COM_STMT_PREP</td>
<td>Prepare a statement</td>
</tr>
<tr>
<td>23</td>
<td>COM_STMT_EXECUTE</td>
<td>Execute a statement</td>
</tr>
<tr>
<td>24</td>
<td>COM_STMT_SEND_LONG_DATA</td>
<td>Used by a client when requesting extended data</td>
</tr>
<tr>
<td>25</td>
<td>COM_STMT_CLOSE</td>
<td>Close a prepared statement</td>
</tr>
<tr>
<td>26</td>
<td>COM_STMT_RESET</td>
<td>Reset a prepared statement</td>
</tr>
<tr>
<td>27</td>
<td>COM_SET_OPTION</td>
<td>Set a server option</td>
</tr>
<tr>
<td>28</td>
<td>COM_STMT_FETCH</td>
<td>Fetch a prepared statement</td>
</tr>
</tbody>
</table>

- **user**: The user executing the command.
- **host**: The client host.
- **command-done**: Triggered when the command execution completes. The `status` argument contains 0 if the command executed successfully, or 1 if the statement was terminated before normal completion.

The **command-start** and **command-done** probes are best used when combined with the statement probes to get an idea of overall execution time.

### 5.4.1.3 Query Probes

The **query-start** and **query-done** probes are triggered when a specific query is received by the server and when the query has been completed and the information has been successfully sent to the client.

```plaintext
query-start(query, connectionid, database, user, host)
query-done(status)
```

- **query-start**: Triggered after the query string has been received from the client. The arguments are:
  - **query**: The full text of the submitted query.
  - **connectionid**: The connection ID of the client that submitted the query. The connection ID equals the connection ID returned when the client first connects and the `Id` value in the output from `SHOW PROCESSLIST`.
  - **database**: The database name on which the query is being executed.
  - **user**: The username used to connect to the server.
  - **host**: The hostname of the client.

- **query-done**: Triggered once the query has been executed and the information has been returned to the client. The probe includes a single argument, `status`, which returns 0 when the query is successfully executed and 1 if there was an error.
You can get a simple report of the execution time for each query using the following D script:

```d
#!/usr/sbin/dtrace -s
#pragma D option quiet
dtrace::BEGIN
{
    printf("%-20s %-20s %-40s %-9s\n", "Who", "Database", "Query", "Time(ms)");
}
mysql*:::query-start
{
    self->query = copyinstr(arg0);
    self->connid = arg1;
    self->db = copyinstr(arg2);
    self->who = strjoin(copyinstr(arg3),strjoin("@",copyinstr(arg4)));
    self->querystart = timestamp;
}
mysql*:::query-done
{
    printf("%-20s %-20s %-40s %-9d\n", self->who, self->db, self->query, (timestamp - self->querystart) / 1000000);
}
```

When executing the above script you should get a basic idea of the execution time of your queries:

```
shell> ./query.d
Who                  Database             Query                                    Time(ms)
root@localhost       test                 select * from t1 order by i limit 10     0
root@localhost       test                 set global query_cache_size=0            0
root@localhost       test                 select * from t1 order by i limit 10     776
root@localhost       test                 select * from t1 order by i limit 10     773
root@localhost       test                 select * from t1 order by i desc limit 10 795
```

### 5.4.1.4 Query Parsing Probes

The query parsing probes are triggered before the original SQL statement is parsed and when the parsing of the statement and determination of the execution model required to process the statement has been completed:

- `query-parse-start(query)`
- `query-parse-done(status)`

- **query-parse-start**: Triggered just before the statement is parsed by the MySQL query parser. The single argument, `query`, is a string containing the full text of the original query.

- **query-parse-done**: Triggered when the parsing of the original statement has been completed. The `status` is an integer describing the status of the operation. A `0` indicates that the query was successfully parsed. A `1` indicates that the parsing of the query failed.

For example, you could monitor the execution time for parsing a given query using the following D script:

```d
#!/usr/sbin/dtrace -s
#pragma D option quiet
dtrace:::query-parse-start
{
    self->parsestart = timestamp;
    self->parsequery = copyinstr(arg0);
}
```
In the above script a predicate is used on `query-parse-done` so that different output is generated based on the status value of the probe.

When running the script and monitoring the execution:

```
shell> ./query-parsing.d
Error parsing select from t1 join (t2) on (t1.i = t2.i) order by t1.s,t1.i limit 10: 36 ms
Parsing select * from t1 join (t2) on (t1.i = t2.i) order by t1.s,t1.i limit 10: 176 ms
```

### 5.4.1.5 Query Cache Probes

The query cache probes are fired when executing any query. The `query-cache-hit` query is triggered when a query exists in the query cache and can be used to return the query cache information. The arguments contain the original query text and the number of rows returned from the query cache for the query. If the query is not within the query cache, or the query cache is not enabled, then the `query-cache-miss` probe is triggered instead.

- **query-cache-hit**: Triggered when the query has been found within the query cache. The first argument, `query`, contains the original text of the query. The second argument, `rows`, is an integer containing the number of rows in the cached query.

- **query-cache-miss**: Triggered when the query is not found within the query cache. The first argument, `query`, contains the original text of the query.

The query cache probes are best combined with a probe on the main query so that you can determine the differences in times between using or not using the query cache for specified queries. For example, in the following D script, the query and query cache information are combined into the information output during monitoring:

```
#!/usr/sbin/dtrace -s
#pragma D option quiet
dtrace:::BEGIN
 {
  printf("%-20s %-20s %-40s %2s %-9s\n", "Who", "Database", "Query", "QC", "Time(ms)");
 }
mysql*:::query-start
 {
  self->query = copyinstr(arg0);
  self->connid = arg1;
  self->db    = copyinstr(arg2);
  self->who   = strjoin(copyinstr(arg3),strjoin("@",copyinstr(arg4)));
  self->querystart = timestamp;
  self->qc = 0;
  
  printf("%w %d %d %d %s\n", self->query, self->connid, self->db, self->who, 
         self->querystart, 
         self->qc);
 }
```
When executing the script you can see the effects of the query cache. Initially the query cache is disabled. If you set the query cache size and then execute the query multiple times you should see that the query cache is being used to return the query data:

```
shell> ./query-cache.d
root@localhost       test                 select * from t1 order by i limit 10     N  1072
root@localhost                            set global query_cache_size=262144       N  0
root@localhost       test                 select * from t1 order by i limit 10     Y  0
```

### 5.4.1.6 Query Execution Probes

The query execution probe is triggered when the actual execution of the query starts, after the parsing and checking the query cache but before any privilege checks or optimization. By comparing the difference between the start and done probes you can monitor the time actually spent servicing the query (instead of just handling the parsing and other elements of the query).

```
query-exec-start(query, connectionid, database, user, host, exec_type)
query-exec-done(status)
```

#### Note

The information provided in the arguments for `query-start` and `query-exec-start` are almost identical and designed so that you can choose to monitor either the entire query process (using `query-start`) or only the execution (using `query-exec-start`) while exposing the core information about the user, client, and query being executed.

- **query-exec-start**: Triggered when the execution of an individual query is started. The arguments are:
  - `query`: The full text of the submitted query.
  - `connectionid`: The connection ID of the client that submitted the query. The connection ID equals the connection ID returned when the client first connects and the `Id` value in the output from `SHOW PROCESSLIST`.
  - `database`: The database name on which the query is being executed.
  - `user`: The username used to connect to the server.
  - `host`: The hostname of the client.
  - `exec_type`: The type of execution. Execution types are determined based on the contents of the query and where it was submitted. The values for each type are shown in the following table.
• **query-exec-done**: Triggered when the execution of the query has completed. The probe includes a single argument, `status`, which returns 0 when the query is successfully executed and 1 if there was an error.

### 5.4.1.7 Row-Level Probes

The `{row-}start,done` probes are triggered each time a row operation is pushed down to a storage engine. For example, if you execute an **INSERT** statement with 100 rows of data, then the `insert-row-start` and `insert-row-done` probes will be triggered 100 times each, for each row insert.

```plaintext
insert-row-start(database, table)
insert-row-done(status)
update-row-start(database, table)
update-row-done(status)
delete-row-start(database, table)
delete-row-done(status)
```

• **insert-row-start**: Triggered before a row is inserted into a table.

• **insert-row-done**: Triggered after a row is inserted into a table.

• **update-row-start**: Triggered before a row is updated in a table.

• **update-row-done**: Triggered before a row is updated in a table.

• **delete-row-start**: Triggered before a row is deleted from a table.

• **delete-row-done**: Triggered before a row is deleted from a table.

The arguments supported by the probes are consistent for the corresponding `start` and `done` probes in each case:

• **database**: The database name.

• **table**: The table name.

• **status**: The status; 0 for success or 1 for failure.

Because the row-level probes are triggered for each individual row access, these probes can be triggered many thousands of times each second, which may have a detrimental effect on both the monitoring script and MySQL. The DTrace environment should limit the triggering on these probes to prevent the performance being adversely affected. Either use the probes sparingly, or use counter or aggregation functions to report on these probes and then provide a summary when the script terminates or as part of a **query-done** of **query-exec-done** probes.

The following example script summarizes the duration of each row operation within a larger query:

```plaintext
#!/usr/sbin/dtrace -s
```
#pragma D option quiet

dtrace:::BEGIN
{
    printf("%-2s %-10s %-10s %9s %9s %-s \n",
            "St", "Who", "DB", "ConnID", "Dur ms", "Query");
}

mysql:::query-start
{
    self->query = copyinstr(arg0);
    self->who   = strjoin(copyinstr(arg3), strjoin("@", copyinstr(arg4)));
    self->db    = copyinstr(arg2);
    self->connid = arg1;
    self->querystart = timestamp;
    self->rowdur = 0;
}

mysql:::query-done
{
    this->elapsed = (timestamp - self->querystart) /1000000;
    printf("%2d %-10s %-10s %9d %9d %s
",
            arg0, self->who, self->db,
            self->connid, this->elapsed, self->query);
}

mysql:::query-done
/ self->rowdur /
{
    printf("%34s %9d %s
", "", (self->rowdur/1000000), "-> Row ops");
}

mysql:::insert-row-start
{
    self->rowstart = timestamp;
}

mysql:::delete-row-start
{
    self->rowstart = timestamp;
}

mysql:::update-row-start
{
    self->rowstart = timestamp;
}

mysql:::insert-row-done
{
    self->rowdur += (timestamp-self->rowstart);
}

mysql:::delete-row-done
{
    self->rowdur += (timestamp-self->rowstart);
}

mysql:::update-row-done
{
    self->rowdur += (timestamp-self->rowstart);
}

Running the above script with a query that inserts data into a table, you can monitor the exact time spent performing the raw row insertion:

<table>
<thead>
<tr>
<th>St</th>
<th>Who</th>
<th>DB</th>
<th>ConnID</th>
<th>Dur ms</th>
<th>Query</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>@localhost</td>
<td>test</td>
<td>13</td>
<td>20767</td>
<td>insert into t1(select * from t2)</td>
</tr>
</tbody>
</table>
5.4.1.8 Read Row Probes

The read row probes are triggered at a storage engine level each time a row read operation occurs. These probes are specified within each storage engine (as opposed to the \*row-start probes which are in the storage engine interface). These probes can therefore be used to monitor individual storage engine row-level operations and performance. Because these probes are triggered around the storage engine row read interface, they may be hit a significant number of times during a basic query.

read-row-start(database, table, scan_flag)
read-row-done(status)

- **read-row-start**: Triggered when a row is read by the storage engine from the specified database and table. The scan_flag is set to 1 (true) when the read is part of a table scan (that is, a sequential read), or 0 (false) when the read is of a specific record.

- **read-row-done**: Triggered when a row read operation within a storage engine completes. The status returns 0 on success, or a positive value on failure.

5.4.1.9 Index Probes

The index probes are triggered each time a row is read using one of the indexes for the specified table. The probe is triggered within the corresponding storage engine for the table.

index-read-row-start(database, table)
index-read-row-done(status)

- **index-read-row-start**: Triggered when a row is read by the storage engine from the specified database and table.

- **index-read-row-done**: Triggered when an indexed row read operation within a storage engine completes. The status returns 0 on success, or a positive value on failure.

5.4.1.10 Lock Probes

The lock probes are called whenever an external lock is requested by MySQL for a table using the corresponding lock mechanism on the table as defined by the table’s engine type. There are three different types of lock, the read lock, write lock, and unlock operations. Using the probes you can determine the duration of the external locking routine (that is, the time taken by the storage engine to implement the lock, including any time waiting for another lock to become free) and the total duration of the lock/unlock process.

handler-rdlock-start(database, table)
handler-rdlock-done(status)

handler-wrlock-start(database, table)
handler-wrlock-done(status)

handler-unlock-start(database, table)
handler-unlock-done(status)

- **handler-rdlock-start**: Triggered when a read lock is requested on the specified database and table.

- **handler-wrlock-start**: Triggered when a write lock is requested on the specified database and table.

- **handler-unlock-start**: Triggered when an unlock request is made on the specified database and table.
- **handler-rdlock-done**: Triggered when a read lock request completes. The status is 0 if the lock operation succeeded, or >0 on failure.

- **handler-wrlock-done**: Triggered when a write lock request completes. The status is 0 if the lock operation succeeded, or >0 on failure.

- **handler-unlock-done**: Triggered when an unlock request completes. The status is 0 if the unlock operation succeeded, or >0 on failure.

You can use arrays to monitor the locking and unlocking of individual tables and then calculate the duration of the entire table lock using the following script:

```bash
#!/usr/sbin/dtrace -s
#pragma D option quiet
mysql*:::handler-rdlock-start
{
    self->rdlockstart = timestamp;
    this->lockref = strjoin(copyinstr(arg0),strjoin("@",copyinstr(arg1)));
    self->lockmap[this->lockref] = self->rdlockstart;
    printf("Start: Lock->Read %s.%s\n",copyinstr(arg0),copyinstr(arg1));
}
mysql*:::handler-wrlock-start
{
    self->wrlockstart = timestamp;
    this->lockref = strjoin(copyinstr(arg0),strjoin("@",copyinstr(arg1)));
    self->lockmap[this->lockref] = self->rdlockstart;
    printf("Start: Lock->Write %s.%s\n",copyinstr(arg0),copyinstr(arg1));
}
mysql*:::handler-unlock-start
{
    self->unlockstart = timestamp;
    this->lockref = strjoin(copyinstr(arg0),strjoin("@",copyinstr(arg1)));
    printf("Start: Lock->Unlock %s.%s (%d ms lock duration)\n",copyinstr(arg0),copyinstr(arg1),
        (timestamp - self->lockmap[this->lockref])/1000000);
}
mysql*:::handler-rdlock-done
{
    printf("End:   Lock->Read %d ms\n",(timestamp - self->rdlockstart)/1000000);
}
mysql*:::handler-wrlock-done
{
    printf("End:   Lock->Write %d ms\n",(timestamp - self->wrlockstart)/1000000);
}
mysql*:::handler-unlock-done
{
    printf("End:   Lock->Unlock %d ms\n",(timestamp - self->unlockstart)/1000000);
}
```

When executed, you should get information both about the duration of the locking process itself, and of the locks on a specific table:

```
Start: Lock->Read test.t2
End:   Lock->Read 0 ms
Start: Lock->Unlock test.t2 (25743 ms lock duration)
```
5.4.1.11 Filesort Probes

The filesort probes are triggered whenever a filesort operation is applied to a table. For more information on filesort and the conditions under which it occurs, see Section 8.2.1.11, "ORDER BY Optimization".

filesort-start(database, table)
filesort-done(status, rows)

• filesort-start: Triggered when the filesort operation starts on a table. The two arguments to the probe, database and table, will identify the table being sorted.

• filesort-done: Triggered when the filesort operation completes. Two arguments are supplied, the status (0 for success, 1 for failure), and the number of rows sorted during the filesort process.

An example of this is in the following script, which tracks the duration of the filesort process in addition to the duration of the main query:

```bash
#!/usr/sbin/dtrace -s
#pragma D option quiet

dtrace:::BEGIN
{
  printf("%-2s %-10s %-10s %9s %18s %-s 
",
    "St", "Who", "DB", "ConnID", "Dur microsec", "Query");
}

mysql*:::query-start
{
  self->query = copyinstr(arg0);
  self->who   = strjoin(copyinstr(arg3),strjoin("@",copyinstr(arg4)));
  self->db    = copyinstr(arg2);
  self->connid = arg1;
  self->querystart = timestamp;
  self->filesort = 0;
  self->fsdb = "";
  self->fstable = "";
}

mysql*:::filesort-start
{
  self->filesort = timestamp;
  self->fsdb = copyinstr(arg0);
  self->fstable = copyinstr(arg1);
}

mysql*:::filesort-done
{
  this->elapsed = (timestamp - self->filesort) /1000;
  printf("%2d %-10s %-10s %9d %18d Filesort on %s\n",
    arg0, self->who, self->fsdb,
    self->connid, this->elapsed, self->fstable);
}
Executing a query on a large table with an ORDER BY clause that triggers a filesort, and then creating an index on the table and then repeating the same query, you can see the difference in execution speed:

<table>
<thead>
<tr>
<th>St</th>
<th>Who</th>
<th>DB</th>
<th>ConnID</th>
<th>Dur microsec</th>
<th>Query</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>@localhost</td>
<td>test</td>
<td>14</td>
<td>11335469</td>
<td>Filesort on t1</td>
</tr>
<tr>
<td>0</td>
<td>@localhost</td>
<td>test</td>
<td>14</td>
<td>11335787</td>
<td>select * from t1 order by i limit 100</td>
</tr>
<tr>
<td>0</td>
<td>@localhost</td>
<td>test</td>
<td>14</td>
<td>466734378</td>
<td>create index t1a on t1 (i)</td>
</tr>
<tr>
<td>0</td>
<td>@localhost</td>
<td>test</td>
<td>14</td>
<td>26472</td>
<td>select * from t1 order by i limit 100</td>
</tr>
</tbody>
</table>

5.4.1.12 Statement Probes

The individual statement probes are provided to give specific information about different statement types. For the start probes the string of the query is provided as the only argument. Depending on the statement type, the information provided by the corresponding done probe will differ. For all done probes the status of the operation (0 for success, >0 for failure) is provided. For SELECT, INSERT, INSERT ... (SELECT FROM ...), DELETE, and DELETE FROM t1,t2 operations the number of rows affected is returned.

For UPDATE and UPDATE t1,t2 ... statements the number of rows matched and the number of rows actually changed is provided. This is because the number of rows actually matched by the corresponding WHERE clause, and the number of rows changed can differ. MySQL does not update the value of a row if the value already matches the new setting.

- **select-start**: Triggered before a SELECT statement.
- **select-done**: Triggered at the end of a SELECT statement.
- **insert-start**: Triggered before a INSERT statement.
- **insert-done**: Triggered at the end of an INSERT statement.
- **insert-select-start**: Triggered before an INSERT ... SELECT statement.
- **insert-select-done**: Triggered at the end of an INSERT ... SELECT statement.
• **update-start**: Triggered before an UPDATE statement.
• **update-done**: Triggered at the end of an UPDATE statement.
• **multi-update-start**: Triggered before an UPDATE statement involving multiple tables.
• **multi-update-done**: Triggered at the end of an UPDATE statement involving multiple tables.
• **delete-start**: Triggered before a DELETE statement.
• **delete-done**: Triggered at the end of a DELETE statement.
• **multi-delete-start**: Triggered before a DELETE statement involving multiple tables.
• **multi-delete-done**: Triggered at the end of a DELETE statement involving multiple tables.

The arguments for the statement probes are:

• **query**: The query string.
• **status**: The status of the query. 0 for success, and >0 for failure.
• **rows**: The number of rows affected by the statement. This returns the number rows found for SELECT, the number of rows deleted for DELETE, and the number of rows successfully inserted for INSERT.
• **rowsmatched**: The number of rows matched by the WHERE clause of an UPDATE operation.
• **rowschanged**: The number of rows actually changed during an UPDATE operation.

You use these probes to monitor the execution of these statement types without having to monitor the user or client executing the statements. A simple example of this is to track the execution times:

```bash
#!/usr/sbin/dtrace -s
#pragma D option quiet
dtrace:::BEGIN
{
  printf("%-60s %-8s %-8s %-8s
", "Query", "RowsU", "RowsM", "Dur (ms)");
}
mysql*:::update-start, mysql*:::insert-start,
mysql*:::delete-start, mysql*:::multi-delete-start,
mysql*:::multi-delete-done, mysql*:::select-start,
mysql*:::insert-select-start, mysql*:::multi-update-start
{
  self->query = copyinstr(arg0);
  self->querystart = timestamp;
}
mysql*:::insert-done, mysql*:::select-done,
mysql*:::delete-done, mysql*:::multi-delete-done, mysql*:::insert-select-done
/ self->querystart /
{
  this->elapsed = ((timestamp - self->querystart)/1000000);
  printf("%-60s %-8d %-8d %d
", "Query", "RowsU", "RowsM", "Dur (ms)"),
  self->query, 0, arg1, this->elapsed);
  self->querystart = 0;
}
```
When executed you can see the basic execution times and rows matches:

<table>
<thead>
<tr>
<th>Query</th>
<th>RowsU</th>
<th>RowsM</th>
<th>Dur (ms)</th>
</tr>
</thead>
<tbody>
<tr>
<td>select * from t2</td>
<td>0</td>
<td>275</td>
<td>0</td>
</tr>
<tr>
<td>insert into t2 (select * from t2)</td>
<td>0</td>
<td>275</td>
<td>9</td>
</tr>
<tr>
<td>update t2 set i=5 where i &gt; 75</td>
<td>110</td>
<td>110</td>
<td>8</td>
</tr>
<tr>
<td>update t2 set i=5 where i &lt; 25</td>
<td>254</td>
<td>134</td>
<td>12</td>
</tr>
<tr>
<td>delete from t2 where i &lt; 5</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

Another alternative is to use the aggregation functions in DTrace to aggregate the execution time of individual statements together:

```bash
#!/usr/sbin/dtrace -s
#pragma D option quiet
mysql*:::update-start, mysql*:::insert-start,
mysql*:::delete-start, mysql*:::multi-delete-start,
mysql*:::multi-delete-done, mysql*:::select-start,
mysql*:::insert-select-start, mysql*:::multi-update-start
{  
  self->querystart = timestamp;
}
mysql*:::select-done
{  
  @statements["select"] = sum(((timestamp - self->querystart)/1000000));
}
mysql*:::insert-done, mysql*:::insert-select-done
{  
  @statements["insert"] = sum(((timestamp - self->querystart)/1000000));
}
mysql*:::update-done, mysql*:::multi-update-done
{  
  @statements["update"] = sum(((timestamp - self->querystart)/1000000));
}
mysql*:::delete-done, mysql*:::multi-delete-done
{  
  @statements["delete"] = sum(((timestamp - self->querystart)/1000000));
}
tick-30s
{  
  printa(@statements);
}

The script just shown aggregates the times spent doing each operation, which could be used to help benchmark a standard suite of tests.
5.4.1.13 Network Probes

The network probes monitor the transfer of information from the MySQL server and clients of all types over the network. The probes are defined as follows:

```d
net-read-start()
net-read-done(status, bytes)
net-write-start(bytes)
net-write-done(status)
```

- **net-read-start**: Triggered when a network read operation is started.
- **net-read-done**: Triggered when the network read operation completes. The `status` is an integer representing the return status for the operation, 0 for success and 1 for failure. The `bytes` argument is an integer specifying the number of bytes read during the process.
- **net-write-start**: Triggered when data is written to a network socket. The single argument, `bytes`, specifies the number of bytes written to the network socket.
- **net-write-done**: Triggered when the network write operation has completed. The single argument, `status`, is an integer representing the return status for the operation, 0 for success and 1 for failure.

You can use the network probes to monitor the time spent reading from and writing to network clients during execution. The following D script provides an example of this. Both the cumulative time for the read or write is calculated, and the number of bytes. Note that the dynamic variable size has been increased (using the `dynvarsize` option) to cope with the rapid firing of the individual probes for the network reads/writes.

```d
#!/usr/sbin/dtrace -s
#pragma D option quiet
#pragma D option dynvarsize=4m

dtrace:::BEGIN
{
    printf("%-2s %-30s %-10s %9s %18s %-s 
", "St", "Who", "DB", "ConnID", "Dur microsec", "Query");
}
mysql*:::query-start
{
    self->query = copyinstr(arg0);
    self->who   = strjoin(copyinstr(arg3),strjoin("@",copyinstr(arg4)));
    self->db    = copyinstr(arg2);
}```
When executing the above script on a machine with a remote client, you can see that approximately a third of the time spent executing the query is related to writing the query results back to the client.

<table>
<thead>
<tr>
<th>St</th>
<th>Who</th>
<th>DB</th>
<th>ConnID</th>
<th>Dur microsec</th>
<th>Query</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>root@::ffff:192.168.0.108</td>
<td>test</td>
<td>31</td>
<td>3495</td>

5.4.1.14 Keycache Probes

The keycache probes are triggered when using the index key cache used with the MyISAM storage engine. Probes exist to monitor when data is read into the keycache, cached key data is written from the cache into a cached file, or when accessing the keycache.

Keycache usage indicates when data is read or written from the index files into the cache, and can be used to monitor how efficient the memory allocated to the keycache is being used. A high number of keycache reads across a range of queries may indicate that the keycache is too small for size of data being accessed.

```
keycache-read-start(filepath, bytes, mem_used, mem_free)
```
When reading data from the index files into the keycache, the process first initializes the read operation (indicated by `keycache-read-start`), then loads blocks of data (`keycache-read-block`), and then the read block is either matches the data being identified (`keycache-read-hit`) or more data needs to be read (`keycache-read-miss`). Once the read operation has completed, reading stops with the `keycache-read-done`.

Data will be read from the index file into the keycache only when the specified key is not already within the keycache.

- **keycache-read-start**: Triggered when the keycache read operation is started. Data is read from the specified `filepath`, reading the specified number of `bytes`. The `mem_used` and `memavail` indicate memory currently used by the keycache and the amount of memory available within the keycache.

- **keycache-read-block**: Triggered when the keycache reads a block of data, of the specified number of `bytes`, from the index file into the keycache.

- **keycache-read-hit**: Triggered when the block of data read from the index file matches the key data requested.

- **keycache-read-miss**: Triggered when the block of data read from the index file does not match the key data needed.

- **keycache-read-done**: Triggered when the keycache read operation has completed. The `mem_used` and `memavail` indicate memory currently used by the keycache and the amount of memory available within the keycache.

Keycache writes occur when the index information is updated during an `INSERT`, `UPDATE`, or `DELETE` operation, and the cached key information is flushed back to the index file.

- **keycache-write-start**: Triggered when the keycache write operation is started. Data is written to the specified `filepath`, reading the specified number of `bytes`. The `mem_used` and `memavail` indicate memory currently used by the keycache and the amount of memory available within the keycache.

- **keycache-write-block**: Triggered when the keycache writes a block of data, of the specified number of `bytes`, to the index file from the keycache.

- **keycache-write-done**: Triggered when the keycache write operation has completed. The `mem_used` and `memavail` indicate memory currently used by the keycache and the amount of memory available within the keycache.

When thinking about security within a MySQL installation, you should consider a wide range of possible topics and how they affect the security of your MySQL server and related applications:

- General factors that affect security. These include choosing good passwords, not granting unnecessary privileges to users, ensuring application security by preventing SQL injections and data corruption, and others. See Section 6.1, “General Security Issues”.

- Security of the installation itself. The data files, log files, and the all the application files of your installation should be protected to ensure that they are not readable or writable by unauthorized parties. For more information, see Section 2.10, “Postinstallation Setup and Testing”.

- Access control and security within the database system itself, including the users and databases granted with access to the databases, views and stored programs in use within the database. For more information, see Section 6.2, “The MySQL Access Privilege System”, and Section 6.3, “MySQL User Account Management”.

- Network security of MySQL and your system. The security is related to the grants for individual users, but you may also wish to restrict MySQL so that it is available only locally on the MySQL server host, or to a limited set of other hosts.
• Ensure that you have adequate and appropriate backups of your database files, configuration and log files. Also be sure that you have a recovery solution in place and test that you are able to successfully recover the information from your backups. See Chapter 7, *Backup and Recovery*.

### 6.1 General Security Issues

This section describes general security issues to be aware of and what you can do to make your MySQL installation more secure against attack or misuse. For information specifically about the access control system that MySQL uses for setting up user accounts and checking database access, see Section 2.10, “Postinstallation Setup and Testing”.

For answers to some questions that are often asked about MySQL Server security issues, see Section A.9, “MySQL 5.5 FAQ: Security”.

#### 6.1.1 Security Guidelines

Anyone using MySQL on a computer connected to the Internet should read this section to avoid the most common security mistakes.

In discussing security, it is necessary to consider fully protecting the entire server host (not just the MySQL server) against all types of applicable attacks: eavesdropping, altering, playback, and denial of service. We do not cover all aspects of availability and fault tolerance here.

MySQL uses security based on Access Control Lists (ACLs) for all connections, queries, and other operations that users can attempt to perform. There is also support for SSL-encrypted connections between MySQL clients and servers. Many of the concepts discussed here are not specific to MySQL at all; the same general ideas apply to almost all applications.

When running MySQL, follow these guidelines:

• **Do not ever give anyone (except MySQL root accounts) access to the user table in the mysql database!** This is critical.

• Learn how the MySQL access privilege system works (see Section 6.2, “The MySQL Access Privilege System”). Use the `GRANT` and `REVOKE` statements to control access to MySQL. Do not grant more privileges than necessary. Never grant privileges to all hosts.

Checklist:

• Try `mysql -u root`. If you are able to connect successfully to the server without being asked for a password, anyone can connect to your MySQL server as the MySQL root user with full privileges! Review the MySQL installation instructions, paying particular attention to the information about setting a root password. See Section 2.10.2, “Securing the Initial MySQL Accounts”.

• Use the `SHOW GRANTS` statement to check which accounts have access to what. Then use the `REVOKE` statement to remove those privileges that are not necessary.

• Do not store cleartext passwords in your database. If your computer becomes compromised, the intruder can take the full list of passwords and use them. Instead, use `SHA2()`, `SHA1()`, or some other one-way hashing function and store the hash value.

To prevent password recovery using rainbow tables, do not use these functions on a plain password; instead, choose some string to be used as a salt, and use `hash(hash(password)+salt)` values.

• Do not choose passwords from dictionaries. Special programs exist to break passwords. Even passwords like “xfish98” are very bad. Much better is “duag98” which contains the same word “fish” but typed one key to the left on a standard QWERTY keyboard. Another method is to use a password that
is taken from the first characters of each word in a sentence (for example, “Four score and seven years ago” results in a password of “Fsasya”). The password is easy to remember and type, but difficult to guess for someone who does not know the sentence. In this case, you can additionally substitute digits for the number words to obtain the phrase “4 score and 7 years ago”, yielding the password “4sa7ya” which is even more difficult to guess.

• Invest in a firewall. This protects you from at least 50% of all types of exploits in any software. Put MySQL behind the firewall or in a demilitarized zone (DMZ).

Checklist:

• Try to scan your ports from the Internet using a tool such as `nmap`. MySQL uses port 3306 by default. This port should not be accessible from untrusted hosts. As a simple way to check whether your MySQL port is open, try the following command from some remote machine, where `server_host` is the host name or IP address of the host on which your MySQL server runs:

```
shell> telnet server_host 3306
```

If `telnet` hangs or the connection is refused, the port is blocked, which is how you want it to be. If you get a connection and some garbage characters, the port is open, and should be closed on your firewall or router, unless you really have a good reason to keep it open.

• Applications that access MySQL should not trust any data entered by users, and should be written using proper defensive programming techniques. See Section 6.1.7, “Client Programming Security Guidelines”.

• Do not transmit plain (unencrypted) data over the Internet. This information is accessible to everyone who has the time and ability to intercept it and use it for their own purposes. Instead, use an encrypted protocol such as SSL or SSH. MySQL supports internal SSL connections. Another technique is to use SSH port-forwarding to create an encrypted (and compressed) tunnel for the communication.

• Learn to use the `tcpdump` and `strings` utilities. In most cases, you can check whether MySQL data streams are unencrypted by issuing a command like the following:

```
shell> tcpdump -l -i eth0 -w - src or dst port 3306 | strings
```

This works under Linux and should work with small modifications under other systems.

**Warning**

If you do not see cleartext data, this does not always mean that the information actually is encrypted. If you need high security, consult with a security expert.

### 6.1.2 Keeping Passwords Secure

Passwords occur in several contexts within MySQL. The following sections provide guidelines that enable end users and administrators to keep these passwords secure and avoid exposing them. There is also a discussion of how MySQL uses password hashing internally.

#### 6.1.2.1 End-User Guidelines for Password Security

MySQL users should use the following guidelines to keep passwords secure.

When you run a client program to connect to the MySQL server, it is inadvisable to specify your password in a way that exposes it to discovery by other users. The methods you can use to specify your password when you run client programs are listed here, along with an assessment of the risks of each method.
In short, the safest methods are to have the client program prompt for the password or to specify the password in a properly protected option file.

- **Use a `-p your_pass` or `--password=your_pass` option on the command line.** For example:

  ```shell
  mysql -u francis -pfrank db_name
  ```

  This is convenient *but insecure*. On some systems, your password becomes visible to system status programs such as `ps` that may be invoked by other users to display command lines. MySQL clients typically overwrite the command-line password argument with zeros during their initialization sequence. However, there is still a brief interval during which the value is visible. Also, on some systems this overwriting strategy is ineffective and the password remains visible to `ps`. (SystemV Unix systems and perhaps others are subject to this problem.)

  If your operating environment is set up to display your current command in the title bar of your terminal window, the password remains visible as long as the command is running, even if the command has scrolled out of view in the window content area.

- **Use the `-p` or `--password` option on the command line with no password value specified.** In this case, the client program solicits the password interactively:

  ```shell
  mysql -u francis -p db_name
  Enter password: ********
  ```

  The "*" characters indicate where you enter your password. The password is not displayed as you enter it.

  It is more secure to enter your password this way than to specify it on the command line because it is not visible to other users. However, this method of entering a password is suitable only for programs that you run interactively. If you want to invoke a client from a script that runs noninteractively, there is no opportunity to enter the password from the keyboard. On some systems, you may even find that the first line of your script is read and interpreted (incorrectly) as your password.

- **Store your password in an option file.** For example, on Unix, you can list your password in the `[client]` section of the `.my.cnf` file in your home directory:

  ```
  [client]
  password=your_pass
  ```

  To keep the password safe, the file should not be accessible to anyone but yourself. To ensure this, set the file access mode to 400 or 600. For example:

  ```shell
  chmod 600 .my.cnf
  ```

  To name from the command line a specific option file containing the password, use the `--defaults-file=file_name` option, where `file_name` is the full path name to the file. For example:

  ```shell
  mysql --defaults-file=/home/francis/mysql-opts
  ```

  Section 4.2.6, “Using Option Files”, discusses option files in more detail.

- **Store your password in the `MYSQL_PWD` environment variable.** See Section 2.12, “Environment Variables”.
Keeping Passwords Secure

This method of specifying your MySQL password must be considered *extremely insecure* and should not be used. Some versions of `ps` include an option to display the environment of running processes. On some systems, if you set `MYSQL_PWD`, your password is exposed to any other user who runs `ps`. Even on systems without such a version of `ps`, it is unwise to assume that there are no other methods by which users can examine process environments.

On Unix, the `mysql` client writes a record of executed statements to a history file (see Section 4.5.1.3, "mysql Logging"). By default, this file is named `.mysql_history` and is created in your home directory. Passwords can be written as plain text in SQL statements such as `CREATE USER`, `GRANT`, and `SET PASSWORD`, so if you use these statements, they are logged in the history file. To keep this file safe, use a restrictive access mode, the same as described earlier for the `.my.cnf` file.

If your command interpreter is configured to maintain a history, any file in which the commands are saved will contain MySQL passwords entered on the command line. For example, `bash` uses `~/.bash_history`. Any such file should have a restrictive access mode.

### 6.1.2.2 Administrator Guidelines for Password Security

Database administrators should use the following guidelines to keep passwords secure.

MySQL stores passwords for user accounts in the `mysql.user` table. Access to this table should never be granted to any nonadministrative accounts.

A user who has access to modify the plugin directory (the value of the `plugin_dir` system variable) or the `my.cnf` file that specifies the location of the plugin directory can replace plugins and modify the capabilities provided by plugins, including authentication plugins.

Files such as log files to which passwords might be written should be protected. See Section 6.1.2.3, "Passwords and Logging".

### 6.1.2.3 Passwords and Logging

Passwords can be written as plain text in SQL statements such as `CREATE USER`, `GRANT`, and `SET PASSWORD`, or statements that invoke the `PASSWORD()` function. If these statements are logged by the MySQL server as written, such passwords become available to anyone with access to the logs. This applies to the general query log, the slow query log, and the binary log (see Section 5.2, "MySQL Server Logs").

Contents of the audit log file produced by the audit log plugin are not encrypted. For security reasons, this file should be written to a directory accessible only to the MySQL server and users with a legitimate reason to view the log. See Section 6.3.11.2, "Audit Log Plugin Security Considerations".

To guard against unwarranted exposure to log files, they should be located in a directory that restricts access to only the server and the database administrator. If you log to tables in the `mysql` database, access to the tables should never be granted to any nonadministrative accounts.

Replication slaves store the password for the replication master in the `master.info` file. Restrict this file to be accessible only to the database administrator.

Database backups that include tables or log files containing passwords should be protected using a restricted access mode.

### 6.1.2.4 Password Hashing in MySQL
MySQL lists user accounts in the `user` table of the `mysql` database. Each MySQL account can be assigned a password, although the `user` table does not store the cleartext version of the password, but a hash value computed from it.

MySQL uses passwords in two phases of client/server communication:

- When a client attempts to connect to the server, there is an initial authentication step in which the client must present a password that has a hash value matching the hash value stored in the `user` table for the account the client wants to use.

- After the client connects, it can (if it has sufficient privileges) set or change the password hash for accounts listed in the `user` table. The client can do this by using the `PASSWORD()` function to generate a password hash, or by using a password-generating statement (CREATE USER, GRANT, or SET PASSWORD).

In other words, the server checks hash values during authentication when a client first attempts to connect. The server generates hash values if a connected client invokes the `PASSWORD()` function or uses a password-generating statement to set or change a password.

Password hashing methods in MySQL have the history described following. These changes are illustrated by changes in the result from the `PASSWORD()` function that computes password hash values and in the structure of the `user` table where passwords are stored.

**The Original (Pre-4.1) Hashing Method**

The original hashing method produced a 16-byte string. Such hashes look like this:

```plaintext
mysql> SELECT PASSWORD('mypass');
+--------------------+
| PASSWORD('mypass') |
| 6f8c114b58f2ce9e   |
+--------------------+
```

To store account passwords, the `Password` column of the `user` table was at this point 16 bytes long.

**The 4.1 Hashing Method**

MySQL 4.1 introduced password hashing that provides better security and reduces the risk of passwords being intercepted. There were several aspects to this change:

- Different `PASSWORD()` function result format
- Widening of the `Password` column
- Control over the default hashing method
- Control over the permitted hashing methods for clients attempting to connect to the server

The changes in MySQL 4.1 took place in two stages:

- MySQL 4.1.0 used a preliminary version of the 4.1 hashing method. Because this method was so short lived, the following discussion says no more about it.
- In MySQL 4.1.1, the hashing method was modified to produce a longer 41-byte hash value:

```plaintext
mysql> SELECT PASSWORD('mypass');
+-------------------------------------------+
| PASSWORD('mypass')                        |
+-------------------------------------------+
```
The longer password hash format has better cryptographic properties, and client authentication based on long hashes is more secure than that based on the older short hashes.

To accommodate longer password hashes, the `Password` column in the `user` table was changed at this point to be 41 bytes, its current length.

A widened `Password` column can store password hashes in both the pre-4.1 and 4.1 formats. The format of any given hash value can be determined two ways:

- The length: 4.1 and pre-4.1 hashes are 41 and 16 bytes, respectively.
- Password hashes in the 4.1 format always begin with a "*" character, whereas passwords in the pre-4.1 format never do.

To permit explicit generation of pre-4.1 password hashes, two additional changes were made:

- The `OLD_PASSWORD()` function was added, which returns hash values in the 16-byte format.
- For compatibility purposes, the `old_passwords` system variable was added, to enable DBAs and applications control over the hashing method. The default `old_passwords` value of 0 causes hashing to use the 4.1 method (41-byte hash values), but setting `old_passwords=1` causes hashing to use the pre-4.1 method. In this case, `PASSWORD()` produces 16-byte values and is equivalent to `OLD_PASSWORD()`.

To permit DBAs control over how clients are permitted to connect, the `secure_auth` system variable was added. Starting the server with this variable disabled or enabled permits or prohibits clients to connect using the older pre-4.1 password hashing method. Before MySQL 5.6.5, `secure_auth` is disabled by default. As of 5.6.5, `secure_auth` is enabled by default to promote a more secure default configuration. (DBAs can disable it at their discretion, but this is not recommended.)

In addition, the `mysql` client supports a `--secure-auth` option that is analogous to `secure_auth`, but from the client side. It can be used to prevent connections to less secure accounts that use pre-4.1 password hashing. This option is disabled by default before MySQL 5.6.7, enabled thereafter.

**Compatibility Issues Related to Hashing Methods**

The widening of the `Password` column in MySQL 4.1 from 16 bytes to 41 bytes affects installation or upgrade operations as follows:

- If you perform a new installation of MySQL, the `Password` column is made 41 bytes long automatically.
- Upgrades from MySQL 4.1 or later to current versions of MySQL should not give rise to any issues in regard to the `Password` column because both versions use the same column length and password hashing method.
- For upgrades from a pre-4.1 release to 4.1 or later, you must upgrade the system tables after upgrading. (See Section 4.4.7, "mysql_upgrade — Check and Upgrade MySQL Tables").

The 4.1 hashing method is understood only by MySQL 4.1 (and newer) servers and clients, which can result in some compatibility problems. A 4.1 or newer client can connect to a pre-4.1 server, because the client understands both the pre-4.1 and 4.1 password hashing methods. However, a pre-4.1 client that attempts to connect to a 4.1 or newer server may run into difficulties. For example, a 4.0 `mysql` client may fail with the following error message:
Keeping Passwords Secure

```
shell> mysql -h localhost -u root
Client does not support authentication protocol requested by server; consider upgrading MySQL client
```

This phenomenon also occurs for attempts to use the older PHP `mysql` extension after upgrading to MySQL 4.1 or newer. (See Common Problems with MySQL and PHP.)

The following discussion describes the differences between the pre-4.1 and 4.1 hashing methods, and what you should do if you upgrade your server but need to maintain backward compatibility with pre-4.1 clients. (However, permitting connections by old clients is not recommended and should be avoided if possible.) Additional information can be found in Section B.5.2.4, "Client does not support authentication protocol". This information is of particular importance to PHP programmers migrating MySQL databases from versions older than 4.1 to 4.1 or higher.

The differences between short and long password hashes are relevant both for how the server uses passwords during authentication and for how it generates password hashes for connected clients that perform password-changing operations.

The way in which the server uses password hashes during authentication is affected by the width of the `Password` column:

- If the column is short, only short-hash authentication is used.
- If the column is long, it can hold either short or long hashes, and the server can use either format:
  - Pre-4.1 clients can connect, but because they know only about the pre-4.1 hashing method, they can authenticate only using accounts that have short hashes.
  - 4.1 and later clients can authenticate using accounts that have short or long hashes.

Even for short-hash accounts, the authentication process is actually a bit more secure for 4.1 and later clients than for older clients. In terms of security, the gradient from least to most secure is:

- Pre-4.1 client authenticating with short password hash
- 4.1 or later client authenticating with short password hash
- 4.1 or later client authenticating with long password hash

The way in which the server generates password hashes for connected clients is affected by the width of the `Password` column and by the `old_passwords` system variable. A 4.1 or later server generates long hashes only if certain conditions are met: The `Password` column must be wide enough to hold long values and `old_passwords` must not be set to 1.

Those conditions apply as follows:

- The `Password` column must be wide enough to hold long hashes (41 bytes). If the column has not been updated and still has the pre-4.1 width of 16 bytes, the server notices that long hashes cannot fit into it and generates only short hashes when a client performs password-changing operations using the `PASSWORD()` function or a password-generating statement. This is the behavior that occurs if you have upgraded from a version of MySQL older than 4.1 to 4.1 or later but have not yet run the `mysql_upgrade` program to widen the `Password` column.
- If the `Password` column is wide, it can store either short or long password hashes. In this case, the `PASSWORD()` function and password-generating statements generate long hashes unless the server was started with the `old_passwords` system variable set to 1 to force the server to generate short password hashes instead.
The purpose of the `old_passwords` system variable is to permit backward compatibility with pre-4.1 clients under circumstances where the server would otherwise generate long password hashes. The option does not affect authentication (4.1 and later clients can still use accounts that have long password hashes), but it does prevent creation of a long password hash in the `user` table as the result of a password-changing operation. Were that permitted to occur, the account could no longer be used by pre-4.1 clients. With `old_passwords` disabled, the following undesirable scenario is possible:

- An old pre-4.1 client connects to an account that has a short password hash.
- The client changes its own password. With `old_passwords` disabled, this results in the account having a long password hash.
- The next time the old client attempts to connect to the account, it cannot, because the account has a long password hash that requires the 4.1 hashing method during authentication. (Once an account has a long password hash in the user table, only 4.1 and later clients can authenticate for it because pre-4.1 clients do not understand long hashes.)

This scenario illustrates that, if you must support older pre-4.1 clients, it is problematic to run a 4.1 or newer server without `old_passwords` set to 1. By running the server with `old_passwords=1`, password-changing operations do not generate long password hashes and thus do not cause accounts to become inaccessible to older clients. (Those clients cannot inadvertently lock themselves out by changing their password and ending up with a long password hash.)

The downside of `old_passwords=1` is that any passwords created or changed use short hashes, even for 4.1 or later clients. Thus, you lose the additional security provided by long password hashes. To create an account that has a long hash (for example, for use by 4.1 clients) or to change an existing account to use a long password hash, an administrator can set the session value of `old_passwords` set to 0 while leaving the global value set to 1:

```
mysql> SET @@session.old_passwords = 0;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@session.old_passwords, @@global.old_passwords;
+-------------------------+------------------------+
| @@session.old_passwords | @@global.old_passwords |
|-------------------------+------------------------+
|                      0 |                      1 |
+-------------------------+------------------------+
1 row in set (0.00 sec)

mysql> CREATE USER 'newuser'@'localhost' IDENTIFIED BY 'newpass';
Query OK, 0 rows affected (0.03 sec)

mysql> SET PASSWORD FOR 'existinguser'@'localhost' = PASSWORD('existingpass');
Query OK, 0 rows affected (0.00 sec)
```

The following scenarios are possible in MySQL 4.1 or later. The factors are whether the `Password` column is short or long, and, if long, whether the server is started with `old_passwords` enabled or disabled.

**Scenario 1:** Short `Password` column in user table:

- Only short hashes can be stored in the `Password` column.
- The server uses only short hashes during client authentication.
- For connected clients, password hash-generating operations involving the `PASSWORD()` function or password-generating statements use short hashes exclusively. Any change to an account's password results in that account having a short password hash.
Keeping Passwords Secure

- The value of `old_passwords` is irrelevant because with a short `Password` column, the server generates only short password hashes anyway.

This scenario occurs when a pre-4.1 MySQL installation has been upgraded to 4.1 or later but `mysql_upgrade` has not been run to upgrade the system tables in the `mysql` database. (This is not a recommended configuration because it does not permit use of more secure 4.1 password hashing.)

**Scenario 2:** Long `Password` column; server started with `old_passwords=1`:

- Short or long hashes can be stored in the `Password` column.
- 4.1 and later clients can authenticate for accounts that have short or long hashes.
- Pre-4.1 clients can authenticate only for accounts that have short hashes.
- For connected clients, password hash-generating operations involving the `PASSWORD()` function or password-generating statements use short hashes exclusively. Any change to an account's password results in that account having a short password hash.

In this scenario, newly created accounts have short password hashes because `old_passwords=1` prevents generation of long hashes. Also, if you create an account with a long hash before setting `old_passwords` to 1, changing the account's password while `old_passwords=1` results in the account being given a short password, causing it to lose the security benefits of a longer hash.

To create a new account that has a long password hash, or to change the password of any existing account to use a long hash, first set the session value of `old_passwords` set to 0 while leaving the global value set to 1, as described previously.

In this scenario, the server has an up to date `Password` column, but is running with the default password hashing method set to generate pre-4.1 hash values. This is not a recommended configuration but may be useful during a transitional period in which pre-4.1 clients and passwords are upgraded to 4.1 or later. When that has been done, it is preferable to run the server with `old_passwords=0` and `secure_auth=1`.

**Scenario 3:** Long `Password` column; server started with `old_passwords=0`:

- Short or long hashes can be stored in the `Password` column.
- 4.1 and later clients can authenticate using accounts that have short or long hashes.
- Pre-4.1 clients can authenticate only using accounts that have short hashes.
- For connected clients, password hash-generating operations involving the `PASSWORD()` function or password-generating statements use long hashes exclusively. A change to an account's password results in that account having a long password hash.

As indicated earlier, a danger in this scenario is that it is possible for accounts that have a short password hash to become inaccessible to pre-4.1 clients. A change to such an account's password made using the `PASSWORD()` function or a password-generating statement results in the account being given a long password hash. From that point on, no pre-4.1 client can connect to the server using that account. The client must upgrade to 4.1 or later.

If this is a problem, you can change a password in a special way. For example, normally you use `SET PASSWORD` as follows to change an account password:

```sql
SET PASSWORD FOR 'some_user'@'some_host' = PASSWORD('mypass');
```

To change the password but create a short hash, use the `OLD_PASSWORD()` function instead:
SET PASSWORD FOR 'some_user'@'some_host' = OLD_PASSWORD('mypass');

OLD_PASSWORD() is useful for situations in which you explicitly want to generate a short hash.

The disadvantages for each of the preceding scenarios may be summarized as follows:

In scenario 1, you cannot take advantage of longer hashes that provide more secure authentication.

In scenario 2, old_passwords=1 prevents accounts with short hashes from becoming inaccessible, but password-changing operations cause accounts with long hashes to revert to short hashes unless you take care to change the session value of old_passwords to 0 first.

In scenario 3, accounts with short hashes become inaccessible to pre-4.1 clients if you change their passwords without explicitly using OLD_PASSWORD().

The best way to avoid compatibility problems related to short password hashes is to not use them:

- Upgrade all client programs to MySQL 4.1 or later.
- Run the server with old_passwords=0.
- Reset the password for any account with a short password hash to use a long password hash.
- For additional security, run the server with secure_auth=1.

6.1.2.5 Implications of Password Hashing Changes in MySQL 4.1 for Application Programs

An upgrade to MySQL version 4.1 or later can cause compatibility issues for applications that use PASSWORD() to generate passwords for their own purposes. Applications really should not do this, because PASSWORD() should be used only to manage passwords for MySQL accounts. But some applications use PASSWORD() for their own purposes anyway.

If you upgrade to 4.1 or later from a pre-4.1 version of MySQL and run the server under conditions where it generates long password hashes, an application using PASSWORD() for its own passwords breaks. The recommended course of action in such cases is to modify the application to use another function, such as SHA2(), SHA1(), or MD5(), to produce hashed values. If that is not possible, you can use the OLD_PASSWORD() function, which is provided for generate short hashes in the old format. However, you should note that OLD_PASSWORD() may one day no longer be supported.

If the server is running with old_passwords=1, it generates short hashes and OLD_PASSWORD() is equivalent to PASSWORD().

PHP programmers migrating their MySQL databases from version 4.0 or lower to version 4.1 or higher should see MySQL and PHP.

6.1.3 Making MySQL Secure Against Attackers

When you connect to a MySQL server, you should use a password. The password is not transmitted in clear text over the connection. Password handling during the client connection sequence was upgraded in MySQL 4.1.1 to be very secure. If you are still using pre-4.1.1-style passwords, the encryption algorithm is not as strong as the newer algorithm. With some effort, a clever attacker who can sniff the traffic between the client and the server can crack the password. (See Section 6.1.2.4, “Password Hashing in MySQL”, for a discussion of the different password handling methods.)

All other information is transferred as text, and can be read by anyone who is able to watch the connection. If the connection between the client and the server goes through an untrusted network, and you are
concerned about this, you can use the compressed protocol to make traffic much more difficult to decipher. You can also use MySQL's internal SSL support to make the connection even more secure. See Section 6.3.9, “Using SSL for Secure Connections”. Alternatively, use SSH to get an encrypted TCP/IP connection between a MySQL server and a MySQL client. You can find an Open Source SSH client at http://www.openssh.org/, and a comparison of both Open Source and Commercial SSH clients at http://en.wikipedia.org/wiki/Comparison_of_SSH_clients.

To make a MySQL system secure, you should strongly consider the following suggestions:

- Require all MySQL accounts to have a password. A client program does not necessarily know the identity of the person running it. It is common for client/server applications that the user can specify any user name to the client program. For example, anyone can use the mysql program to connect as any other person simply by invoking it as mysql -u other_user db_name if other_user has no password. If all accounts have a password, connecting using another user's account becomes much more difficult.

  For a discussion of methods for setting passwords, see Section 6.3.5, “Assigning Account Passwords”.

- Make sure that the only Unix user account with read or write privileges in the database directories is the account that is used for running mysqld.

- Never run the MySQL server as the Unix root user. This is extremely dangerous, because any user with the FILE privilege is able to cause the server to create files as root (for example, ~root/.bashrc). To prevent this, mysqld refuses to run as root unless that is specified explicitly using the --user=root option.

  mysqld can (and should) be run as an ordinary, unprivileged user instead. You can create a separate Unix account named mysql to make everything even more secure. Use this account only for administering MySQL. To start mysqld as a different Unix user, add a user option that specifies the user name in the [mysqld] group of the my.cnf option file where you specify server options. For example:

  ![MySQL Configuration]

  This causes the server to start as the designated user whether you start it manually or by using mysqld_safe or mysql.server. For more details, see Section 6.1.5, “How to Run MySQL as a Normal User”.

  Running mysqld as a Unix user other than root does not mean that you need to change the root user name in the user table. User names for MySQL accounts have nothing to do with user names for Unix accounts.

- Do not grant the FILE privilege to nonadministrative users. Any user that has this privilege can write a file anywhere in the file system with the privileges of the mysqld daemon. This includes the server's data directory containing the files that implement the privilege tables. To make FILE-privilege operations a bit safer, files generated with SELECT ... INTO OUTFILE do not overwrite existing files and are writable by everyone.

  The FILE privilege may also be used to read any file that is world-readable or accessible to the Unix user that the server runs as. With this privilege, you can read any file into a database table. This could be abused, for example, by using LOAD DATA to load /etc/passwd into a table, which then can be displayed with SELECT.

  To limit the location in which files can be read and written, set the secure_file_priv system to a specific directory. See Section 5.1.4, “Server System Variables”.

726
Do not grant the `PROCESS` or `SUPER` privilege to nonadministrative users. The output of `mysqladmin processlist` and `SHOW PROCESSLIST` shows the text of any statements currently being executed, so any user who is permitted to see the server process list might be able to see statements issued by other users such as `UPDATE user SET password=PASSWORD('not_secure')`.

`mysqld` reserves an extra connection for users who have the `SUPER` privilege, so that a MySQL `root` user can log in and check server activity even if all normal connections are in use.

The `SUPER` privilege can be used to terminate client connections, change server operation by changing the value of system variables, and control replication servers.

Do not permit the use of symlinks to tables. (This capability can be disabled with the `--skip-symbolic-links` option.) This is especially important if you run `mysqld` as `root`, because anyone that has write access to the server’s data directory then could delete any file in the system! See Using Symbolic Links for MyISAM Tables on Unix.

Stored programs and views should be written using the security guidelines discussed in Section 20.6, “Access Control for Stored Programs and Views”.

If you do not trust your DNS, you should use IP addresses rather than host names in the grant tables. In any case, you should be very careful about creating grant table entries using host name values that contain wildcards.

If you want to restrict the number of connections permitted to a single account, you can do so by setting the `max_user_connections` variable in `mysqld`. The `GRANT` statement also supports resource control options for limiting the extent of server use permitted to an account. See Section 13.7.1.3, “GRANT Syntax”.

If the plugin directory is writable by the server, it may be possible for a user to write executable code to a file in the directory using `SELECT ... INTO DUMPFILE`. This can be prevented by making `plugin_dir` read only to the server or by setting `--secure-file-priv` to a directory where `SELECT` writes can be made safely.

### 6.1.4 Security-Related `mysqld` Options and Variables

The following table shows `mysqld` options and system variables that affect security. For descriptions of each of these, see Section 5.1.3, “Server Command Options”, and Section 5.1.4, “Server System Variables”.

6.1.5 How to Run MySQL as a Normal User

On Windows, you can run the server as a Windows service using a normal user account.

On Unix, the MySQL server `mysqld` can be started and run by any user. However, you should avoid running the server as the Unix `root` user for security reasons. To change `mysqld` to run as a normal unprivileged Unix user `user_name`, you must do the following:

1. Stop the server if it is running (use `mysqladmin shutdown`).

2. Change the database directories and files so that `user_name` has privileges to read and write files in them (you might need to do this as the Unix `root` user):

   ```shell
   chown -R user_name /path/to/mysql/datadir
   ```

   If you do not do this, the server will not be able to access databases or tables when it runs as `user_name`.

   If directories or files within the MySQL data directory are symbolic links, `chown -R` might not follow symbolic links for you. If it does not, you will also need to follow those links and change the directories and files they point to.

3. Start the server as user `user_name`. Another alternative is to start `mysqld` as the Unix `root` user and use the `--user=user_name` option. `mysqld` starts up, then switches to run as the Unix user `user_name` before accepting any connections.

4. To start the server as the given user automatically at system startup time, specify the user name by adding a `user` option to the `[mysqld]` group of the `/etc/my.cnf` option file or the `my.cnf` option file in the server's data directory. For example:
Security Issues with LOAD DATA LOCAL

If your Unix machine itself is not secured, you should assign passwords to the MySQL root accounts in the grant tables. Otherwise, any user with a login account on that machine can run the mysql client with a \(-user=root\) option and perform any operation. (It is a good idea to assign passwords to MySQL accounts in any case, but especially so when other login accounts exist on the server host.) See Section 2.10.2, “Securing the Initial MySQL Accounts”.

6.1.6 Security Issues with LOAD DATA LOCAL

The LOAD DATA statement can load a file that is located on the server host, or it can load a file that is located on the client host when the LOCAL keyword is specified.

There are two potential security issues with supporting the LOCAL version of LOAD DATA statements:

• The transfer of the file from the client host to the server host is initiated by the MySQL server. In theory, a patched server could be built that would tell the client program to transfer a file of the server's choosing rather than the file named by the client in the LOAD DATA statement. Such a server could access any file on the client host to which the client user has read access.

• In a Web environment where the clients are connecting from a Web server, a user could use LOAD DATA LOCAL to read any files that the Web server process has read access to (assuming that a user could run any command against the SQL server). In this environment, the client with respect to the MySQL server actually is the Web server, not the remote program being run by the user who connects to the Web server.

To deal with these problems, we changed how LOAD DATA LOCAL is handled as of MySQL 3.23.49 and MySQL 4.0.2 (4.0.13 on Windows):

• By default, all MySQL clients and libraries in binary distributions are compiled with the \(-DENABLED_LOCAL_INFILE=1\) option, to be compatible with MySQL 3.23.48 and before.

• If you build MySQL from source but do not invoke CMake with the \(-DENABLED_LOCAL_INFILE=1\) option, LOAD DATA LOCAL cannot be used by any client unless it is written explicitly to invoke mysql_options(... MYSQL_OPT_LOCAL_INFILE, 0). See Section 23.8.7.49, "mysql_options()".

• You can disable all LOAD DATA LOCAL statements from the server side by starting mysqld with the \(--local-infile=0\) option.

• For the mysql command-line client, enable LOAD DATA LOCAL by specifying the \(--local-infile=1\) option, or disable it with the \(--local-infile=0\) option. For mysqlimport, local data file loading is off by default; enable it with the \(--local\) or \(-L\) option. In any case, successful use of a local load operation requires that the server permits it.

• If you use LOAD DATA LOCAL in Perl scripts or other programs that read the [client] group from option files, you can add the \(local-infile=1\) option to that group. However, to keep this from causing problems for programs that do not understand \(local-infile\), specify it using the loose- prefix:

  [client]
  loose-local-infile=1

• If LOAD DATA LOCAL is disabled, either in the server or the client, a client that attempts to issue such a statement receives the following error message:

  ERROR 1148: The used command is not allowed with this MySQL version
6.1.7 Client Programming Security Guidelines

Applications that access MySQL should not trust any data entered by users, who can try to trick your code by entering special or escaped character sequences in Web forms, URLs, or whatever application you have built. Be sure that your application remains secure if a user enters something like "; DROP DATABASE mysql;". This is an extreme example, but large security leaks and data loss might occur as a result of hackers using similar techniques, if you do not prepare for them.

A common mistake is to protect only string data values. Remember to check numeric data as well. If an application generates a query such as `SELECT * FROM table WHERE ID=234` when a user enters the value `234`, the user can enter the value `234 OR 1=1` to cause the application to generate the query `SELECT * FROM table WHERE ID=234 OR 1=1`. As a result, the server retrieves every row in the table. This exposes every row and causes excessive server load. The simplest way to protect from this type of attack is to use single quotation marks around the numeric constants: `SELECT * FROM table WHERE ID='234'`. If the user enters extra information, it all becomes part of the string. In a numeric context, MySQL automatically converts this string to a number and strips any trailing nonnumeric characters from it.

Sometimes people think that if a database contains only publicly available data, it need not be protected. This is incorrect. Even if it is permissible to display any row in the database, you should still protect against denial of service attacks (for example, those that are based on the technique in the preceding paragraph that causes the server to waste resources). Otherwise, your server becomes unresponsive to legitimate users.

Checklist:

- Enable strict SQL mode to tell the server to be more restrictive of what data values it accepts. See Section 5.1.7, “Server SQL Modes”.
- Try to enter single and double quotation marks ("'") in all of your Web forms. If you get any kind of MySQL error, investigate the problem right away.
- Try to modify dynamic URLs by adding `%22` (""), `%23` (#), and `%27` ("') to them.
- Try to modify data types in dynamic URLs from numeric to character types using the characters shown in the previous examples. Your application should be safe against these and similar attacks.
- Try to enter characters, spaces, and special symbols rather than numbers in numeric fields. Your application should remove them before passing them to MySQL or else generate an error. Passing unchecked values to MySQL is very dangerous!
- Check the size of data before passing it to MySQL.
- Have your application connect to the database using a user name different from the one you use for administrative purposes. Do not give your applications any access privileges they do not need.

Many application programming interfaces provide a means of escaping special characters in data values. Properly used, this prevents application users from entering values that cause the application to generate statements that have a different effect than you intend:

- MySQL C API: Use the `mysql_real_escape_string()` API call.
- MySQL++: Use the `escape` and `quote` modifiers for query streams.
- PHP: Use either the `mysqli` or `pdo_mysql` extensions, and not the older `ext/mysql` extension. The preferred API's support the improved MySQL authentication protocol and passwords, as well as prepared statements with placeholders. See also Choosing an API.
If the older \texttt{ext/mysql} extension must be used, then for escaping use the \texttt{mysql_real_escape_string()} function and not \texttt{mysql_escape_string()} or \texttt{addslashes()} because only \texttt{mysql_real_escape_string()} is character set-aware; the other functions can be “bypassed” when using (invalid) multi-byte character sets.

• Perl DBI: Use placeholders or the \texttt{quote()} method.

• Ruby DBI: Use placeholders or the \texttt{quote()} method.

• Java JDBC: Use a \texttt{PreparedStatement} object and placeholders.

Other programming interfaces might have similar capabilities.

\section*{6.2 The MySQL Access Privilege System}

The primary function of the MySQL privilege system is to authenticate a user who connects from a given host and to associate that user with privileges on a database such as \texttt{SELECT}, \texttt{INSERT}, \texttt{UPDATE}, and \texttt{DELETE}. Additional functionality includes the ability to have anonymous users and to grant privileges for MySQL-specific functions such as \texttt{LOAD DATA INFILE} and administrative operations.

There are some things that you cannot do with the MySQL privilege system:

• You cannot explicitly specify that a given user should be denied access. That is, you cannot explicitly match a user and then refuse the connection.

• You cannot specify that a user has privileges to create or drop tables in a database but not to create or drop the database itself.

• A password applies globally to an account. You cannot associate a password with a specific object such as a database, table, or routine.

The user interface to the MySQL privilege system consists of SQL statements such as \texttt{CREATE USER}, \texttt{GRANT}, and \texttt{REVOKE}. See Section 13.7.1, “Account Management Statements”.

Internally, the server stores privilege information in the grant tables of the \texttt{mysql} database (that is, in the database named \texttt{mysql}). The MySQL server reads the contents of these tables into memory when it starts and bases access-control decisions on the in-memory copies of the grant tables.

The MySQL privilege system ensures that all users may perform only the operations permitted to them. As a user, when you connect to a MySQL server, your identity is determined by the host from which you connect and the user name you specify. When you issue requests after connecting, the system grants privileges according to your identity and what you want to do.

MySQL considers both your host name and user name in identifying you because there is no reason to assume that a given user name belongs to the same person on all hosts. For example, the user \texttt{joe} who connects from \texttt{office.example.com} need not be the same person as the user \texttt{joe} who connects from \texttt{home.example.com}. MySQL handles this by enabling you to distinguish users on different hosts that happen to have the same name: You can grant one set of privileges for connections by \texttt{joe} from \texttt{office.example.com}, and a different set of privileges for connections by \texttt{joe} from \texttt{home.example.com}. To see what privileges a given account has, use the \texttt{SHOW GRANTS} statement. For example:

```
SHOW GRANTS FOR 'joe'@'office.example.com';
SHOW GRANTS FOR 'joe'@'home.example.com';
```

MySQL access control involves two stages when you run a client program that connects to the server:
Stage 1: The server accepts or rejects the connection based on your identity and whether you can verify your identity by supplying the correct password.

Stage 2: Assuming that you can connect, the server checks each statement you issue to determine whether you have sufficient privileges to perform it. For example, if you try to select rows from a table in a database or drop a table from the database, the server verifies that you have the SELECT privilege for the table or the DROP privilege for the database.

For a more detailed description of what happens during each stage, see Section 6.2.4, “Access Control, Stage 1: Connection Verification”, and Section 6.2.5, “Access Control, Stage 2: Request Verification”.

If your privileges are changed (either by yourself or someone else) while you are connected, those changes do not necessarily take effect immediately for the next statement that you issue. For details about the conditions under which the server reloads the grant tables, see Section 6.2.6, “When Privilege Changes Take Effect”.

For general security-related advice, see Section 6.1, “General Security Issues”. For help in diagnosing privilege-related problems, see Section 6.2.7, “Causes of Access-Denied Errors”.

6.2.1 Privileges Provided by MySQL

MySQL provides privileges that apply in different contexts and at different levels of operation:

- Administrative privileges enable users to manage operation of the MySQL server. These privileges are global because they are not specific to a particular database.
- Database privileges apply to a database and to all objects within it. These privileges can be granted for specific databases, or globally so that they apply to all databases.
- Privileges for database objects such as tables, indexes, views, and stored routines can be granted for specific objects within a database, for all objects of a given type within a database (for example, all tables in a database), or globally for all objects of a given type in all databases).

Information about account privileges is stored in the user, db, host, tables_priv, columns_priv, and procs_priv tables in the mysql database (see Section 6.2.2, “Privilege System Grant Tables”). The MySQL server reads the contents of these tables into memory when it starts and reloads them under the circumstances indicated in Section 6.2.6, “When Privilege Changes Take Effect”. Access-control decisions are based on the in-memory copies of the grant tables.

Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features. To make sure that you can take advantage of any new capabilities, update your grant tables to have the current structure whenever you update to a new version of MySQL. See Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”.

The following table shows the privilege names used at the SQL level in the GRANT and REVOKE statements, along with the column name associated with each privilege in the grant tables and the context in which the privilege applies.

</tbody>
</table>

The following list provides a general description of each privilege available in MySQL. Particular SQL statements might have more specific privilege requirements than indicated here. If so, the description for the statement in question provides the details.

- The **ALL** or **ALL PRIVILEGES** privilege specifier is shorthand. It stands for “all privileges available at a given privilege level” (except **GRANT OPTION**). For example, granting **ALL** at the global or table level grants all global privileges or all table-level privileges.
- The **ALTER** privilege enables use of **ALTER TABLE** to change the structure of tables. **ALTER TABLE** also requires the **CREATE** and **INSERT** privileges. Renaming a table requires **ALTER** and **DROP** on the old table, **ALTER**, **CREATE**, and **INSERT** on the new table.
- The **ALTER ROUTINE** privilege is needed to alter or drop stored routines (procedures and functions).
- The **CREATE** privilege enables creation of new databases and tables.
Privileges Provided by MySQL

- The **CREATE ROUTINE** privilege is needed to create stored routines (procedures and functions).
- The **CREATE TABLESPACE** privilege is needed to create, alter, or drop tablespaces and log file groups.
- The **CREATE TEMPORARY TABLES** privilege enables the creation of temporary tables using the `CREATE TEMPORARY TABLE` statement.

However, other operations on a temporary table, such as `INSERT`, `UPDATE`, or `SELECT`, require additional privileges for those operations for the database containing the temporary table, or for the nontemporary table of the same name.

To keep privileges for temporary and nontemporary tables separate, a common workaround for this situation is to create a database dedicated to the use of temporary tables. Then for that database, a user can be granted the **CREATE TEMPORARY TABLES** privilege, along with any other privileges required for temporary table operations done by that user.

- The **CREATE USER** privilege enables use of **CREATE USER**, **DROP USER**, **RENAME USER**, and **REVOKE ALL PRIVILEGES**.
- The **CREATE VIEW** privilege enables use of **CREATE VIEW**.
- The **DELETE** privilege enables rows to be deleted from tables in a database.
- The **DROP** privilege enables you to drop (remove) existing databases, tables, and views. The **DROP** privilege is required in order to use the statement `ALTER TABLE ... DROP PARTITION` on a partitioned table. The **DROP** privilege is also required for **TRUNCATE TABLE**. **If you grant the DROP privilege for the mysql database to a user, that user can drop the database in which the MySQL access privileges are stored.**
- The **EVENT** privilege is required to create, alter, drop, or see events for the Event Scheduler.
- The **EXECUTE** privilege is required to execute stored routines (procedures and functions).
- The **FILE** privilege gives you permission to read and write files on the server host using the `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` function. A user who has the **FILE** privilege can read any file on the server host that is either world-readable or readable by the MySQL server. (This implies the user can read any file in any database directory, because the server can access any of those files.) The **FILE** privilege also enables the user to create new files in any directory where the MySQL server has write access. This includes the server’s data directory containing the files that implement the privilege tables. As a security measure, the server will not overwrite existing files.

To limit the location in which files can be read and written, set the `secure_file_priv` system to a specific directory. See Section 5.1.4, “Server System Variables”.

- The **GRANT OPTION** privilege enables you to give to other users or remove from other users those privileges that you yourself possess.
- The **INDEX** privilege enables you to create or drop (remove) indexes. **INDEX** applies to existing tables. If you have the **CREATE** privilege for a table, you can include index definitions in the **CREATE TABLE** statement.
- The **INSERT** privilege enables rows to be inserted into tables in a database. **INSERT** is also required for the **ANALYZE TABLE**, **OPTIMIZE TABLE**, and **REPAIR TABLE** table-maintenance statements.
- The **LOCK TABLES** privilege enables the use of explicit **LOCK TABLES** statements to lock tables for which you have the **SELECT** privilege. This includes the use of write locks, which prevents other sessions from reading the locked table.
Privileges Provided by MySQL

- The **PROCESS** privilege pertains to display of information about the threads executing within the server (that is, information about the statements being executed by sessions). The privilege enables use of `SHOW PROCESSLIST` or `mysqladmin processlist` to see threads belonging to other accounts; you can always see your own threads. The **PROCESS** privilege also enables use of `SHOW ENGINE`.

- The **PROXY** privilege enables a user to impersonate or become known as another user. See Section 6.3.8, “Proxy Users”. This privilege was added in MySQL 5.5.7.

- The **REFERENCES** privilege currently is unused.

- The **RELOAD** privilege enables use of the **FLUSH** statement. It also enables `mysqladmin` commands that are equivalent to **FLUSH** operations: `flush-hosts`, `flush-logs`, `flush-privileges`, `flush-status`, `flush-tables`, `flush-threads`, `refresh`, and `reload`.

  The `reload` command tells the server to reload the grant tables into memory. `flush-privileges` is a synonym for `reload`. The `refresh` command closes and reopens the log files and flushes all tables. The other `flush-xxx` commands perform functions similar to `refresh`, but are more specific and may be preferable in some instances. For example, if you want to flush just the log files, `flush-logs` is a better choice than `refresh`.

- The **REPLICATION CLIENT** privilege enables the use of `SHOW MASTER STATUS` and `SHOW SLAVE STATUS`. In MySQL 5.5.25 and later, it also enables the use of the `SHOW BINARY LOGS` statement.

- The **REPLICATION SLAVE** privilege should be granted to accounts that are used by slave servers to connect to the current server as their master. Without this privilege, the slave cannot request updates that have been made to databases on the master server.

- The **SELECT** privilege enables you to select rows from tables in a database. **SELECT** statements require the **SELECT** privilege only if they actually retrieve rows from a table. Some **SELECT** statements do not access tables and can be executed without permission for any database. For example, you can use **SELECT** as a simple calculator to evaluate expressions that make no reference to tables:

  ```sql
  SELECT 1+1;
  SELECT PI()*2;
  ```

  The **SELECT** privilege is also needed for other statements that read column values. For example, **SELECT** is needed for columns referenced on the right hand side of `col_name=expr` assignment in **UPDATE** statements or for columns named in the **WHERE** clause of **DELETE** or **UPDATE** statements.

- The **SHOW DATABASES** privilege enables the account to see database names by issuing the **SHOW DATABASE** statement. Accounts that do not have this privilege see only databases for which they have some privileges, and cannot use the statement at all if the server was started with the `--skip-show-database` option. Note that any global privilege is a privilege for the database.

- The **SHOW VIEW** privilege enables use of **SHOW CREATE VIEW**.

- The **SHUTDOWN** privilege enables use of the `mysqladmin shutdown` command. There is no corresponding SQL statement.

- The **SUPER** privilege enables an account to use **CHANGE MASTER TO**, **KILL** or `mysqladmin kill` to kill threads belonging to other accounts (you can always kill your own threads), **PURGE BINARY LOGS**, configuration changes using `SET GLOBAL` to modify global system variables, the `mysqladmin debug` command, enabling or disabling logging, performing updates even if the `read_only` system variable is enabled, starting and stopping replication on slave servers, specification of any account in the **DEFINER** attribute of stored programs and views, and enables you to connect (once) even if the connection limit controlled by the `max_connections` system variable is reached.
To create or alter stored functions if binary logging is enabled, you may also need the **SUPER** privilege, as described in Section 20.7, “Binary Logging of Stored Programs”.

- The **TRIGGER** privilege enables trigger operations. You must have this privilege for a table to create, drop, or execute triggers for that table.
- The **UPDATE** privilege enables rows to be updated in tables in a database.
- The **USAGE** privilege specifier stands for “no privileges.” It is used at the global level with **GRANT** to modify account attributes such as resource limits or SSL characteristics without affecting existing account privileges.

It is a good idea to grant to an account only those privileges that it needs. You should exercise particular caution in granting the **FILE** and administrative privileges:

- The **FILE** privilege can be abused to read into a database table any files that the MySQL server can read on the server host. This includes all world-readable files and files in the server’s data directory. The table can then be accessed using **SELECT** to transfer its contents to the client host.
- The **GRANT OPTION** privilege enables users to give their privileges to other users. Two users that have different privileges and with the **GRANT OPTION** privilege are able to combine privileges.
- The **ALTER** privilege may be used to subvert the privilege system by renaming tables.
- The **SHUTDOWN** privilege can be abused to deny service to other users entirely by terminating the server.
- The **PROCESS** privilege can be used to view the plain text of currently executing statements, including statements that set or change passwords.
- The **SUPER** privilege can be used to terminate other sessions or change how the server operates.
- Privileges granted for the **mysql** database itself can be used to change passwords and other access privilege information. Passwords are stored encrypted, so a malicious user cannot simply read them to know the plain text password. However, a user with write access to the **user** table **Password** column can change an account’s password, and then connect to the MySQL server using that account.

### 6.2.2 Privilege System Grant Tables

Normally, you manipulate the contents of the grant tables in the **mysql** database indirectly by using statements such as **GRANT** and **REVOKE** to set up accounts and control the privileges available to each one. See Section 13.7.1, “Account Management Statements”. The discussion here describes the underlying structure of the grant tables and how the server uses their contents when interacting with clients.

These **mysql** database tables contain grant information:

- **user**: Contains user accounts, global privileges, and other non-privilege columns.
- **db**: Contains database-level privileges.
- **host**: Obsolete.
- **tables_priv**: Contains table-level privileges.
- **columns_priv**: Contains column-level privileges.
- **procs_priv**: Contains stored procedure and function privileges.
Privilege System Grant Tables

- **proxies_priv**: Contains proxy-user privileges.

Other tables in the `mysql` database do not hold grant information and are discussed elsewhere:

- **event**: Contains information about Event Scheduler events: See Section 20.4, “Using the Event Scheduler”.

- **func**: Contains information about user-defined functions: See Section 24.3, “Adding New Functions to MySQL”.

- **help_xxx**: These tables are used for server-side help: See Section 5.1.10, “Server-Side Help”.

- **plugin**: Contains information about server plugins: See Section 5.1.8.1, “Installing and Uninstalling Plugins”, and Section 24.2, “The MySQL Plugin API”.

- **proc**: Contains information about stored procedures and functions: See Section 20.2, “Using Stored Routines (Procedures and Functions)”.

- **servers**: Used by the FEDERATED storage engine: See Section 15.9.2.2, “Creating a FEDERATED Table Using CREATE SERVER”.

- **time_zone_xxx**: These tables contain time zone information: See Section 10.6, “MySQL Server Time Zone Support”.

- Tables with _log in their name are used for logging: See Section 5.2, “MySQL Server Logs”.

**Note**

Modifications to tables in the `mysql` database normally are made by the server in response to statements such as `CREATE USER`, `GRANT`, or `CREATE PROCEDURE`. Direct modification of these tables using statements such as `INSERT`, `UPDATE`, or `DELETE` is not encouraged. The server is free to ignore rows that become malformed as a result of such modifications.

Each grant table contains scope columns and privilege columns:

- Scope columns determine the scope of each row (entry) in the tables; that is, the context in which the row applies. For example, a `user` table row with Host and User values of 'thomas.loc.gov' and 'bob' would be used for authenticating connections made to the server from the host `thomas.loc.gov` by a client that specifies a user name of `bob`. Similarly, a `db` table row with Host, User, and Db column values of 'thomas.loc.gov', 'bob' and 'reports' would be used when `bob` connects from the host `thomas.loc.gov` to access the `reports` database. The `tables_priv` and `columns_priv` tables contain scope columns indicating tables or table/column combinations to which each row applies. The `procs_priv` scope columns indicate the stored routine to which each row applies.

- Privilege columns indicate which privileges are granted by a table row; that is, what operations can be performed. The server combines the information in the various grant tables to form a complete description of a user's privileges. Section 6.2.5, “Access Control, Stage 2: Request Verification”, describes the rules that are used to do this.

The server uses the grant tables in the following manner:

- The `user` table scope columns determine whether to reject or permit incoming connections. For permitted connections, any privileges granted in the `user` table indicate the user's global privileges. Any privilege granted in this table applies to all databases on the server.
Because any global privilege is considered a privilege for all databases, any global privilege enables a user to see all database names with `SHOW DATABASES` or by examining the `SCHEMATA` table of `INFORMATION_SCHEMA`.

- The `db` table scope columns determine which users can access which databases from which hosts. The privilege columns determine which operations are permitted. A privilege granted at the database level applies to the database and to all objects in the database, such as tables and stored programs.

- The `host` table is used in conjunction with the `db` table when you want a given `db` table row to apply to several hosts. For example, if you want a user to be able to use a database from several hosts in your network, leave the `Host` value empty in the user's `db` table row, then populate the `host` table with a row for each of those hosts. This mechanism is described more detail in Section 6.2.5, “Access Control, Stage 2: Request Verification”.

The `host` table must be modified directly with statements such as `INSERT`, `UPDATE`, and `DELETE`. It is not affected by statements such as `GRANT` and `REVOKE` that modify the grant tables indirectly. Most MySQL installations need not use this table at all.

- The `tables_priv` and `columns_priv` tables are similar to the `db` table, but are more fine-grained: They apply at the table and column levels rather than at the database level. A privilege granted at the table level applies to the table and to all its columns. A privilege granted at the column level applies only to a specific column.

- The `procs_priv` table applies to stored routines. A privilege granted at the routine level applies only to a single routine.

- The `proxies_priv` table indicates which users can act as proxies for other users and whether proxy users can grant the `PROXY` privilege to other users.

The server uses the `user`, `db`, and `host` tables in the `mysql` database at both the first and second stages of access control (see Section 6.2, “The MySQL Access Privilege System”). The columns in the `user` and `db` tables are shown here. The `host` table is similar to the `db` table but has a specialized use as described in Section 6.2.5, “Access Control, Stage 2: Request Verification”.

### Table 6.3 user and db Table Columns

</tbody>
</table>

#### Resource control columns

<table>
<thead>
<tr>
<th>Resource control columns</th>
</tr>
</thead>
<tbody>
<tr>
<td>max_questions</td>
</tr>
<tr>
<td>max_updates</td>
</tr>
<tr>
<td>max_connections</td>
</tr>
<tr>
<td>max_user_connections</td>
</tr>
</tbody>
</table>

As of MySQL 5.5.7, the `mysql.user` table has `plugin` and `authentication_string` columns for storing authentication plugin information.

If the `plugin` column for an account row is empty, the server authenticates the account using either the `mysql_native_password` or `mysql_old_password` plugin, depending on whether the password hash value in the `Password` column used native hashing or the older pre-4.1 hashing method. Clients must match the password in the `Password` column of the account row.
If an account row names a plugin in the `plugin` column, the server uses it to authenticate connection attempts for the account. Whether the plugin uses the value in the `Password` column is up to the plugin.

Prior to MySQL 5.5.11, the length of the `plugin` column was 60 characters. This was increased to 64 characters in MySQL 5.5.11 for compatibility with the `mysql.plugin` table's `name` column. (Bug #11766610, Bug #59752)

During the second stage of access control, the server performs request verification to make sure that each client has sufficient privileges for each request that it issues. In addition to the `user`, `db`, and `host` grant tables, the server may also consult the `tables_priv` and `columns_priv` tables for requests that involve tables. The latter tables provide finer privilege control at the table and column levels. They have the columns shown in the following table.

**Table 6.4 tables_priv and columns_priv Table Columns**

<table>
<thead>
<tr>
<th><strong>Table Name</strong></th>
<th><strong>tables_priv</strong></th>
<th><strong>columns_priv</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Scope columns</strong></td>
<td>Host</td>
<td>Host</td>
</tr>
<tr>
<td></td>
<td>Db</td>
<td>Db</td>
</tr>
<tr>
<td></td>
<td>User</td>
<td>User</td>
</tr>
<tr>
<td></td>
<td><code>Table_name</code></td>
<td><code>Table_name</code></td>
</tr>
<tr>
<td></td>
<td><code>Column_name</code></td>
<td><code>Column_name</code></td>
</tr>
<tr>
<td><strong>Privilege columns</strong></td>
<td><code>Table_priv</code></td>
<td><code>Column_priv</code></td>
</tr>
<tr>
<td></td>
<td><code>Column_priv</code></td>
<td></td>
</tr>
<tr>
<td><strong>Other columns</strong></td>
<td><code>Timestamp</code></td>
<td><code>Timestamp</code></td>
</tr>
<tr>
<td></td>
<td><code>Grantor</code></td>
<td></td>
</tr>
</tbody>
</table>

The `Timestamp` and `Grantor` columns are set to the current timestamp and the `CURRENT_USER` value, respectively. However, they are unused and are discussed no further here.

For verification of requests that involve stored routines, the server may consult the `procs_priv` table, which has the columns shown in the following table.

**Table 6.5 procs_priv Table Columns**

<table>
<thead>
<tr>
<th><strong>Table Name</strong></th>
<th><strong>procs_priv</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Scope columns</strong></td>
<td>Host</td>
</tr>
<tr>
<td></td>
<td>Db</td>
</tr>
<tr>
<td></td>
<td>User</td>
</tr>
<tr>
<td></td>
<td><code>Routine_name</code></td>
</tr>
<tr>
<td></td>
<td><code>Routine_type</code></td>
</tr>
<tr>
<td><strong>Privilege columns</strong></td>
<td><code>Proc_priv</code></td>
</tr>
<tr>
<td><strong>Other columns</strong></td>
<td><code>Timestamp</code></td>
</tr>
<tr>
<td></td>
<td><code>Grantor</code></td>
</tr>
</tbody>
</table>

The `Routine_type` column is an `ENUM` column with values of 'FUNCTION' or 'PROCEDURE' to indicate the type of routine the row refers to. This column enables privileges to be granted separately for a function and a procedure with the same name.
The Timestamp and Grantor columns currently are unused and are discussed no further here.

The proxies_priv table was added in MySQL 5.5.7 and records information about proxy users. It has these columns:

- **Host, User**: These columns indicate the user account that has the PROXY privilege for the proxied account.
- **Proxied_host, Proxied_user**: These columns indicate the account of the proxied user.
- **Grantor**: Currently unused.
- **Timestamp**: Currently unused.
- **With_grant**: This column indicates whether the proxy account can grant the PROXY privilege to other accounts.

Scope columns in the grant tables contain strings. They are declared as shown here; the default value for each is the empty string.

### Table 6.6 Grant Table Scope Column Types

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host, Proxied_host</td>
<td>CHAR(60)</td>
</tr>
<tr>
<td>User, Proxied_user</td>
<td>CHAR(16)</td>
</tr>
<tr>
<td>Password</td>
<td>CHAR(41)</td>
</tr>
<tr>
<td>Db</td>
<td>CHAR(64)</td>
</tr>
<tr>
<td>Table_name</td>
<td>CHAR(64)</td>
</tr>
<tr>
<td>Column_name</td>
<td>CHAR(64)</td>
</tr>
<tr>
<td>Routine_name</td>
<td>CHAR(64)</td>
</tr>
</tbody>
</table>

For access-checking purposes, comparisons of User, Proxied_user, Password, Db, and Table_name values are case sensitive. Comparisons of Host, Proxied_host, Column_name, and Routine_name values are not case sensitive.

In the user, db, and host tables, each privilege is listed in a separate column that is declared as ENUM('N', 'Y') DEFAULT 'N'. In other words, each privilege can be disabled or enabled, with the default being disabled.

In the tables_priv, columns_priv, and procs_priv tables, the privilege columns are declared as SET columns. Values in these columns can contain any combination of the privileges controlled by the table. Only those privileges listed in the column value are enabled.

### Table 6.7 Set-Type Privilege Column Values

<table>
<thead>
<tr>
<th>Table Name</th>
<th>Column Name</th>
<th>Possible Set Elements</th>
</tr>
</thead>
<tbody>
<tr>
<td>tables_priv</td>
<td>Table_priv</td>
<td>'Select', 'Insert', 'Update', 'Delete', 'Create', 'Drop', 'Grant', 'References', 'Index', 'Alter', 'Create View', 'Show view', 'Trigger'</td>
</tr>
</tbody>
</table>
### 6.2.3 Specifying Account Names

MySQL account names consist of a user name and a host name. This enables creation of accounts for users with the same name who can connect from different hosts. This section describes how to write account names, including special values and wildcard rules.

In SQL statements such as `CREATE USER`, `GRANT`, and `SET PASSWORD`, write account names using the following rules:

- **Syntax for account names is** `user_name'@'host_name'`.
- **An account name consisting only of a user name is equivalent to** `user_name'@'%`. For example, `me` is equivalent to `me'@'%`.
- **The user name and host name need not be quoted if they are legal as unquoted identifiers.** However, if they contain special characters (such as `"`), you must quote them as `user_name'` or `host_name'`.
- **Quote user names and host names as identifiers or as strings, using either backticks (` ```), single quotation marks (`'`), or double quotation marks (`"`).
- **The user name and host name parts, if quoted, must be quoted separately.** That is, write `me'@'localhost'`, not `me@localhost`; the latter is interpreted as `me@localhost'@'%`.
- **A reference to the CURRENT_USER or CURRENT_USER() function is equivalent to specifying the current client's user name and host name literally.**
Specifying Account Names

MySQL stores account names in grant tables in the `mysql` database using separate columns for the user name and host name parts:

- The `user` table contains one row for each account. The `User` and `Host` columns store the user name and host name. This table also indicates which global privileges the account has.

- Other grant tables indicate privileges an account has for databases and objects within databases. These tables have `User` and `Host` columns to store the account name. Each row in these tables associates with the account in the `user` table that has the same `User` and `Host` values.

For additional detail about grant table structure, see Section 6.2.2, "Privilege System Grant Tables".

User names and host names have certain special values or wildcard conventions, as described following.

A user name is either a nonblank value that literally matches the user name for incoming connection attempts, or a blank value (empty string) that matches any user name. An account with a blank user name is an anonymous user. To specify an anonymous user in SQL statements, use a quoted empty user name part, such as `''@'localhost'`.

The host name part of an account name can take many forms, and wildcards are permitted:

- A host value can be a host name or an IP address (IPv4 or IPv6). The name `localhost` indicates the local host. The IP address `127.0.0.1` indicates the IPv4 loopback interface. The IP address `::1` indicates the IPv6 loopback interface.

- You can use the wildcard characters `"%"` and `"_"` in host name or IP address values. These have the same meaning as for pattern-matching operations performed with the LIKE operator. For example, a host value of `%` matches any host name, whereas a value of `%.mysql.com` matches any host in the `mysql.com` domain. `192.168.1.%` matches any host in the 192.168.1 class C network.

Because you can use IP wildcard values in host values (for example, `192.168.1.%` to match every host on a subnet), someone could try to exploit this capability by naming a host `192.168.1.somewhere.com`. To foil such attempts, MySQL disallows matching on host names that start with digits and a dot. Thus, if you have a host named something like `1.2.example.com`, its name never matches the host part of account names. An IP wildcard value can match only IP addresses, not host names.

- For a host value specified as an IPv4 address, you can specify a netmask indicating how many address bits to use for the network number. Netmask notation cannot be used for IPv6 addresses.

The syntax is `host_ip/netmask`. For example:

```
CREATE USER 'david'@'192.58.197.0/255.255.255.0';
```

This enables `david` to connect from any client host having an IP address `client_ip` for which the following condition is true:

```
client_ip & netmask = host_ip
```

That is, for the `CREATE USER` statement just shown:

```
client_ip & 255.255.255.0 = 192.58.197.0
```

IP addresses that satisfy this condition and can connect to the MySQL server are those in the range from `192.58.197.0` to `192.58.197.255`.

743
Access Control, Stage 1: Connection Verification

The netmask can only be used to tell the server to use 8, 16, 24, or 32 bits of the address. Examples:

- **192.0.0.0/255.0.0.0**: Any host on the 192 class A network
- **192.168.0.0/255.255.0.0**: Any host on the 192.168 class B network
- **192.168.1.0/255.255.255.0**: Any host on the 192.168.1 class C network
- **192.168.1.1**: Only the host with this specific IP address

The following netmask will not work because it masks 28 bits, and 28 is not a multiple of 8:

```
192.168.0.0/255.255.255.240
```

The server performs matching of host values in account names against the client host using the value returned by the system DNS resolver for the client host name or IP address. Except in the case that the account host value is specified using netmask notation, this comparison is performed as a string match, even for an account host value given as an IP address. This means that you should specify account host values in the same format used by DNS. Here are examples of problems to watch out for:

- Suppose that a host on the local network has a fully qualified name of `host1.example.com`. If DNS returns name lookups for this host as `host1.example.com`, use that name in account host values. But if DNS returns just `host1`, use `host1` instead.

- If DNS returns the IP address for a given host as `192.168.1.2`, that will match an account host value of `192.168.1.2` but not `192.168.01.2`. Similarly, it will match an account host pattern like `192.168.1.%` but not `192.168.01.%`.

To avoid problems like this, it is advisable to check the format in which your DNS returns host names and addresses, and use values in the same format in MySQL account names.

### 6.2.4 Access Control, Stage 1: Connection Verification

When you attempt to connect to a MySQL server, the server accepts or rejects the connection based on your identity and whether you can verify your identity by supplying the correct password. If not, the server denies access to you completely. Otherwise, the server accepts the connection, and then enters Stage 2 and waits for requests.

Your identity is based on two pieces of information:

- The client host from which you connect
- Your MySQL user name

Identity checking is performed using the three `user` table scope columns (`Host`, `User`, and `Password`). The server accepts the connection only if the `Host` and `User` columns in some `user` table row match the client host name and user name and the client supplies the password specified in that row. The rules for permissible `Host` and `User` values are given in [Section 6.2.3, “Specifying Account Names”](#).

If the `User` column value is nonblank, the user name in an incoming connection must match exactly. If the `User` value is blank, it matches any user name. If the `user` table row that matches an incoming connection has a blank user name, the user is considered to be an anonymous user with no name, not a user with the name that the client actually specified. This means that a blank user name is used for all further access checking for the duration of the connection (that is, during Stage 2).
The **Password** column can be blank. This is not a wildcard and does not mean that any password matches. It means that the user must connect without specifying a password. If the server authenticates a client using a plugin, the authentication method that the plugin implements may or may not use the password in the **Password** column. In this case, it is possible that an external password is also used to authenticate to the MySQL server.

Nonblank **Password** values in the **user** table represent encrypted passwords. MySQL does not store passwords in plaintext form for anyone to see. Rather, the password supplied by a user who is attempting to connect is encrypted (using the `PASSWORD()` function). The encrypted password then is used during the connection process when checking whether the password is correct. This is done without the encrypted password ever traveling over the connection. See Section 6.3.1, “User Names and Passwords”.

From MySQL’s point of view, the encrypted password is the real password, so you should never give anyone access to it. In particular, **do not give nonadministrative users read access to tables in the mysql database**.

The following table shows how various combinations of **Host** and **User** values in the **user** table apply to incoming connections.

<table>
<thead>
<tr>
<th>Host Value</th>
<th>User Value</th>
<th>Permissible Connections</th>
</tr>
</thead>
<tbody>
<tr>
<td>'thomas.loc.gov'</td>
<td>'fred'</td>
<td><em>fred</em>, connecting from <em>thomas.loc.gov</em></td>
</tr>
<tr>
<td>'thomas.loc.gov'</td>
<td>''</td>
<td>Any user, connecting from <em>thomas.loc.gov</em></td>
</tr>
<tr>
<td>'%'</td>
<td>'fred'</td>
<td><em>fred</em>, connecting from any host</td>
</tr>
<tr>
<td>'%'</td>
<td>''</td>
<td>Any user, connecting from any host</td>
</tr>
<tr>
<td>'%.loc.gov'</td>
<td>'fred'</td>
<td><em>fred</em>, connecting from any host in the <em>loc.gov</em> domain</td>
</tr>
<tr>
<td>'x.y.%'</td>
<td>'fred'</td>
<td><em>fred</em>, connecting from <em>x.y.net</em>, <em>x.y.com</em>, <em>x.y.edu</em>, and so on; this is probably not useful</td>
</tr>
<tr>
<td>'144.155.166.177'</td>
<td>'fred'</td>
<td><em>fred</em>, connecting from the host with IP address 144.155.166.177</td>
</tr>
<tr>
<td>'144.155.166.%'</td>
<td>'fred'</td>
<td><em>fred</em>, connecting from any host in the 144.155.166 class C subnet</td>
</tr>
<tr>
<td>'144.155.166.0/255.255.255.0'</td>
<td>'fred'</td>
<td>Same as previous example</td>
</tr>
</tbody>
</table>

It is possible for the client host name and user name of an incoming connection to match more than one row in the **user** table. The preceding set of examples demonstrates this: Several of the entries shown match a connection from *thomas.loc.gov* by *fred*.

When multiple matches are possible, the server must determine which of them to use. It resolves this issue as follows:

- Whenever the server reads the **user** table into memory, it sorts the rows.
- When a client attempts to connect, the server looks through the rows in sorted order.
- The server uses the first row that matches the client host name and user name.

The server uses sorting rules that order rows with the most-specific **Host** values first. Literal host names and IP addresses are the most specific. (The specificity of a literal IP address is not affected by whether it has a netmask, so *192.168.1.13* and *192.168.1.0/255.255.255.0* are considered equally specific.) The pattern `'%'` means “any host” and is least specific. The empty string `''' also means “any host” but sorts after `'%'`. Rows with the same **Host** value are ordered with the most-specific **User** values first (a
blank User value means “any user” and is least specific). For rows with equally-specific Host and User values, the order is indeterminate.

To see how this works, suppose that the user table looks like this:

<table>
<thead>
<tr>
<th>Host</th>
<th>User</th>
<th>...</th>
</tr>
</thead>
<tbody>
<tr>
<td>%</td>
<td>root</td>
<td></td>
</tr>
<tr>
<td>%</td>
<td>jeffrey</td>
<td></td>
</tr>
<tr>
<td>localhost</td>
<td>root</td>
<td></td>
</tr>
<tr>
<td>localhost</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

When the server reads the table into memory, it sorts the rows using the rules just described. The result after sorting looks like this:

<table>
<thead>
<tr>
<th>Host</th>
<th>User</th>
<th>...</th>
</tr>
</thead>
<tbody>
<tr>
<td>localhost</td>
<td>root</td>
<td></td>
</tr>
<tr>
<td>localhost</td>
<td></td>
<td></td>
</tr>
<tr>
<td>%</td>
<td>jeffrey</td>
<td></td>
</tr>
<tr>
<td>%</td>
<td>root</td>
<td></td>
</tr>
</tbody>
</table>

When a client attempts to connect, the server looks through the sorted rows and uses the first match found. For a connection from localhost by jeffrey, two of the rows from the table match: the one with Host and User values of 'localhost' and '', and the one with values of '%' and 'jeffrey'. The 'localhost' row appears first in sorted order, so that is the one the server uses.

Here is another example. Suppose that the user table looks like this:

<table>
<thead>
<tr>
<th>Host</th>
<th>User</th>
<th>...</th>
</tr>
</thead>
<tbody>
<tr>
<td>%</td>
<td>jeffrey</td>
<td></td>
</tr>
<tr>
<td>thomas.loc.gov</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The sorted table looks like this:

<table>
<thead>
<tr>
<th>Host</th>
<th>User</th>
<th>...</th>
</tr>
</thead>
<tbody>
<tr>
<td>thomas.loc.gov</td>
<td></td>
<td></td>
</tr>
<tr>
<td>%</td>
<td>jeffrey</td>
<td></td>
</tr>
</tbody>
</table>

A connection by jeffrey from thomas.loc.gov is matched by the first row, whereas a connection by jeffrey from any host is matched by the second.

Note

It is a common misconception to think that, for a given user name, all rows that explicitly name that user are used first when the server attempts to find a match for the connection. This is not true. The preceding example illustrates this, where
a connection from \texttt{thomas.loc.gov} by \texttt{jeffrey} is first matched not by the row containing \texttt{'jeffrey'} as the User column value, but by the row with no user name. As a result, \texttt{jeffrey} is authenticated as an anonymous user, even though he specified a user name when connecting.

If you are able to connect to the server, but your privileges are not what you expect, you probably are being authenticated as some other account. To find out what account the server used to authenticate you, use the \texttt{CURRENT_USER()} function. (See \texttt{Section 12.14, "Information Functions"}.) It returns a value in \texttt{user_name@host_name} format that indicates the User and Host values from the matching user table row. Suppose that \texttt{jeffrey} connects and issues the following query:

\begin{verbatim}
mysql> SELECT CURRENT_USER();
+----------------+
| CURRENT_USER() |
+----------------+
| @localhost     |
+----------------+
\end{verbatim}

The result shown here indicates that the matching user table row had a blank User column value. In other words, the server is treating \texttt{jeffrey} as an anonymous user.

Another way to diagnose authentication problems is to print out the user table and sort it by hand to see where the first match is being made.

\textbf{6.2.5 Access Control, Stage 2: Request Verification}

After you establish a connection, the server enters Stage 2 of access control. For each request that you issue through that connection, the server determines what operation you want to perform, then checks whether you have sufficient privileges to do so. This is where the privilege columns in the grant tables come into play. These privileges can come from any of the user, db, host, tables_priv, columns_priv, or procs_priv tables. (You may find it helpful to refer to \texttt{Section 6.2.2, "Privilege System Grant Tables"}, which lists the columns present in each of the grant tables.)

The user table grants privileges that are assigned to you on a global basis and that apply no matter what the default database is. For example, if the user table grants you the \texttt{DELETE} privilege, you can delete rows from any table in any database on the server host! It is wise to grant privileges in the user table only to people who need them, such as database administrators. For other users, you should leave all privileges in the user table set to \texttt{'N'} and grant privileges at more specific levels only. You can grant privileges for particular databases, tables, columns, or routines.

The db and host tables grant database-specific privileges. Values in the scope columns of these tables can take the following forms:

- A blank User value in the db table matches the anonymous user. A nonblank value matches literally; there are no wildcards in user names.

- The wildcard characters \texttt{"\_\_"} and \texttt{"\_\_\_\_"} can be used in the Host and Db columns of either table. These have the same meaning as for pattern-matching operations performed with the LIKE operator. If you want to use either character literally when granting privileges, you must escape it with a backslash. For example, to include the underscore character (\texttt{"\_"}) as part of a database name, specify it as \texttt{"\_\_"} in the GRANT statement.

- A \texttt{"\_\_\_\_"} Host value in the db table means “any host.” A blank Host value in the db table means “consult the host table for further information” (a process that is described later in this section).

- A \texttt{"\_\_\_\_"} or blank Host value in the host table means “any host.”
• A '%', or blank `Db` value in either table means “any database.”

The server reads the `db` and `host` tables into memory and sorts them at the same time that it reads the `user` table. The server sorts the `db` table based on the `Host`, `Db`, and `User` scope columns, and sorts the `host` table based on the `Host` and `Db` scope columns. As with the `user` table, sorting puts the most-specific values first and least-specific values last, and when the server looks for matching entries, it uses the first match that it finds.

The `tables_priv`, `columns_priv`, and `procs_priv` tables grant table-specific, column-specific, and routine-specific privileges. Values in the scope columns of these tables can take the following forms:

• The wildcard characters “%” and “_” can be used in the `Host` column. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator.

• A '%', or blank `Host` value means “any host.”

• The `Db`, `Table_name`, `Column_name`, and `Routine_name` columns cannot contain wildcards or be blank.

The server sorts the `tables_priv`, `columns_priv`, and `procs_priv` tables based on the `Host`, `Db`, and `User` columns. This is similar to `db` table sorting, but simpler because only the `Host` column can contain wildcards.

The server uses the sorted tables to verify each request that it receives. For requests that require administrative privileges such as `SHUTDOWN` or `RELOAD`, the server checks only the `user` table row because that is the only table that specifies administrative privileges. The server grants access if the row permits the requested operation and denies access otherwise. For example, if you want to execute `mysqladmin shutdown` but your `user` table row does not grant the `SHUTDOWN` privilege to you, the server denies access without even checking the `db` or `host` tables. (They contain no `Shutdown_priv` column, so there is no need to do so.)

For database-related requests (`INSERT`, `UPDATE`, and so on), the server first checks the user’s global privileges by looking in the `user` table row. If the row permits the requested operation, access is granted. If the global privileges in the `user` table are insufficient, the server determines the user’s database-specific privileges by checking the `db` and `host` tables:

1. The server looks in the `db` table for a match on the `Host`, `Db`, and `User` columns. The `Host` and `User` columns are matched to the connecting user’s host name and MySQL user name. The `Db` column is matched to the database that the user wants to access. If there is no row for the `Host` and `User`, access is denied.

2. If there is a matching `db` table row and its `Host` column is not blank, that row defines the user’s database-specific privileges.

3. If the matching `db` table row's `Host` column is blank, it signifies that the `host` table enumerates which hosts should be permitted access to the database. In this case, a further lookup is done in the `host` table to find a match on the `Host` and `Db` columns. If no `host` table row matches, access is denied. If there is a match, the user’s database-specific privileges are computed as the intersection (not the union) of the privileges in the `db` and `host` table entries; that is, the privileges that are 'Y' in both entries. (This way you can grant general privileges in the `db` table row and then selectively restrict them on a host-by-host basis using the `host` table entries.)

After determining the database-specific privileges granted by the `db` and `host` table entries, the server adds them to the global privileges granted by the `user` table. If the result permits the requested operation, access is granted. Otherwise, the server successively checks the user's table and column privileges in
the `tables_priv` and `columns_priv` tables, adds those to the user's privileges, and permits or denies
access based on the result. For stored-routine operations, the server uses the `procs_priv` table rather
than `tables_priv` and `columns_priv`.

Expressed in boolean terms, the preceding description of how a user's privileges are calculated may be
summarized like this:

<table>
<thead>
<tr>
<th>Global privileges</th>
</tr>
</thead>
<tbody>
<tr>
<td>OR database privileges AND host privileges</td>
</tr>
<tr>
<td>OR table privileges</td>
</tr>
<tr>
<td>OR column privileges</td>
</tr>
<tr>
<td>OR routine privileges</td>
</tr>
</tbody>
</table>

It may not be apparent why, if the global user row privileges are initially found to be insufficient for the
requested operation, the server adds those privileges to the database, table, and column privileges later.
The reason is that a request might require more than one type of privilege. For example, if you execute
an `INSERT INTO ... SELECT` statement, you need both the `INSERT` and the `SELECT` privileges. Your
privileges might be such that the `user` table row grants one privilege and the `db` table row grants the other.
In this case, you have the necessary privileges to perform the request, but the server cannot tell that from
either table by itself; the privileges granted by the entries in both tables must be combined.

The `host` table is not affected by the `GRANT` or `REVOKE` statements, so it is unused in most MySQL
installations. If you modify it directly, you can use it for some specialized purposes, such as to maintain a
list of secure servers on the local network that are granted all privileges.

You can also use the `host` table to indicate hosts that are not secure. Suppose that you have a machine
public.your.domain that is located in a public area that you do not consider secure. You can enable
access to all hosts on your network except that machine by using `host` table entries like this:

<table>
<thead>
<tr>
<th>Host</th>
<th>Db</th>
<th>...</th>
</tr>
</thead>
<tbody>
<tr>
<td>public.your.domain</td>
<td>%</td>
<td>... (all privileges set to 'N')</td>
</tr>
<tr>
<td>%.your.domain</td>
<td>%</td>
<td>... (all privileges set to 'Y')</td>
</tr>
</tbody>
</table>

### 6.2.6 When Privilege Changes Take Effect

When `mysql` starts, it reads all grant table contents into memory. The in-memory tables become effective
for access control at that point.

If you modify the grant tables indirectly using account-management statements such as `GRANT`, `REVOKE`,
`SET PASSWORD`, or `RENAME USER`, the server notices these changes and loads the grant tables into
memory again immediately.

If you modify the grant tables directly using statements such as `INSERT`, `UPDATE`, or `DELETE`, your
changes have no effect on privilege checking until you either restart the server or tell it to reload the tables.
If you change the grant tables directly but forget to reload them, your changes have no effect until you
restart the server. This may leave you wondering why your changes seem to make no difference!

To tell the server to reload the grant tables, perform a flush-privileges operation. This can be done by
issuing a `FLUSH PRIVILEGES` statement or by executing a `mysqladmin flush-privileges` or
`mysqladmin reload` command.

A grant table reload affects privileges for each existing client connection as follows:

- Table and column privilege changes take effect with the client's next request.
Causes of Access-Denied Errors

- Database privilege changes take effect the next time the client executes a `USE db_name` statement.

  ![Note]
  
  Client applications may cache the database name; thus, this effect may not be visible to them without actually changing to a different database or flushing the privileges.

- Global privileges and passwords are unaffected for a connected client. These changes take effect only for subsequent connections.

If the server is started with the `--skip-grant-tables` option, it does not read the grant tables or implement any access control. Anyone can connect and do anything, which is insecure. To cause a server thus started to read the tables and enable access checking, flush the privileges.

### 6.2.7 Causes of Access-Denied Errors

If you encounter problems when you try to connect to the MySQL server, the following items describe some courses of action you can take to correct the problem.

- Make sure that the server is running. If it is not, clients cannot connect to it. For example, if an attempt to connect to the server fails with a message such as one of those following, one cause might be that the server is not running:

```shell
shell> mysql
ERROR 2003: Can't connect to MySQL server on 'host_name' (111)

shell> mysql
ERROR 2002: Can't connect to local MySQL server through socket '/tmp/mysql.sock' (111)
```

- It might be that the server is running, but you are trying to connect using a TCP/IP port, named pipe, or Unix socket file different from the one on which the server is listening. To correct this when you invoke a client program, specify a `--port` option to indicate the proper port number, or a `--socket` option to indicate the proper named pipe or Unix socket file. To find out where the socket file is, you can use this command:

```shell
shell> netstat -ln | grep mysql
```

- Make sure that the server has not been configured to ignore network connections or (if you are attempting to connect remotely) that it has not been configured to listen only locally on its network interfaces. If the server was started with `--skip-networking`, it will not accept TCP/IP connections at all. If the server was started with `--bind-address=127.0.0.1`, it will listen for TCP/IP connections only locally on the loopback interface and will not accept remote connections.

- Check to make sure that there is no firewall blocking access to MySQL. Your firewall may be configured on the basis of the application being executed, or the port number used by MySQL for communication (3306 by default). Under Linux or Unix, check your IP tables (or similar) configuration to ensure that the port has not been blocked. Under Windows, applications such as ZoneAlarm or the Windows XP personal firewall may need to be configured not to block the MySQL port.

- The grant tables must be properly set up so that the server can use them for access control. For some distribution types (such as binary distributions on Windows, or RPM distributions on Linux), the installation process initializes the `mysql` database containing the grant tables. For distributions that do not do this, you must initialize the grant tables manually by running the `mysql_install_db` script. For details, see Section 2.10.1, “Postinstallation Procedures for Unix-like Systems”.
Causes of Access-Denied Errors

To determine whether you need to initialize the grant tables, look for a `mysql` directory under the data directory. (The data directory normally is named `data` or `var` and is located under your MySQL installation directory.) Make sure that you have a file named `user.MYD` in the `mysql` database directory. If not, execute the `mysql_install_db` script. After running this script and starting the server, test the initial privileges by executing this command:

```
shell> mysql -u root test
```

The server should let you connect without error.

- After a fresh installation, you should connect to the server and set up your users and their access permissions:

```
shell> mysql -u root mysql
```

The server should let you connect because the MySQL root user has no password initially. That is also a security risk, so setting the password for the root accounts is something you should do while you’re setting up your other MySQL accounts. For instructions on setting the initial passwords, see Section 2.10.2, “Securing the Initial MySQL Accounts”.

- If you have updated an existing MySQL installation to a newer version, did you run the `mysql_upgrade` script? If not, do so. The structure of the grant tables changes occasionally when new capabilities are added, so after an upgrade you should always make sure that your tables have the current structure. For instructions, see Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”.

- If a client program receives the following error message when it tries to connect, it means that the server expects passwords in a newer format than the client is capable of generating:

```
shell> mysql
Client does not support authentication protocol requested by server; consider upgrading MySQL client
```

For information on how to deal with this, see Section 6.1.2.4, “Password Hashing in MySQL”, and Section B.5.2.4, “Client does not support authentication protocol”.

- Remember that client programs use connection parameters specified in option files or environment variables. If a client program seems to be sending incorrect default connection parameters when you have not specified them on the command line, check any applicable option files and your environment. For example, if you get Access denied when you run a client without any options, make sure that you have not specified an old password in any of your option files!

You can suppress the use of option files by a client program by invoking it with the `--no-defaults` option. For example:

```
shell> mysqladmin --no-defaults -u root version
```

The option files that clients use are listed in Section 4.2.6, “Using Option Files”. Environment variables are listed in Section 2.12, “Environment Variables”.

- If you get the following error, it means that you are using an incorrect root password:

```
shell> mysqladmin -u root -pxxxxx ver
Access denied for user 'root'@'localhost' (using password: YES)
```
Causes of Access-Denied Errors

If the preceding error occurs even when you have not specified a password, it means that you have an incorrect password listed in some option file. Try the `--no-defaults` option as described in the previous item.

For information on changing passwords, see Section 6.3.5, “Assigning Account Passwords”.

If you have lost or forgotten the root password, see Section B.5.4.1, “How to Reset the Root Password”.

- If you change a password by using `SET PASSWORD`, `INSERT`, or `UPDATE`, you must encrypt the password using the `PASSWORD()` function. If you do not use `PASSWORD()` for these statements, the password will not work. For example, the following statement assigns a password, but fails to encrypt it, so the user is not able to connect afterward:

  ```
  SET PASSWORD FOR 'abe'@'host_name' = 'eagle';
  ```

  Instead, set the password like this:

  ```
  SET PASSWORD FOR 'abe'@'host_name' = PASSWORD('eagle');
  ```

  The `PASSWORD()` function is unnecessary when you specify a password using the `CREATE USER` or `GRANT` statements or the `mysqladmin password` command. Each of those automatically uses `PASSWORD()` to encrypt the password. See Section 6.3.5, “Assigning Account Passwords”, and Section 13.7.1.1, “CREATE USER Syntax”.

- `localhost` is a synonym for your local host name, and is also the default host to which clients try to connect if you specify no host explicitly.

  To avoid this problem on such systems, you can use a `--host=127.0.0.1` option to name the server host explicitly. This will make a TCP/IP connection to the local `mysqld` server. You can also use TCP/IP by specifying a `--host` option that uses the actual host name of the local host. In this case, the host name must be specified in a `user` table row on the server host, even though you are running the client program on the same host as the server.

- The Access denied error message tells you who you are trying to log in as, the client host from which you are trying to connect, and whether you were using a password. Normally, you should have one row in the `user` table that exactly matches the host name and user name that were given in the error message. For example, if you get an error message that contains `using password: NO`, it means that you tried to log in without a password.

- If you get an Access denied error when trying to connect to the database with `mysql -u user_name`, you may have a problem with the `user` table. Check this by executing `mysql -u root mysql` and issuing this SQL statement:

  ```
  SELECT * FROM user;
  ```

  The result should include a row with the Host and User columns matching your client's host name and your MySQL user name.

- If the following error occurs when you try to connect from a host other than the one on which the MySQL server is running, it means that there is no row in the `user` table with a Host value that matches the client host:

  ```
  Host ... is not allowed to connect to this MySQL server
  ```
Causes of Access-Denied Errors

You can fix this by setting up an account for the combination of client host name and user name that you are using when trying to connect.

If you do not know the IP address or host name of the machine from which you are connecting, you should put a row with '%’ as the Host column value in the user table. After trying to connect from the client machine, use a SELECT USER() query to see how you really did connect. Then change the '%’ in the user table row to the actual host name that shows up in the log. Otherwise, your system is left insecure because it permits connections from any host for the given user name.

On Linux, another reason that this error might occur is that you are using a binary MySQL version that is compiled with a different version of the glibc library than the one you are using. In this case, you should either upgrade your operating system or glibc, or download a source distribution of MySQL version and compile it yourself. A source RPM is normally trivial to compile and install, so this is not a big problem.

• If you specify a host name when trying to connect, but get an error message where the host name is not shown or is an IP address, it means that the MySQL server got an error when trying to resolve the IP address of the client host to a name:

```
shell> mysqladmin -u root -pxxxx -h some_hostname ver
Access denied for user 'root'@'' (using password: YES)
```

If you try to connect as root and get the following error, it means that you do not have a row in the user table with a User column value of 'root' and that mysqld cannot resolve the host name for your client:

```
Access denied for user ''@'unknown'
```

These errors indicate a DNS problem. To fix it, execute mysqladmin flush-hosts to reset the internal DNS host cache. See Section 8.11.5.2, “DNS Lookup Optimization and the Host Cache”.

Some permanent solutions are:

• Determine what is wrong with your DNS server and fix it.

• Specify IP addresses rather than host names in the MySQL grant tables.

• Put an entry for the client machine name in /etc/hosts on Unix or \windows\hosts on Windows.

• Start mysql with the --skip-name-resolve option.

• Start mysql with the --skip-host-cache option.

• On Unix, if you are running the server and the client on the same machine, connect to localhost. Unix connections to localhost use a Unix socket file rather than TCP/IP.

• On Windows, if you are running the server and the client on the same machine and the server supports named pipe connections, connect to the host name . (period). Connections to . use a named pipe rather than TCP/IP.

• If mysql -u root test works but mysql -h your_hostname -u root test results in Access denied (where your_hostname is the actual host name of the local host), you may not have the correct name for your host in the user table. A common problem here is that the Host value in the user table row specifies an unqualified host name, but your system's name resolution routines return a fully qualified domain name (or vice versa). For example, if you have an entry with host ‘pluto’ in the
Causes of Access-Denied Errors

user table, but your DNS tells MySQL that your host name is 'pluto.example.com', the entry does not work. Try adding an entry to the user table that contains the IP address of your host as the Host column value. (Alternatively, you could add an entry to the user table with a Host value that contains a wildcard; for example, 'pluto.%'. However, use of Host values ending with "%" is insecure and is not recommended!)

- If `mysql -u user_name test` works but `mysql -u user_name other_db` does not, you have not granted access to the given user for the database named other_db.

- If `mysql -u user_name` works when executed on the server host, but `mysql -h host_name -u user_name` does not work when executed on a remote client host, you have not enabled access to the server for the given user name from the remote host.

- If you cannot figure out why you get Access denied, remove from the user table all entries that have Host values containing wildcards (entries that contain '%', '._', or '._' characters). A very common error is to insert a new entry with Host='%', and User='some_user', thinking that this enables you to specify localhost to connect from the same machine. The reason that this does not work is that the default privileges include an entry with Host='localhost' and User=''. Because that entry has a Host value 'localhost' that is more specific than '%', it is used in preference to the new entry when connecting from localhost! The correct procedure is to insert a second entry with Host='localhost' and User='some_user', or to delete the entry with Host='localhost' and User=''. After deleting the entry, remember to issue a FLUSH PRIVILEGES statement to reload the grant tables. See also Section 6.2.4, “Access Control, Stage 1: Connection Verification”.

- If you are able to connect to the MySQL server, but get an Access denied message whenever you issue a SELECT ... INTO OUTFILE or LOAD DATA INFILE statement, your entry in the user table does not have the FILE privilege enabled.

- If you change the grant tables directly (for example, by using INSERT, UPDATE, or DELETE statements) and your changes seem to be ignored, remember that you must execute a FLUSH PRIVILEGES statement or a mysqladmin flush-privileges command to cause the server to reload the privilege tables. Otherwise, your changes have no effect until the next time the server is restarted. Remember that after you change the root password with an UPDATE statement, you will not need to specify the new password until after you flush the privileges, because the server will not know you've changed the password yet!

- If your privileges seem to have changed in the middle of a session, it may be that a MySQL administrator has changed them. Reloading the grant tables affects new client connections, but it also affects existing connections as indicated in Section 6.2.6, “When Privilege Changes Take Effect”.

- If you have access problems with a Perl, PHP, Python, or ODBC program, try to connect to the server with `mysql -u user_name db_name` or `mysql -u user_name -p your_pass db_name`. If you are able to connect using the mysql client, the problem lies with your program, not with the access privileges. (There is no space between `-p` and the password; you can also use the `--password=your_pass` syntax to specify the password. If you use the `-p` or `--password` option with no password value, MySQL prompts you for the password.)

- For testing purposes, start the mysqld server with the `--skip-grant-tables` option. Then you can change the MySQL grant tables and use the mysqlaccess script to check whether your modifications have the desired effect. When you are satisfied with your changes, execute mysqladmin flush-privileges to tell the mysqld server to reload the privileges. This enables you to begin using the new grant table contents without stopping and restarting the server.

- If you get the following error, you may have a problem with the db or host table:

```
Access to database denied
```
If the entry selected from the `db` table has an empty value in the `Host` column, make sure that there are one or more corresponding entries in the `host` table specifying which hosts the `db` table entry applies to. This problem occurs infrequently because the `host` table is rarely used.

- If everything else fails, start the `mysqld` server with a debugging option (for example, `--debug=d,general,query`). This prints host and user information about attempted connections, as well as information about each command issued. See Section 24.4.3, “The DBUG Package”.

- If you have any other problems with the MySQL grant tables and feel you must post the problem to the mailing list, always provide a dump of the MySQL grant tables. You can dump the tables with the `mysqldump mysql` command. To file a bug report, see the instructions at Section 1.7, “How to Report Bugs or Problems”. In some cases, you may need to restart `mysqld` with `--skip-grant-tables` to run `mysqldump`.

6.3 MySQL User Account Management

This section describes how to set up accounts for clients of your MySQL server. It discusses the following topics:

- The meaning of account names and passwords as used in MySQL and how that compares to names and passwords used by your operating system
- How to set up new accounts and remove existing accounts
- How to change passwords
- Guidelines for using passwords securely
- How to use secure connections with SSL

See also Section 13.7.1, “Account Management Statements”, which describes the syntax and use for all user-management SQL statements.

6.3.1 User Names and Passwords

MySQL stores accounts in the `user` table of the `mysql` database. An account is defined in terms of a user name and the client host or hosts from which the user can connect to the server. The account may also have a password. For information about account representation in the `user` table, see Section 6.2.2, “Privilege System Grant Tables”. MySQL 5.5 supports authentication plugins, so it is possible that an account authenticates using some external authentication method. See Section 6.3.6, “Pluggable Authentication”.

There are several distinctions between the way user names and passwords are used by MySQL and the way they are used by your operating system:

- User names, as used by MySQL for authentication purposes, have nothing to do with user names (login names) as used by Windows or Unix. On Unix, most MySQL clients by default try to log in using the current Unix user name as the MySQL user name, but that is for convenience only. The default can be overridden easily, because client programs permit any user name to be specified with a `-u` or `--user` option. Because this means that anyone can attempt to connect to the server using any user name, you cannot make a database secure in any way unless all MySQL accounts have passwords. Anyone who specifies a user name for an account that has no password is able to connect successfully to the server.

- MySQL user names can be up to 16 characters long. Operating system user names, because they are completely unrelated to MySQL user names, may be of a different maximum length. For example, Unix user names typically are limited to eight characters.
Warning

The limit on MySQL user name length is hard-coded in the MySQL servers and clients, and trying to circumvent it by modifying the definitions of the tables in the mysql database does not work.

You should never alter any of the tables in the mysql database in any manner whatsoever except by means of the procedure that is described in Section 4.4.7, "mysql_upgrade - Check and Upgrade MySQL Tables". Attempting to redefine MySQL's system tables in any other fashion results in undefined (and unsupported!) behavior.

- The server uses MySQL passwords stored in the user table to authenticate client connections using MySQL native authentication (against passwords stored in the mysql.user table). These passwords have nothing to do with passwords for logging in to your operating system. There is no necessary connection between the "external" password you use to log in to a Windows or Unix machine and the password you use to access the MySQL server on that machine.

If the server authenticates a client using a plugin, the authentication method that the plugin implements may or may not use the password in the user table. In this case, it is possible that an external password is also used to authenticate to the MySQL server.

- MySQL encrypts passwords stored in the user table using its own algorithm. This encryption is the same as that implemented by the PASSWORD() SQL function but differs from that used during the Unix login process. Unix password encryption is the same as that implemented by the ENCRYPT() SQL function. See the descriptions of the PASSWORD() and ENCRYPT() functions in Section 12.13, "Encryption and Compression Functions".

From version 4.1 on, MySQL employs a stronger authentication method that has better password protection during the connection process than in earlier versions. It is secure even if TCP/IP packets are sniffed or the mysql database is captured. (In earlier versions, even though passwords are stored in encrypted form in the user table, knowledge of the encrypted password value could be used to connect to the MySQL server.) Section 6.1.2.4, “Password Hashing in MySQL”, discusses password encryption further.

- It is possible to connect to the server regardless of character set settings if the user name and password contain only ASCII characters. To connect when the user name or password contain non-ASCII characters, the client should call the mysql_options() C API function with the MYSQL_SET_CHARSET_NAME option and appropriate character set name as arguments. This causes authentication to take place using the specified character set. Otherwise, authentication will fail unless the server default character set is the same as the encoding in the authentication defaults.

Standard MySQL client programs support a --default-character-set option that causes mysql_options() to be called as just described. In addition, character set autodetection is supported as described in Section 10.1.4, “Connection Character Sets and Collations”. For programs that use a connector that is not based on the C API, the connector may provide an equivalent to mysql_options() that can be used instead. Check the connector documentation.

The preceding notes do not apply for ucs2, utf16, and utf32, which are not permitted as client character sets.

When you install MySQL, the grant tables are populated with an initial set of accounts. The names and access privileges for these accounts are described in Section 2.10.2, “Securing the Initial MySQL Accounts”, which also discusses how to assign passwords to them. Thereafter, you normally set up,
Adding User Accounts

modify, and remove MySQL accounts using statements such as CREATE USER, GRANT, and REVOKE. See Section 13.7.1, “Account Management Statements”.

When you connect to a MySQL server with a command-line client, specify the user name and password as necessary for the account that you want to use:

```
shell> mysql --user=monty --password=password db_name
```

If you prefer short options, the command looks like this:

```
shell> mysql -u monty -p password db_name
```

There must be no space between the -p option and the following password value.

If you omit the password value following the --password or -p option on the command line, the client prompts for one.

Specifying a password on the command line should be considered insecure. See Section 6.1.2.1, “End-User Guidelines for Password Security”. You can use an option file to avoid giving the password on the command line.

For additional information about specifying user names, passwords, and other connection parameters, see Section 4.2.2, “Connecting to the MySQL Server”.

### 6.3.2 Adding User Accounts

You can create MySQL accounts in two ways:

- By using statements intended for creating accounts, such as CREATE USER or GRANT. These statements cause the server to make appropriate modifications to the grant tables.

- By manipulating the MySQL grant tables directly with statements such as INSERT, UPDATE, or DELETE.

The preferred method is to use account-creation statements because they are more concise and less error-prone than manipulating the grant tables directly. CREATE USER and GRANT are described in Section 13.7.1, “Account Management Statements”.

Another option for creating accounts is to use the GUI tool MySQL Workbench. Or one of several available third-party programs that offer capabilities for MySQL account administration. phpMyAdmin is one such program.

The following examples show how to use the mysql client program to set up new accounts. These examples assume that privileges have been set up according to the defaults described in Section 2.10.2, “Securing the Initial MySQL Accounts”. This means that to make changes, you must connect to the MySQL server as the MySQL root user, and the root account must have the INSERT privilege for the mysql database and the RELOAD administrative privilege.

As noted in the examples where appropriate, some of the statements will fail if the server’s SQL mode has been set to enable certain restrictions. In particular, strict mode (STRICT_TRANS_TABLES, STRICT_ALL_TABLES) and NO_AUTO_CREATE_USER will prevent the server from accepting some of the statements. Workarounds are indicated for these cases. For more information about SQL modes and their effect on grant table manipulation, see Section 5.1.7, “Server SQL Modes”, and Section 13.7.1.3, “GRANT Syntax”.

First, use the mysql program to connect to the server as the MySQL root user:
Adding User Accounts

If you have assigned a password to the root account, you will also need to supply a --password or -p option, both for this mysql command and for those later in this section.

After connecting to the server as root, you can add new accounts. The following statements use GRANT to set up four new accounts:

```
shell> mysql --user=root mysql

If you have assigned a password to the root account, you will also need to supply a --password or -p option, both for this mysql command and for those later in this section.

After connecting to the server as root, you can add new accounts. The following statements use GRANT to set up four new accounts:

```

The accounts created by these statements have the following properties:

- Two of the accounts have a user name of monty and a password of some_pass. Both accounts are superuser accounts with full privileges to do anything. The 'monty'@'localhost' account can be used only when connecting from the local host. The 'monty'@'%' account uses the '%' wildcard for the host part, so it can be used to connect from any host.

It is necessary to have both accounts for monty to be able to connect from anywhere as monty. Without the localhost account, the anonymous-user account for localhost that is created by mysql_install_db would take precedence when monty connects from the local host. As a result, monty would be treated as an anonymous user. The reason for this is that the anonymous-user account has a more specific Host column value than the 'monty'@'%' account and thus comes earlier in the user table sort order. (user table sorting is discussed in Section 6.2.4, “Access Control, Stage 1: Connection Verification”.)

- The 'admin'@'localhost' account has no password. This account can be used only by admin to connect from the local host. It is granted the RELOAD and PROCESS administrative privileges. These privileges enable the admin user to execute the mysqladmin reload, mysqladmin refresh, and mysqladmin flush-xxx commands, as well as mysqladmin processlist. No privileges are granted for accessing any databases. You could add such privileges later by issuing other GRANT statements.

- The 'dummy'@'localhost' account has no password. This account can be used only to connect from the local host. No privileges are granted. It is assumed that you will grant specific privileges to the account later.

The statements that create accounts with no password will fail if the NO_AUTO_CREATE_USER SQL mode is enabled. To deal with this, use an IDENTIFIED BY clause that specifies a nonempty password.

To check the privileges for an account, use SHOW GRANTS:

```
```
Adding User Accounts

When you create accounts with \texttt{INSERT}, it is necessary to use \texttt{FLUSH PRIVILEGES} to tell the server to reload the grant tables. Otherwise, the changes go unnoticed until you restart the server. With \texttt{CREATE USER}, \texttt{FLUSH PRIVILEGES} is unnecessary.

The reason for using the \texttt{PASSWORD()} function with \texttt{INSERT} is to encrypt the password. The \texttt{CREATE USER} statement encrypts the password for you, so \texttt{PASSWORD()} is unnecessary.

The 'Y' values enable privileges for the accounts. Depending on your MySQL version, you may have to use a different number of 'Y' values in the first two \texttt{INSERT} statements. The \texttt{INSERT} statement for the \texttt{admin} account employs the more readable extended \texttt{INSERT} syntax using \texttt{SET}.

In the \texttt{INSERT} statement for the \texttt{dummy} account, only the Host, User, and Password columns in the \texttt{user} table row are assigned values. None of the privilege columns are set explicitly, so MySQL assigns them all the default value of 'N'. This is equivalent to what \texttt{CREATE USER} does.

If strict SQL mode is enabled, all columns that have no default value must have a value specified. In this case, \texttt{INSERT} statements must explicitly specify values for the \texttt{ssl_cipher}, \texttt{x509_issuer}, and \texttt{x509_subject} columns.

To set up a superuser account, it is necessary only to insert a \texttt{user} table row with all privilege columns set to 'Y'. The \texttt{user} table privileges are global, so no entries in any of the other grant tables are needed.

The next examples create three accounts and give them access to specific databases. Each of them has a user name of \texttt{custom} and password of \texttt{obscure}.

To create the accounts with \texttt{CREATE USER} and \texttt{GRANT}, use the following statements:

```
shell> mysql --user=root mysql
mysql> CREATE USER 'custom'@'localhost' IDENTIFIED BY 'obscure';
mysql> GRANT SELECT, INSERT, UPDATE, DELETE, CREATE, DROP
     -> ON bankaccount.*
     -> TO 'custom'@'localhost';
mysql> CREATE USER 'custom'@'host47.example.com' IDENTIFIED BY 'obscure';
mysql> GRANT SELECT, INSERT, UPDATE, DELETE, CREATE, DROP
     -> ON expenses.*
     -> TO 'custom'@'host47.example.com';
mysql> CREATE USER 'custom'@'server.domain' IDENTIFIED BY 'obscure';
mysql> GRANT SELECT, INSERT, UPDATE, DELETE, CREATE, DROP
     -> ON customer.*
     -> TO 'custom'@'server.domain';
```

The three accounts can be used as follows:

- The first account can access the \texttt{bankaccount} database, but only from the local host.
Removing User Accounts

- The second account can access the expenses database, but only from the host host47.example.com.

- The third account can access the customer database, but only from the host server.domain.

To set up the custom accounts without GRANT, use INSERT statements as follows to modify the grant tables directly:

```
shell> mysql --user=root mysql
mysql> INSERT INTO user (Host,User,Password) VALUES('localhost','custom',PASSWORD('obscure'));
mysql> INSERT INTO user (Host,User,Password) VALUES('host47.example.com','custom',PASSWORD('obscure'));
mysql> INSERT INTO user (Host,User,Password) VALUES('server.domain','custom',PASSWORD('obscure'));
```

The first three INSERT statements add user table entries that permit the user custom to connect from the various hosts with the given password, but grant no global privileges (all privileges are set to the default value of 'N'). The next three INSERT statements add db table entries that grant privileges to custom for the bankaccount, expenses, and customer databases, but only when accessed from the proper hosts. As usual when you modify the grant tables directly, you must tell the server to reload them with FLUSH PRIVILEGES so that the privilege changes take effect.

To create a user who has access from all machines in a given domain (for example, mydomain.com), you can use the "%" wildcard character in the host part of the account name:

```
mysql> CREATE USER 'myname'@'%'.mydomain.com IDENTIFIED BY 'mypass';
```

To do the same thing by modifying the grant tables directly, do this:

```
mysql> INSERT INTO user (Host,User,Password,...) VALUES('%'.mydomain.com,'myname',PASSWORD('mypass'),...);
```

6.3.3 Removing User Accounts

To remove an account, use the DROP USER statement, which is described in Section 13.7.1.2, "DROP USER Syntax".

6.3.4 Setting Account Resource Limits

One means of limiting use of MySQL server resources is to set the global max_user_connections system variable to a nonzero value. This limits the number of simultaneous connections that can be made
by any given account, but places no limits on what a client can do once connected. In addition, setting `max_user_connections` does not enable management of individual accounts. Both types of control are of interest to many MySQL administrators, particularly those working for Internet Service Providers.

In MySQL 5.5, you can limit use of the following server resources for individual accounts:

- The number of queries that an account can issue per hour
- The number of updates that an account can issue per hour
- The number of times an account can connect to the server per hour
- The number of simultaneous connections to the server by an account

Any statement that a client can issue counts against the query limit (unless its results are served from the query cache). Only statements that modify databases or tables count against the update limit.

An “account” in this context corresponds to a row in the `mysql.user` table. That is, a connection is assessed against the `User` and `Host` values in the `user` table row that applies to the connection. For example, an account `usera@%.example.com` corresponds to a row in the `user` table that has `User` and `Host` values of `usera` and `%.example.com`, to permit `usera` to connect from any host in the `example.com` domain. In this case, the server applies resource limits in this row collectively to all connections by `usera` from any host in the `example.com` domain because all such connections use the same account.

Before MySQL 5.0.3, an “account” was assessed against the actual host from which a user connects. This older method accounting may be selected by starting the server with the `--old-style-user-limits` option. In this case, if `usera` connects simultaneously from `host1.example.com` and `host2.example.com`, the server applies the account resource limits separately to each connection. If `usera` connects again from `host1.example.com`, the server applies the limits for that connection together with the existing connection from that host.

To set resource limits for an account, use the `GRANT` statement (see Section 13.7.1.3, “GRANT Syntax”). Provide a `WITH` clause that names each resource to be limited. The default value for each limit is zero (no limit). For example, to create a new account that can access the `customer` database, but only in a limited fashion, issue these statements:

```sql
mysql> create user 'francis'@'localhost' identified by 'frank';
mysql> grant all on customer.* to 'francis'@'localhost'
  -> with max_queries_per_hour 20
  -> max_updates_per_hour 10
  -> max_connections_per_hour 5
  -> max_user_connections 2;
```

The limit types need not all be named in the `WITH` clause, but those named can be present in any order. The value for each per-hour limit should be an integer representing a count per hour. For `max_user_connections`, the limit is an integer representing the maximum number of simultaneous connections by the account. If this limit is set to zero, the global `max_user_connections` system variable value determines the number of simultaneous connections. If `max_user_connections` is also zero, there is no limit for the account.

To modify existing limits for an account, use a `GRANT USAGE` statement at the global level (on `*.*`). The following statement changes the query limit for `francis` to 100:

```sql
mysql> grant usage on *.* to 'francis'@'localhost'
  -> with max_queries_per_hour 100;
```
Setting Account Resource Limits

The statement modifies only the limit value specified and leaves the account otherwise unchanged.

To remove a limit, set its value to zero. For example, to remove the limit on how many times per hour francis can connect, use this statement:

```
mysql> GRANT USAGE ON *.* TO 'francis'@'localhost'
    -> WITH MAX_CONNECTIONS_PER_HOUR 0;
```

As mentioned previously, the simultaneous-connection limit for an account is determined from the MAX_USER_CONNECTIONS limit and the max_user_connections system variable. Suppose that the global max_user_connections value is 10 and three accounts have resource limits specified with GRANT:

```
GRANT ... TO 'user1'@'localhost' WITH MAX_USER_CONNECTIONS 0;
GRANT ... TO 'user2'@'localhost' WITH MAX_USER_CONNECTIONS 5;
GRANT ... TO 'user3'@'localhost' WITH MAX_USER_CONNECTIONS 20;
```

user1 has a connection limit of 10 (the global max_user_connections value) because it has a zero MAX_USER_CONNECTIONS limit. user2 and user3 have connection limits of 5 and 20, respectively, because they have nonzero MAX_USER_CONNECTIONS limits.

The server stores resource limits for an account in the user table row corresponding to the account. The max_questions, max_updates, and max_connections columns store the per-hour limits, and the max_user_connections column stores the MAX_USER_CONNECTIONS limit. (See Section 6.2.2, “Privilege System Grant Tables”.)

Resource-use counting takes place when any account has a nonzero limit placed on its use of any of the resources.

As the server runs, it counts the number of times each account uses resources. If an account reaches its limit on number of connections within the last hour, further connections for the account are rejected until that hour is up. Similarly, if the account reaches its limit on the number of queries or updates, further queries or updates are rejected until the hour is up. In all such cases, an appropriate error message is issued.

Resource counting is done per account, not per client. For example, if your account has a query limit of 50, you cannot increase your limit to 100 by making two simultaneous client connections to the server. Queries issued on both connections are counted together.

The current per-hour resource-use counts can be reset globally for all accounts, or individually for a given account:

- To reset the current counts to zero for all accounts, issue a FLUSH USER_RESOURCES statement. The counts also can be reset by reloading the grant tables (for example, with a FLUSH PRIVILEGES statement or a mysqladmin reload command).
- The counts for an individual account can be set to zero by re-granting it any of its limits. To do this, use GRANT USAGE as described earlier and specify a limit value equal to the value that the account currently has.

Counter resets do not affect the MAX_USER_CONNECTIONS limit.

All counts begin at zero when the server starts; counts are not carried over through a restart.

For the MAX_USER_CONNECTIONS limit, an edge case can occur if the account currently has open the maximum number of connections permitted to it: A disconnect followed quickly by a connect can result in an error (ER_TOO_MANY_USER_CONNECTIONS or ER_USER_LIMIT_REACHED) if the server has not fully
processed the disconnect by the time the connect occurs. When the server finishes disconnect processing, another connection will once more be permitted.

### 6.3.5 Assigning Account Passwords

Required credentials for clients that connect to the MySQL server can include a password. This section describes how to assign passwords for MySQL accounts. Client authentication occurs using plugins; see Section 6.3.6, “Pluggable Authentication”.

To assign a password when you create a new account with `CREATE USER`, include an `IDENTIFIED BY` clause:

```
mysql> CREATE USER 'jeffrey'@'localhost'
    -> IDENTIFIED BY 'mypass';
```

To assign or change a password for an existing account, one way is to issue a `SET PASSWORD` statement:

```
mysql> SET PASSWORD FOR 'jeffrey'@'localhost' = PASSWORD('mypass');
```

MySQL stores passwords in the `user` table in the `mysql` database. Only users such as `root` that have the `UPDATE` privilege for the `mysql` database can change the password for other users. If you are not connected as an anonymous user, you can change your own password by omitting the `FOR` clause:

```
mysql> SET PASSWORD = PASSWORD('mypass');
```

The `old_passwords` system variable value determines the hashing method used by `PASSWORD()`. If you specify the password using that function and `SET PASSWORD` rejects the password as not being in the correct format, it may be necessary to set `old_passwords` to change the hashing method. For descriptions of the permitted values, see Section 5.1.4, “Server System Variables”.

Enabling the `read_only` system variable prevents the use of the `SET PASSWORD` statement by any user not having the `SUPER` privilege.

You can also use a `GRANT USAGE` statement at the global level (`ON *.*`) to assign a password to an account without affecting the account's current privileges:

```
mysql> GRANT USAGE ON *.* TO 'jeffrey'@'localhost'
    -> IDENTIFIED BY 'mypass';
```

To assign a password from the command line, use the `mysqladmin` command:

```shell
mysqladmin -u user_name -h host_name password "newpwd"
```

The account for which this command sets the password is the one with a `user` table row that matches `user_name` in the `User` column and the client host `from which you connect` in the `Host` column.

During authentication when a client connects to the server, MySQL treats the password in the `user` table as an encrypted hash value (the value that `PASSWORD()` would return for the password). When assigning a password to an account, it is important to store an encrypted value, not the plaintext password. Use the following guidelines:

- When you assign a password using `CREATE USER`, `GRANT` with an `IDENTIFIED BY` clause, or the `mysqladmin password` command, they encrypt the password for you. Specify the literal plaintext password:
### Pluggable Authentication

When a client connects to the MySQL server, the server uses the user name provided by the client and the client host to select the appropriate account row from the `mysql.user` table. The server then consults this row to authenticate the client.

Before MySQL 5.5.7, the server authenticates the password provided by the client against the `Password` column of the account row.

As of MySQL 5.5.7, the server authenticates clients using a plugin. Selection of the proper account row from the `mysql.user` table is based on the user name and client host, as before, but the server authenticates the client by determining from the account row which authentication plugin applies for the client:

- If the account row specifies a plugin, the server invokes it to authenticate the user. If the server cannot find the plugin, an error occurs.
- If the account row specifies no plugin name, the server authenticates the account using either the `mysql_native_password` or `mysql_old_password` plugin, depending on whether the password hash value in the `Password` column used native hashing or the older pre-4.1 hashing method. Clients must match the password in the `Password` column of the account row.

The plugin returns a status to the server indicating whether the user is permitted to connect.

---

**Note**

`PASSWORD()` encryption differs from Unix password encryption. See Section 6.3.1, “User Names and Passwords”.

It is preferable to assign passwords using `SET PASSWORD`, `GRANT`, or `mysqladmin`, but it is also possible to modify the `user` table directly. In this case, you must also use `FLUSH PRIVILEGES` to cause the server to reread the grant tables. Otherwise, the change remains unnoticed by the server until you restart it.

---

**6.3.6 Pluggable Authentication**

When CREATE USER or GRANT, you can avoid sending the plaintext password if you know the hash value that `PASSWORD()` would return for the password. Specify the hash value preceded by the keyword `PASSWORD`:

```sql
CREATE USER 'jeffrey'@'localhost'
  IDENTIFIED BY PASSWORD '*90E462C37378CED12064BB3388827D2BA3A9B689';
```

When you assign an account a nonempty password using `SET PASSWORD`, you must use the `PASSWORD()` function to encrypt the password, otherwise the password is stored as plaintext. Suppose that you assign a password like this:

```sql
SET PASSWORD FOR 'jeffrey'@'localhost' = 'mypass';
```

The result is that the literal value `mypass` is stored as the password in the `user` table, not the encrypted value. When `jeffrey` attempts to connect to the server using this password, the value is encrypted and compared to the value stored in the `user` table. However, the stored value is the literal string `mypass`, so the comparison fails and the server rejects the connection with an Access denied error.
Pluggable authentication enables two important capabilities:

- **External authentication**: Pluggable authentication makes it possible for clients to connect to the MySQL server with credentials that are appropriate for authentication methods other than native authentication based on passwords stored in the `mysql.user` table. For example, plugins can be created to use external authentication methods such as PAM, Windows login IDs, LDAP, or Kerberos.

- **Proxy users**: If a user is permitted to connect, an authentication plugin can return to the server a user name different from the name of the connecting user, to indicate that the connecting user is a proxy for another user. While the connection lasts, the proxy user is treated, for purposes of access control, as having the privileges of a different user. In effect, one user impersonates another. For more information, see Section 6.3.8, “Proxy Users”.

Several authentication plugins are available in MySQL:

- Plugins that perform native authentication that matches the password against the `Password` column of the account row. The `mysql_native_password` plugin implements authentication based on the native password hashing method. The `mysql_old_password` plugin implements native authentication based on the older (pre-4.1) password hashing method. See Section 6.3.7.1, “The Native Authentication Plugin”, and Section 6.3.7.2, “The “Old” Native Authentication Plugin”. Native authentication using `mysql_native_password` is the default for accounts that have no plugin named explicitly in their account row.

- A plugin that performs external authentication against PAM (Pluggable Authentication Modules), enabling MySQL Server to use PAM to authenticate MySQL users. This plugin supports proxy users as well. See Section 6.3.7.3, “The PAM Authentication Plugin”.

- A plugin that performs external authentication on Windows, enabling MySQL Server to use native Windows services to authenticate client connections. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password. This plugin supports proxy users as well. See Section 6.3.7.4, “The Windows Native Authentication Plugin”.

- A client-side plugin that sends the password to the server without hashing or encryption. This plugin can be used by server-side plugins that require access to the password exactly as provided by the client user. See Section 6.3.7.5, “The Cleartext Client-Side Authentication Plugin”.

- A plugin that authenticates clients that connect from the local host through the Unix socket file. See Section 6.3.7.6, “The Socket Peer-Credential Authentication Plugin”.

- A test plugin that authenticates using MySQL native authentication. This plugin is intended for testing and development purposes, and as an example of how to write an authentication plugin. See Section 6.3.7.7, “The Test Authentication Plugin”.

---

**Note**

For information about current restrictions on the use of pluggable authentication, including which connectors support which plugins, see Section D.9, “Restrictions on Pluggable Authentication”.

Third-party connector developers should read that section to determine the extent to which a connector can take advantage of pluggable authentication capabilities and what steps to take to become more compliant.

If you are interested in writing your own authentication plugins, see Section 24.2.4.9, “Writing Authentication Plugins”.

765
Authentication Plugin Usage Instructions

This section provides general instructions for installing and using authentication plugins.

In general, pluggable authentication uses corresponding plugins on the server and client sides, so you use a given authentication method like this:

- On the server host, install the library containing the appropriate server plugin, if necessary, so that the server can use it to authenticate client connections. Similarly, on each client host, install the library containing the appropriate client plugin for use by client programs.

- Create MySQL accounts that specify use of the plugin for authentication.

- When a client connects, the server plugin tells the client program which client plugin to use for authentication.

The instructions here use an example authentication plugin included in MySQL distributions (see Section 6.3.7.7, “The Test Authentication Plugin”). The procedure is similar for other authentication plugins; substitute the appropriate plugin and file names.

The example authentication plugin has these characteristics:

- The server-side plugin name is `test_plugin_server`.

- The client-side plugin name is `auth_test_plugin`.

- Both plugins are located in the shared library object file named `auth_test_plugin.so` in the plugin directory (the directory named by the `plugin_dir` system variable). The file name suffix might differ on your system.

Install and use the example authentication plugin as follows:

1. Make sure that the plugin library is installed on the server and client hosts.

2. Install the server-side test plugin at server startup or at runtime:

   - To install the plugin at startup, use the `--plugin-load` option. With this plugin-loading method, the option must be given each time you start the server. For example, use these lines in a `my.cnf` option file:

     ```
     [mysqld]
    plugin-load=test_plugin_server=auth_test_plugin.so
     ```

   - To install the plugin at runtime, use the `INSTALL PLUGIN` statement:

     ```
     mysql>
