

MySQL 5.5 Reference Manual

Including MySQL Cluster NDB 7.2 Reference Guide

MySQL 5.5 Reference Manual: Including MySQL Cluster NDB 7.2 Reference Guide

Abstract

This is the MySQL™ Reference Manual. It documents MySQL 5.5 through 5.5.40, as well as MySQL Cluster releases based on version 7.2 of [NDBCLUSTER](#) through 5.5.38-ndb-7.2.18.

MySQL 5.5 features. This manual describes features that are not included in every edition of MySQL 5.5; such features may not be included in the edition of MySQL 5.5 licensed to you. If you have any questions about the features included in your edition of MySQL 5.5, refer to your MySQL 5.5 license agreement or contact your Oracle sales representative.

For notes detailing the changes in each release, see the [MySQL 5.5 Release Notes](#).

For legal information, see the [Legal Notices](#).

Preface and Legal Notices	xxv
1 General Information	1
1.1 About This Manual	2
1.2 Typographical and Syntax Conventions	3
1.3 Overview of the MySQL Database Management System	5
1.3.1 What is MySQL?	5
1.3.2 The Main Features of MySQL	6
1.3.3 History of MySQL	9
1.4 What Is New in MySQL 5.5	9
1.4.1 Scalability Improvements	14
1.4.2 InnoDB I/O Subsystem Changes	15
1.4.3 Diagnostic and Monitoring Capabilities	15
1.4.4 Enhanced Solaris Support	16
1.5 MySQL Development History	17
1.6 MySQL Information Sources	17
1.6.1 MySQL Mailing Lists	17
1.6.2 MySQL Community Support at the MySQL Forums	20
1.6.3 MySQL Community Support on Internet Relay Chat (IRC)	20
1.6.4 MySQL Enterprise	21
1.7 How to Report Bugs or Problems	21
1.8 MySQL Standards Compliance	25
1.8.1 MySQL Extensions to Standard SQL	27
1.8.2 MySQL Differences from Standard SQL	30
1.8.3 How MySQL Deals with Constraints	34
1.9 Credits	38
1.9.1 Contributors to MySQL	38
1.9.2 Documenters and translators	42
1.9.3 Packages that support MySQL	44
1.9.4 Tools that were used to create MySQL	44
1.9.5 Supporters of MySQL	45
2 Installing and Upgrading MySQL	47
2.1 General Installation Guidance	49
2.1.1 Operating Systems Supported by MySQL Community Server	50
2.1.2 Choosing Which MySQL Distribution to Install	50
2.1.3 How to Get MySQL	53
2.1.4 Verifying Package Integrity Using MD5 Checksums or GnuPG	53
2.1.5 Installation Layouts	63
2.1.6 Compiler-Specific Build Characteristics	63
2.2 Installing MySQL on Unix/Linux Using Generic Binaries	63
2.3 Installing MySQL on Microsoft Windows	66
2.3.1 MySQL Installation Layout on Microsoft Windows	68
2.3.2 Choosing An Installation Package	68
2.3.3 Installing MySQL on Microsoft Windows Using MySQL Installer	69
2.3.4 MySQL Notifier for Microsoft Windows	87
2.3.5 Installing MySQL on Microsoft Windows Using an MSI Package	98
2.3.6 MySQL Server Instance Configuration Wizard	105
2.3.7 Installing MySQL on Microsoft Windows Using a noinstall Zip Archive	120
2.3.8 Troubleshooting a Microsoft Windows MySQL Server Installation	128
2.3.9 Upgrading MySQL on Windows	129
2.3.10 Windows Postinstallation Procedures	131
2.4 Installing MySQL on Mac OS X	132

2.4.1 General Notes on Installing MySQL on Mac OS X	133
2.4.2 Installing MySQL on Mac OS X Using Native Packages	134
2.4.3 Installing the MySQL Startup Item	137
2.4.4 Installing and Using the MySQL Preference Pane	141
2.4.5 Using the Bundled MySQL on Mac OS X Server	143
2.5 Installing MySQL on Linux	144
2.5.1 Installing MySQL on Linux Using RPM Packages	144
2.5.2 Installing MySQL on Linux Using Debian Packages	149
2.5.3 Installing MySQL on Linux Using Native Package Managers	150
2.6 Installing MySQL Using Unbreakable Linux Network (ULN)	154
2.7 Installing MySQL on Solaris and OpenSolaris	154
2.7.1 Installing MySQL on Solaris Using a Solaris PKG	155
2.7.2 Installing MySQL on OpenSolaris Using IPS	156
2.8 Installing MySQL on FreeBSD	157
2.9 Installing MySQL from Source	158
2.9.1 MySQL Layout for Source Installation	160
2.9.2 Installing MySQL Using a Standard Source Distribution	160
2.9.3 Installing MySQL Using a Development Source Tree	164
2.9.4 MySQL Source-Configuration Options	166
2.9.5 Dealing with Problems Compiling MySQL	177
2.9.6 MySQL Configuration and Third-Party Tools	179
2.10 Postinstallation Setup and Testing	179
2.10.1 Postinstallation Procedures for Unix-like Systems	180
2.10.2 Securing the Initial MySQL Accounts	191
2.11 Upgrading or Downgrading MySQL	195
2.11.1 Upgrading MySQL	195
2.11.2 Downgrading MySQL	207
2.11.3 Checking Whether Tables or Indexes Must Be Rebuilt	210
2.11.4 Rebuilding or Repairing Tables or Indexes	212
2.11.5 Copying MySQL Databases to Another Machine	213
2.12 Environment Variables	214
2.13 Perl Installation Notes	215
2.13.1 Installing Perl on Unix	216
2.13.2 Installing ActiveState Perl on Windows	217
2.13.3 Problems Using the Perl DBI/DBD Interface	217
3 Tutorial	219
3.1 Connecting to and Disconnecting from the Server	219
3.2 Entering Queries	220
3.3 Creating and Using a Database	224
3.3.1 Creating and Selecting a Database	225
3.3.2 Creating a Table	225
3.3.3 Loading Data into a Table	227
3.3.4 Retrieving Information from a Table	228
3.4 Getting Information About Databases and Tables	242
3.5 Using mysql in Batch Mode	243
3.6 Examples of Common Queries	244
3.6.1 The Maximum Value for a Column	245
3.6.2 The Row Holding the Maximum of a Certain Column	245
3.6.3 Maximum of Column per Group	246
3.6.4 The Rows Holding the Group-wise Maximum of a Certain Column	246
3.6.5 Using User-Defined Variables	247
3.6.6 Using Foreign Keys	247
3.6.7 Searching on Two Keys	249
3.6.8 Calculating Visits Per Day	249

3.6.9 Using <code>AUTO_INCREMENT</code>	250
3.7 Using MySQL with Apache	252
4 MySQL Programs	253
4.1 Overview of MySQL Programs	254
4.2 Using MySQL Programs	258
4.2.1 Invoking MySQL Programs	258
4.2.2 Connecting to the MySQL Server	259
4.2.3 Specifying Program Options	263
4.2.4 Using Options on the Command Line	264
4.2.5 Program Option Modifiers	265
4.2.6 Using Option Files	266
4.2.7 Command-Line Options that Affect Option-File Handling	270
4.2.8 Using Options to Set Program Variables	271
4.2.9 Option Defaults, Options Expecting Values, and the = Sign	272
4.2.10 Setting Environment Variables	276
4.3 MySQL Server and Server-Startup Programs	277
4.3.1 <code>mysqld</code> — The MySQL Server	277
4.3.2 <code>mysqld_safe</code> — MySQL Server Startup Script	277
4.3.3 <code>mysql.server</code> — MySQL Server Startup Script	282
4.3.4 <code>mysqld_multi</code> — Manage Multiple MySQL Servers	283
4.4 MySQL Installation-Related Programs	288
4.4.1 <code>comp_err</code> — Compile MySQL Error Message File	288
4.4.2 <code>mysqlbug</code> — Generate Bug Report	289
4.4.3 <code>mysql_install_db</code> — Initialize MySQL Data Directory	289
4.4.4 <code>mysql_plugin</code> — Configure MySQL Server Plugins	291
4.4.5 <code>mysql_secure_installation</code> — Improve MySQL Installation Security	293
4.4.6 <code>mysql_tzinfo_to_sql</code> — Load the Time Zone Tables	294
4.4.7 <code>mysql_upgrade</code> — Check and Upgrade MySQL Tables	295
4.5 MySQL Client Programs	299
4.5.1 <code>mysql</code> — The MySQL Command-Line Tool	299
4.5.2 <code>mysqladmin</code> — Client for Administering a MySQL Server	322
4.5.3 <code>mysqlcheck</code> — A Table Maintenance Program	330
4.5.4 <code>mysqldump</code> — A Database Backup Program	337
4.5.5 <code>mysqlimport</code> — A Data Import Program	356
4.5.6 <code>mysqlshow</code> — Display Database, Table, and Column Information	362
4.5.7 <code>mysqlslap</code> — Load Emulation Client	366
4.6 MySQL Administrative and Utility Programs	375
4.6.1 <code>innochecksum</code> — Offline InnoDB File Checksum Utility	375
4.6.2 <code>myisam_ftdump</code> — Display Full-Text Index information	375
4.6.3 <code>myisamchk</code> — MyISAM Table-Maintenance Utility	377
4.6.4 <code>myisamlog</code> — Display MyISAM Log File Contents	394
4.6.5 <code>myisampack</code> — Generate Compressed, Read-Only MyISAM Tables	395
4.6.6 <code>mysqlaccess</code> — Client for Checking Access Privileges	401
4.6.7 <code>mysqlbinlog</code> — Utility for Processing Binary Log Files	404
4.6.8 <code>mysqldumpslow</code> — Summarize Slow Query Log Files	420
4.6.9 <code>mysqlhotcopy</code> — A Database Backup Program	422
4.6.10 <code>mysql_convert_table_format</code> — Convert Tables to Use a Given Storage Engine	425
4.6.11 <code>mysql_find_rows</code> — Extract SQL Statements from Files	426
4.6.12 <code>mysql_fix_extensions</code> — Normalize Table File Name Extensions	427
4.6.13 <code>mysql_setpermission</code> — Interactively Set Permissions in Grant Tables	427
4.6.14 <code>mysql_waitpid</code> — Kill Process and Wait for Its Termination	428
4.6.15 <code>mysql_zap</code> — Kill Processes That Match a Pattern	428
4.7 MySQL Program Development Utilities	429

4.7.1	<code>mysql2mysql</code> — Convert mSQL Programs for Use with MySQL	429
4.7.2	<code>mysql_config</code> — Display Options for Compiling Clients	430
4.7.3	<code>my_print_defaults</code> — Display Options from Option Files	431
4.7.4	<code>resolve_stack_dump</code> — Resolve Numeric Stack Trace Dump to Symbols	432
4.8	Miscellaneous Programs	432
4.8.1	<code>pererror</code> — Explain Error Codes	432
4.8.2	<code>replace</code> — A String-Replacement Utility	433
4.8.3	<code>resolveip</code> — Resolve Host name to IP Address or Vice Versa	434
5	MySQL Server Administration	435
5.1	The MySQL Server	435
5.1.1	Server Option and Variable Reference	436
5.1.2	Server Configuration Defaults	465
5.1.3	Server Command Options	466
5.1.4	Server System Variables	501
5.1.5	Using System Variables	609
5.1.6	Server Status Variables	621
5.1.7	Server SQL Modes	648
5.1.8	Server Plugins	656
5.1.9	IPv6 Support	660
5.1.10	Server-Side Help	665
5.1.11	Server Response to Signals	665
5.1.12	The Shutdown Process	666
5.2	MySQL Server Logs	667
5.2.1	Selecting General Query and Slow Query Log Output Destinations	668
5.2.2	The Error Log	670
5.2.3	The General Query Log	672
5.2.4	The Binary Log	673
5.2.5	The Slow Query Log	686
5.2.6	Server Log Maintenance	687
5.3	Running Multiple MySQL Instances on One Machine	688
5.3.1	Setting Up Multiple Data Directories	690
5.3.2	Running Multiple MySQL Instances on Windows	691
5.3.3	Running Multiple MySQL Instances on Unix	694
5.3.4	Using Client Programs in a Multiple-Server Environment	695
5.4	Tracing <code>mysqld</code> Using DTrace	696
5.4.1	<code>mysqld</code> DTrace Probe Reference	697
6	Security	715
6.1	General Security Issues	716
6.1.1	Security Guidelines	716
6.1.2	Keeping Passwords Secure	717
6.1.3	Making MySQL Secure Against Attackers	725
6.1.4	Security-Related <code>mysqld</code> Options and Variables	727
6.1.5	How to Run MySQL as a Normal User	728
6.1.6	Security Issues with <code>LOAD DATA LOCAL</code>	729
6.1.7	Client Programming Security Guidelines	730
6.2	The MySQL Access Privilege System	731
6.2.1	Privileges Provided by MySQL	732
6.2.2	Privilege System Grant Tables	736
6.2.3	Specifying Account Names	742
6.2.4	Access Control, Stage 1: Connection Verification	744
6.2.5	Access Control, Stage 2: Request Verification	747
6.2.6	When Privilege Changes Take Effect	749
6.2.7	Causes of Access-Denied Errors	750
6.3	MySQL User Account Management	755

6.3.1 User Names and Passwords	755
6.3.2 Adding User Accounts	757
6.3.3 Removing User Accounts	760
6.3.4 Setting Account Resource Limits	760
6.3.5 Assigning Account Passwords	763
6.3.6 Pluggable Authentication	764
6.3.7 Authentication Plugins Available in MySQL	767
6.3.8 Proxy Users	782
6.3.9 Using SSL for Secure Connections	786
6.3.10 Connecting to MySQL Remotely from Windows with SSH	798
6.3.11 MySQL Enterprise Audit Log Plugin	799
6.3.12 SQL-Based MySQL Account Activity Auditing	816
7 Backup and Recovery	819
7.1 Backup and Recovery Types	820
7.2 Database Backup Methods	823
7.3 Example Backup and Recovery Strategy	825
7.3.1 Establishing a Backup Policy	826
7.3.2 Using Backups for Recovery	828
7.3.3 Backup Strategy Summary	828
7.4 Using <code>mysqldump</code> for Backups	829
7.4.1 Dumping Data in SQL Format with <code>mysqldump</code>	829
7.4.2 Reloading SQL-Format Backups	830
7.4.3 Dumping Data in Delimited-Text Format with <code>mysqldump</code>	831
7.4.4 Reloading Delimited-Text Format Backups	832
7.4.5 <code>mysqldump</code> Tips	833
7.5 Point-in-Time (Incremental) Recovery Using the Binary Log	835
7.5.1 Point-in-Time Recovery Using Event Times	836
7.5.2 Point-in-Time Recovery Using Event Positions	837
7.6 <code>MyISAM</code> Table Maintenance and Crash Recovery	837
7.6.1 Using <code>myisamchk</code> for Crash Recovery	838
7.6.2 How to Check <code>MyISAM</code> Tables for Errors	839
7.6.3 How to Repair <code>MyISAM</code> Tables	839
7.6.4 <code>MyISAM</code> Table Optimization	842
7.6.5 Setting Up a <code>MyISAM</code> Table Maintenance Schedule	842
8 Optimization	845
8.1 Optimization Overview	846
8.2 Optimizing SQL Statements	847
8.2.1 Optimizing <code>SELECT</code> Statements	848
8.2.2 Optimizing DML Statements	885
8.2.3 Optimizing Database Privileges	886
8.2.4 Optimizing <code>INFORMATION_SCHEMA</code> Queries	886
8.2.5 Other Optimization Tips	891
8.3 Optimization and Indexes	892
8.3.1 How MySQL Uses Indexes	892
8.3.2 Using Primary Keys	893
8.3.3 Using Foreign Keys	894
8.3.4 Column Indexes	894
8.3.5 Multiple-Column Indexes	895
8.3.6 Verifying Index Usage	896
8.3.7 <code>InnoDB</code> and <code>MyISAM</code> Index Statistics Collection	896
8.3.8 Comparison of B-Tree and Hash Indexes	898
8.4 Optimizing Database Structure	899
8.4.1 Optimizing Data Size	899
8.4.2 Optimizing MySQL Data Types	901

8.4.3 Optimizing for Many Tables	903
8.4.4 How MySQL Uses Internal Temporary Tables	905
8.5 Optimizing for InnoDB Tables	905
8.5.1 Optimizing Storage Layout for InnoDB Tables	905
8.5.2 Optimizing InnoDB Transaction Management	906
8.5.3 Optimizing InnoDB Logging	907
8.5.4 Bulk Data Loading for InnoDB Tables	907
8.5.5 Optimizing InnoDB Queries	908
8.5.6 Optimizing InnoDB DDL Operations	909
8.5.7 Optimizing InnoDB Disk I/O	909
8.5.8 Optimizing InnoDB Configuration Variables	910
8.5.9 Optimizing InnoDB for Systems with Many Tables	911
8.6 Optimizing for MyISAM Tables	911
8.6.1 Optimizing MyISAM Queries	911
8.6.2 Bulk Data Loading for MyISAM Tables	913
8.6.3 Speed of REPAIR TABLE Statements	914
8.7 Optimizing for MEMORY Tables	916
8.8 Understanding the Query Execution Plan	916
8.8.1 Optimizing Queries with EXPLAIN	916
8.8.2 EXPLAIN Output Format	917
8.8.3 EXPLAIN EXTENDED Output Format	928
8.8.4 Estimating Query Performance	929
8.8.5 Controlling the Query Optimizer	929
8.9 Buffering and Caching	932
8.9.1 The InnoDB Buffer Pool	932
8.9.2 The MyISAM Key Cache	935
8.9.3 The MySQL Query Cache	939
8.10 Optimizing Locking Operations	945
8.10.1 Internal Locking Methods	946
8.10.2 Table Locking Issues	948
8.10.3 Concurrent Inserts	949
8.10.4 Metadata Locking	950
8.10.5 External Locking	951
8.11 Optimizing the MySQL Server	952
8.11.1 System Factors and Startup Parameter Tuning	952
8.11.2 Tuning Server Parameters	952
8.11.3 Optimizing Disk I/O	959
8.11.4 Optimizing Memory Use	963
8.11.5 Optimizing Network Use	967
8.11.6 The Thread Pool Plugin	969
8.12 Measuring Performance (Benchmarking)	975
8.12.1 Measuring the Speed of Expressions and Functions	975
8.12.2 The MySQL Benchmark Suite	975
8.12.3 Using Your Own Benchmarks	976
8.12.4 Measuring Performance with performance_schema	977
8.12.5 Examining Thread Information	977
9 Language Structure	993
9.1 Literal Values	993
9.1.1 String Literals	993
9.1.2 Number Literals	996
9.1.3 Date and Time Literals	996
9.1.4 Hexadecimal Literals	998
9.1.5 Boolean Literals	999
9.1.6 Bit-Field Literals	999

9.1.7	NULL Values	1000
9.2	Schema Object Names	1000
9.2.1	Identifier Qualifiers	1002
9.2.2	Identifier Case Sensitivity	1003
9.2.3	Mapping of Identifiers to File Names	1005
9.2.4	Function Name Parsing and Resolution	1007
9.3	Reserved Words	1010
9.4	User-Defined Variables	1013
9.5	Expression Syntax	1016
9.6	Comment Syntax	1018
10	Globalization	1021
10.1	Character Set Support	1021
10.1.1	Character Sets and Collations in General	1022
10.1.2	Character Sets and Collations in MySQL	1023
10.1.3	Specifying Character Sets and Collations	1024
10.1.4	Connection Character Sets and Collations	1031
10.1.5	Configuring the Character Set and Collation for Applications	1034
10.1.6	Character Set for Error Messages	1036
10.1.7	Collation Issues	1037
10.1.8	String Repertoire	1047
10.1.9	Operations Affected by Character Set Support	1049
10.1.10	Unicode Support	1052
10.1.11	Upgrading from Previous to Current Unicode Support	1056
10.1.12	UTF-8 for Metadata	1058
10.1.13	Column Character Set Conversion	1059
10.1.14	Character Sets and Collations That MySQL Supports	1061
10.2	Setting the Error Message Language	1073
10.3	Adding a Character Set	1074
10.3.1	Character Definition Arrays	1076
10.3.2	String Collating Support for Complex Character Sets	1077
10.3.3	Multi-Byte Character Support for Complex Character Sets	1078
10.4	Adding a Collation to a Character Set	1078
10.4.1	Collation Implementation Types	1079
10.4.2	Choosing a Collation ID	1080
10.4.3	Adding a Simple Collation to an 8-Bit Character Set	1081
10.4.4	Adding a UCA Collation to a Unicode Character Set	1082
10.5	Character Set Configuration	1086
10.6	MySQL Server Time Zone Support	1087
10.6.1	Staying Current with Time Zone Changes	1089
10.6.2	Time Zone Leap Second Support	1091
10.7	MySQL Server Locale Support	1092
11	Data Types	1095
11.1	Data Type Overview	1096
11.1.1	Numeric Type Overview	1096
11.1.2	Date and Time Type Overview	1099
11.1.3	String Type Overview	1101
11.2	Numeric Types	1104
11.2.1	Integer Types (Exact Value) - <code>INTEGER</code> , <code>INT</code> , <code>SMALLINT</code> , <code>TINYINT</code> , <code>MEDIUMINT</code> , <code>BIGINT</code>	1105
11.2.2	Fixed-Point Types (Exact Value) - <code>DECIMAL</code> , <code>NUMERIC</code>	1105
11.2.3	Floating-Point Types (Approximate Value) - <code>FLOAT</code> , <code>DOUBLE</code>	1106
11.2.4	Bit-Value Type - <code>BIT</code>	1106
11.2.5	Numeric Type Attributes	1106
11.2.6	Out-of-Range and Overflow Handling	1107

11.3 Date and Time Types	1109
11.3.1 The <code>DATE</code> , <code>DATETIME</code> , and <code>TIMESTAMP</code> Types	1110
11.3.2 The <code>TIME</code> Type	1111
11.3.3 The <code>YEAR</code> Type	1112
11.3.4 <code>YEAR(2)</code> Limitations and Migrating to <code>YEAR(4)</code>	1113
11.3.5 Automatic Initialization and Updating for <code>TIMESTAMP</code>	1114
11.3.6 Fractional Seconds in Time Values	1117
11.3.7 Conversion Between Date and Time Types	1118
11.3.8 Two-Digit Years in Dates	1118
11.4 String Types	1119
11.4.1 The <code>CHAR</code> and <code>VARCHAR</code> Types	1119
11.4.2 The <code>BINARY</code> and <code>VARBINARY</code> Types	1121
11.4.3 The <code>BLOB</code> and <code>TEXT</code> Types	1122
11.4.4 The <code>ENUM</code> Type	1123
11.4.5 The <code>SET</code> Type	1126
11.5 Extensions for Spatial Data	1129
11.5.1 Spatial Data Types	1130
11.5.2 The OpenGIS Geometry Model	1131
11.5.3 Using Spatial Data	1137
11.6 Data Type Default Values	1144
11.7 Data Type Storage Requirements	1145
11.8 Choosing the Right Type for a Column	1149
11.9 Using Data Types from Other Database Engines	1149
12 Functions and Operators	1151
12.1 Function and Operator Reference	1152
12.2 Type Conversion in Expression Evaluation	1161
12.3 Operators	1164
12.3.1 Operator Precedence	1165
12.3.2 Comparison Functions and Operators	1166
12.3.3 Logical Operators	1172
12.3.4 Assignment Operators	1174
12.4 Control Flow Functions	1175
12.5 String Functions	1177
12.5.1 String Comparison Functions	1190
12.5.2 Regular Expressions	1193
12.6 Numeric Functions and Operators	1199
12.6.1 Arithmetic Operators	1200
12.6.2 Mathematical Functions	1203
12.7 Date and Time Functions	1212
12.8 What Calendar Is Used By MySQL?	1234
12.9 Full-Text Search Functions	1235
12.9.1 Natural Language Full-Text Searches	1236
12.9.2 Boolean Full-Text Searches	1239
12.9.3 Full-Text Searches with Query Expansion	1241
12.9.4 Full-Text Stopwords	1242
12.9.5 Full-Text Restrictions	1245
12.9.6 Fine-Tuning MySQL Full-Text Search	1246
12.9.7 Adding a Collation for Full-Text Indexing	1248
12.10 Cast Functions and Operators	1250
12.11 XML Functions	1253
12.12 Bit Functions	1264
12.13 Encryption and Compression Functions	1266
12.14 Information Functions	1273
12.15 Miscellaneous Functions	1283

12.16 Functions and Modifiers for Use with <code>GROUP BY</code> Clauses	1288
12.16.1 <code>GROUP BY</code> (Aggregate) Functions	1288
12.16.2 <code>GROUP BY</code> Modifiers	1292
12.16.3 MySQL Extensions to <code>GROUP BY</code>	1295
12.17 Spatial Analysis Functions	1296
12.17.1 Spatial Function Reference	1297
12.17.2 Functions That Create Geometry Values from WKT Values	1299
12.17.3 Functions That Create Geometry Values from WKB Values	1299
12.17.4 MySQL-Specific Functions That Create Geometry Values	1300
12.17.5 Geometry Format Conversion Functions	1301
12.17.6 Geometry Property Functions	1301
12.17.7 Spatial Operator Functions	1308
12.17.8 Functions That Test Spatial Relations Between Geometry Objects	1308
12.18 Precision Math	1311
12.18.1 Types of Numeric Values	1311
12.18.2 <code>DECIMAL</code> Data Type Characteristics	1312
12.18.3 Expression Handling	1313
12.18.4 Rounding Behavior	1314
12.18.5 Precision Math Examples	1315
13 SQL Statement Syntax	1321
13.1 Data Definition Statements	1322
13.1.1 <code>ALTER DATABASE</code> Syntax	1322
13.1.2 <code>ALTER EVENT</code> Syntax	1323
13.1.3 <code>ALTER LOGFILE GROUP</code> Syntax	1325
13.1.4 <code>ALTER FUNCTION</code> Syntax	1326
13.1.5 <code>ALTER PROCEDURE</code> Syntax	1327
13.1.6 <code>ALTER SERVER</code> Syntax	1327
13.1.7 <code>ALTER TABLE</code> Syntax	1327
13.1.8 <code>ALTER TABLESPACE</code> Syntax	1348
13.1.9 <code>ALTER VIEW</code> Syntax	1349
13.1.10 <code>CREATE DATABASE</code> Syntax	1349
13.1.11 <code>CREATE EVENT</code> Syntax	1350
13.1.12 <code>CREATE FUNCTION</code> Syntax	1355
13.1.13 <code>CREATE INDEX</code> Syntax	1355
13.1.14 <code>CREATE LOGFILE GROUP</code> Syntax	1358
13.1.15 <code>CREATE PROCEDURE</code> and <code>CREATE FUNCTION</code> Syntax	1360
13.1.16 <code>CREATE SERVER</code> Syntax	1365
13.1.17 <code>CREATE TABLE</code> Syntax	1366
13.1.18 <code>CREATE TABLESPACE</code> Syntax	1396
13.1.19 <code>CREATE TRIGGER</code> Syntax	1398
13.1.20 <code>CREATE VIEW</code> Syntax	1400
13.1.21 <code>DROP DATABASE</code> Syntax	1404
13.1.22 <code>DROP EVENT</code> Syntax	1405
13.1.23 <code>DROP FUNCTION</code> Syntax	1405
13.1.24 <code>DROP INDEX</code> Syntax	1405
13.1.25 <code>DROP LOGFILE GROUP</code> Syntax	1406
13.1.26 <code>DROP PROCEDURE</code> and <code>DROP FUNCTION</code> Syntax	1406
13.1.27 <code>DROP SERVER</code> Syntax	1406
13.1.28 <code>DROP TABLE</code> Syntax	1407
13.1.29 <code>DROP TABLESPACE</code> Syntax	1407
13.1.30 <code>DROP TRIGGER</code> Syntax	1408
13.1.31 <code>DROP VIEW</code> Syntax	1408
13.1.32 <code>RENAME TABLE</code> Syntax	1408
13.1.33 <code>TRUNCATE TABLE</code> Syntax	1409

13.2 Data Manipulation Statements	1410
13.2.1 <code>CALL</code> Syntax	1410
13.2.2 <code>DELETE</code> Syntax	1412
13.2.3 <code>DO</code> Syntax	1416
13.2.4 <code>HANDLER</code> Syntax	1417
13.2.5 <code>INSERT</code> Syntax	1418
13.2.6 <code>LOAD DATA INFILE</code> Syntax	1427
13.2.7 <code>LOAD XML</code> Syntax	1436
13.2.8 <code>REPLACE</code> Syntax	1442
13.2.9 <code>SELECT</code> Syntax	1444
13.2.10 Subquery Syntax	1463
13.2.11 <code>UPDATE</code> Syntax	1476
13.3 MySQL Transactional and Locking Statements	1478
13.3.1 <code>START TRANSACTION</code> , <code>COMMIT</code> , and <code>ROLLBACK</code> Syntax	1478
13.3.2 Statements That Cannot Be Rolled Back	1480
13.3.3 Statements That Cause an Implicit Commit	1481
13.3.4 <code>SAVEPOINT</code> , <code>ROLLBACK TO SAVEPOINT</code> , and <code>RELEASE SAVEPOINT</code> Syntax	1482
13.3.5 <code>LOCK TABLES</code> and <code>UNLOCK TABLES</code> Syntax	1482
13.3.6 <code>SET TRANSACTION</code> Syntax	1489
13.3.7 XA Transactions	1491
13.4 Replication Statements	1495
13.4.1 SQL Statements for Controlling Master Servers	1495
13.4.2 SQL Statements for Controlling Slave Servers	1497
13.5 SQL Syntax for Prepared Statements	1504
13.5.1 <code>PREPARE</code> Syntax	1507
13.5.2 <code>EXECUTE</code> Syntax	1508
13.5.3 <code>DEALLOCATE PREPARE</code> Syntax	1508
13.5.4 Automatic Prepared Statement Repreparation	1508
13.6 MySQL Compound-Statement Syntax	1509
13.6.1 <code>BEGIN ... END</code> Compound-Statement Syntax	1509
13.6.2 Statement Label Syntax	1510
13.6.3 <code>DECLARE</code> Syntax	1510
13.6.4 Variables in Stored Programs	1511
13.6.5 Flow Control Statements	1512
13.6.6 Cursors	1517
13.6.7 Condition Handling	1519
13.7 Database Administration Statements	1534
13.7.1 Account Management Statements	1534
13.7.2 Table Maintenance Statements	1550
13.7.3 Plugin and User-Defined Function Statements	1558
13.7.4 <code>SET</code> Syntax	1561
13.7.5 <code>SHOW</code> Syntax	1565
13.7.6 Other Administrative Statements	1607
13.8 MySQL Utility Statements	1615
13.8.1 <code>DESCRIBE</code> Syntax	1615
13.8.2 <code>EXPLAIN</code> Syntax	1615
13.8.3 <code>HELP</code> Syntax	1616
13.8.4 <code>USE</code> Syntax	1618
14 The <code>InnoDB</code> Storage Engine	1621
14.1 Introduction to <code>InnoDB 1.1</code>	1623
14.1.1 Features of the <code>InnoDB</code> Storage Engine	1624
14.1.2 <code>InnoDB</code> as the Default MySQL Storage Engine	1626
14.1.3 Checking <code>InnoDB</code> Availability	1629
14.1.4 Turning Off <code>InnoDB</code>	1629

14.1.5	Obtaining and Installing the InnoDB Storage Engine	1629
14.1.6	Viewing the InnoDB Storage Engine Version Number	1630
14.1.7	Compatibility Considerations for Downgrade and Backup	1630
14.1.8	InnoDB Storage Engine Change History	1631
14.1.9	Third-Party Software Contributions	1632
14.2	Installing the InnoDB Storage Engine	1635
14.3	Upgrading the InnoDB Storage Engine	1635
14.4	Downgrading the InnoDB Storage Engine	1635
14.4.1	Overview	1635
14.5	InnoDB Concepts and Architecture	1635
14.5.1	MySQL and the ACID Model	1636
14.5.2	The InnoDB Transaction Model and Locking	1637
14.5.3	InnoDB Lock Modes	1638
14.5.4	Consistent Nonlocking Reads	1640
14.5.5	Locking Reads (<code>SELECT ... FOR UPDATE</code> and <code>SELECT ... LOCK IN SHARE MODE</code>)	1642
14.5.6	InnoDB Record, Gap, and Next-Key Locks	1644
14.5.7	Avoiding the Phantom Problem Using Next-Key Locking	1645
14.5.8	Locks Set by Different SQL Statements in InnoDB	1646
14.5.9	Implicit Transaction Commit and Rollback	1649
14.5.10	Deadlock Detection and Rollback	1649
14.5.11	How to Cope with Deadlocks	1650
14.5.12	InnoDB Multi-Versioning	1651
14.5.13	InnoDB Table and Index Structures	1652
14.6	InnoDB Configuration	1656
14.7	InnoDB Administration	1661
14.8	InnoDB Tablespace Management	1661
14.8.1	Creating the InnoDB Tablespace	1661
14.8.2	InnoDB File-Per-Table Mode	1662
14.8.3	Enabling and Disabling File-Per-Table Mode	1665
14.8.4	Changing the Number or Size of InnoDB Log Files and Resizing the InnoDB Tablespace	1666
14.8.5	Using Raw Disk Partitions for the Shared Tablespace	1668
14.9	InnoDB Table Management	1669
14.9.1	Creating InnoDB Tables	1669
14.9.2	Moving or Copying InnoDB Tables to Another Machine	1670
14.9.3	Grouping DML Operations with Transactions	1671
14.9.4	Converting Tables from MyISAM to InnoDB	1671
14.9.5	<code>AUTO_INCREMENT</code> Handling in InnoDB	1676
14.9.6	InnoDB and <code>FOREIGN KEY</code> Constraints	1682
14.9.7	Limits on InnoDB Tables	1683
14.10	InnoDB Compressed Tables	1686
14.10.1	Overview of Table Compression	1686
14.10.2	Enabling Compression for a Table	1687
14.10.3	Tuning Compression for InnoDB Tables	1688
14.10.4	Monitoring Compression at Runtime	1691
14.10.5	How Compression Works for InnoDB Tables	1692
14.10.6	SQL Compression Syntax Warnings and Errors	1695
14.11	InnoDB File-Format Management	1697
14.11.1	Enabling File Formats	1698
14.11.2	Verifying File Format Compatibility	1698
14.11.3	Identifying the File Format in Use	1702
14.11.4	Downgrading the File Format	1703
14.11.5	Future InnoDB File Formats	1703

14.12	InnoDB Row Storage and Row Formats	1703
14.12.1	Overview of InnoDB Row Storage	1704
14.12.2	Specifying the Row Format for a Table	1704
14.12.3	DYNAMIC and COMPRESSED Row Formats	1704
14.12.4	COMPACT and REDUNDANT Row Formats	1705
14.13	InnoDB Disk I/O and File Space Management	1705
14.13.1	InnoDB Disk I/O	1706
14.13.2	File Space Management	1706
14.13.3	InnoDB Checkpoints	1707
14.13.4	Defragmenting a Table	1708
14.13.5	Reclaiming Disk Space with TRUNCATE TABLE	1708

14.21	InnoDB Troubleshooting	1788
14.21.1	Troubleshooting InnoDB I/O Problems	1788
14.21.2	Starting InnoDB on a Corrupted Database	1789
14.21.3	Troubleshooting InnoDB Data Dictionary Operations	1790

14.21.4 InnoDB Error Handling	1792
14.21.5 InnoDB Error Codes	1793
14.21.6 Operating System Error Codes	1795
15 Alternative Storage Engines	1799
15.1 Setting the Storage Engine	1803
15.2 Overview of MySQL Storage Engine Architecture	1804
15.2.1 Pluggable Storage Engine Architecture	1804
15.2.2 The Common Database Server Layer	1805
15.3 The MyISAM Storage Engine	1805
15.3.1 MyISAM Startup Options	1808
15.3.2 Space Needed for Keys	1810
15.3.3 MyISAM Table Storage Formats	1810
15.3.4 MyISAM Table Problems	1812
15.4 The MEMORY Storage Engine	1814
15.5 The CSV Storage Engine	1818
15.5.1 Repairing and Checking CSV Tables	1819
15.5.2 CSV Limitations	1820
15.6 The ARCHIVE Storage Engine	1820
15.7 The BLACKHOLE Storage Engine	1821
15.8 The MERGE Storage Engine	1824
15.8.1 MERGE Table Advantages and Disadvantages	1826
15.8.2 MERGE Table Problems	1827
15.9 The FEDERATED Storage Engine	1829
15.9.1 FEDERATED Storage Engine Overview	1829
15.9.2 How to Create FEDERATED Tables	1830
15.9.3 FEDERATED Storage Engine Notes and Tips	1833
15.9.4 FEDERATED Storage Engine Resources	1834
15.10 The EXAMPLE Storage Engine	1834
15.11 Other Storage Engines	1835
16 High Availability and Scalability	1837
16.1 Oracle VM Template for MySQL Enterprise Edition	1840
16.2 Overview of MySQL with DRBD/Pacemaker/Corosync/Oracle Linux	1841
16.3 Overview of MySQL with Windows Failover Clustering	1843
16.4 Using MySQL within an Amazon EC2 Instance	1845
16.4.1 Setting Up MySQL on an EC2 AMI	1846
16.4.2 EC2 Instance Limitations	1847
16.4.3 Deploying a MySQL Database Using EC2	1847
16.5 Using ZFS Replication	1850
16.5.1 Using ZFS for File System Replication	1852
16.5.2 Configuring MySQL for ZFS Replication	1853
16.5.3 Handling MySQL Recovery with ZFS	1853
16.6 Using MySQL with memcached	1854
16.6.1 Installing memcached	1855
16.6.2 Using memcached	1856
16.6.3 Developing a memcached Application	1876
16.6.4 Getting memcached Statistics	1902
16.6.5 memcached FAQ	1911
16.7 MySQL Proxy	1914
16.7.1 MySQL Proxy Supported Platforms	1915
16.7.2 Installing MySQL Proxy	1915
16.7.3 MySQL Proxy Command Options	1918
16.7.4 MySQL Proxy Scripting	1928
16.7.5 Using MySQL Proxy	1943
16.7.6 MySQL Proxy FAQ	1949

17 Replication	1955
17.1 Replication Configuration	1956
17.1.1 How to Set Up Replication	1957
17.1.2 Replication Formats	1966
17.1.3 Replication and Binary Logging Options and Variables	1974
17.1.4 Common Replication Administration Tasks	2023
17.2 Replication Implementation	2026
17.2.1 Replication Implementation Details	2026
17.2.2 Replication Relay and Status Logs	2028
17.2.3 How Servers Evaluate Replication Filtering Rules	2031
17.3 Replication Solutions	2037
17.3.1 Using Replication for Backups	2038
17.3.2 Using Replication with Different Master and Slave Storage Engines	2041
17.3.3 Using Replication for Scale-Out	2043
17.3.4 Replicating Different Databases to Different Slaves	2044
17.3.5 Improving Replication Performance	2045
17.3.6 Switching Masters During Failover	2046
17.3.7 Setting Up Replication Using SSL	2049
17.3.8 Semisynchronous Replication	2050
17.4 Replication Notes and Tips	2055
17.4.1 Replication Features and Issues	2055
17.4.2 Replication Compatibility Between MySQL Versions	2081
17.4.3 Upgrading a Replication Setup	2082
17.4.4 Troubleshooting Replication	2083
17.4.5 How to Report Replication Bugs or Problems	2084
18 MySQL Cluster NDB 7.2	2087
18.1 MySQL Cluster Overview	2091
18.1.1 MySQL Cluster Core Concepts	2092
18.1.2 MySQL Cluster Nodes, Node Groups, Replicas, and Partitions	2095
18.1.3 MySQL Cluster Hardware, Software, and Networking Requirements	2098
18.1.4 MySQL Cluster Development History	2100
18.1.5 MySQL Server Using InnoDB Compared with MySQL Cluster	2102
18.1.6 Known Limitations of MySQL Cluster	2106
18.2 MySQL Cluster Installation and Upgrades	2117
18.2.1 Installing MySQL Cluster on Linux	2119
18.2.2 Installing MySQL Cluster on Windows	2125
18.2.3 Initial Configuration of MySQL Cluster	2135
18.2.4 Initial Startup of MySQL Cluster	2136
18.2.5 MySQL Cluster Example with Tables and Data	2137
18.2.6 Safe Shutdown and Restart of MySQL Cluster	2141
18.2.7 Upgrading and Downgrading MySQL Cluster NDB 7.2	2142
18.3 Configuration of MySQL Cluster NDB 7.2	2144
18.3.1 Quick Test Setup of MySQL Cluster	2145
18.3.2 MySQL Cluster Configuration Files	2147
18.3.3 Overview of MySQL Cluster Configuration Parameters	2243
18.3.4 MySQL Server Options and Variables for MySQL Cluster	2269
18.3.5 Using High-Speed Interconnects with MySQL Cluster	2320
18.4 MySQL Cluster Programs	2322
18.4.1 ndbd — The MySQL Cluster Data Node Daemon	2322
18.4.2 ndbinfo_select_all — Select From ndbinfo Tables	2329
18.4.3 ndbmtd — The MySQL Cluster Data Node Daemon (Multi-Threaded)	2330
18.4.4 ndb_mgmd — The MySQL Cluster Management Server Daemon	2332
18.4.5 ndb_mgm — The MySQL Cluster Management Client	2340

18.4.6 <code>ndb_blob_tool</code> — Check and Repair BLOB and TEXT columns of MySQL Cluster Tables	2342
18.4.7 <code>ndb_config</code> — Extract MySQL Cluster Configuration Information	2344
18.4.8 <code>ndb_cpcd</code> — Automate Testing for NDB Development	2352
18.4.9 <code>ndb_delete_all</code> — Delete All Rows from an NDB Table	2353
18.4.10 <code>ndb_desc</code> — Describe NDB Tables	2353
18.4.11 <code>ndb_drop_index</code> — Drop Index from an NDB Table	2358
18.4.12 <code>ndb_drop_table</code> — Drop an NDB Table	2359
18.4.13 <code>ndb_error_reporter</code> — NDB Error-Reporting Utility	2360
18.4.14 <code>ndb_index_stat</code> — NDB Index Statistics Utility	2361
18.4.15 <code>ndb_print_backup_file</code> — Print NDB Backup File Contents	2367
18.4.16 <code>ndb_print_schema_file</code> — Print NDB Schema File Contents	2367
18.4.17 <code>ndb_print_sys_file</code> — Print NDB System File Contents	2367
18.4.18 <code>ndbd_redo_log_reader</code> — Check and Print Content of Cluster Redo Log	2368
18.4.19 <code>ndb_restore</code> — Restore a MySQL Cluster Backup	2369
18.4.20 <code>ndb_select_all</code> — Print Rows from an NDB Table	2383
18.4.21 <code>ndb_select_count</code> — Print Row Counts for NDB Tables	2386
18.4.22 <code>ndb_show_tables</code> — Display List of NDB Tables	2387
18.4.23 <code>ndb_size.pl</code> — NDBCLUSTER Size Requirement Estimator	2389
18.4.24 <code>ndb_waiter</code> — Wait for MySQL Cluster to Reach a Given Status	2391
18.4.25 Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs	2394
18.5 Management of MySQL Cluster	2397
18.5.1 Summary of MySQL Cluster Start Phases	2399
18.5.2 Commands in the MySQL Cluster Management Client	2400

Preface and Legal Notices

This is the Reference Manual for the MySQL Database System, version 5.5, through release 5.5.40. Differences between minor versions of MySQL 5.5 are noted in the present text with reference to release numbers (5.5.x). For license information, see the [Legal Notices](#). This product may contain third-party code. For license information on third-party code, see [Appendix E, Licenses for Third-Party Components](#).

This manual is not intended for use with older versions of the MySQL software due to the many functional and other differences between MySQL 5.5 and previous versions. If you are using an earlier release of the MySQL software, please refer to the appropriate manual. For example, [MySQL 5.1 Reference Manual](#) covers the 5.1 series of MySQL software releases.

If you are using MySQL 5.6, please refer to the [MySQL 5.6 Reference Manual](#).

This software and related documentation are provided under a license agreement containing restrictions on use and disclosure and are protected by intellectual property laws. Except as expressly permitted in your license agreement or allowed by law, you may not use, copy, reproduce, translate, broadcast, modify, license, transmit, distribute, exhibit, perform, publish, or display any part, in any form, or by any means. Reverse engineering, disassembly, or decompilation of this software, unless required by law for interoperability, is prohibited.

The information contained herein is subject to change without notice and is not warranted to be error-free. If you find any errors, please report them to us in writing.

If this software or related documentation is delivered to the U.S. Government or anyone licensing it on behalf of the U.S. Government, the following notice is applicable:

U.S. GOVERNMENT RIGHTS Programs, software, databases, and related documentation and technical data delivered to U.S. Government customers are "commercial computer software" or "commercial technical data" pursuant to the applicable Federal Acquisition Regulation and agency-specific supplemental regulations. As such, the use, duplication, disclosure, modification, and adaptation shall be subject to the restrictions and license terms set forth in the applicable Government contract, and, to the extent applicable by the terms of the Government contract, the additional rights set forth in FAR 52.227-19, Commercial Computer Software License (December 2007). Oracle USA, Inc., 500 Oracle Parkway, Redwood City, CA 94065.

This software is developed for general use in a variety of information management applications. It is not developed or intended for use in any inherently dangerous applications, including applications which may create a risk of personal injury. If you use this software in dangerous applications, then you shall be responsible to take all appropriate fail-safe, backup, redundancy, and other measures to ensure the safe use of this software. Oracle Corporation and its affiliates disclaim any liability for any damages caused by use of this software in dangerous applications.

Oracle is a registered trademark of Oracle Corporation and/or its affiliates. MySQL is a trademark of Oracle Corporation and/or its affiliates, and shall not be used without Oracle's express written authorization. Other names may be trademarks of their respective owners.

This software and documentation may provide access to or information on content, products, and services from third parties. Oracle Corporation and its affiliates are not responsible for and expressly disclaim all warranties of any kind with respect to third-party content, products, and services. Oracle Corporation and

its affiliates will not be responsible for any loss, costs, or damages incurred due to your access to or use of third-party content, products, or services.

This document in any form, software or printed matter, contains proprietary information that is the exclusive property of Oracle. Your access to and use of this material is subject to the terms and conditions of your Oracle Software License and Service Agreement, which has been executed and with which you agree to comply. This document and information contained herein may not be disclosed, copied, reproduced, or distributed to anyone outside Oracle without prior written consent of Oracle or as specifically provided below. This document is not part of your license agreement nor can it be incorporated into any contractual agreement with Oracle or its subsidiaries or affiliates.

This documentation is NOT distributed under a GPL license. Use of this documentation is subject to the following terms:

You may create a printed copy of this documentation solely for your own personal use. Conversion to other formats is allowed as long as the actual content is not altered or edited in any way. You shall not publish or distribute this documentation in any form or on any media, except if you distribute the documentation in a manner similar to how Oracle disseminates it (that is, electronically for download on a Web site with the software) or on a CD-ROM or similar medium, provided however that the documentation is disseminated together with the software on the same medium. Any other use, such as any dissemination of printed copies or use of this documentation, in whole or in part, in another publication, requires the prior written consent from an authorized representative of Oracle. Oracle and/or its affiliates reserve any and all rights to this documentation not expressly granted above.

For more information on the terms of this license, or for details on how the MySQL documentation is built and produced, please visit [MySQL Contact & Questions](#).

For additional licensing information, including licenses for third-party libraries used by MySQL products, see [Preface and Legal Notices](#).

For help with using MySQL, please visit either the [MySQL Forums](#) or [MySQL Mailing Lists](#) where you can discuss your issues with other MySQL users.

For additional documentation on MySQL products, including translations of the documentation into other languages, and downloadable versions in variety of formats, including HTML and PDF formats, see the [MySQL Documentation Library](#).

Chapter 1 General Information

Table of Contents

1.1 About This Manual	2
1.2 Typographical and Syntax Conventions	3
1.3 Overview of the MySQL Database Management System	5
1.3.1 What is MySQL?	5
1.3.2 The Main Features of MySQL	6
1.3.3 History of MySQL	9
1.4 What Is New in MySQL 5.5	9
1.4.1 Scalability Improvements	14
1.4.2 InnoDB I/O Subsystem Changes	15
1.4.3 Diagnostic and Monitoring Capabilities	15
1.4.4 Enhanced Solaris Support	16
1.5 MySQL Development History	17
1.6 MySQL Information Sources	17
1.6.1 MySQL Mailing Lists	17
1.6.2 MySQL Community Support at the MySQL Forums	20
1.6.3 MySQL Community Support on Internet Relay Chat (IRC)	20
1.6.4 MySQL Enterprise	21
1.7 How to Report Bugs or Problems	21
1.8 MySQL Standards Compliance	25
1.8.1 MySQL Extensions to Standard SQL	27
1.8.2 MySQL Differences from Standard SQL	30
1.8.3 How MySQL Deals with Constraints	34
1.9 Credits	38
1.9.1 Contributors to MySQL	38
1.9.2 Documenters and translators	42
1.9.3 Packages that support MySQL	44
1.9.4 Tools that were used to create MySQL	44
1.9.5 Supporters of MySQL	45

The MySQL™ software delivers a very fast, multi-threaded, multi-user, and robust SQL (Structured Query Language) database server. MySQL Server is intended for mission-critical, heavy-load production systems as well as for embedding into mass-deployed software. Oracle is a registered trademark of Oracle Corporation and/or its affiliates. MySQL is a trademark of Oracle Corporation and/or its affiliates, and shall not be used by Customer without Oracle's express written authorization. Other names may be trademarks of their respective owners.

The MySQL software is Dual Licensed. Users can choose to use the MySQL software as an Open Source product under the terms of the GNU General Public License (<http://www.fsf.org/licenses/>) or can purchase a standard commercial license from Oracle. See <http://www.mysql.com/company/legal/licensing/> for more information on our licensing policies.

The following list describes some sections of particular interest in this manual:

- For a discussion of MySQL Database Server capabilities, see [Section 1.3.2, “The Main Features of MySQL”](#).
- For an overview of new MySQL features, see [Section 1.4, “What Is New in MySQL 5.5”](#). For information about the changes in each version, see the [Release Notes](#).

- For installation instructions, see [Chapter 2, *Installing and Upgrading MySQL*](#). For information about upgrading MySQL, see [Section 2.11.1, “Upgrading MySQL”](#).
- For a tutorial introduction to the MySQL Database Server, see [Chapter 3, *Tutorial*](#).
- For information about configuring and administering MySQL Server, see [Chapter 5, *MySQL Server Administration*](#).
- For information about security in MySQL, see [Chapter 6, *Security*](#).
- For information about setting up replication servers, see [Chapter 17, *Replication*](#).
- For information about MySQL Enterprise, the commercial MySQL release with advanced features and management tools, see [Chapter 25, *MySQL Enterprise Edition*](#).
- For answers to a number of questions that are often asked concerning the MySQL Database Server and its capabilities, see [Appendix A, *MySQL 5.5 Frequently Asked Questions*](#).
- For a history of new features and bug fixes, see the [Release Notes](#).

**Important**

To report problems or bugs, please use the instructions at [Section 1.7, “How to Report Bugs or Problems”](#). If you find a sensitive security bug in MySQL Server, please let us know immediately by sending an email message to [<secalert_us@oracle.com>](mailto:secalert_us@oracle.com). Exception: Support customers should report all problems, including security bugs, to Oracle Support.

1.1 About This Manual

This is the Reference Manual for the MySQL Database System, version 5.5, through release 5.5.40. Differences between minor versions of MySQL 5.5 are noted in the present text with reference to release numbers (5.5.x). For license information, see the [Legal Notices](#). This product may contain third-party code. For license information on third-party code, see [Appendix E, *Licenses for Third-Party Components*](#).

This manual is not intended for use with older versions of the MySQL software due to the many functional and other differences between MySQL 5.5 and previous versions. If you are using an earlier release of the MySQL software, please refer to the appropriate manual. For example, [MySQL 5.1 Reference Manual](#) covers the 5.1 series of MySQL software releases.

If you are using MySQL 5.6, please refer to the [MySQL 5.6 Reference Manual](#).

Because this manual serves as a reference, it does not provide general instruction on SQL or relational database concepts. It also does not teach you how to use your operating system or command-line interpreter.

The MySQL Database Software is under constant development, and the Reference Manual is updated frequently as well. The most recent version of the manual is available online in searchable form at <http://dev.mysql.com/doc/>. Other formats also are available there, including HTML, PDF, and EPUB versions.

The Reference Manual source files are written in DocBook XML format. The HTML version and other formats are produced automatically, primarily using the DocBook XSL stylesheets. For information about DocBook, see <http://docbook.org/>

If you have questions about using MySQL, you can ask them using our mailing lists or forums. See [Section 1.6.1, “MySQL Mailing Lists”](#), and [Section 1.6.2, “MySQL Community Support at the MySQL](#)

[Forums](#)". If you have suggestions concerning additions or corrections to the manual itself, please send them to the <http://www.mysql.com/company/contact/>.

This manual was originally written by David Axmark and Michael "Monty" Widenius. It is maintained by the MySQL Documentation Team, consisting of Paul DuBois, Stefan Hinz, Philip Olson, Daniel Price, Daniel So, Edward Gilmore, and Jon Stephens.

1.2 Typographical and Syntax Conventions

This manual uses certain typographical conventions:

- *Text in this style* is used for SQL statements; database, table, and column names; program listings and source code; and environment variables. Example: "To reload the grant tables, use the `FLUSH PRIVILEGES` statement."
- *Text in this style* indicates input that you type in examples.
- *Text in this style* indicates the names of executable programs and scripts, examples being `mysql` (the MySQL command-line client program) and `mysqld` (the MySQL server executable).
- *Text in this style* is used for variable input for which you should substitute a value of your own choosing.
- *Text in this style* is used for emphasis.
- **Text in this style** is used in table headings and to convey especially strong emphasis.
- *Text in this style* is used to indicate a program option that affects how the program is executed, or that supplies information that is needed for the program to function in a certain way. *Example*: "The `--host` option (short form `-h`) tells the `mysql` client program the hostname or IP address of the MySQL server that it should connect to".
- File names and directory names are written like this: "The global `my.cnf` file is located in the `/etc` directory."
- Character sequences are written like this: "To specify a wildcard, use the `'%'` character."

When commands are shown that are meant to be executed from within a particular program, the prompt shown preceding the command indicates which command to use. For example, `shell>` indicates a command that you execute from your login shell, `root-shell>` is similar but should be executed as `root`, and `mysql>` indicates a statement that you execute from the `mysql` client program:

```
shell> type a shell command here
root-shell> type a shell command as root here
mysql> type a mysql statement here
```

In some areas different systems may be distinguished from each other to show that commands should be executed in two different environments. For example, while working with replication the commands might be prefixed with `master` and `slave`:

```
master> type a mysql command on the replication master here
slave> type a mysql command on the replication slave here
```

The "shell" is your command interpreter. On Unix, this is typically a program such as `sh`, `csh`, or `bash`. On Windows, the equivalent program is `command.com` or `cmd.exe`, typically run in a console window.

When you enter a command or statement shown in an example, do not type the prompt shown in the example.

Database, table, and column names must often be substituted into statements. To indicate that such substitution is necessary, this manual uses *db_name*, *tbl_name*, and *col_name*. For example, you might see a statement like this:

```
mysql> SELECT col_name FROM db_name.tbl_name;
```

This means that if you were to enter a similar statement, you would supply your own database, table, and column names, perhaps like this:

```
mysql> SELECT author_name FROM biblio_db.author_list;
```

SQL keywords are not case sensitive and may be written in any lettercase. This manual uses uppercase.

In syntax descriptions, square brackets (“[” and “]”) indicate optional words or clauses. For example, in the following statement, `IF EXISTS` is optional:

```
DROP TABLE [IF EXISTS] tbl_name
```

When a syntax element consists of a number of alternatives, the alternatives are separated by vertical bars (“|”). When one member from a set of choices *may* be chosen, the alternatives are listed within square brackets (“[” and “]”):

```
TRIM([[BOTH | LEADING | TRAILING] [remstr] FROM] str)
```

When one member from a set of choices *must* be chosen, the alternatives are listed within braces (“{” and “}”):

```
{DESCRIBE | DESC} tbl_name [col_name | wild]
```

An ellipsis (...) indicates the omission of a section of a statement, typically to provide a shorter version of more complex syntax. For example, `SELECT ... INTO OUTFILE` is shorthand for the form of `SELECT` statement that has an `INTO OUTFILE` clause following other parts of the statement.

An ellipsis can also indicate that the preceding syntax element of a statement may be repeated. In the following example, multiple *reset_option* values may be given, with each of those after the first preceded by commas:

```
RESET reset_option [,reset_option] ...
```

Commands for setting shell variables are shown using Bourne shell syntax. For example, the sequence to set the `CC` environment variable and run the `configure` command looks like this in Bourne shell syntax:

```
shell> CC=gcc ./configure
```

If you are using `csh` or `tcsh`, you must issue commands somewhat differently:

```
shell> setenv CC gcc
shell> ./configure
```

1.3 Overview of the MySQL Database Management System

1.3.1 What is MySQL?

MySQL, the most popular Open Source SQL database management system, is developed, distributed, and supported by Oracle Corporation.

The MySQL Web site (<http://www.mysql.com/>) provides the latest information about MySQL software.

- **MySQL is a database management system.**

A database is a structured collection of data. It may be anything from a simple shopping list to a picture gallery or the vast amounts of information in a corporate network. To add, access, and process data stored in a computer database, you need a database management system such as MySQL Server. Since computers are very good at handling large amounts of data, database management systems play a central role in computing, as standalone utilities, or as parts of other applications.

- **MySQL databases are relational.**

A relational database stores data in separate tables rather than putting all the data in one big storeroom. The database structures are organized into physical files optimized for speed. The logical model, with objects such as databases, tables, views, rows, and columns, offers a flexible programming environment. You set up rules governing the relationships between different data fields, such as one-to-one, one-to-many, unique, required or optional, and “pointers” between different tables. The database enforces these rules, so that with a well-designed database, your application never sees inconsistent, duplicate, orphan, out-of-date, or missing data.

The SQL part of “MySQL” stands for “Structured Query Language”. SQL is the most common standardized language used to access databases. Depending on your programming environment, you might enter SQL directly (for example, to generate reports), embed SQL statements into code written in another language, or use a language-specific API that hides the SQL syntax.

SQL is defined by the ANSI/ISO SQL Standard. The SQL standard has been evolving since 1986 and several versions exist. In this manual, “SQL-92” refers to the standard released in 1992, “SQL:1999” refers to the standard released in 1999, and “SQL:2003” refers to the current version of the standard. We use the phrase “the SQL standard” to mean the current version of the SQL Standard at any time.

- **MySQL software is Open Source.**

Open Source means that it is possible for anyone to use and modify the software. Anybody can download the MySQL software from the Internet and use it without paying anything. If you wish, you may study the source code and change it to suit your needs. The MySQL software uses the GPL (GNU General Public License), <http://www.fsf.org/licenses/>, to define what you may and may not do with the software in different situations. If you feel uncomfortable with the GPL or need to embed MySQL code into a commercial application, you can buy a commercially licensed version from us. See the MySQL Licensing Overview for more information (<http://www.mysql.com/company/legal/licensing/>).

- **The MySQL Database Server is very fast, reliable, scalable, and easy to use.**

If that is what you are looking for, you should give it a try. MySQL Server can run comfortably on a desktop or laptop, alongside your other applications, web servers, and so on, requiring little or no attention. If you dedicate an entire machine to MySQL, you can adjust the settings to take advantage

of all the memory, CPU power, and I/O capacity available. MySQL can also scale up to clusters of machines, networked together.

You can find a performance comparison of MySQL Server with other database managers on our benchmark page. See [Section 8.12.2, “The MySQL Benchmark Suite”](#).

MySQL Server was originally developed to handle large databases much faster than existing solutions and has been successfully used in highly demanding production environments for several years. Although under constant development, MySQL Server today offers a rich and useful set of functions. Its connectivity, speed, and security make MySQL Server highly suited for accessing databases on the Internet.

- **MySQL Server works in client/server or embedded systems.**

The MySQL Database Software is a client/server system that consists of a multi-threaded SQL server that supports different backends, several different client programs and libraries, administrative tools, and a wide range of application programming interfaces (APIs).

We also provide MySQL Server as an embedded multi-threaded library that you can link into your application to get a smaller, faster, easier-to-manage standalone product.

- **A large amount of contributed MySQL software is available.**

MySQL Server has a practical set of features developed in close cooperation with our users. It is very likely that your favorite application or language supports the MySQL Database Server.

The official way to pronounce “MySQL” is “My Ess Que Ell” (not “my sequel”), but we do not mind if you pronounce it as “my sequel” or in some other localized way.

1.3.2 The Main Features of MySQL

This section describes some of the important characteristics of the MySQL Database Software. See also [Section 1.5, “MySQL Development History”](#). In most respects, the roadmap applies to all versions of MySQL. For information about features as they are introduced into MySQL on a series-specific basis, see the “In a Nutshell” section of the appropriate Manual:

- MySQL 5.6: [MySQL 5.6 in a Nutshell](#)
- MySQL 5.5: [MySQL 5.5 in a Nutshell](#)
- MySQL 5.1: [MySQL 5.1 in a Nutshell](#)
- MySQL 5.0: [MySQL 5.0 in a Nutshell](#)

Internals and Portability

- Written in C and C++.
- Tested with a broad range of different compilers.
- Works on many different platforms. See <http://www.mysql.com/support/supportedplatforms/database.html>.
- For portability, uses CMake in MySQL 5.5 and up. Previous series use GNU Automake, Autoconf, and Libtool.

- Tested with Purify (a commercial memory leakage detector) as well as with Valgrind, a GPL tool (<http://developer.kde.org/~sewardj/>).
- Uses multi-layered server design with independent modules.
- Designed to be fully multi-threaded using kernel threads, to easily use multiple CPUs if they are available.
- Provides transactional and nontransactional storage engines.
- Uses very fast B-tree disk tables ([MyISAM](#)) with index compression.
- Designed to make it relatively easy to add other storage engines. This is useful if you want to provide an SQL interface for an in-house database.
- Uses a very fast thread-based memory allocation system.
- Executes very fast joins using an optimized nested-loop join.
- Implements in-memory hash tables, which are used as temporary tables.
- Implements SQL functions using a highly optimized class library that should be as fast as possible. Usually there is no memory allocation at all after query initialization.
- Provides the server as a separate program for use in a client/server networked environment, and as a library that can be embedded (linked) into standalone applications. Such applications can be used in isolation or in environments where no network is available.

Data Types

- Many data types: signed/unsigned integers 1, 2, 3, 4, and 8 bytes long, [FLOAT](#), [DOUBLE](#), [CHAR](#), [VARCHAR](#), [BINARY](#), [VARBINARY](#), [TEXT](#), [BLOB](#), [DATE](#), [TIME](#), [DATETIME](#), [TIMESTAMP](#), [YEAR](#), [SET](#), [ENUM](#), and OpenGIS spatial types. See [Chapter 11, Data Types](#).
- Fixed-length and variable-length string types.

Statements and Functions

- Full operator and function support in the [SELECT](#) list and [WHERE](#) clause of queries. For example:

```
mysql> SELECT CONCAT(first_name, ' ', last_name)
-> FROM citizen
-> WHERE income/dependents > 10000 AND age > 30;
```

- Full support for SQL [GROUP BY](#) and [ORDER BY](#) clauses. Support for group functions ([COUNT\(\)](#), [AVG\(\)](#), [STD\(\)](#), [SUM\(\)](#), [MAX\(\)](#), [MIN\(\)](#), and [GROUP_CONCAT\(\)](#)).
- Support for [LEFT OUTER JOIN](#) and [RIGHT OUTER JOIN](#) with both standard SQL and ODBC syntax.
- Support for aliases on tables and columns as required by standard SQL.
- Support for [DELETE](#), [INSERT](#), [REPLACE](#), and [UPDATE](#) to return the number of rows that were changed (affected), or to return the number of rows matched instead by setting a flag when connecting to the server.
- Support for MySQL-specific [SHOW](#) statements that retrieve information about databases, storage engines, tables, and indexes. MySQL 5.0 adds support for the [INFORMATION_SCHEMA](#) database, implemented according to standard SQL.

- An [EXPLAIN](#) statement to show how the optimizer resolves a query.
- Independence of function names from table or column names. For example, [ABS](#) is a valid column name. The only restriction is that for a function call, no spaces are permitted between the function name and the "(" that follows it. See [Section 9.3, "Reserved Words"](#).
- You can refer to tables from different databases in the same statement.

Security

- A privilege and password system that is very flexible and secure, and that enables host-based verification.
- Password security by encryption of all password traffic when you connect to a server.

Scalability and Limits

- Support for large databases. We use MySQL Server with databases that contain 50 million records. We also know of users who use MySQL Server with 200,000 tables and about 5,000,000,000 rows.
- Support for up to 64 indexes per table (32 before MySQL 4.1.2). Each index may consist of 1 to 16 columns or parts of columns. The maximum index width is 767 bytes for [InnoDB](#) tables, or 1000 for [MyISAM](#); before MySQL 4.1.2, the limit is 500 bytes. An index may use a prefix of a column for [CHAR](#), [VARCHAR](#), [BLOB](#), or [TEXT](#) column types.

Connectivity

- Clients can connect to MySQL Server using several protocols:
 - Clients can connect using TCP/IP sockets on any platform.
 - On Windows systems in the NT family (NT, 2000, XP, 2003, or Vista), clients can connect using named pipes if the server is started with the [--enable-named-pipe](#) option. In MySQL 4.1 and higher, Windows servers also support shared-memory connections if started with the [--shared-memory](#) option. Clients can connect through shared memory by using the [--protocol=memory](#) option.
 - On Unix systems, clients can connect using Unix domain socket files.
- MySQL client programs can be written in many languages. A client library written in C is available for clients written in C or C++, or for any language that provides C bindings.
- APIs for C, C++, Eiffel, Java, Perl, PHP, Python, Ruby, and Tcl are available, enabling MySQL clients to be written in many languages. See [Chapter 23, Connectors and APIs](#).
- The Connector/ODBC (MyODBC) interface provides MySQL support for client programs that use ODBC (Open Database Connectivity) connections. For example, you can use MS Access to connect to your MySQL server. Clients can be run on Windows or Unix. Connector/ODBC source is available. All ODBC 2.5 functions are supported, as are many others. See [MySQL Connector/ODBC Developer Guide](#).
- The Connector/J interface provides MySQL support for Java client programs that use JDBC connections. Clients can be run on Windows or Unix. Connector/J source is available. See [MySQL Connector/J Developer Guide](#).
- MySQL Connector/Net enables developers to easily create .NET applications that require secure, high-performance data connectivity with MySQL. It implements the required ADO.NET interfaces and

integrates into ADO.NET aware tools. Developers can build applications using their choice of .NET languages. MySQL Connector/Net is a fully managed ADO.NET driver written in 100% pure C#. See [MySQL Connector/Net Developer Guide](#).

Localization

- The server can provide error messages to clients in many languages. See [Section 10.2, “Setting the Error Message Language”](#).
- Full support for several different character sets, including `latin1` (cp1252), `german`, `big5`, `ujis`, and more. For example, the Scandinavian characters “å”, “ä” and “ö” are permitted in table and column names. Unicode support is available as of MySQL 4.1.
- All data is saved in the chosen character set.
- Sorting and comparisons are done according to the chosen character set and collation (using `latin1` and Swedish collation by default). It is possible to change this when the MySQL server is started. To see an example of very advanced sorting, look at the Czech sorting code. MySQL Server supports many different character sets that can be specified at compile time and runtime.
- As of MySQL 4.1, the server time zone can be changed dynamically, and individual clients can specify their own time zone. [Section 10.6, “MySQL Server Time Zone Support”](#).

Clients and Tools

- MySQL includes several client and utility programs. These include both command-line programs such as `mysqldump` and `mysqladmin`, and graphical programs such as [MySQL Workbench](#).
- MySQL Server has built-in support for SQL statements to check, optimize, and repair tables. These statements are available from the command line through the `mysqlcheck` client. MySQL also includes `myisamchk`, a very fast command-line utility for performing these operations on `MyISAM` tables. See [Chapter 4, MySQL Programs](#).
- MySQL programs can be invoked with the `--help` or `-?` option to obtain online assistance.

1.3.3 History of MySQL

We started out with the intention of using the `mSQL` database system to connect to our tables using our own fast low-level (ISAM) routines. However, after some testing, we came to the conclusion that `mSQL` was not fast enough or flexible enough for our needs. This resulted in a new SQL interface to our database but with almost the same API interface as `mSQL`. This API was designed to enable third-party code that was written for use with `mSQL` to be ported easily for use with MySQL.

MySQL is named after co-founder Monty Widenius's daughter, My.

The name of the MySQL Dolphin (our logo) is “Sakila,” which was chosen from a huge list of names suggested by users in our “Name the Dolphin” contest. The winning name was submitted by Ambrose Twebaze, an Open Source software developer from Swaziland, Africa. According to Ambrose, the feminine name Sakila has its roots in SiSwati, the local language of Swaziland. Sakila is also the name of a town in Arusha, Tanzania, near Ambrose's country of origin, Uganda.

1.4 What Is New in MySQL 5.5

This section summarizes what has been added to, deprecated in, and removed from MySQL 5.5.

Added Features

The following features have been added to MySQL 5.5:

- **MySQL Enterprise Thread Pool.** The default thread-handling model in MySQL Server executes statements using one thread per client connection. As more clients connect to the server and execute statements, overall performance degrades. As of MySQL 5.5.16, MySQL Enterprise Edition distributions include a thread pool plugin that provides an alternative thread-handling model designed to reduce overhead and improve performance. The plugin implements a thread pool that increases server performance by efficiently managing statement execution threads for large numbers of client connections. For more information, see [Section 8.11.6, “The Thread Pool Plugin”](#).
- **MySQL Enterprise Audit.** MySQL Enterprise Edition now includes MySQL Enterprise Audit, implemented using a server plugin named `audit_log`. MySQL Enterprise Audit uses the open MySQL Audit API to enable standard, policy-based monitoring and logging of connection and query activity executed on specific MySQL servers. Designed to meet the Oracle audit specification, MySQL Enterprise Audit provides an out of box, easy to use auditing and compliance solution for applications that are governed by both internal and external regulatory guidelines. When installed, the audit plugin enables MySQL Server to produce a log file containing an audit record of server activity. The log contents include when clients connect and disconnect, and what actions they perform while connected, such as which databases and tables they access. For more information, see [Section 6.3.11, “MySQL Enterprise Audit Log Plugin”](#).
- **Pluggable authentication.** MySQL authentication supports two new capabilities, pluggable authentication and proxy users. With pluggable authentication, the server can use plugins to authenticate incoming client connections, and clients can load an authentication plugin that interacts properly with the corresponding server plugin. This capability enables clients to connect to the MySQL server with credentials that are appropriate for authentication methods other than the built-in MySQL authentication based on native MySQL passwords stored in the `mysql.user` table. For example, plugins can be created to use external authentication methods such as LDAP, Kerberos, PAM, or Windows login IDs. Proxy user capability enables a client who connects and authenticates as one user to be treated, for purposes of access control while connected, as having the privileges of a different user. In effect, one user impersonates another. Proxy capability depends on pluggable authentication because it is based on having an authentication plugin return to the server the user name that the connecting user impersonates. See [Section 6.3.6, “Pluggable Authentication”](#), and [Section 6.3.8, “Proxy Users”](#).

As of MySQL 5.5.16, commercial distributions of MySQL include two plugins that enable MySQL Server to use external authentication methods to authenticate MySQL users:

- PAM (Pluggable Authentication Modules) enables a system to access various kinds of authentication methods through a standard interface. A PAM authentication plugin enables MySQL Server to use PAM to authenticate MySQL users.
- Distributions of MySQL for Windows include an authentication plugin that enables MySQL Server to use native Windows services to authenticate client connections. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password.

These authentication plugins enable MySQL Server to accept connections from users defined outside the MySQL grant tables. They also support the MySQL proxy-user capability. Each plugin can return to MySQL a user name different from the login user, which means that the plugin can return the MySQL user that defines the privileges the externally authenticated user should have.

For more information, see [Section 6.3.7.3, “The PAM Authentication Plugin”](#), and [Section 6.3.7.4, “The Windows Native Authentication Plugin”](#).

- **Multi-core scalability.** Scalability on multi-core CPUs is improved. The trend in hardware development now is toward more cores rather than continued increases in CPU clock speeds, which renders “wait until CPUs get faster” a nonviable means of improving database performance. Instead, it is necessary to make better use of multiple cores to maximally exploit the processing cycles they make available. MySQL 5.5 takes advantage of features of SMP systems and tries to eliminate bottlenecks in MySQL architecture that hinder full use of multiple cores. The focus has been on [InnoDB](#), especially locking and memory management. See [Section 1.4.1, “Scalability Improvements”](#).
- **InnoDB I/O subsystem.** [InnoDB](#) I/O subsystem changes enable more effective use of available I/O capacity. See [Section 1.4.2, “InnoDB I/O Subsystem Changes”](#).
- **Diagnostic improvements.** There is better access to execution and performance information. Diagnostic improvements include Performance Schema (a feature for monitoring MySQL Server execution at a low level), DTrace probes, expanded `SHOW ENGINE INNODB STATUS` output, Debug Sync, and a new status variable. See [Section 1.4.3, “Diagnostic and Monitoring Capabilities”](#).
- **Solaris.** Several modifications improve operation of MySQL Server on Solaris. See [Section 1.4.4, “Enhanced Solaris Support”](#).
- **Default storage engine.** The default storage engine for new tables is [InnoDB](#) rather than [MyISAM](#). See [Section 14.1.2, “InnoDB as the Default MySQL Storage Engine”](#).
- **MySQL Cluster.** MySQL Cluster is released as a separate product, with new development for version 7.2 of the [NDB](#) storage engine being based on MySQL 5.5. Clustering support is not available in mainline MySQL Server 5.5 releases. For more information about MySQL Cluster NDB 7.2, see [Chapter 18, MySQL Cluster NDB 7.2](#).

MySQL Cluster releases are identified by a 3-part NDB version number. Currently, MySQL Cluster NDB 7.1 is the most recent GA release series. MySQL Cluster NDB 6.3 and MySQL Cluster NDB 7.0 are also still available. These versions of MySQL Cluster are based on MySQL Server 5.1 and documented in the *MySQL 5.1 Manual*. See [MySQL Cluster NDB 6.1 - 7.1](#).

- **Semisynchronous replication.** A commit performed on the master side blocks before returning to the session that performed the transaction until at least one slave acknowledges that it has received and logged the events for the transaction. Semisynchronous replication is implemented through an optional plugin component. See [Section 17.3.8, “Semisynchronous Replication”](#)
- **Unicode.** Support for supplementary Unicode characters; that is, characters outside the Basic Multilingual Plane (BMP). These new Unicode character sets include supplementary characters: `utf16`, `utf32`, and `utf8mb4`. See [Section 10.1.10, “Unicode Support”](#).
- **Partitioning.** Enhancements to table partitioning:
 - Two new types of user-defined partitioning are supported: `RANGE COLUMNS` partitioning is an extension to `RANGE` partitioning; `LIST COLUMNS` partitioning is an extension to `LIST` partitioning. Each of these extensions provides two enhancements to MySQL partitioning capabilities:
 - It is possible to define partitioning ranges or lists based on `DATE`, `DATETIME`, or string values (such as `CHAR` or `VARCHAR`).

You can also define ranges or lists based on multiple column values when partitioning tables by `RANGE COLUMNS` or `LIST COLUMNS`, respectively. Such a range or list may refer to up to 16 columns.

 - For tables defined using these partitioning types, partition pruning can now optimize queries with `WHERE` conditions that use multiple comparisons between (different) column values and constants, such as `a = 10 AND b > 5` or `a < "2005-11-25" AND b = 10 AND c = 50`.

See [Section 19.2.1, “RANGE Partitioning”](#), and [Section 19.2.2, “LIST Partitioning”](#).

- It is now possible to delete all rows from one or more partitions of a partitioned table using the `ALTER TABLE ... TRUNCATE PARTITION` statement. Executing the statement deletes rows without affecting the structure of the table. The partitions named in the `TRUNCATE PARTITION` clause do not have to be contiguous.
- Key caches are now supported for indexes on partitioned `MyISAM` tables, using the `CACHE INDEX` and `LOAD INDEX INTO CACHE` statements. In addition, a key cache can be defined for and loaded with indexes from an entire partitioned table, or for one or more partitions. In the latter case, the partitions are not required to be contiguous.
- The new `TO_SECONDS ()` function converts a date or datetime expression to a number of seconds since the year 0. This is a general-purpose function, but is useful for partitioning. You may use it in partitioning expressions, and partition pruning is supported for tables defined using such expressions.
- **SIGNAL and RESIGNAL.** Support for the SQL standard `SIGNAL` and `RESIGNAL` statements. See [Section 13.6.7, “Condition Handling”](#).
- **Metadata locking.** The server now prevents DDL statements from compromising transaction serializability by using a new class of locks called metadata locks. See [Section 8.10.4, “Metadata Locking”](#).
- **IPv6 support.** MySQL Server can accept TCP/IP connections from clients connecting over IPv6. See [Section 5.1.9, “IPv6 Support”](#).
- **XML.** Enhancements to XML functionality, including a new `LOAD XML INFILE` statement. See [Section 13.2.7, “LOAD XML Syntax”](#).
- **Build configuration.** MySQL releases are now built using `CMake` rather than the GNU autotools. Accordingly, the instructions for installing MySQL from source have been updated to discuss how to build MySQL using `CMake`. See [Section 2.9, “Installing MySQL from Source”](#).

The build process is now similar enough on all platforms, including Windows, that there are no longer sections dedicated to notes for specific platforms.

Deprecated Features

The following features are deprecated in MySQL 5.5 and may be or will be removed in a future series. Where alternatives are shown, applications should be updated to use them.

- Relying on implicit `GROUP BY` sorting in MySQL 5.5 is deprecated. To achieve a specific sort order of grouped results, it is preferable to use an explicit `ORDER BY` clause. `GROUP BY` sorting is a MySQL extension that may change in a future release; for example, to make it possible for the optimizer to order groupings in whatever manner it deems most efficient and to avoid the sorting overhead.
- The `YEAR(2)` data type. `YEAR(2)` columns in existing tables are treated as before, but `YEAR(2)` in new or altered tables are converted to `YEAR(4)`. For more information, see [Section 11.3.4, “YEAR\(2\) Limitations and Migrating to YEAR\(4\)”](#).

The `SHOW AUTHORS` and `SHOW CONTRIBUTORS` statements.

- The `--ignore-builtin-innodb` server option. It does nothing and has no effect.
- The `--language` server option. Use the `lc_messages_dir` and `lc_messages` system variables instead.

- The `ALWAYS` value for the `--base64-output` option for `mysqlbinlog`.
- The `--config-file` option for `mysqld_multi`. Use `--defaults-extra-file` instead.
- Use of unambiguous option prefixes. If an unambiguous prefix is given, a warning occurs to provide feedback. Option prefixes are no longer supported in MySQL 5.7; only full options are accepted.
- The `engine_condition_pushdown` system variable. Use the `engine_condition_pushdown` flag of the `optimizer_switch` variable instead.
- The `timed_mutexes` system variable. It does nothing and has no effect.
- The `storage_engine` system variable. Use `default_storage_engine` instead.
- Use of the data directory as the location for `my.cnf`.

Removed Features

The following constructs are obsolete and have been removed in MySQL 5.5. Where alternatives are shown, applications should be updated to use them.

- The `language` system variable (use `lc_messages_dir` and `lc_messages`).
- The `log_bin_trust_routine_creators` system variable (use `log_bin_trust_function_creators`).
- The `myisam_max_extra_sort_file_size` system variable.
- The `record_buffer` system variable (use `read_buffer_size`).
- The `sql_log_update` system variable.
- The `Innodb_buffer_pool_read_ahead_rnd` and `Innodb_buffer_pool_read_ahead_seq` status variables (use `Innodb_buffer_pool_read_ahead` and `Innodb_buffer_pool_read_ahead_evicted`).
- The `table_lock_wait_timeout` system variable.
- The `table_type` system variable (use `default_storage_engine`).
- The `FRAC_SECOND` modifier for the `TIMESTAMPADD()` function (use `MICROSECOND`).
- The `TYPE` table option to specify the storage engine for `CREATE TABLE` or `ALTER TABLE` (use `ENGINE`).
- The `SHOW TABLE TYPES` SQL statement (use `SHOW ENGINES`).
- The `SHOW INNODB STATUS` and `SHOW MUTEX STATUS` SQL statements (use `SHOW ENGINE INNODB STATUS` and `SHOW ENGINE INNODB MUTEX`).
- The `SHOW PLUGIN` SQL statement (use `SHOW PLUGINS`).
- The `LOAD TABLE ... FROM MASTER` and `LOAD DATA FROM MASTER` SQL statements (use `mysqldump` or `mysqlhotcopy` to dump tables and `mysql` to reload dump files).
- The `BACKUP TABLE` and `RESTORE TABLE` SQL statements (use `mysqldump` or `mysqlhotcopy` to dump tables and `mysql` to reload dump files).
- `TIMESTAMP(N)` data type: The ability to specify a display width of `N` (use without `N`).

- The `--default-character-set` and `--default-collation` server options (use `--character-set-server` and `--collation-server`).
- The `--default-table-type` server option (use `--default-storage-engine`).
- The `--delay-key-write-for-all-tables` server option (use `--delay-key-write=ALL`).
- The `--enable-locking` and `--skip-locking` server options (use `--external-locking` and `--skip-external-locking`).
- The `--log-bin-trust-routine-creators` server option (use `--log-bin-trust-function-creators`).
- The `--log-long-format` server option.
- The `--log-update` server option.
- The `--master-xxx` server options to set replication parameters (use the `CHANGE MASTER TO` statement instead): `--master-host`, `--master-user`, `--master-password`, `--master-port`, `--master-connect-retry`, `--master-ssl`, `--master-ssl-ca`, `--master-ssl-capath`, `--master-ssl-cert`, `--master-ssl-cipher`, `--master-ssl-key`.
- The `--safe-show-database` server option.
- The `--skip-symlink` and `--use-symbolic-links` server options (use `--skip-symbolic-links` and `--symbolic-links`).
- The `--sql-bin-update-same` server option.
- The `--warnings` server option (use `--log-warnings`).
- The `--no-named-commands` option for `mysql` (use `--skip-named-commands`).
- The `--no-pager` option for `mysql` (use `--skip-pager`).
- The `--no-tee` option for `mysql` (use `--skip-tee`).
- The `--position` option for `mysqlbinlog` (use `--start-position`).
- The `--all` option for `mysqldump` (use `--create-options`).
- The `--first-slave` option for `mysqldump` (use `--lock-all-tables`).
- The `--config-file` option for `mysqld_multi` (use `--defaults-extra-file`).
- The `--set-variable=var_name=value` and `-O var_name=value` general-purpose options for setting program variables (use `--var_name=value`).
- The `--with-pstack` option for `configure` and the `--enable-pstack` option for `mysqld`.

1.4.1 Scalability Improvements

MySQL 5.5 modifications improve performance on SMP systems to increase scalability on multi-core systems. The changes affect `InnoDB` locking and memory management.

MySQL 5.5 incorporates changes in `InnoDB` that improve the performance of RW-locks by using atomic CPU instructions (on platforms where they are available), rather than less scalable mutexes. It is also possible for `InnoDB` memory allocation to be disabled and replaced by the normal `malloc` library, or by a different library that implements `malloc` such as `tcmalloc` on Linux or `mtalloc` on Solaris.

The reimplementation of RW-locks requires atomic instructions. A status variable, `InnoDB_have_atomic_builtins`, shows whether the server was built with atomic instructions.

1.4.2 InnoDB I/O Subsystem Changes

MySQL 5.5 changes to the InnoDB I/O subsystem enable more effective use of available I/O capacity. The changes also provide more control over configuration of the I/O subsystem.

Background I/O Threads

InnoDB uses background threads to perform I/O for several kinds of activities, two of which are prefetching disk blocks and flushing dirty pages. Previously, InnoDB used only one thread each to perform these activities, but that can underutilize server capacity. MySQL 5.5 enables use of multiple background read and write threads, making it possible to read and write pages faster.

The patch makes the number of background I/O threads configurable using system variables: `innodb_read_io_threads` controls the number of threads to use for read prefetch requests. `innodb_write_io_threads` controls the number of threads to use for writing dirty pages from the buffer cache to disk. The default for both variables is 4.

The ability to increase the number of I/O threads can benefit systems that use multiple disks for InnoDB. However, the type of I/O being done should be considered. On systems that use buffered writes rather than direct writes, increasing the write thread count higher than 1 might yield little benefit because writes will be quick already.

Adjustable I/O Rate

Previously, the number of input/output operations per second (IOPS) that InnoDB will perform was a compile-time parameter. The rate was chosen to prevent background I/O from exhausting server capacity and the compiled-in value of 100 reflected an assumption that the server can perform 100 IOPS. However, many modern systems can exceed this, so the value is low and unnecessarily restricts I/O utilization.

MySQL 5.5 exposes this I/O rate parameter as a system variable, `innodb_io_capacity`. This variable can be set at server startup, which enables higher values to be selected for systems capable of higher I/O rates. Having a higher I/O rate can help the server handle a higher rate of row changes because it may be able to increase dirty-page flushing, deleted-row removal, and application of changes to the insert buffer. The default value of `innodb_io_capacity` is 200. In general, you can increase the value as a function of the number of drives used for InnoDB I/O.

The ability to raise the I/O limit should be especially beneficial on platforms that support many IOPS. For example, systems that use multiple disks or solid-state disks for InnoDB are likely to benefit from the ability to control this parameter.

1.4.3 Diagnostic and Monitoring Capabilities

MySQL 5.5 provides improved access to execution and performance information. Diagnostic improvements include Performance Schema, Dtrace probes, expanded `SHOW ENGINE INNODB STATUS` output, Debug Sync, and a new status variable.

Performance Schema

Performance Schema is a feature for monitoring MySQL Server execution at a low level. See [Chapter 22, MySQL Performance Schema](#).

DTrace Support

The DTrace probes work on Solaris, Mac OS X, and FreeBSD. For information on using DTrace in MySQL, see [Section 5.4, “Tracing `mysqld` Using DTrace”](#).

Enhanced `SHOW ENGINE INNODB STATUS` Output

The output from `SHOW ENGINE INNODB STATUS` includes more information due to changes made for [InnoDB Plugin](#). A description of revisions to statement output follows.

A new `BACKGROUND THREAD` section has `srv_master_thread` lines that show work done by the main background thread.

```
-----  
BACKGROUND THREAD  
-----  
srv_master_thread loops: 53 1_second, 44 sleeps, 5 10_second, 7 background,  
  7 flush  
srv_master_thread log flush and writes: 48
```

The `SEMAPHORES` section includes a line to show the number of spinlock rounds per OS wait for a mutex.

```
-----  
SEMAPHORES  
-----  
...  
Spin rounds per wait: 0.00 mutex, 20.00 RW-shared, 0.00 RW-excl
```

Debug Sync

The Debug Sync facility provides synchronization points for debugging, see [MySQL Internals: Test Synchronization](#).

New Status Variable

The `Innodb_have_atomic_builtins` status variable provides information about availability of atomic instructions; see [Section 1.4.1, “Scalability Improvements”](#).

1.4.4 Enhanced Solaris Support

MySQL 5.5 incorporates several modifications for improved operation of MySQL Server on Solaris:

- DTrace support for execution monitoring. See [Section 1.4.3, “Diagnostic and Monitoring Capabilities”](#).
- Atomic instructions, which are needed for the improvements to RW-locking described in [Section 1.4.1, “Scalability Improvements”](#). Atomic instructions now are supported for Sun Studio on SPARC and x86 platforms. This extends their previous availability (supported for `gcc` 4.1 and up on all platforms).
- The SMP improvements described in [Section 1.4.1, “Scalability Improvements”](#), were originally intended for x86 platforms. In MySQL 5.5, these also work on SPARC platforms. Also, Solaris optimizations have been implemented.
- Large page support is enhanced for recent SPARC platforms. Standard use of large pages in MySQL attempts to use the largest size supported, up to 4MB. Under Solaris, a “super large pages” feature enables uses of pages up to 256MB. This feature can be enabled or disabled by using the `--super-large-pages` or `--skip-super-large-pages` option.
- Inline handling for `InnoDB` and processor instruction prefetching support, previously not enabled for builds created using Sun Studio, now are supported for that build environment.

1.5 MySQL Development History

This section describes the general MySQL development history, provides an overview about features that have been implemented in previous series and that are new in MySQL 5.5, the release series covered in this manual. The maturity level this release series is general availability. Information about maturity levels can be found in [Section 2.1.2.1, “Choosing Which Version of MySQL to Install”](#).

Before upgrading from one release series to the next, please see the notes in [Section 2.11.1, “Upgrading MySQL”](#).

The most requested features and the versions in which they were implemented are summarized in the following table.

Feature	MySQL Series
Unions	4.0
Subqueries	4.1
R-trees	4.1 (for the MyISAM storage engine)
Stored procedures and functions	5.0
Views	5.0
Cursors	5.0
XA transactions	5.0
Triggers	5.0 and 5.1
Event scheduler	5.1
Partitioning	5.1
Pluggable storage engine API	5.1
Plugin API	5.1
InnoDB Plugin	5.1
Row-based replication	5.1
Server log tables	5.1
Scalability and performance improvements	5.1 (with InnoDB Plugin)
DTrace support	5.5
InnoDB as default storage engine	5.5
Semisynchronous replication	5.5
SIGNAL/RESIGNAL support in stored routines	5.5
Performance Schema	5.5
Supplementary Unicode characters	5.5

1.6 MySQL Information Sources

This section lists sources of additional information that you may find helpful, such as the MySQL mailing lists and user forums, and Internet Relay Chat.

1.6.1 MySQL Mailing Lists

This section introduces the MySQL mailing lists and provides guidelines as to how the lists should be used. When you subscribe to a mailing list, you receive all postings to the list as email messages. You can also send your own questions and answers to the list.

To subscribe to or unsubscribe from any of the mailing lists described in this section, visit <http://lists.mysql.com/>. For most of them, you can select the regular version of the list where you get individual messages, or a digest version where you get one large message per day.

Please *do not* send messages about subscribing or unsubscribing to any of the mailing lists, because such messages are distributed automatically to thousands of other users.

Your local site may have many subscribers to a MySQL mailing list. If so, the site may have a local mailing list, so that messages sent from lists.mysql.com to your site are propagated to the local list. In such cases, please contact your system administrator to be added to or dropped from the local MySQL list.

To have traffic for a mailing list go to a separate mailbox in your mail program, set up a filter based on the message headers. You can use either the `List-ID:` or `Delivered-To:` headers to identify list messages.

The MySQL mailing lists are as follows:

- [announce](#)

The list for announcements of new versions of MySQL and related programs. This is a low-volume list to which all MySQL users should subscribe.

- [mysql](#)

The main list for general MySQL discussion. Please note that some topics are better discussed on the more-specialized lists. If you post to the wrong list, you may not get an answer.

- [bugs](#)

The list for people who want to stay informed about issues reported since the last release of MySQL or who want to be actively involved in the process of bug hunting and fixing. See [Section 1.7, “How to Report Bugs or Problems”](#).

- [internals](#)

The list for people who work on the MySQL code. This is also the forum for discussions on MySQL development and for posting patches.

- [mysqldoc](#)

The list for people who work on the MySQL documentation.

- [benchmarks](#)

The list for anyone interested in performance issues. Discussions concentrate on database performance (not limited to MySQL), but also include broader categories such as performance of the kernel, file system, disk system, and so on.

- [packagers](#)

The list for discussions on packaging and distributing MySQL. This is the forum used by distribution maintainers to exchange ideas on packaging MySQL and on ensuring that MySQL looks and feels as similar as possible on all supported platforms and operating systems.

- [java](#)

The list for discussions about the MySQL server and Java. It is mostly used to discuss JDBC drivers such as MySQL Connector/J.

- [win32](#)

The list for all topics concerning the MySQL software on Microsoft operating systems, such as Windows 9x, Me, NT, 2000, XP, and 2003.

- [myodbc](#)

The list for all topics concerning connecting to the MySQL server with ODBC.

- [gui-tools](#)

The list for all topics concerning MySQL graphical user interface tools such as MySQL Workbench.

- [cluster](#)

The list for discussion of MySQL Cluster.

- [dotnet](#)

The list for discussion of the MySQL server and the .NET platform. It is mostly related to MySQL Connector/Net.

- [plusplus](#)

The list for all topics concerning programming with the C++ API for MySQL.

- [perl](#)

The list for all topics concerning Perl support for MySQL with `DBD::mysql`.

If you're unable to get an answer to your questions from a MySQL mailing list or forum, one option is to purchase support from Oracle. This puts you in direct contact with MySQL developers.

The following MySQL mailing lists are in languages other than English. These lists are not operated by Oracle.

- [<mysql-france-subscribe@yahoogroups.com>](mailto:mysql-france-subscribe@yahoogroups.com)

A French mailing list.

- [<list@tinc.net>](mailto:list@tinc.net)

A Korean mailing list. To subscribe, email `subscribe mysql your@email.address` to this list.

- [<mysql-de-request@lists.4t2.com>](mailto:mysql-de-request@lists.4t2.com)

A German mailing list. To subscribe, email `subscribe mysql-de your@email.address` to this list. You can find information about this mailing list at <http://www.4t2.com/mysql/>.

- [<mysql-br-request@listas.linkway.com.br>](mailto:mysql-br-request@listas.linkway.com.br)

A Portuguese mailing list. To subscribe, email `subscribe mysql-br your@email.address` to this list.

- [<mysql-alta@elistas.net>](mailto:mysql-alta@elistas.net)

A Spanish mailing list. To subscribe, email subscribe_mysql_your@email.address to this list.

1.6.1.1 Guidelines for Using the Mailing Lists

Please do not post mail messages from your browser with HTML mode turned on. Many users do not read mail with a browser.

When you answer a question sent to a mailing list, if you consider your answer to have broad interest, you may want to post it to the list instead of replying directly to the individual who asked. Try to make your answer general enough that people other than the original poster may benefit from it. When you post to the list, please make sure that your answer is not a duplication of a previous answer.

Try to summarize the essential part of the question in your reply. Do not feel obliged to quote the entire original message.

When answers are sent to you individually and not to the mailing list, it is considered good etiquette to summarize the answers and send the summary to the mailing list so that others may have the benefit of responses you received that helped you solve your problem.

1.6.2 MySQL Community Support at the MySQL Forums

The forums at <http://forums.mysql.com> are an important community resource. Many forums are available, grouped into these general categories:

- Migration
- MySQL Usage
- MySQL Connectors
- Programming Languages
- Tools
- 3rd-Party Applications
- Storage Engines
- MySQL Technology
- SQL Standards
- Business

1.6.3 MySQL Community Support on Internet Relay Chat (IRC)

In addition to the various MySQL mailing lists and forums, you can find experienced community people on Internet Relay Chat (IRC). These are the best networks/channels currently known to us:

freenode (see <http://www.freenode.net/> for servers)

- [#mysql](#) is primarily for MySQL questions, but other database and general SQL questions are welcome. Questions about PHP, Perl, or C in combination with MySQL are also common.

If you are looking for IRC client software to connect to an IRC network, take a look at [xChat](#) (<http://www.xchat.org/>). X-Chat (GPL licensed) is available for Unix as well as for Windows platforms (a free Windows build of X-Chat is available at <http://www.silverex.org/download/>).

1.6.4 MySQL Enterprise

Oracle offers technical support in the form of MySQL Enterprise. For organizations that rely on the MySQL DBMS for business-critical production applications, MySQL Enterprise is a commercial subscription offering which includes:

- MySQL Enterprise Server
- MySQL Enterprise Monitor
- Monthly Rapid Updates and Quarterly Service Packs
- MySQL Knowledge Base
- 24x7 Technical and Consultative Support

MySQL Enterprise is available in multiple tiers, giving you the flexibility to choose the level of service that best matches your needs. For more information, see [MySQL Enterprise](#).

1.7 How to Report Bugs or Problems

Before posting a bug report about a problem, please try to verify that it is a bug and that it has not been reported already:

- Start by searching the MySQL online manual at <http://dev.mysql.com/doc/>. We try to keep the manual up to date by updating it frequently with solutions to newly found problems. In addition, the release notes accompanying the manual can be particularly useful since it is quite possible that a newer version contains a solution to your problem. The release notes are available at the location just given for the manual.
- If you get a parse error for an SQL statement, please check your syntax closely. If you cannot find something wrong with it, it is extremely likely that your current version of MySQL Server doesn't support the syntax you are using. If you are using the current version and the manual doesn't cover the syntax that you are using, MySQL Server doesn't support your statement.

If the manual covers the syntax you are using, but you have an older version of MySQL Server, you should check the MySQL change history to see when the syntax was implemented. In this case, you have the option of upgrading to a newer version of MySQL Server.

- For solutions to some common problems, see [Section B.5, “Problems and Common Errors”](#).
- Search the bugs database at <http://bugs.mysql.com/> to see whether the bug has been reported and fixed.
- Search the MySQL mailing list archives at <http://lists.mysql.com/>. See [Section 1.6.1, “MySQL Mailing Lists”](#).
- You can also use <http://www.mysql.com/search/> to search all the Web pages (including the manual) that are located at the MySQL Web site.

If you cannot find an answer in the manual, the bugs database, or the mailing list archives, check with your local MySQL expert. If you still cannot find an answer to your question, please use the following guidelines for reporting the bug.

The normal way to report bugs is to visit <http://bugs.mysql.com/>, which is the address for our bugs database. This database is public and can be browsed and searched by anyone. If you log in to the system, you can enter new reports.

Bugs posted in the bugs database at <http://bugs.mysql.com/> that are corrected for a given release are noted in the release notes.

If you find a sensitive security bug in MySQL Server, please let us know immediately by sending an email message to [<secalert_us@oracle.com>](mailto:secalert_us@oracle.com). Exception: Support customers should report all problems, including security bugs, to Oracle Support at <http://support.oracle.com/>.

To discuss problems with other users, you can use one of the MySQL mailing lists. [Section 1.6.1, “MySQL Mailing Lists”](#).

Writing a good bug report takes patience, but doing it right the first time saves time both for us and for yourself. A good bug report, containing a full test case for the bug, makes it very likely that we will fix the bug in the next release. This section helps you write your report correctly so that you do not waste your time doing things that may not help us much or at all. Please read this section carefully and make sure that all the information described here is included in your report.

Preferably, you should test the problem using the latest production or development version of MySQL Server before posting. Anyone should be able to repeat the bug by just using `mysql test <script_file` on your test case or by running the shell or Perl script that you include in the bug report. Any bug that we are able to repeat has a high chance of being fixed in the next MySQL release.

It is most helpful when a good description of the problem is included in the bug report. That is, give a good example of everything you did that led to the problem and describe, in exact detail, the problem itself. The best reports are those that include a full example showing how to reproduce the bug or problem. See [Section 24.4, “Debugging and Porting MySQL”](#).

Remember that it is possible for us to respond to a report containing too much information, but not to one containing too little. People often omit facts because they think they know the cause of a problem and assume that some details do not matter. A good principle to follow is that if you are in doubt about stating something, state it. It is faster and less troublesome to write a couple more lines in your report than to wait longer for the answer if we must ask you to provide information that was missing from the initial report.

The most common errors made in bug reports are (a) not including the version number of the MySQL distribution that you use, and (b) not fully describing the platform on which the MySQL server is installed (including the platform type and version number). These are highly relevant pieces of information, and in 99 cases out of 100, the bug report is useless without them. Very often we get questions like, “Why doesn't this work for me?” Then we find that the feature requested wasn't implemented in that MySQL version, or that a bug described in a report has been fixed in newer MySQL versions. Errors often are platform-dependent. In such cases, it is next to impossible for us to fix anything without knowing the operating system and the version number of the platform.

If you compiled MySQL from source, remember also to provide information about your compiler if it is related to the problem. Often people find bugs in compilers and think the problem is MySQL-related. Most compilers are under development all the time and become better version by version. To determine whether your problem depends on your compiler, we need to know what compiler you used. Note that every compiling problem should be regarded as a bug and reported accordingly.

If a program produces an error message, it is very important to include the message in your report. If we try to search for something from the archives, it is better that the error message reported exactly matches the one that the program produces. (Even the lettercase should be observed.) It is best to copy and paste the entire error message into your report. You should never try to reproduce the message from memory.

If you have a problem with Connector/ODBC (MyODBC), please try to generate a trace file and send it with your report. See [How to Report Connector/ODBC Problems or Bugs](#).

If your report includes long query output lines from test cases that you run with the `mysql` command-line tool, you can make the output more readable by using the `--vertical` option or the `\G` statement terminator. The `EXPLAIN SELECT` example later in this section demonstrates the use of `\G`.

Please include the following information in your report:

- The version number of the MySQL distribution you are using (for example, MySQL 5.0.19). You can find out which version you are running by executing `mysqladmin version`. The `mysqladmin` program can be found in the `bin` directory under your MySQL installation directory.
- The manufacturer and model of the machine on which you experience the problem.
- The operating system name and version. If you work with Windows, you can usually get the name and version number by double-clicking your My Computer icon and pulling down the “Help/About Windows” menu. For most Unix-like operating systems, you can get this information by executing the command `uname -a`.
- Sometimes the amount of memory (real and virtual) is relevant. If in doubt, include these values.
- If you are using a source distribution of the MySQL software, include the name and version number of the compiler that you used. If you have a binary distribution, include the distribution name.
- If the problem occurs during compilation, include the exact error messages and also a few lines of context around the offending code in the file where the error occurs.
- If `mysqld` died, you should also report the statement that crashed `mysqld`. You can usually get this information by running `mysqld` with query logging enabled, and then looking in the log after `mysqld` crashes. See [Section 24.4, “Debugging and Porting MySQL”](#).
- If a database table is related to the problem, include the output from the `SHOW CREATE TABLE db_name.tbl_name` statement in the bug report. This is a very easy way to get the definition of any table in a database. The information helps us create a situation matching the one that you have experienced.
- The SQL mode in effect when the problem occurred can be significant, so please report the value of the `sql_mode` system variable. For stored procedure, stored function, and trigger objects, the relevant `sql_mode` value is the one in effect when the object was created. For a stored procedure or function, the `SHOW CREATE PROCEDURE` or `SHOW CREATE FUNCTION` statement shows the relevant SQL mode, or you can query `INFORMATION_SCHEMA` for the information:

```
SELECT ROUTINE_SCHEMA, ROUTINE_NAME, SQL_MODE
FROM INFORMATION_SCHEMA.ROUTINES;
```

For triggers, you can use this statement:

```
SELECT EVENT_OBJECT_SCHEMA, EVENT_OBJECT_TABLE, TRIGGER_NAME, SQL_MODE
FROM INFORMATION_SCHEMA.TRIGGERS;
```

- For performance-related bugs or problems with `SELECT` statements, you should always include the output of `EXPLAIN SELECT ...`, and at least the number of rows that the `SELECT` statement produces. You should also include the output from `SHOW CREATE TABLE tbl_name` for each table that is involved. The more information you provide about your situation, the more likely it is that someone can help you.

The following is an example of a very good bug report. The statements are run using the `mysql` command-line tool. Note the use of the `\G` statement terminator for statements that would otherwise provide very long output lines that are difficult to read.

```
mysql> SHOW VARIABLES;
mysql> SHOW COLUMNS FROM ... \G
      <output from SHOW COLUMNS>
mysql> EXPLAIN SELECT ... \G
      <output from EXPLAIN>
mysql> FLUSH STATUS;
mysql> SELECT ...;
      <A short version of the output from SELECT,
      including the time taken to run the query>
mysql> SHOW STATUS;
      <output from SHOW STATUS>
```

- If a bug or problem occurs while running `mysqld`, try to provide an input script that reproduces the anomaly. This script should include any necessary source files. The more closely the script can reproduce your situation, the better. If you can make a reproducible test case, you should upload it to be attached to the bug report.

If you cannot provide a script, you should at least include the output from `mysqladmin variables extended-status processlist` in your report to provide some information on how your system is performing.

- If you cannot produce a test case with only a few rows, or if the test table is too big to be included in the bug report (more than 10 rows), you should dump your tables using `mysqldump` and create a `README` file that describes your problem. Create a compressed archive of your files using `tar` and `gzip` or `zip`. After you initiate a bug report for our bugs database at <http://bugs.mysql.com/>, click the Files tab in the bug report for instructions on uploading the archive to the bugs database.
- If you believe that the MySQL server produces a strange result from a statement, include not only the result, but also your opinion of what the result should be, and an explanation describing the basis for your opinion.
- When you provide an example of the problem, it is better to use the table names, variable names, and so forth that exist in your actual situation than to come up with new names. The problem could be related to the name of a table or variable. These cases are rare, perhaps, but it is better to be safe than sorry. After all, it should be easier for you to provide an example that uses your actual situation, and it is by all means better for us. If you have data that you do not want to be visible to others in the bug report, you can upload it using the Files tab as previously described. If the information is really top secret and you do not want to show it even to us, go ahead and provide an example using other names, but please regard this as the last choice.
- Include all the options given to the relevant programs, if possible. For example, indicate the options that you use when you start the `mysqld` server, as well as the options that you use to run any MySQL client programs. The options to programs such as `mysqld` and `mysql`, and to the `configure` script, are often key to resolving problems and are very relevant. It is never a bad idea to include them. If your problem involves a program written in a language such as Perl or PHP, please include the language processor's version number, as well as the version for any modules that the program uses. For example, if you have a Perl script that uses the `DBI` and `DBD::mysql` modules, include the version numbers for Perl, `DBI`, and `DBD::mysql`.
- If your question is related to the privilege system, please include the output of `mysqlaccess`, the output of `mysqladmin reload`, and all the error messages you get when trying to connect. When you test your privileges, you should first run `mysqlaccess`. After this, execute `mysqladmin reload version` and try to connect with the program that gives you trouble. `mysqlaccess` can be found in the `bin` directory under your MySQL installation directory.
- If you have a patch for a bug, do include it. But do not assume that the patch is all we need, or that we can use it, if you do not provide some necessary information such as test cases showing the bug that

your patch fixes. We might find problems with your patch or we might not understand it at all. If so, we cannot use it.

If we cannot verify the exact purpose of the patch, we will not use it. Test cases help us here. Show that the patch handles all the situations that may occur. If we find a borderline case (even a rare one) where the patch will not work, it may be useless.

- Guesses about what the bug is, why it occurs, or what it depends on are usually wrong. Even the MySQL team cannot guess such things without first using a debugger to determine the real cause of a bug.
- Indicate in your bug report that you have checked the reference manual and mail archive so that others know you have tried to solve the problem yourself.
- If your data appears corrupt or you get errors when you access a particular table, first check your tables with `CHECK TABLE`. If that statement reports any errors:
 - The `InnoDB` crash recovery mechanism handles cleanup when the server is restarted after being killed, so in typical operation there is no need to “repair” tables. If you encounter an error with `InnoDB` tables, restart the server and see whether the problem persists, or whether the error affected only cached data in memory. If data is corrupted on disk, consider restarting with the `innodb_force_recovery` option enabled so that you can dump the affected tables.
 - For non-transactional tables, try to repair them with `REPAIR TABLE` or with `myisamchk`. See [Chapter 5, MySQL Server Administration](#).

If you are running Windows, please verify the value of `lower_case_table_names` using the `SHOW VARIABLES LIKE 'lower_case_table_names'` statement. This variable affects how the server handles lettercase of database and table names. Its effect for a given value should be as described in [Section 9.2.2, “Identifier Case Sensitivity”](#).

- If you often get corrupted tables, you should try to find out when and why this happens. In this case, the error log in the MySQL data directory may contain some information about what happened. (This is the file with the `.err` suffix in the name.) See [Section 5.2.2, “The Error Log”](#). Please include any relevant information from this file in your bug report. Normally `mysqld` should *never* crash a table if nothing killed it in the middle of an update. If you can find the cause of `mysqld` dying, it is much easier for us to provide you with a fix for the problem. See [Section B.5.1, “How to Determine What Is Causing a Problem”](#).
- If possible, download and install the most recent version of MySQL Server and check whether it solves your problem. All versions of the MySQL software thoroughly tested and should work without problems. We believe in making everything as backward-compatible as possible, and you should be able to switch MySQL versions without difficulty. See [Section 2.1.2, “Choosing Which MySQL Distribution to Install”](#).

1.8 MySQL Standards Compliance

This section describes how MySQL relates to the ANSI/ISO SQL standards. MySQL Server has many extensions to the SQL standard, and here you can find out what they are and how to use them. You can also find information about functionality missing from MySQL Server, and how to work around some of the differences.

The SQL standard has been evolving since 1986 and several versions exist. In this manual, “SQL-92” refers to the standard released in 1992, “SQL:1999” refers to the standard released in 1999, “SQL:2003” refers to the standard released in 2003, and “SQL:2008” refers to the most recent version of the standard, released in 2008. We use the phrase “the SQL standard” or “standard SQL” to mean the current version of the SQL Standard at any time.

One of our main goals with the product is to continue to work toward compliance with the SQL standard, but without sacrificing speed or reliability. We are not afraid to add extensions to SQL or support for non-SQL features if this greatly increases the usability of MySQL Server for a large segment of our user base. The `HANDLER` interface is an example of this strategy. See [Section 13.2.4, “HANDLER Syntax”](#).

We continue to support transactional and nontransactional databases to satisfy both mission-critical 24/7 usage and heavy Web or logging usage.

MySQL Server was originally designed to work with medium-sized databases (10-100 million rows, or about 100MB per table) on small computer systems. Today MySQL Server handles terabyte-sized databases, but the code can also be compiled in a reduced version suitable for hand-held and embedded devices. The compact design of the MySQL server makes development in both directions possible without any conflicts in the source tree.

Currently, we are not targeting real-time support, although MySQL replication capabilities offer significant functionality.

MySQL supports ODBC levels 0 to 3.51.

MySQL supports high-availability database clustering using the `NDBCLUSTER` storage engine. See [Chapter 18, MySQL Cluster NDB 7.2](#).

We are implementing XML functionality beginning in MySQL 5.1, which supports most of the W3C XPath standard. See [Section 12.11, “XML Functions”](#).

Selecting SQL Modes

The MySQL server can operate in different SQL modes, and can apply these modes differently for different clients, depending on the value of the `sql_mode` system variable. DBAs can set the global SQL mode to match site server operating requirements, and each application can set its session SQL mode to its own requirements.

Modes affect the SQL syntax MySQL supports and the data validation checks it performs. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers.

For more information on setting the SQL mode, see [Section 5.1.7, “Server SQL Modes”](#).

Running MySQL in ANSI Mode

To run MySQL Server in ANSI mode, start `mysqld` with the `--ansi` option. Running the server in ANSI mode is the same as starting it with the following options:

```
--transaction-isolation=SERIALIZABLE --sql-mode=ANSI
```

To achieve the same effect at runtime, execute these two statements:

```
SET GLOBAL TRANSACTION ISOLATION LEVEL SERIALIZABLE;
SET GLOBAL sql_mode = 'ANSI';
```

You can see that setting the `sql_mode` system variable to `'ANSI'` enables all SQL mode options that are relevant for ANSI mode as follows:

```
mysql> SET GLOBAL sql_mode='ANSI';
mysql> SELECT @@global.sql_mode;
-> 'REAL_AS_FLOAT,PIPES_AS_CONCAT,ANSI_QUOTES,IGNORE_SPACE,ANSI'
```

Running the server in ANSI mode with `--ansi` is not quite the same as setting the SQL mode to `'ANSI'` because the `--ansi` option also sets the transaction isolation level.

See [Section 5.1.3, “Server Command Options”](#).

1.8.1 MySQL Extensions to Standard SQL

MySQL Server supports some extensions that you probably won't find in other SQL DBMSs. Be warned that if you use them, your code won't be portable to other SQL servers. In some cases, you can write code that includes MySQL extensions, but is still portable, by using comments of the following form:

```
/*! MySQL-specific code */
```

In this case, MySQL Server parses and executes the code within the comment as it would any other SQL statement, but other SQL servers will ignore the extensions. For example, MySQL Server recognizes the `STRAIGHT_JOIN` keyword in the following statement, but other servers will not:

```
SELECT /*! STRAIGHT_JOIN */ coll FROM table1,table2 WHERE ...
```

If you add a version number after the `!` character, the syntax within the comment is executed only if the MySQL version is greater than or equal to the specified version number. The `TEMPORARY` keyword in the following comment is executed only by servers from MySQL 3.23.02 or higher:

```
CREATE /*!32302 TEMPORARY */ TABLE t (a INT);
```

The following descriptions list MySQL extensions, organized by category.

- Organization of data on disk

MySQL Server maps each database to a directory under the MySQL data directory, and maps tables within a database to file names in the database directory. This has a few implications:

- Database and table names are case sensitive in MySQL Server on operating systems that have case-sensitive file names (such as most Unix systems). See [Section 9.2.2, “Identifier Case Sensitivity”](#).
- You can use standard system commands to back up, rename, move, delete, and copy tables that are managed by the `MyISAM` storage engine. For example, it is possible to rename a `MyISAM` table by renaming the `.MYD`, `.MYI`, and `.frm` files to which the table corresponds. (Nevertheless, it is preferable to use `RENAME TABLE` or `ALTER TABLE ... RENAME` and let the server rename the files.)

- General language syntax

- By default, strings can be enclosed by either `“”` or `‘’`, not just by `“”`. (If the `ANSI_QUOTES` SQL mode is enabled, strings can be enclosed only by `“”` and the server interprets strings enclosed by `“”` as identifiers.)
- `“\”` is the escape character in strings.
- In SQL statements, you can access tables from different databases with the `db_name.tbl_name` syntax. Some SQL servers provide the same functionality but call this `User space`. MySQL Server doesn't support tablespaces such as used in statements like this: `CREATE TABLE ralph.my_table ... IN my_tablespace`.

- SQL statement syntax

- The `ANALYZE TABLE`, `CHECK TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements.
- The `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE` statements. See [Section 13.1.10](#), “`CREATE DATABASE Syntax`”, [Section 13.1.21](#), “`DROP DATABASE Syntax`”, and [Section 13.1.1](#), “`ALTER DATABASE Syntax`”.
- The `DO` statement.
- `EXPLAIN SELECT` to obtain a description of how tables are processed by the query optimizer.
- The `FLUSH` and `RESET` statements.
- The `SET` statement. See [Section 13.7.4](#), “`SET Syntax`”.
- The `SHOW` statement. See [Section 13.7.5](#), “`SHOW Syntax`”. The information produced by many of the MySQL-specific `SHOW` statements can be obtained in more standard fashion by using `SELECT` to query `INFORMATION_SCHEMA`. See [Chapter 21](#), *INFORMATION_SCHEMA Tables*.
- Use of `LOAD DATA INFILE`. In many cases, this syntax is compatible with Oracle's `LOAD DATA INFILE`. See [Section 13.2.6](#), “`LOAD DATA INFILE Syntax`”.
- Use of `RENAME TABLE`. See [Section 13.1.32](#), “`RENAME TABLE Syntax`”.
- Use of `REPLACE` instead of `DELETE` plus `INSERT`. See [Section 13.2.8](#), “`REPLACE Syntax`”.
- Use of `CHANGE col_name`, `DROP col_name`, or `DROP INDEX`, `IGNORE` or `RENAME` in `ALTER TABLE` statements. Use of multiple `ADD`, `ALTER`, `DROP`, or `CHANGE` clauses in an `ALTER TABLE` statement. See [Section 13.1.7](#), “`ALTER TABLE Syntax`”.
- Use of index names, indexes on a prefix of a column, and use of `INDEX` or `KEY` in `CREATE TABLE` statements. See [Section 13.1.17](#), “`CREATE TABLE Syntax`”.
- Use of `TEMPORARY` or `IF NOT EXISTS` with `CREATE TABLE`.
- Use of `IF EXISTS` with `DROP TABLE` and `DROP DATABASE`.
- The capability of dropping multiple tables with a single `DROP TABLE` statement.
- The `ORDER BY` and `LIMIT` clauses of the `UPDATE` and `DELETE` statements.
- `INSERT INTO tbl_name SET col_name = ...` syntax.
- The `DELAYED` clause of the `INSERT` and `REPLACE` statements.
- The `LOW_PRIORITY` clause of the `INSERT`, `REPLACE`, `DELETE`, and `UPDATE` statements.
- Use of `INTO OUTFILE` or `INTO DUMPFILE` in `SELECT` statements. See [Section 13.2.9](#), “`SELECT Syntax`”.
- Options such as `STRAIGHT_JOIN` or `SQL_SMALL_RESULT` in `SELECT` statements.
- You don't need to name all selected columns in the `GROUP BY` clause. This gives better performance for some very specific, but quite normal queries. See [Section 12.16](#), “`Functions and Modifiers for Use with GROUP BY Clauses`”.
- You can specify `ASC` and `DESC` with `GROUP BY`, not just with `ORDER BY`.

- The ability to set variables in a statement with the `:=` assignment operator. See [Section 9.4, “User-Defined Variables”](#).
- Data types
 - The `MEDIUMINT`, `SET`, and `ENUM` data types, and the various `BLOB` and `TEXT` data types.
 - The `AUTO_INCREMENT`, `BINARY`, `NULL`, `UNSIGNED`, and `ZEROFILL` data type attributes.
- Functions and operators
 - To make it easier for users who migrate from other SQL environments, MySQL Server supports aliases for many functions. For example, all string functions support both standard SQL syntax and ODBC syntax.
 - MySQL Server understands the `||` and `&&` operators to mean logical OR and AND, as in the C programming language. In MySQL Server, `||` and `OR` are synonyms, as are `&&` and `AND`. Because of this nice syntax, MySQL Server doesn't support the standard SQL `||` operator for string concatenation; use `CONCAT()` instead. Because `CONCAT()` takes any number of arguments, it is easy to convert use of the `||` operator to MySQL Server.
 - Use of `COUNT(DISTINCT value_list)` where `value_list` has more than one element.
 - String comparisons are case-insensitive by default, with sort ordering determined by the collation of the current character set, which is `latin1` (cp1252 West European) by default. If you don't like this, you should declare your columns with the `BINARY` attribute or use the `BINARY` cast, which causes comparisons to be done using the underlying character code values rather than a lexical ordering.
 - The `%` operator is a synonym for `MOD()`. That is, `N % M` is equivalent to `MOD(N,M)`. `%` is supported for C programmers and for compatibility with PostgreSQL.
 - The `=`, `<>`, `<=`, `<`, `>=`, `>`, `<<`, `>>`, `<=>`, `AND`, `OR`, or `LIKE` operators may be used in expressions in the output column list (to the left of the `FROM`) in `SELECT` statements. For example:

```
mysql> SELECT col1=1 AND col2=2 FROM my_table;
```

- The `LAST_INSERT_ID()` function returns the most recent `AUTO_INCREMENT` value. See [Section 12.14, “Information Functions”](#).
- `LIKE` is permitted on numeric values.
- The `REGEXP` and `NOT REGEXP` extended regular expression operators.
- `CONCAT()` or `CHAR()` with one argument or more than two arguments. (In MySQL Server, these functions can take a variable number of arguments.)
- The `BIT_COUNT()`, `CASE`, `ELT()`, `FROM_DAYS()`, `FORMAT()`, `IF()`, `PASSWORD()`, `ENCRYPT()`, `MD5()`, `ENCODE()`, `DECODE()`, `PERIOD_ADD()`, `PERIOD_DIFF()`, `TO_DAYS()`, and `WEEKDAY()` functions.
- Use of `TRIM()` to trim substrings. Standard SQL supports removal of single characters only.
- The `GROUP BY` functions `STD()`, `BIT_OR()`, `BIT_AND()`, `BIT_XOR()`, and `GROUP_CONCAT()`. See [Section 12.16, “Functions and Modifiers for Use with GROUP BY Clauses”](#).

1.8.2 MySQL Differences from Standard SQL

We try to make MySQL Server follow the ANSI SQL standard and the ODBC SQL standard, but MySQL Server performs operations differently in some cases:

- There are several differences between the MySQL and standard SQL privilege systems. For example, in MySQL, privileges for a table are not automatically revoked when you delete a table. You must explicitly issue a `REVOKE` statement to revoke privileges for a table. For more information, see [Section 13.7.1.5, “REVOKE Syntax”](#).
- The `CAST()` function does not support cast to `REAL` or `BIGINT`. See [Section 12.10, “Cast Functions and Operators”](#).

1.8.2.1 `SELECT INTO TABLE` Differences

MySQL Server doesn't support the `SELECT ... INTO TABLE` Sybase SQL extension. Instead, MySQL Server supports the `INSERT INTO ... SELECT` standard SQL syntax, which is basically the same thing. See [Section 13.2.5.1, “INSERT ... SELECT Syntax”](#). For example:

```
INSERT INTO tbl_temp2 (fld_id)
  SELECT tbl_temp1.fld_order_id
  FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

Alternatively, you can use `SELECT ... INTO OUTFILE` or `CREATE TABLE ... SELECT`.

You can use `SELECT ... INTO` with user-defined variables. The same syntax can also be used inside stored routines using cursors and local variables. See [Section 13.2.9.1, “SELECT ... INTO Syntax”](#).

1.8.2.2 `UPDATE` Differences

If you access a column from the table to be updated in an expression, `UPDATE` uses the current value of the column. The second assignment in the following statement sets `col2` to the current (updated) `col1` value, not the original `col1` value. The result is that `col1` and `col2` have the same value. This behavior differs from standard SQL.

```
UPDATE t1 SET col1 = col1 + 1, col2 = col1;
```

1.8.2.3 Transaction and Atomic Operation Differences

MySQL Server (version 3.23-max and all versions 4.0 and above) supports transactions with the `InnoDB` transactional storage engine. `InnoDB` provides *full* ACID compliance. See [Chapter 15, *Alternative Storage Engines*](#). For information about `InnoDB` differences from standard SQL with regard to treatment of transaction errors, see [Section 14.21.4, “InnoDB Error Handling”](#).

The other nontransactional storage engines in MySQL Server (such as `MyISAM`) follow a different paradigm for data integrity called “atomic operations.” In transactional terms, `MyISAM` tables effectively always operate in `autocommit = 1` mode. Atomic operations often offer comparable integrity with higher performance.

Because MySQL Server supports both paradigms, you can decide whether your applications are best served by the speed of atomic operations or the use of transactional features. This choice can be made on a per-table basis.

As noted, the tradeoff for transactional versus nontransactional storage engines lies mostly in performance. Transactional tables have significantly higher memory and disk space requirements, and more CPU overhead. On the other hand, transactional storage engines such as `InnoDB` also offer many significant

features. MySQL Server's modular design enables the concurrent use of different storage engines to suit different requirements and deliver optimum performance in all situations.

Workarounds for Reliability with Non-Transactional Tables

But how do you use the features of MySQL Server to maintain integrity even with the nontransactional [MyISAM](#) tables, and how do these features compare with the transactional storage engines?

- If your applications are written in a way that is dependent on being able to call [ROLLBACK](#) rather than [COMMIT](#) in critical situations, transactions are more convenient. Transactions also ensure that unfinished updates or corrupting activities are not committed to the database; the server is given the opportunity to do an automatic rollback and your database is saved.

If you use nontransactional tables, you must resolve potential problems at the application level by including simple checks before updates and by running simple scripts that check the databases for inconsistencies and automatically repair or warn if such an inconsistency occurs. You can normally fix tables perfectly with no data integrity loss just by using the MySQL log or even adding one extra log.

- More often than not, critical transactional updates can be rewritten to be atomic. Generally speaking, all integrity problems that transactions solve can be done with [LOCK TABLES](#) or atomic updates, ensuring that there are no automatic aborts from the server, which is a common problem with transactional database systems.
- To be safe with MySQL Server, regardless of what kinds of tables you use, make regular backups and have binary logging turned on. It is always good to have backups, regardless of which database system you use.

The transactional paradigm has its advantages and disadvantages. Many users and application developers depend on the ease with which they can code around problems where an abort appears to be necessary, or is necessary. However, even if you are new to the atomic operations paradigm, or more familiar with transactions, do consider the speed benefit that nontransactional tables can offer on the order of three to five times the speed of the fastest and most optimally tuned transactional tables.

In situations where integrity is of highest importance, MySQL Server offers transaction-level reliability and integrity even for nontransactional tables. If you lock tables with [LOCK TABLES](#), all updates stall until integrity checks are made. If you obtain a [READ LOCAL](#) lock (as opposed to a write lock) for a table that enables concurrent inserts at the end of the table, reads are permitted, as are inserts by other clients. The newly inserted records are not be seen by the client that has the read lock until it releases the lock. With [INSERT DELAYED](#), you can write inserts that go into a local queue until the locks are released, without having the client wait for the insert to complete. See [Section 8.10.3, "Concurrent Inserts"](#), and [Section 13.2.5.2, "INSERT DELAYED Syntax"](#).

"Atomic," in the sense that we mean it, is nothing magical. It only means that you can be sure that while each specific update is running, no other user can interfere with it, and there can never be an automatic rollback (which can happen with transactional tables if you are not very careful). MySQL Server also guarantees that there are no dirty reads.

Following are some techniques for working with nontransactional tables:

- Loops that need transactions normally can be coded with the help of [LOCK TABLES](#), and you don't need cursors to update records on the fly.
- To avoid using [ROLLBACK](#), you can employ the following strategy:
 1. Use [LOCK TABLES](#) to lock all the tables you want to access.
 2. Test the conditions that must be true before performing the update.

3. Update if the conditions are satisfied.
4. Use `UNLOCK TABLES` to release your locks.

**Note**

This solution does not handle the situation when someone kills the threads in the middle of an update. In that case, all locks are released but some of the updates may not have been executed.

- You can also use functions to update records in a single operation, using the following techniques:
 - Modify columns relative to their current value. This makes the update correct even if another client has changed the column values in the meantime.
 - Update only those columns that actually have changed. This is a good database practice in general.
- When managing unique identifiers, you can avoid statements such as `LOCK TABLES` or `ROLLBACK` by using an `AUTO_INCREMENT` column and either the `LAST_INSERT_ID()` SQL function or the `mysql_insert_id()` C API function. See [Section 12.14, “Information Functions”](#), and [Section 23.8.7.37, “mysql_insert_id\(\)”](#).

For situations that require row-level locking, use `InnoDB` tables. Otherwise, with `MyISAM` tables, you can use a flag column in the table and do something like the following:

```
UPDATE tbl_name SET row_flag=1 WHERE id=ID;
```

MySQL returns `1` for the number of affected rows if the row was found and `row_flag` wasn't `1` in the original row. You can think of this as though MySQL Server changed the preceding statement to:

```
UPDATE tbl_name SET row_flag=1 WHERE id=ID AND row_flag <> 1;
```

1.8.2.4 Foreign Key Differences

The `InnoDB` storage engine supports checking of foreign key constraints, including `CASCADE`, `ON DELETE`, and `ON UPDATE`. See [Section 14.9.6, “InnoDB and FOREIGN KEY Constraints”](#).

For storage engines other than `InnoDB`, MySQL Server parses the `FOREIGN KEY` syntax in `CREATE TABLE` statements, but does not use or store it. This information is also present in `mysqldump`, and can be retrieved using Connector/ODBC. You can see which tables have foreign key constraints by checking the `INFORMATION_SCHEMA.TABLE_CONSTRAINTS` table in the `INFORMATION_SCHEMA` information database. You can obtain more detailed information about foreign keys from the `INFORMATION_SCHEMA.REFERENTIAL_CONSTRAINTS` table.

Foreign key enforcement offers several benefits to database developers:

- Assuming proper design of the relationships, foreign key constraints make it more difficult for a programmer to introduce an inconsistency into the database.
- Centralized checking of constraints by the database server makes it unnecessary to perform these checks on the application side. This eliminates the possibility that different applications may not all check the constraints in the same way.
- Using cascading updates and deletes can simplify the application code.
- Properly designed foreign key rules aid in documenting relationships between tables.

Foreign keys in SQL are used to check and enforce referential integrity, not to join tables. If you want to get results from multiple tables from a `SELECT` statement, you do this by performing a join between them:

```
SELECT * FROM t1 INNER JOIN t2 ON t1.id = t2.id;
```

See [Section 13.2.9.2, “JOIN Syntax”](#), and [Section 3.6.6, “Using Foreign Keys”](#).

The `FOREIGN KEY` syntax without `ON DELETE ...` is often used by ODBC applications to produce automatic `WHERE` clauses.

1.8.2.5 ‘--’ as the Start of a Comment

Standard SQL uses the C syntax `/* this is a comment */` for comments, and MySQL Server supports this syntax as well. MySQL also support extensions to this syntax that enable MySQL-specific SQL to be embedded in the comment, as described in [Section 9.6, “Comment Syntax”](#).

Standard SQL uses “--” as a start-comment sequence. MySQL Server uses “#” as the start comment character. MySQL Server 3.23.3 and up also supports a variant of the “--” comment style. That is, the “--” start-comment sequence must be followed by a space (or by a control character such as a newline). The space is required to prevent problems with automatically generated SQL queries that use constructs such as the following, where we automatically insert the value of the payment for `payment`:

```
UPDATE account SET credit=credit-payment
```

Consider about what happens if `payment` has a negative value such as `-1`:

```
UPDATE account SET credit=credit--1
```

`credit--1` is a valid expression in SQL, but “--” is interpreted as the start of a comment, part of the expression is discarded. The result is a statement that has a completely different meaning than intended:

```
UPDATE account SET credit=credit
```

The statement produces no change in value at all. This illustrates that permitting comments to start with “--” can have serious consequences.

Using our implementation requires a space following the “--” for it to be recognized as a start-comment sequence in MySQL Server 3.23.3 and newer. Therefore, `credit--1` is safe to use.

Another safe feature is that the `mysql` command-line client ignores lines that start with “--”.

The following information is relevant only if you are running a MySQL version earlier than 3.23.3:

If you have an SQL script in a text file that contains “--” comments, you should use the `replace` utility as follows to convert the comments to use “#” characters before executing the script:

```
shell> replace " --" " #" < text-file-with-funny-comments.sql \
| mysql db_name
```

That is safer than executing the script in the usual way:

```
shell> mysql db_name < text-file-with-funny-comments.sql
```

You can also edit the script file “in place” to change the “--” comments to “#” comments:

```
shell> replace " --" " #" -- text-file-with-funny-comments.sql
```

Change them back with this command:

```
shell> replace " #" " --" -- text-file-with-funny-comments.sql
```

See [Section 4.8.2, “replace — A String-Replacement Utility”](#).

1.8.3 How MySQL Deals with Constraints

MySQL enables you to work both with transactional tables that permit rollback and with nontransactional tables that do not. Because of this, constraint handling is a bit different in MySQL than in other DBMSs. We must handle the case when you have inserted or updated a lot of rows in a nontransactional table for which changes cannot be rolled back when an error occurs.

The basic philosophy is that MySQL Server tries to produce an error for anything that it can detect while parsing a statement to be executed, and tries to recover from any errors that occur while executing the statement. We do this in most cases, but not yet for all.

The options MySQL has when an error occurs are to stop the statement in the middle or to recover as well as possible from the problem and continue. By default, the server follows the latter course. This means, for example, that the server may coerce invalid values to the closest valid values.

Several SQL mode options are available to provide greater control over handling of bad data values and whether to continue statement execution or abort when errors occur. Using these options, you can configure MySQL Server to act in a more traditional fashion that is like other DBMSs that reject improper input. The SQL mode can be set globally at server startup to affect all clients. Individual clients can set the SQL mode at runtime, which enables each client to select the behavior most appropriate for its requirements. See [Section 5.1.7, “Server SQL Modes”](#).

The following sections describe how MySQL Server handles different types of constraints.

1.8.3.1 PRIMARY KEY and UNIQUE Index Constraints

Normally, errors occur for data-change statements (such as [INSERT](#) or [UPDATE](#)) that would violate primary-key, unique-key, or foreign-key constraints. If you are using a transactional storage engine such as [InnoDB](#), MySQL automatically rolls back the statement. If you are using a nontransactional storage engine, MySQL stops processing the statement at the row for which the error occurred and leaves any remaining rows unprocessed.

MySQL supports an [IGNORE](#) keyword for [INSERT](#), [UPDATE](#), and so forth. If you use it, MySQL ignores primary-key or unique-key violations and continues processing with the next row. See the section for the statement that you are using ([Section 13.2.5, “INSERT Syntax”](#), [Section 13.2.11, “UPDATE Syntax”](#), and so forth).

You can get information about the number of rows actually inserted or updated with the [mysql_info\(\)](#) C API function. You can also use the [SHOW WARNINGS](#) statement. See [Section 23.8.7.35, “mysql_info\(\)”](#), and [Section 13.7.5.41, “SHOW WARNINGS Syntax”](#).

Currently, only [InnoDB](#) tables support foreign keys. See [Section 14.9.6, “InnoDB and FOREIGN KEY Constraints”](#).

1.8.3.2 FOREIGN KEY Constraints

Foreign keys let you cross-reference related data across tables, and [foreign key constraints](#) help keep this spread-out data consistent.

MySQL supports `ON UPDATE` and `ON DELETE` foreign key references in `CREATE TABLE` and `ALTER TABLE` statements. The available referential actions are `RESTRICT` (the default), `CASCADE`, `SET NULL`, and `NO ACTION`.

`SET DEFAULT` is also supported by the MySQL Server but is currently rejected as invalid by `InnoDB`. Since MySQL does not support deferred constraint checking, `NO ACTION` is treated as `RESTRICT`. For the exact syntax supported by MySQL for foreign keys, see [Section 13.1.17.2, “Using FOREIGN KEY Constraints”](#).

`MATCH FULL`, `MATCH PARTIAL`, and `MATCH SIMPLE` are allowed, but their use should be avoided, as they cause the MySQL Server to ignore any `ON DELETE` or `ON UPDATE` clause used in the same statement. `MATCH` options do not have any other effect in MySQL, which in effect enforces `MATCH SIMPLE` semantics full-time.

MySQL requires that foreign key columns be indexed; if you create a table with a foreign key constraint but no index on a given column, an index is created.

You can obtain information about foreign keys from the `INFORMATION_SCHEMA.KEY_COLUMN_USAGE` table. An example of a query against this table is shown here:

```
mysql> SELECT TABLE_SCHEMA, TABLE_NAME, COLUMN_NAME, CONSTRAINT_NAME
> FROM INFORMATION_SCHEMA.KEY_COLUMN_USAGE
> WHERE REFERENCED_TABLE_SCHEMA IS NOT NULL;
```

TABLE_SCHEMA	TABLE_NAME	COLUMN_NAME	CONSTRAINT_NAME
fk1	myuser	myuser_id	f
fk1	product_order	customer_id	f2
fk1	product_order	product_id	f1

```
3 rows in set (0.01 sec)
```

Information about foreign keys on `InnoDB` tables can also be found in the `INNODB_SYS_FOREIGN` and `INNODB_SYS_FOREIGN_COLS` tables, in the `INFORMATION_SCHEMA` database.

Currently, only `InnoDB` tables support foreign keys. See [Section 14.9.6, “InnoDB and FOREIGN KEY Constraints”](#), for information specific to foreign key support in `InnoDB`.

Deviations from SQL Standards

MySQL's implementation of foreign keys differs from the SQL standard in the following key respects:

- If there are several rows in the parent table that have the same referenced key value, `InnoDB` acts in foreign key checks as if the other parent rows with the same key value do not exist. For example, if you have defined a `RESTRICT` type constraint, and there is a child row with several parent rows, `InnoDB` does not permit the deletion of any of those parent rows.

`InnoDB` performs cascading operations through a depth-first algorithm, based on records in the indexes corresponding to the foreign key constraints.

- A `FOREIGN KEY` constraint that references a non-`UNIQUE` key is not standard SQL but rather an `InnoDB` extension.
- If `ON UPDATE CASCADE` or `ON UPDATE SET NULL` recurses to update the *same table* it has previously updated during the same cascade, it acts like `RESTRICT`. This means that you cannot use self-referential `ON UPDATE CASCADE` or `ON UPDATE SET NULL` operations. This is to prevent infinite loops resulting from cascaded updates. A self-referential `ON DELETE SET NULL`, on the other hand, is possible, as is a self-referential `ON DELETE CASCADE`. Cascading operations may not be nested more than 15 levels deep.

- In an SQL statement that inserts, deletes, or updates many rows, foreign key constraints (like unique constraints) are checked row-by-row. When performing foreign key checks, [InnoDB](#) sets shared row-level locks on child or parent records that it must examine. MySQL checks foreign key constraints immediately; the check is not deferred to transaction commit. According to the SQL standard, the default behavior should be deferred checking. That is, constraints are only checked after the *entire SQL statement* has been processed. This means that it is not possible to delete a row that refers to itself using a foreign key.

For information how [InnoDB](#) foreign keys differ from the SQL standard, see [Section 14.9.6, “InnoDB and FOREIGN KEY Constraints”](#).

1.8.3.3 Constraints on Invalid Data

By default, MySQL is forgiving of invalid or improper data values and coerces them to valid values for data entry. However, you can enable strict SQL mode to select more traditional treatment of bad values such that the server rejects them and aborts the statement in which they occur. See [Section 5.1.7, “Server SQL Modes”](#).

This section describes the default (forgiving) behavior of MySQL, as well as the strict SQL mode and how it differs.

If you are not using strict mode, then whenever you insert an “incorrect” value into a column, such as a [NULL](#) into a [NOT NULL](#) column or a too-large numeric value into a numeric column, MySQL sets the column to the “best possible value” instead of producing an error: The following rules describe in more detail how this works:

- If you try to store an out of range value into a numeric column, MySQL Server instead stores zero, the smallest possible value, or the largest possible value, whichever is closest to the invalid value.
- For strings, MySQL stores either the empty string or as much of the string as can be stored in the column.
- If you try to store a string that does not start with a number into a numeric column, MySQL Server stores 0.
- Invalid values for [ENUM](#) and [SET](#) columns are handled as described in [Section 1.8.3.4, “ENUM and SET Constraints”](#).
- MySQL permits you to store certain incorrect date values into [DATE](#) and [DATETIME](#) columns (such as `'2000-02-31'` or `'2000-02-00'`). In this case, when an application that has not enabled strict SQL mode, it is up to the application to validate the dates before storing them. If MySQL can store a date value and retrieve exactly the same value, MySQL stores it as given. If the date is totally wrong (outside the server's ability to store it), the special “zero” date value `'0000-00-00'` is stored in the column instead.
- If you try to store [NULL](#) into a column that doesn't take [NULL](#) values, an error occurs for single-row [INSERT](#) statements. For multiple-row [INSERT](#) statements or for [INSERT INTO ... SELECT](#) statements, MySQL Server stores the implicit default value for the column data type. In general, this is 0 for numeric types, the empty string (`' '`) for string types, and the “zero” value for date and time types. Implicit default values are discussed in [Section 11.6, “Data Type Default Values”](#).
- If an [INSERT](#) statement specifies no value for a column, MySQL inserts its default value if the column definition includes an explicit [DEFAULT](#) clause. If the definition has no such [DEFAULT](#) clause, MySQL inserts the implicit default value for the column data type.

The reason for using the preceding rules in nonstrict mode is that we can't check these conditions until the statement has begun executing. We can't just roll back if we encounter a problem after updating a few

rows, because the storage engine may not support rollback. The option of terminating the statement is not that good; in this case, the update would be “half done,” which is probably the worst possible scenario. In this case, it is better to “do the best you can” and then continue as if nothing happened.

In MySQL 5.0.2 and up, you can select stricter treatment of input values by using the [STRICT_TRANS_TABLES](#) or [STRICT_ALL_TABLES](#) SQL modes:

```
SET sql_mode = 'STRICT_TRANS_TABLES';
SET sql_mode = 'STRICT_ALL_TABLES';
```

[STRICT_TRANS_TABLES](#) enables strict mode for transactional storage engines, and also to some extent for nontransactional engines. It works like this:

- For transactional storage engines, bad data values occurring anywhere in a statement cause the statement to abort and roll back.
- For nontransactional storage engines, a statement aborts if the error occurs in the first row to be inserted or updated. (When the error occurs in the first row, the statement can be aborted to leave the table unchanged, just as for a transactional table.) Errors in rows after the first do not abort the statement, because the table has already been changed by the first row. Instead, bad data values are adjusted and result in warnings rather than errors. In other words, with [STRICT_TRANS_TABLES](#), a wrong value causes MySQL to roll back all updates done so far, if that can be done without changing the table. But once the table has been changed, further errors result in adjustments and warnings.

For even stricter checking, enable [STRICT_ALL_TABLES](#). This is the same as [STRICT_TRANS_TABLES](#) except that for nontransactional storage engines, errors abort the statement even for bad data in rows following the first row. This means that if an error occurs partway through a multiple-row insert or update for a nontransactional table, a partial update results. Earlier rows are inserted or updated, but those from the point of the error on are not. To avoid this for nontransactional tables, either use single-row statements or else use [STRICT_TRANS_TABLES](#) if conversion warnings rather than errors are acceptable. To avoid problems in the first place, do not use MySQL to check column content. It is safest (and often faster) to let the application ensure that it passes only valid values to the database.

With either of the strict mode options, you can cause errors to be treated as warnings by using [INSERT IGNORE](#) or [UPDATE IGNORE](#) rather than [INSERT](#) or [UPDATE](#) without [IGNORE](#).

1.8.3.4 [ENUM](#) and [SET](#) Constraints

[ENUM](#) and [SET](#) columns provide an efficient way to define columns that can contain only a given set of values. See [Section 11.4.4, “The \[ENUM\]\(#\) Type”](#), and [Section 11.4.5, “The \[SET\]\(#\) Type”](#). However, before MySQL 5.0.2, [ENUM](#) and [SET](#) columns do not provide true constraints on entry of invalid data:

- [ENUM](#) columns always have a default value. If you specify no default value, then it is [NULL](#) for columns that can have [NULL](#), otherwise it is the first enumeration value in the column definition.
- If you insert an incorrect value into an [ENUM](#) column or if you force a value into an [ENUM](#) column with [IGNORE](#), it is set to the reserved enumeration value of 0, which is displayed as an empty string in string context.
- If you insert an incorrect value into a [SET](#) column, the incorrect value is ignored. For example, if the column can contain the values 'a', 'b', and 'c', an attempt to assign 'a,x,b,y' results in a value of 'a,b'.

As of MySQL 5.0.2, you can configure the server to use strict SQL mode. See [Section 5.1.7, “Server SQL Modes”](#). With strict mode enabled, the definition of a [ENUM](#) or [SET](#) column does act as a constraint on values entered into the column. An error occurs for values that do not satisfy these conditions:

- An `ENUM` value must be one of those listed in the column definition, or the internal numeric equivalent thereof. The value cannot be the error value (that is, 0 or the empty string). For a column defined as `ENUM('a','b','c')`, values such as `' '`, `'d'`, or `'ax'` are invalid and are rejected.
- A `SET` value must be the empty string or a value consisting only of the values listed in the column definition separated by commas. For a column defined as `SET('a','b','c')`, values such as `'d'` or `'a,b,c,d'` are invalid and are rejected.

Errors for invalid values can be suppressed in strict mode if you use `INSERT IGNORE` or `UPDATE IGNORE`. In this case, a warning is generated rather than an error. For `ENUM`, the value is inserted as the error member (0). For `SET`, the value is inserted as given except that any invalid substrings are deleted. For example, `'a,x,b,y'` results in a value of `'a,b'`.

1.9 Credits

The following sections list developers, contributors, and supporters that have helped to make MySQL what it is today.

1.9.1 Contributors to MySQL

Although Oracle Corporation and/or its affiliates own all copyrights in the `MySQL server` and the `MySQL manual`, we wish to recognize those who have made contributions of one kind or another to the `MySQL distribution`. Contributors are listed here, in somewhat random order:

- Gianmassimo Vigazzola <qwerg@mbbox.vol.it> or <qwerg@tin.it>

The initial port to Win32/NT.

- Per Eric Olsson

For constructive criticism and real testing of the dynamic record format.

- Irena Pancirov <irena@mail.yacc.it>

Win32 port with Borland compiler. `mysqlshutdown.exe` and `mysqlwatch.exe`.

- David J. Hughes

For the effort to make a shareware SQL database. At TcX, the predecessor of MySQL AB, we started with `mSQL`, but found that it couldn't satisfy our purposes so instead we wrote an SQL interface to our application builder Unireg. `mysqladmin` and `mysql` client are programs that were largely influenced by their `mSQL` counterparts. We have put a lot of effort into making the MySQL syntax a superset of `mSQL`. Many of the API's ideas are borrowed from `mSQL` to make it easy to port free `mSQL` programs to the MySQL API. The MySQL software doesn't contain any code from `mSQL`. Two files in the distribution (`client/insert_test.c` and `client/select_test.c`) are based on the corresponding (noncopyrighted) files in the `mSQL` distribution, but are modified as examples showing the changes necessary to convert code from `mSQL` to MySQL Server. (`mSQL` is copyrighted David J. Hughes.)

- Patrick Lynch

For helping us acquire <http://www.mysql.com/>.

- Fred Lindberg

For setting up gmail to handle the MySQL mailing list and for the incredible help we got in managing the MySQL mailing lists.

- Igor Romanenko <igor@frog.kiev.ua>
[mysqldump](#) (previously [msqldump](#), but ported and enhanced by Monty).
- Yuri Dario
For keeping up and extending the MySQL OS/2 port.
- Tim Bunce
Author of [mysqlhotcopy](#).
- Zarko Mocnik <zarko.mocnik@dem.si>
Sorting for Slovenian language.
- "TAMITO" <tommy@valley.ne.jp>
The `_MB` character set macros and the `ujis` and `sjis` character sets.
- Joshua Chamas <joshua@chamas.com>
Base for concurrent insert, extended date syntax, debugging on NT, and answering on the MySQL mailing list.
- Yves Carlier <Yves.Carlier@rug.ac.be>
[mysqlaccess](#), a program to show the access rights for a user.
- Rhys Jones <rhys@wales.com> (And GWE Technologies Limited)
For one of the early JDBC drivers.
- Dr Xiaokun Kelvin ZHU <X.Zhu@brad.ac.uk>
Further development of one of the early JDBC drivers and other MySQL-related Java tools.
- James Cooper <pixel@organic.com>
For setting up a searchable mailing list archive at his site.
- Rick Mehalick <Rick_Mehalick@i-o.com>
For [xmysql](#), a graphical X client for MySQL Server.
- Doug Sisk <sisk@wix.com>
For providing RPM packages of MySQL for Red Hat Linux.
- Diemand Alexander V. <axeld@vial.ethz.ch>
For providing RPM packages of MySQL for Red Hat Linux-Alpha.
- Antoni Pamies Olive <toni@readysoft.es>
For providing RPM versions of a lot of MySQL clients for Intel and SPARC.
- Jay Bloodworth <jay@pathways.sde.state.sc.us>
For providing RPM versions for MySQL 3.21.

- David Sacerdote <davids@secnet.com>
Ideas for secure checking of DNS host names.
- Wei-Jou Chen <jou@nematic.ieo.nctu.edu.tw>
Some support for Chinese(BIG5) characters.
- Wei He <hewei@mail.ied.ac.cn>
A lot of functionality for the Chinese(GBK) character set.
- Jan Pazdziora <adelton@fi.muni.cz>
Czech sorting order.
- Zeev Suraski <bourbon@netvision.net.il>
`FROM_UNIXTIME()` time formatting, `ENCRYPT()` functions, and `bison` advisor. Active mailing list member.
- Luuk de Boer <luuk@wxs.nl>
Ported (and extended) the benchmark suite to `DBI/DBD`. Have been of great help with `crash-me` and running benchmarks. Some new date functions. The `mysql_setpermission` script.
- Alexis Mikhailov <root@medinf.chuvashia.su>
User-defined functions (UDFs); `CREATE FUNCTION` and `DROP FUNCTION`.
- Andreas F. Bobak <bobak@relog.ch>
The `AGGREGATE` extension to user-defined functions.
- Ross Wakelin <R.Wakelin@march.co.uk>
Help to set up InstallShield for MySQL-Win32.
- Jethro Wright III <jetman@li.net>
The `libmysql.dll` library.
- James Pereria <jpereira@iafrica.com>
Mysqlmanager, a Win32 GUI tool for administering MySQL Servers.
- Curt Sampson <cjs@portal.ca>
Porting of MIT-pthreads to NetBSD/Alpha and NetBSD 1.3/i386.
- Martin Ramsch <m.ramsch@computer.org>
Examples in the MySQL Tutorial.
- Steve Harvey
For making `mysqlaccess` more secure.
- Konark IA-64 Centre of Persistent Systems Private Limited

Help with the Win64 port of the MySQL server.

- Albert Chin-A-Young.

Configure updates for Tru64, large file support and better TCP wrappers support.

- John Birrell

Emulation of `pthread_mutex()` for OS/2.

- Benjamin Pflugmann

Extended `MERGE` tables to handle `INSERTS`. Active member on the MySQL mailing lists.

- Jocelyn Fournier

Excellent spotting and reporting innumerable bugs (especially in the MySQL 4.1 subquery code).

- Marc Liyanage

Maintaining the Mac OS X packages and providing invaluable feedback on how to create Mac OS X packages.

- Robert Rutherford

Providing invaluable information and feedback about the QNX port.

- Previous developers of NDB Cluster

Lots of people were involved in various ways summer students, master thesis students, employees. In total more than 100 people so too many to mention here. Notable name is Ataulah Dabaghi who up until 1999 contributed around a third of the code base. A special thanks also to developers of the AXE system which provided much of the architectural foundations for NDB Cluster with blocks, signals and crash tracing functionality. Also credit should be given to those who believed in the ideas enough to allocate of their budgets for its development from 1992 to present time.

- Google Inc.

We wish to recognize Google Inc. for contributions to the MySQL distribution: Mark Callaghan's SMP Performance patches and other patches.

Other contributors, bugfinders, and testers: James H. Thompson, Maurizio Menghini, Wojciech Tryc, Luca Berra, Zarko Mocnik, Wim Bonis, Elmar Haneke, <jehamby@lightside>, <psmith@BayNetworks.com>, <duane@connect.com.au>, Ted Deppner <ted@psyber.com>, Mike Simons, Jaakko Hyvatti.

And lots of bug report/patches from the folks on the mailing list.

A big tribute goes to those that help us answer questions on the MySQL mailing lists:

- Daniel Koch <dkoch@amcity.com>

Irix setup.

- Luuk de Boer <luuk@wxs.nl>

Benchmark questions.

- Tim Sailer <tps@users.buoy.com>
[DBD::mysql](#) questions.
- Boyd Lynn Gerber <gerberb@zenez.com>
SCO-related questions.
- Richard Mehalick <RM186061@shellus.com>
[xmysql](#)-related questions and basic installation questions.
- Zeev Suraski <bourbon@netvision.net.il>
Apache module configuration questions (log & auth), PHP-related questions, SQL syntax-related questions and other general questions.
- Francesc Guasch <frankie@citel.upc.es>
General questions.
- Jonathan J Smith <jsmith@wtp.net>
Questions pertaining to OS-specifics with Linux, SQL syntax, and other things that might need some work.
- David Sklar <sklar@student.net>
Using MySQL from PHP and Perl.
- Alistair MacDonald <A.MacDonald@uel.ac.uk>
Is flexible and can handle Linux and perhaps HP-UX.
- John Lyon <jlyon@imag.net>
Questions about installing MySQL on Linux systems, using either [.rpm](#) files or compiling from source.
- Lorvid Ltd. <lorvid@WOLFENET.com>
Simple billing/license/support/copyright issues.
- Patrick Sherrill <patrick@coconet.com>
ODBC and VisualC++ interface questions.
- Randy Harmon <rjharmon@uptimecomputers.com>
[DBD](#), Linux, some SQL syntax questions.

1.9.2 Documenters and translators

The following people have helped us with writing the MySQL documentation and translating the documentation or error messages in MySQL.

- Paul DuBois
Ongoing help with making this manual correct and understandable. That includes rewriting Monty's and David's attempts at English into English as other people know it.

- Kim Aldale

Helped to rewrite Monty's and David's early attempts at English into English.

- Michael J. Miller Jr. <mke@terrapin.turbolift.com>

For the first MySQL manual. And a lot of spelling/language fixes for the FAQ (that turned into the MySQL manual a long time ago).

- Yan Cailin

First translator of the MySQL Reference Manual into simplified Chinese in early 2000 on which the Big5 and HK coded versions were based.

- Jay Flaherty <fty@mediapulse.com>

Big parts of the Perl DBI/DBD section in the manual.

- Paul Southworth <pauls@etext.org>, Ray Loyzaga <yar@cs.su.oz.au>

Proof-reading of the Reference Manual.

- Therrien Gilbert <gilbert@ican.net>, Jean-Marc Pouyot <jmp@scaltaire.fr>

French error messages.

- Petr Snajdr, <snajdr@pvt.net>

Czech error messages.

- Jaroslaw Lewandowski <jotel@itnet.com.pl>

Polish error messages.

- Miguel Angel Fernandez Roiz

Spanish error messages.

- Roy-Magne Mo <rmo@www.hivolda.no>

Norwegian error messages and testing of MySQL 3.21.xx.

- Timur I. Bakeyev <root@timur.tatarstan.ru>

Russian error messages.

- <brenno@dewinter.com> & Filippo Grassilli <phil@hyppo.com>

Italian error messages.

- Dirk Munzinger <dirk@trinity.saar.de>

German error messages.

- Billik Stefan <billik@sun.uniag.sk>

Slovak error messages.

- Stefan Saroiu <tzoompy@cs.washington.edu>

Romanian error messages.

- Peter Feher

Hungarian error messages.

- Roberto M. Serqueira

Portuguese error messages.

- Carsten H. Pedersen

Danish error messages.

- Arjen Lentz

Dutch error messages, completing earlier partial translation (also work on consistency and spelling).

1.9.3 Packages that support MySQL

The following is a list of creators/maintainers of some of the most important API/packages/applications that a lot of people use with MySQL.

We cannot list every possible package here because the list would then be way to hard to maintain. For other packages, please refer to the software portal at <http://solutions.mysql.com/software/>.

- Tim Bunce, Alligator Descartes

For the `DBD` (Perl) interface.

- Andreas Koenig <a.koenig@mind.de>

For the Perl interface for MySQL Server.

- Jochen Wiedmann <wiedmann@neckar-alb.de>

For maintaining the Perl `DBD::mysql` module.

- Eugene Chan <eugene@acenet.com.sg>

For porting PHP for MySQL Server.

- Georg Richter

MySQL 4.1 testing and bug hunting. New PHP 5.0 `mysqli` extension (API) for use with MySQL 4.1 and up.

- Giovanni Maruzzelli <maruzz@matrice.it>

For porting iODBC (Unix ODBC).

- Xavier Leroy <Xavier.Leroy@inria.fr>

The author of LinuxThreads (used by the MySQL Server on Linux).

1.9.4 Tools that were used to create MySQL

The following is a list of some of the tools we have used to create MySQL. We use this to express our thanks to those that has created them as without these we could not have made MySQL what it is today.

- Free Software Foundation

From whom we got an excellent compiler ([gcc](#)), an excellent debugger ([gdb](#) and the [libc](#) library (from which we have borrowed [strtoc.c](#) to get some code working in Linux).

- Free Software Foundation & The XEmacs development team

For a really great editor/environment.

- Julian Seward

Author of [valgrind](#), an excellent memory checker tool that has helped us find a lot of otherwise hard to find bugs in MySQL.

- Dorothea Lütkehaus and Andreas Zeller

For [DDD](#) (The Data Display Debugger) which is an excellent graphical front end to [gdb](#).

1.9.5 Supporters of MySQL

Although Oracle Corporation and/or its affiliates own all copyrights in the [MySQL server](#) and the [MySQL manual](#), we wish to recognize the following companies, which helped us finance the development of the [MySQL server](#), such as by paying us for developing a new feature or giving us hardware for development of the [MySQL server](#).

- VA Linux / Andover.net

Funded replication.

- NuSphere

Editing of the MySQL manual.

- Stork Design studio

The MySQL Web site in use between 1998-2000.

- Intel

Contributed to development on Windows and Linux platforms.

- Compaq

Contributed to Development on Linux/Alpha.

- SWSOft

Development on the embedded [mysqld](#) version.

- FutureQuest

The [--skip-show-database](#) option.

Chapter 2 Installing and Upgrading MySQL

Table of Contents

2.1 General Installation Guidance	49
2.1.1 Operating Systems Supported by MySQL Community Server	50
2.1.2 Choosing Which MySQL Distribution to Install	50
2.1.3 How to Get MySQL	53
2.1.4 Verifying Package Integrity Using MD5 Checksums or GnuPG	53
2.1.5 Installation Layouts	63
2.1.6 Compiler-Specific Build Characteristics	63
2.2 Installing MySQL on Unix/Linux Using Generic Binaries	63
2.3 Installing MySQL on Microsoft Windows	66
2.3.1 MySQL Installation Layout on Microsoft Windows	68
2.3.2 Choosing An Installation Package	68
2.3.3 Installing MySQL on Microsoft Windows Using MySQL Installer	69
2.3.4 MySQL Notifier for Microsoft Windows	87
2.3.5 Installing MySQL on Microsoft Windows Using an MSI Package	98
2.3.6 MySQL Server Instance Configuration Wizard	105
2.3.7 Installing MySQL on Microsoft Windows Using a noinstall Zip Archive	120
2.3.8 Troubleshooting a Microsoft Windows MySQL Server Installation	128
2.3.9 Upgrading MySQL on Windows	129
2.3.10 Windows Postinstallation Procedures	131
2.4 Installing MySQL on Mac OS X	132
2.4.1 General Notes on Installing MySQL on Mac OS X	133
2.4.2 Installing MySQL on Mac OS X Using Native Packages	134
2.4.3 Installing the MySQL Startup Item	137
2.4.4 Installing and Using the MySQL Preference Pane	141
2.4.5 Using the Bundled MySQL on Mac OS X Server	143
2.5 Installing MySQL on Linux	144
2.5.1 Installing MySQL on Linux Using RPM Packages	144
2.5.2 Installing MySQL on Linux Using Debian Packages	149
2.5.3 Installing MySQL on Linux Using Native Package Managers	150
2.6 Installing MySQL Using Unbreakable Linux Network (ULN)	154
2.7 Installing MySQL on Solaris and OpenSolaris	154
2.7.1 Installing MySQL on Solaris Using a Solaris PKG	155
2.7.2 Installing MySQL on OpenSolaris Using IPS	156
2.8 Installing MySQL on FreeBSD	157
2.9 Installing MySQL from Source	158
2.9.1 MySQL Layout for Source Installation	160
2.9.2 Installing MySQL Using a Standard Source Distribution	160
2.9.3 Installing MySQL Using a Development Source Tree	164
2.9.4 MySQL Source-Configuration Options	166
2.9.5 Dealing with Problems Compiling MySQL	177
2.9.6 MySQL Configuration and Third-Party Tools	179
2.10 Postinstallation Setup and Testing	179
2.10.1 Postinstallation Procedures for Unix-like Systems	180
2.10.2 Securing the Initial MySQL Accounts	191
2.11 Upgrading or Downgrading MySQL	195
2.11.1 Upgrading MySQL	195
2.11.2 Downgrading MySQL	207

2.11.3 Checking Whether Tables or Indexes Must Be Rebuilt	210
2.11.4 Rebuilding or Repairing Tables or Indexes	212
2.11.5 Copying MySQL Databases to Another Machine	213
2.12 Environment Variables	214
2.13 Perl Installation Notes	215
2.13.1 Installing Perl on Unix	216
2.13.2 Installing ActiveState Perl on Windows	217
2.13.3 Problems Using the Perl DBI/DBD Interface	217

This chapter describes how to obtain and install MySQL. A summary of the procedure follows and later sections provide the details. If you plan to upgrade an existing version of MySQL to a newer version rather than install MySQL for the first time, see [Section 2.11.1, “Upgrading MySQL”](#), for information about upgrade procedures and about issues that you should consider before upgrading.

If you are interested in migrating to MySQL from another database system, you may wish to read [Section A.8, “MySQL 5.5 FAQ: Migration”](#), which contains answers to some common questions concerning migration issues.

If you are migrating from MySQL Enterprise Edition to MySQL Community Server, see [Section 2.11.2.2, “Downgrading from MySQL Enterprise Edition to MySQL Community Server”](#).

Installation of MySQL generally follows the steps outlined here:

- Determine whether MySQL runs and is supported on your platform.**

Please note that not all platforms are equally suitable for running MySQL, and that not all platforms on which MySQL is known to run are officially supported by Oracle Corporation:

- Choose which distribution to install.**

Several versions of MySQL are available, and most are available in several distribution formats. You can choose from pre-packaged distributions containing binary (precompiled) programs or source code. When in doubt, use a binary distribution. We also provide public access to our current source tree for those who want to see our most recent developments and help us test new code. To determine which version and type of distribution you should use, see [Section 2.1.2, “Choosing Which MySQL Distribution to Install”](#).

- Download the distribution that you want to install.**

For instructions, see [Section 2.1.3, “How to Get MySQL”](#). To verify the integrity of the distribution, use the instructions in [Section 2.1.4, “Verifying Package Integrity Using MD5 Checksums or GnuPG”](#).

- Install the distribution.**

To install MySQL from a binary distribution, use the instructions in [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#).

To install MySQL from a source distribution or from the current development source tree, use the instructions in [Section 2.9, “Installing MySQL from Source”](#).

- Perform any necessary postinstallation setup.**

After installing MySQL, see [Section 2.10, “Postinstallation Setup and Testing”](#) for information about making sure the MySQL server is working properly. Also refer to the information provided in [Section 2.10.2, “Securing the Initial MySQL Accounts”](#). This section describes how to secure the initial

MySQL user accounts, *which have no passwords* until you assign passwords. The section applies whether you install MySQL using a binary or source distribution.

6. If you want to run the MySQL benchmark scripts, Perl support for MySQL must be available. See [Section 2.13, “Perl Installation Notes”](#).

Instructions for installing MySQL on different platforms and environments is available on a platform by platform basis:

- **Unix, Linux, FreeBSD**

For instructions on installing MySQL on most Linux and Unix platforms using a generic binary (for example, a `.tar.gz` package), see [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#).

For information on building MySQL entirely from the source code distributions or the source code repositories, see [Section 2.9, “Installing MySQL from Source”](#)

For specific platform help on installation, configuration, and building from source see the corresponding platform section:

- Linux, including notes on distribution specific methods, see [Section 2.5, “Installing MySQL on Linux”](#).
- Solaris and OpenSolaris, including PKG and IPS formats, see [Section 2.7, “Installing MySQL on Solaris and OpenSolaris”](#).
- IBM AIX, see [Section 2.7, “Installing MySQL on Solaris and OpenSolaris”](#).
- FreeBSD, see [Section 2.8, “Installing MySQL on FreeBSD”](#).

- **Microsoft Windows**

For instructions on installing MySQL on Microsoft Windows, using either a Zipped binary or an MSI package, see [Section 2.3, “Installing MySQL on Microsoft Windows”](#).

For information on using the MySQL Server Instance Config Wizard, see [Section 2.3.6, “MySQL Server Instance Configuration Wizard”](#).

For details and instructions on building MySQL from source code using Microsoft Visual Studio, see [Section 2.9, “Installing MySQL from Source”](#).

- **Mac OS X**

For installation on Mac OS X, including using both the binary package and native PKG formats, see [Section 2.4, “Installing MySQL on Mac OS X”](#).

For information on making use of the MySQL Startup Item to automatically start and stop MySQL, see [Section 2.4.3, “Installing the MySQL Startup Item”](#).

For information on the MySQL Preference Pane, see [Section 2.4.4, “Installing and Using the MySQL Preference Pane”](#).

2.1 General Installation Guidance

The immediately following sections contain the information necessary to choose, download, and verify your distribution. The instructions in later sections of the chapter describe how to install the distribution that you choose. For binary distributions, see the instructions at [Section 2.2, “Installing MySQL on Unix/Linux Using](#)

[Generic Binaries](#)” or the corresponding section for your platform if available. To build MySQL from source, use the instructions in [Section 2.9, “Installing MySQL from Source”](#).

2.1.1 Operating Systems Supported by MySQL Community Server

MySQL is available on a number of operating systems and platforms. For information about those platforms that are officially supported, see <http://www.mysql.com/support/supportedplatforms/database.html> on the MySQL Web site.

2.1.2 Choosing Which MySQL Distribution to Install

When preparing to install MySQL, you should decide which version to use. MySQL development occurs in several release series, and you can pick the one that best fits your needs. After deciding which version to install, you can choose a distribution format. Releases are available in binary or source format.

2.1.2.1 Choosing Which Version of MySQL to Install

The first decision to make is whether you want to use a production (stable) release or a development release. In the MySQL development process, multiple release series co-exist, each at a different stage of maturity.

Production Releases

- MySQL 5.6: Latest General Availability (Production) release
- MySQL 5.5: Previous General Availability (Production) release
- MySQL 5.1: Older General Availability (Production) release
- MySQL 5.0: Older Production release nearing the end of the product lifecycle

MySQL 4.1, 4.0, and 3.23 are old releases that are no longer supported.

See <http://www.mysql.com/about/legal/lifecycle/> for information about support policies and schedules.

Normally, if you are beginning to use MySQL for the first time or trying to port it to some system for which there is no binary distribution, use the most recent General Availability series listed in the preceding descriptions. All MySQL releases, even those from development series, are checked with the MySQL benchmarks and an extensive test suite before being issued.

If you are running an older system and want to upgrade, but do not want to take the chance of having a nonseamless upgrade, you should upgrade to the latest version in the same release series you are using (where only the last part of the version number is newer than yours). We have tried to fix only fatal bugs and make only small, relatively “safe” changes to that version.

If you want to use new features not present in the production release series, you can use a version from a development series. Be aware that development releases are not as stable as production releases.

We do not use a complete code freeze because this prevents us from making bugfixes and other fixes that must be done. We may add small things that should not affect anything that currently works in a production release. Naturally, relevant bugfixes from an earlier series propagate to later series.

If you want to use the very latest sources containing all current patches and bugfixes, you can use one of our source code repositories (see [Section 2.9.3, “Installing MySQL Using a Development Source Tree”](#)). These are not “releases” as such, but are available as previews of the code on which future releases are to be based.

The naming scheme in MySQL 5.5 uses release names that consist of three numbers and a suffix; for example, **mysql-5.5.6-m3**. The numbers within the release name are interpreted as follows:

- The first number (**5**) is the major version and describes the file format. All MySQL 5 releases have the same file format.
- The second number (**5**) is the release level. Taken together, the major version and release level constitute the release series number.
- The third number (**6**) is the version number within the release series. This is incremented for each new release. Usually you want the latest version for the series you have chosen.

For each minor update, the last number in the version string is incremented. When there are major new features or minor incompatibilities with previous versions, the second number in the version string is incremented. When the file format changes, the first number is increased.

Release names also include a suffix that indicates the stability level of the release. Releases within a series progress through a set of suffixes to indicate how the stability level improves. The possible suffixes are:

- **mN** (for example, **m1**, **m2**, **m3**, ...) indicate a milestone number. MySQL development uses a milestone model, in which each milestone proceeds through a small number of versions with a tight focus on a small subset of thoroughly tested features. Following the releases for one milestone, development proceeds with another small number of releases that focuses on the next small set of features, also thoroughly tested. Features within milestone releases may be considered to be of pre-production quality.
- **rc** indicates a Release Candidate. Release candidates are believed to be stable, having passed all of MySQL's internal testing, and with all known fatal runtime bugs fixed. However, the release has not been in widespread use long enough to know for sure that all bugs have been identified. Only minor fixes are added.
- If there is no suffix, it indicates that the release is a General Availability (GA) or Production release. GA releases are stable, having successfully passed through all earlier release stages and are believed to be reliable, free of serious bugs, and suitable for use in production systems. Only critical bugfixes are applied to the release.

All releases of MySQL are run through our standard tests and benchmarks to ensure that they are relatively safe to use. Because the standard tests are extended over time to check for all previously found bugs, the test suite keeps getting better.

All releases have been tested at least with these tools:

- **An internal test suite.** The `mysql-test` directory contains an extensive set of test cases. We run these tests for every server binary. See [Section 24.1.2, “The MySQL Test Suite”](#), for more information about this test suite.
- **The MySQL benchmark suite.** This suite runs a range of common queries. It is also a test to determine whether the latest batch of optimizations actually made the code faster. See [Section 8.12.2, “The MySQL Benchmark Suite”](#).

We also perform additional integration and nonfunctional testing of the latest MySQL version in our internal production environment. Integration testing is done with different connectors, storage engines, replication modes, backup, partitioning, stored programs, and so forth in various combinations. Additional nonfunctional testing is done in areas of performance, concurrency, stress, high volume, upgrade and downgrade.

2.1.2.2 Choosing a Distribution Format

After choosing which version of MySQL to install, you should decide whether to use a binary distribution or a source distribution. In most cases, you should probably use a binary distribution, if one exists for your platform. Binary distributions are available in native format for many platforms, such as RPM packages

for Linux, DMG packages for Mac OS X, and PKG packages for Solaris. Distributions are also available in more generic formats such as Zip archives or compressed `tar` files.

Reasons to choose a binary distribution include the following:

- Binary distributions generally are easier to install than source distributions.
- To satisfy different user requirements, we provide several servers in binary distributions. `mysqld` is an optimized server that is a smaller, faster binary. `mysqld-debug` is compiled with debugging support.

Each of these servers is compiled from the same source distribution, though with different configuration options. All native MySQL clients can connect to servers from either MySQL version.

Under some circumstances, you may be better off installing MySQL from a source distribution:

- You want to install MySQL at some explicit location. The standard binary distributions are ready to run at any installation location, but you might require even more flexibility to place MySQL components where you want.
- You want to configure `mysqld` to ensure that features are available that might not be included in the standard binary distributions. Here is a list of the most common extra options that you may want to use to ensure feature availability:
 - `-DWITH_LIBWRAP=1` for TCP wrappers support.
 - `-DWITH_ZLIB={system|bundled}` for features that depend on compression
 - `-DWITH_DEBUG=1` for debugging support

For additional information, see [Section 2.9.4, “MySQL Source-Configuration Options”](#).

- You want to configure `mysqld` without some features that are included in the standard binary distributions. For example, distributions normally are compiled with support for all character sets. If you want a smaller MySQL server, you can recompile it with support for only the character sets you need.
- You want to use the latest sources from one of the Bazaar repositories to have access to all current bugfixes. For example, if you have found a bug and reported it to the MySQL development team, the bugfix is committed to the source repository and you can access it there. The bugfix does not appear in a release until a release actually is issued.
- You want to read (or modify) the C and C++ code that makes up MySQL. For this purpose, you should get a source distribution, because the source code is always the ultimate manual.
- Source distributions contain more tests and examples than binary distributions.

2.1.2.3 How and When Updates Are Released

MySQL is evolving quite rapidly and we want to share new developments with other MySQL users. We try to produce a new release whenever we have new and useful features that others also seem to have a need for.

We also try to help users who request features that are easy to implement. We take note of what our licensed users want, and we especially take note of what our support customers want and try to help them in this regard.

No one is *required* to download a new release. The [Release Notes](#) help you determine whether the new release has something you really want.

We use the following policy when updating MySQL:

- Enterprise Server releases are meant to appear every 18 months, supplemented by quarterly service packs and monthly rapid updates. Community Server releases are meant to appear 2 to 3 times per year.
- Releases are issued within each series. For each release, the last number in the version is one more than the previous release within the same series.
- Binary distributions for some platforms are made by us for major releases. Other people may make binary distributions for other systems, but probably less frequently.
- We make fixes available as soon as we have identified and corrected small or noncritical but annoying bugs. The fixes are available in source form immediately from our public Bazaar repositories, and are included in the next release.
- If by any chance a security vulnerability or critical bug is found in a release, our policy is to fix it in a new release as soon as possible. (We would like other companies to do this, too!)

2.1.3 How to Get MySQL

Check our downloads page at <http://dev.mysql.com/downloads/> for information about the current version of MySQL and for downloading instructions. For a complete up-to-date list of MySQL download mirror sites, see <http://dev.mysql.com/downloads/mirrors.html>. You can also find information there about becoming a MySQL mirror site and how to report a bad or out-of-date mirror.

To obtain the latest development source, see [Section 2.9.3, “Installing MySQL Using a Development Source Tree”](#).

2.1.4 Verifying Package Integrity Using MD5 Checksums or **GnuPG**

After you have downloaded the MySQL package that suits your needs and before you attempt to install it, you should make sure that it is intact and has not been tampered with. There are three means of integrity checking:

- MD5 checksums
- Cryptographic signatures using **GnuPG**, the GNU Privacy Guard
- For RPM packages, the built-in RPM integrity verification mechanism

The following sections describe how to use these methods.

If you notice that the MD5 checksum or GPG signatures do not match, first try to download the respective package one more time, perhaps from another mirror site.

2.1.4.1 Verifying the MD5 Checksum

After you have downloaded a MySQL package, you should make sure that its MD5 checksum matches the one provided on the MySQL download pages. Each package has an individual checksum that you can verify against the package that you downloaded. The correct MD5 checksum is listed on the downloads page for each MySQL product, and you will compare it against the MD5 checksum of the file (product) that you download.

Each operating system and setup offers its own version of tools for checking the MD5 checksum. Typically the command is named `md5sum`, or it may be named `md5`, and some operating systems do not ship it at all. On Linux, it is part of the **GNU Text Utilities** package, which is available for a wide range of platforms. You can also download the source code from <http://www.gnu.org/software/textutils/>. If you have OpenSSL installed, you can use the command `openssl md5 package_name` instead. A Windows implementation of the `md5` command line utility is available from <http://www.fourmilab.ch/md5/>. `winMd5Sum` is a graphical

MD5 checking tool that can be obtained from <http://www.nullriver.com/index/products/winmd5sum>. Our Microsoft Windows examples will assume the name `md5.exe`.

Linux and Microsoft Windows examples:

```
shell> md5sum mysql-standard-5.5.40-linux-i686.tar.gz
aaab65abbec64d5e907dcd41b8699945  mysql-standard-5.5.40-linux-i686.tar.gz
```

```
shell> md5.exe mysql-installer-community-5.5.40.msi
aaab65abbec64d5e907dcd41b8699945  mysql-installer-community-5.5.40.msi
```

You should verify that the resulting checksum (the string of hexadecimal digits) matches the one displayed on the download page immediately below the respective package.

Note

Make sure to verify the checksum of the *archive file* (for example, the `.zip`, `.tar.gz`, or `.msi` file) and not of the files that are contained inside of the archive. In other words, verify the file before extracting its contents.

2.1.4.2 Signature Checking Using [GnuPG](#)

Another method of verifying the integrity and authenticity of a package is to use cryptographic signatures. This is more reliable than using [MD5 checksums](#), but requires more work.

We sign MySQL downloadable packages with [GnuPG](#) (GNU Privacy Guard). [GnuPG](#) is an Open Source alternative to the well-known Pretty Good Privacy ([PGP](#)) by Phil Zimmermann. See <http://www.gnupg.org/> for more information about [GnuPG](#) and how to obtain and install it on your system. Most Linux distributions ship with [GnuPG](#) installed by default. For more information about [GnuPG](#), see <http://www.openpgp.org/>.

To verify the signature for a specific package, you first need to obtain a copy of our public GPG build key, which you can download from <http://pgp.mit.edu/>. The key that you want to obtain is named `mysql-build@oss.oracle.com`. Alternatively, you can cut and paste the key directly from the following text:

```

```
=443I
-----END PGP PUBLIC KEY BLOCK-----
```

To import the build key into your personal public GPG keyring, use `gpg --import`. For example, if you have saved the key in a file named `mysql_pubkey.asc`, the import command looks like this:

```
shell> gpg --import mysql_pubkey.asc
gpg: key 5072E1F5: public key "MySQL Release Engineering
<mysql-build@oss.oracle.com>" imported
gpg: Total number processed: 1
gpg:             imported: 1
gpg: no ultimately trusted keys found
```

You can also download the key from the public keyserver using the public key id, `5072E1F5`:

```
shell> gpg --recv-keys 5072E1F5
gpg: requesting key 5072E1F5 from hkp server keys.gnupg.net
gpg: key 5072E1F5: "MySQL Release Engineering <mysql-build@oss.oracle.com>"
1 new user ID
gpg: key 5072E1F5: "MySQL Release Engineering <mysql-build@oss.oracle.com>"
53 new signatures
gpg: no ultimately trusted keys found
gpg: Total number processed: 1
gpg:             new user IDs: 1
gpg:             new signatures: 53
```

If you want to import the key into your RPM configuration to validate RPM install packages, you should be able to import the key directly:

```
shell> rpm --import mysql_pubkey.asc
```

If you experience problems or require RPM specific information, see [Section 2.1.4.4, "Signature Checking Using RPM"](#).

After you have downloaded and imported the public build key, download your desired MySQL package and the corresponding signature, which also is available from the download page. The signature file has the same name as the distribution file with an `.asc` extension, as shown by the examples in the following table.

Table 2.1 MySQL Package and Signature Files for Source files

File Type	File Name
Distribution file	<code>mysql-standard-5.5.40-linux-i686.tar.gz</code>
Signature file	<code>mysql-standard-5.5.40-linux-i686.tar.gz.asc</code>

Make sure that both files are stored in the same directory and then run the following command to verify the signature for the distribution file:

```
shell> gpg --verify package_name.asc
```

If the downloaded package is valid, you will see a "Good signature" similar to:

```
shell> gpg --verify mysql-standard-5.5.40-linux-i686.tar.gz.asc
gpg: Signature made Tue 01 Feb 2011 02:38:30 AM CST using DSA key ID 5072E1F5
```

```
gpg: Good signature from "MySQL Release Engineering <mysql-build@oss.oracle.com>"
```

The [Good signature](#) message indicates that the file signature is valid, when compared to the signature listed on our site. But you might also see warnings, like so:

```
shell> gpg --verify mysql-standard-5.5.40-linux-i686.tar.gz.asc
gpg: Signature made Wed 23 Jan 2013 02:25:45 AM PST using DSA key ID 5072E1F5
gpg: checking the trustdb
gpg: no ultimately trusted keys found
gpg: Good signature from "MySQL Release Engineering <mysql-build@oss.oracle.com>"
gpg: WARNING: This key is not certified with a trusted signature!
gpg:          There is no indication that the signature belongs to the owner.
Primary key fingerprint: A4A9 4068 76FC BD3C 4567 70C8 8C71 8D3B 5072 E1F5
```

That is normal, as they depend on your setup and configuration. Here are explanations for these warnings:

- *gpg: no ultimately trusted keys found*: This means that the specific key is not "ultimately trusted" by you or your web of trust, which is okay for the purposes of verifying file signatures.
- *WARNING: This key is not certified with a trusted signature! There is no indication that the signature belongs to the owner.*: This refers to your level of trust in your belief that you possess our real public key. This is a personal decision. Ideally, a MySQL developer would hand you the key in person, but more commonly, you downloaded it. Was the download tampered with? Probably not, but this decision is up to you. Setting up a web of trust is one method for trusting them.

See the GPG documentation for more information on how to work with public keys.

2.1.4.3 Signature Checking Using [Gpg4win](#) for Windows

The [Section 2.1.4.2, "Signature Checking Using \[GnuPG\]\(#\)"](#) section describes how to verify MySQL downloads using GPG. That guide also applies to Microsoft Windows, but another option is to use a GUI tool like [Gpg4win](#). You may use a different tool but our examples are based on Gpg4win, and utilize its bundled [Kleopatra](#) GUI.

Download and install Gpg4win, and then load Kleopatra. The dialog should look similar to:

Figure 2.1 Initial screen after loading Kleopatra

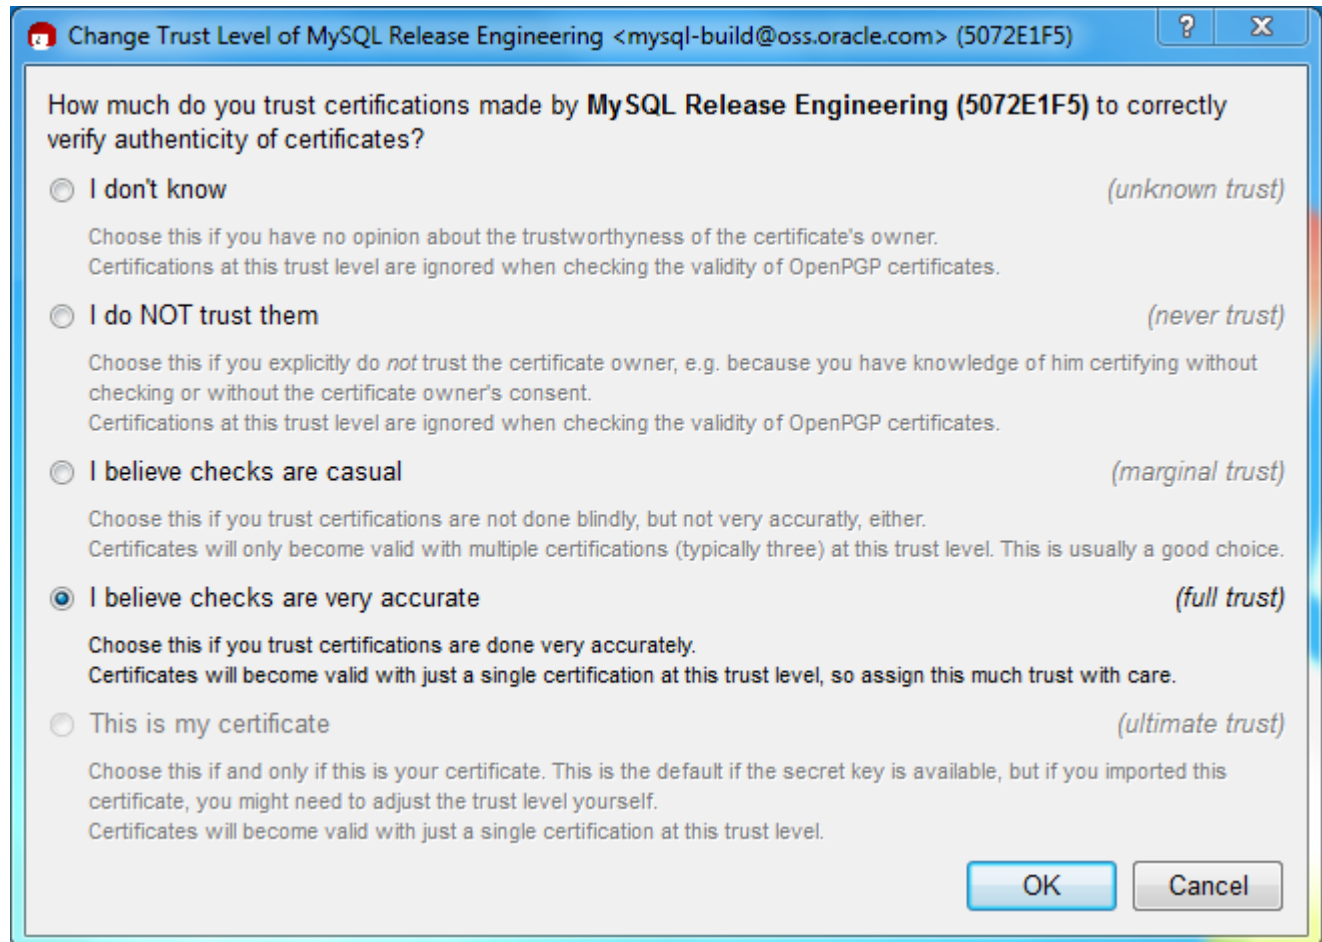

Next, add the MySQL Release Engineering certificate. Do this by clicking **File, Lookup Certificates on Server**. Type "Mysql Release Engineering" into the search box and press **Search**.

Figure 2.2 Finding the MySQL Release Engineering certificate

Select the "MySQL Release Engineering" certificate. The Fingerprint and Key-ID must be "5072E1F5", or choose **Details...** to confirm the certificate is valid. Now, import it by clicking **Import**. An import dialog will be displayed, choose **Okay**, and this certificate will now be listed under the **Imported Certificates** tab.

Next, configure the trust level for our certificate. Select our certificate, then from the main menu select **Certificates, Change Owner Trust...** We suggest choosing **I believe checks are very accurate** for our certificate, as otherwise you might not be able to verify our signature. Select **I believe checks are very accurate** and then press **OK**.

Figure 2.3 Changing the Trust level

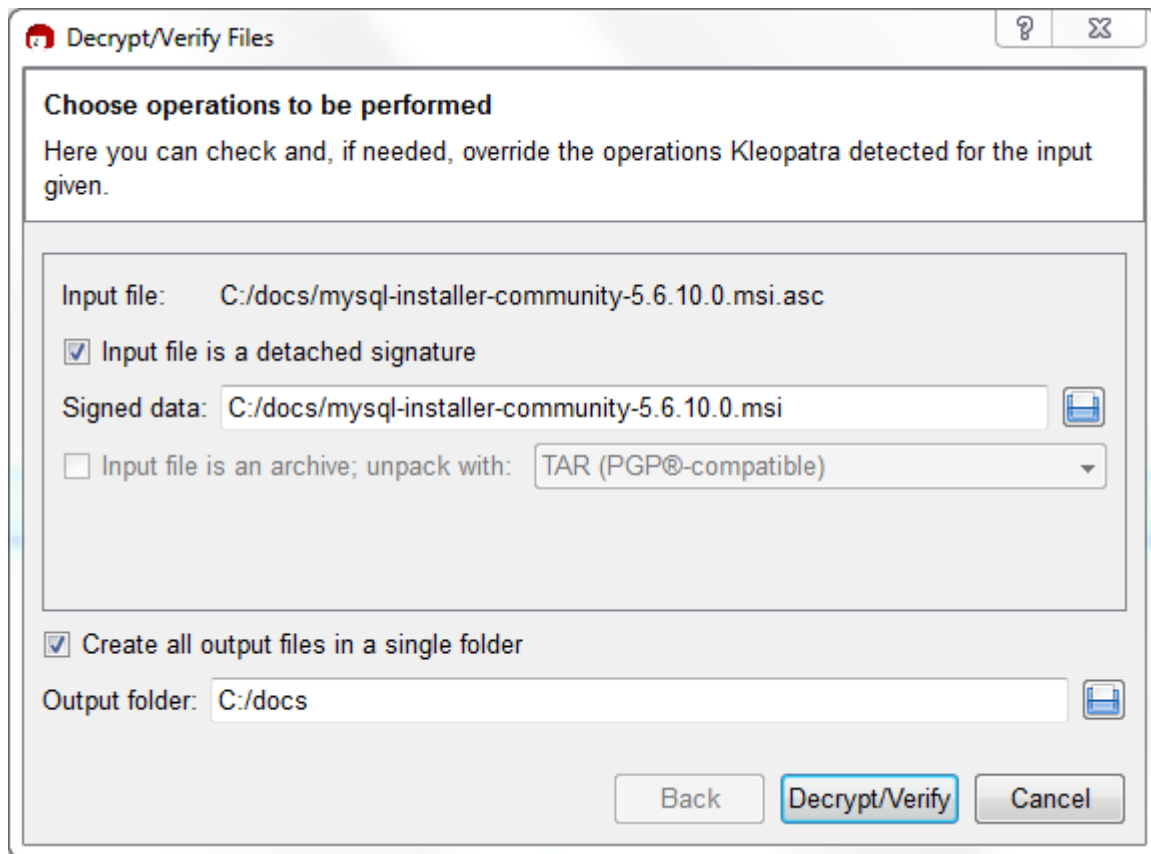

Next, verify the downloaded MySQL package file. This requires files for both the packaged file, and the signature. The signature file must have the same name as the packaged file but with an appended `.asc` extension, as shown by the example in the following table. The signature is linked to on the downloads page for each MySQL product. You must create the `.asc` file with this signature.

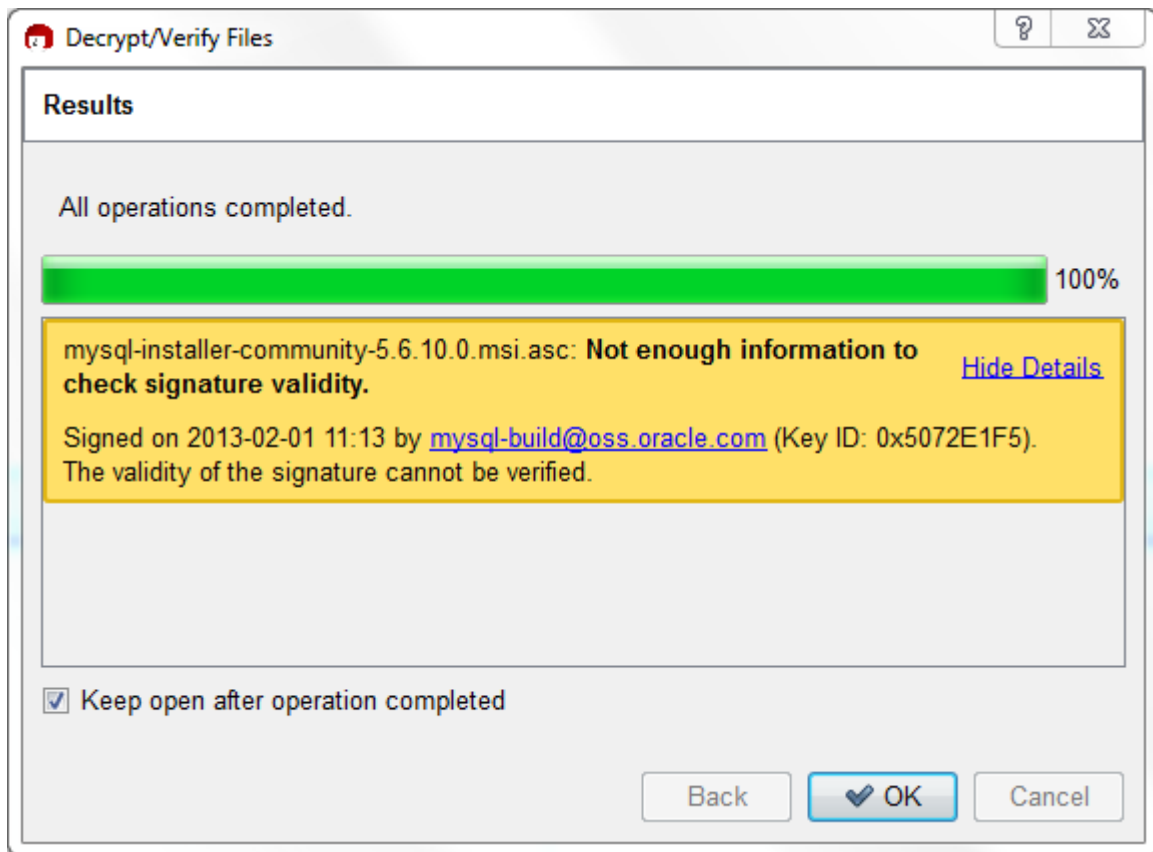

Table 2.2 MySQL Package and Signature Files for MySQL Installer for Microsoft Windows

File Type	File Name
Distribution file	<code>mysql-installer-community-5.5.40.msi</code>
Signature file	<code>mysql-installer-community-5.5.40.msi.asc</code>

Make sure that both files are stored in the same directory and then run the following command to verify the signature for the distribution file. Either drag and drop the signature (`.asc`) file into Kleopatra, or load the dialog from **File, Decrypt/Verify Files...**, and then choose either the `.msi` or `.asc` file.

Figure 2.4 The Decrypt/Verify Files dialog

Click **Decrypt/Verify** to check the file. The two most common results will look like the following, and although the yellow warning looks problematic, the following means that the file check passed with success. You may now run this installer.

Figure 2.5 The Decrypt/Verify Results: Good

Seeing a red "The signature is bad" error means the file is invalid. Do not execute the MSI file if you see this error.

Figure 2.6 The Decrypt/Verify Results: Bad

The [Section 2.1.4.2, “Signature Checking Using GnuPG”](#) section explains why you probably don't see a green [Good signature](#) result.

2.1.4.4 Signature Checking Using [RPM](#)

For RPM packages, there is no separate signature. RPM packages have a built-in GPG signature and MD5 checksum. You can verify a package by running the following command:

```
shell> rpm --checksig package_name.rpm
```

Example:

```
shell> rpm --checksig MySQL-server-5.5.40-0.glibc23.i386.rpm
MySQL-server-5.5.40-0.glibc23.i386.rpm: md5 gpg OK
```

Note

If you are using RPM 4.1 and it complains about [\(GPG\) NOT OK \(MISSING KEYS: GPG#5072e1f5\)](#), even though you have imported the MySQL public build

key into your own GPG keyring, you need to import the key into the RPM keyring first. RPM 4.1 no longer uses your personal GPG keyring (or GPG itself). Rather, RPM maintains a separate keyring because it is a system-wide application and a user's GPG public keyring is a user-specific file. To import the MySQL public key into the RPM keyring, first obtain the key, then use `rpm --import` to import the key. For example:

```
shell> gpg --export -a 5072elf5 > 5072elf5.asc
shell> rpm --import 5072elf5.asc
```

Alternatively, `rpm` also supports loading the key directly from a URL, and you can use this manual page:

```
shell> rpm --import http://dev.mysql.com/doc/refman/5.5/en/checking-gpg-signature.html
```

If you need to obtain the MySQL public key, see [Section 2.1.4.2, “Signature Checking Using GnuPG”](#).

2.1.5 Installation Layouts

The installation layout differs for different installation types (for example, native packages, binary tarballs, and source tarballs), which can lead to confusion when managing different systems or using different installation sources. The individual layouts are given in the corresponding installation type or platform chapter, as described following. Note that the layout of installations from vendors other than Oracle may differ from these layouts.

- [Section 2.3.1, “MySQL Installation Layout on Microsoft Windows”](#)
- [Section 2.9.1, “MySQL Layout for Source Installation”](#)
- [Table 2.3, “MySQL Installation Layout for Generic Unix/Linux Binary Package”](#)
- [Table 2.12, “MySQL Installation Layout for Linux RPM Packages”](#)
- [Table 2.9, “MySQL Installation Layout on Mac OS X”](#)

2.1.6 Compiler-Specific Build Characteristics

In some cases, the compiler used to build MySQL affects the features available for use. The notes in this section apply for binary distributions provided by Oracle Corporation or that you compile yourself from source.

`icc` (Intel C++ Compiler) Builds

A server built with `icc` has these characteristics:

- SSL support is not included.

2.2 Installing MySQL on Unix/Linux Using Generic Binaries

Oracle provides a set of binary distributions of MySQL. These include binary distributions in the form of compressed `tar` files (files with a `.tar.gz` extension) for a number of platforms, as well as binaries in platform-specific package formats for selected platforms.

This section covers the installation of MySQL from a compressed `tar` file binary distribution. For other platform-specific package formats, see the other platform-specific sections. For example, for Windows distributions, see [Section 2.3, “Installing MySQL on Microsoft Windows”](#).

To obtain MySQL, see [Section 2.1.3, “How to Get MySQL”](#).

MySQL compressed `tar` file binary distributions have names of the form `mysql-VERSION-OS.tar.gz`, where `VERSION` is a number (for example, `5.5.40`), and `OS` indicates the type of operating system for which the distribution is intended (for example, `pc-linux-i686` or `winx64`).

To install MySQL from a compressed `tar` file binary distribution, your system must have GNU `gunzip` to uncompress the distribution and a reasonable `tar` to unpack it. If your `tar` program supports the `z` option, it can both uncompress and unpack the file.

GNU `tar` is known to work. The standard `tar` provided with some operating systems is not able to unpack the long file names in the MySQL distribution. You should download and install GNU `tar`, or if available, use a preinstalled version of GNU `tar`. Usually this is available as `gnutar`, `gtar`, or as `tar` within a GNU or Free Software directory, such as `/usr/sfw/bin` or `/usr/local/bin`. GNU `tar` is available from <http://www.gnu.org/software/tar/>.

Warning

If you have previously installed MySQL using your operating system native package management system, such as `yum` or `apt-get`, you may experience problems installing using a native binary. Make sure your previous MySQL previous installation has been removed entirely (using your package management system), and that any additional files, such as old versions of your data files, have also been removed. You should also check the existence of configuration files such as `/etc/my.cnf` or the `/etc/mysql` directory have been deleted.

If you run into problems and need to file a bug report, please use the instructions in [Section 1.7, “How to Report Bugs or Problems”](#).

On Unix, to install a compressed `tar` file binary distribution, unpack it at the installation location you choose (typically `/usr/local/mysql`). This creates the directories shown in the following table.

Table 2.3 MySQL Installation Layout for Generic Unix/Linux Binary Package

Directory	Contents of Directory
<code>bin</code>	Client programs and the <code>mysqld</code> server
<code>data</code>	Log files, databases
<code>docs</code>	Manual in Info format
<code>man</code>	Unix manual pages
<code>include</code>	Include (header) files
<code>lib</code>	Libraries
<code>scripts</code>	<code>mysql_install_db</code>
<code>share</code>	Miscellaneous support files, including error messages, sample configuration files, SQL for database installation
<code>sql-bench</code>	Benchmarks

Debug versions of the `mysqld` binary are available as `mysqld-debug`. To compile your own debug version of MySQL from a source distribution, use the appropriate configuration options to enable debugging support. For more information on compiling from source, see [Section 2.9, “Installing MySQL from Source”](#).

To install and use a MySQL binary distribution, the basic command sequence looks like this:

```

shell> groupadd mysql
shell> useradd -r -g mysql mysql
shell> cd /usr/local
shell> tar zxvf /path/to/mysql-VERSION-OS.tar.gz
shell> ln -s full-path-to-mysql-VERSION-OS mysql
shell> cd mysql
shell> chown -R mysql .
shell> chgrp -R mysql .
shell> scripts/mysql_install_db --user=mysql
shell> chown -R root .
shell> chown -R mysql data
# Next command is optional
shell> cp support-files/my-medium.cnf /etc/my.cnf
shell> bin/mysqld_safe --user=mysql &
# Next command is optional
shell> cp support-files/mysql.server /etc/init.d/mysql.server

```

A more detailed version of the preceding description for installing a binary distribution follows.

Note

This procedure assumes that you have `root` (administrator) access to your system. Alternatively, you can prefix each command using the `sudo` (Linux) or `pfexec` (OpenSolaris) command.

The procedure does not set up any passwords for MySQL accounts. After following the procedure, proceed to [Section 2.10.2, “Securing the Initial MySQL Accounts”](#).

Create a `mysql` User and Group

If your system does not already have a user and group for `mysqld` to run as, you may need to create one. The following commands add the `mysql` group and the `mysql` user. You might want to call the user and group something else instead of `mysql`. If so, substitute the appropriate name in the following instructions. The syntax for `useradd` and `groupadd` may differ slightly on different versions of Unix, or they may have different names such as `adduser` and `addgroup`.

```

shell> groupadd mysql
shell> useradd -r -g mysql mysql

```

Note

Because the user is required only for ownership purposes, not login purposes, the `useradd` command uses the `-r` option to create a user that does not have login permissions to your server host. Omit this option to permit logins for the user (or if your `useradd` does not support the option).

Obtain and Unpack the Distribution

Pick the directory under which you want to unpack the distribution and change location into it. The example here unpacks the distribution under `/usr/local`. The instructions, therefore, assume that you have permission to create files and directories in `/usr/local`. If that directory is protected, you must perform the installation as `root`.

```

shell> cd /usr/local

```

Obtain a distribution file using the instructions in [Section 2.1.3, “How to Get MySQL”](#). For a given release, binary distributions for all platforms are built from the same MySQL source distribution.

Unpack the distribution, which creates the installation directory. Then create a symbolic link to that directory. `tar` can uncompress and unpack the distribution if it has `z` option support:

```
shell> tar zxvf /path/to/mysql-VERSION-OS.tar.gz
shell> ln -s full-path-to-mysql-VERSION-OS mysql
```

The `tar` command creates a directory named `mysql-VERSION-OS`. The `ln` command makes a symbolic link to that directory. This enables you to refer more easily to the installation directory as `/usr/local/mysql`.

If your `tar` does not have `z` option support, use `gunzip` to unpack the distribution and `tar` to unpack it. Replace the preceding `tar` command with the following alternative command to uncompress and extract the distribution:

```
shell> gunzip < /path/to/mysql-VERSION-OS.tar.gz | tar xvf -
```

Perform Postinstallation Setup

The remainder of the installation process involves setting up the configuration file, creating the core databases, and starting the MySQL server. For next steps, see [Section 2.10, “Postinstallation Setup and Testing”](#).

Note

The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in [Section 2.10.2, “Securing the Initial MySQL Accounts”](#).

2.3 Installing MySQL on Microsoft Windows

MySQL is available for Microsoft Windows, for both 32-bit and 64-bit versions. For supported Windows platform information, see <http://www.mysql.com/support/supportedplatforms/database.html>.

It is possible to run MySQL as a standard application or as a Windows service. By using a service, you can monitor and control the operation of the server through the standard Windows service management tools. For more information, see [Section 2.3.7.7, “Starting MySQL as a Windows Service”](#).

Generally, you should install MySQL on Windows using an account that has administrator rights. Otherwise, you may encounter problems with certain operations such as editing the `PATH` environment variable or accessing the [Service Control Manager](#). Once installed, MySQL does not need to be executed using a user with Administrator privileges.

For a list of limitations on the use of MySQL on the Windows platform, see [Section D.10.6, “Windows Platform Limitations”](#).

In addition to the MySQL Server package, you may need or want additional components to use MySQL with your application or development environment. These include, but are not limited to:

- To connect to the MySQL server using ODBC, you must have a Connector/ODBC driver. For more information, including installation and configuration instructions, see [MySQL Connector/ODBC Developer Guide](#).
- To use MySQL server with .NET applications, you must have the Connector/Net driver. For more information, including installation and configuration instructions, see [MySQL Connector/Net Developer Guide](#).

MySQL distributions for Windows can be downloaded from <http://dev.mysql.com/downloads/>. See [Section 2.1.3, “How to Get MySQL”](#).

MySQL for Windows is available in several distribution formats, detailed below. Generally speaking, you should use MySQL Installer. It contains more features and MySQL products than the older MSI, is simpler to use than the ZIP file, and you need no additional tools to get MySQL up and running. MySQL Installer automatically installs MySQL Server and additional MySQL products, creates an options file, starts the server, and enables you to create default user accounts. For more information on choosing a package, see [Section 2.3.2, “Choosing An Installation Package”](#).

- Binary installer distributions. There are two different installable distributions that come packaged as a Microsoft Windows Installer (MSI) package that you can install manually or automatically on your systems. The preferred MySQL Installer package includes MySQL Server and additional MySQL products including MySQL Workbench, MySQL Notifier, and MySQL for Excel. MySQL Installer can also be used to upgrade these product in the future. The older MSI package contains all the files you need to install and configure MySQL server, but no additional components.

For instructions on installing MySQL using MySQL Installer, see [Section 2.3.3, “Installing MySQL on Microsoft Windows Using MySQL Installer”](#).

- The standard binary distribution (packaged as a Zip file) contains all of the necessary files that you unpack into your chosen location. This package contains all of the files in the full Windows MSI Installer package, but does not include an installation program.

For instructions on installing MySQL using the Zip file, see [Section 2.3.7, “Installing MySQL on Microsoft Windows Using a noinstall Zip Archive”](#).

- The source distribution format contains all the code and support files for building the executables using the Visual Studio compiler system.

For instructions on building MySQL from source on Windows, see [Section 2.9, “Installing MySQL from Source”](#).

MySQL on Windows considerations:

- **Large Table Support**

If you need tables with a size larger than 4GB, install MySQL on an NTFS or newer file system. Do not forget to use `MAX_ROWS` and `AVG_ROW_LENGTH` when you create tables. See [Section 13.1.17, “CREATE TABLE Syntax”](#).

- **MySQL and Virus Checking Software**

Virus-scanning software such as Norton/Symantec Anti-Virus on directories containing MySQL data and temporary tables can cause issues, both in terms of the performance of MySQL and the virus-scanning software misidentifying the contents of the files as containing spam. This is due to the fingerprinting mechanism used by the virus-scanning software, and the way in which MySQL rapidly updates different files, which may be identified as a potential security risk.

After installing MySQL Server, it is recommended that you disable virus scanning on the main directory (`datadir`) used to store your MySQL table data. There is usually a system built into the virus-scanning software to enable specific directories to be ignored.

In addition, by default, MySQL creates temporary files in the standard Windows temporary directory. To prevent the temporary files also being scanned, configure a separate temporary directory for MySQL temporary files and add this directory to the virus scanning exclusion list. To do this, add a

configuration option for the `tmpdir` parameter to your `my.ini` configuration file. For more information, see [Section 2.3.7.2, “Creating an Option File”](#).

2.3.1 MySQL Installation Layout on Microsoft Windows

For MySQL 5.5 on Windows, the default installation directory is `C:\Program Files\MySQL\MySQL Server 5.5`. Some Windows users prefer to install in `C:\mysql`, the directory that formerly was used as the default. However, the layout of the subdirectories remains the same.

All of the files are located within this parent directory, using the structure shown in the following table.

Table 2.4 Default MySQL Installation Layout for Microsoft Windows

Directory	Contents of Directory	Notes
<code>bin</code>	Client programs and the <code>mysqld</code> server	
<code>%ALLUSERSPROFILE%\MySQL\MySQL Server 5.5\</code>	Log files, databases (Windows XP, Windows Server 2003)	The Windows system variable <code>%ALLUSERSPROFILE%</code> defaults to <code>C:\Documents and Settings\All Users\Application Data</code>
<code>%PROGRAMDATA%\MySQL\MySQL Server 5.5\</code>	Log files, databases (Vista, Windows 7, Windows Server 2008, and newer)	The Windows system variable <code>%PROGRAMDATA%</code> defaults to <code>C:\ProgramData</code>
<code>examples</code>	Example programs and scripts	
<code>include</code>	Include (header) files	
<code>lib</code>	Libraries	
<code>scripts</code>	Utility scripts	
<code>share</code>	Miscellaneous support files, including error messages, character set files, sample configuration files, SQL for database installation	

If you install MySQL using a Windows MSI package, this package creates and sets up the data directory that the installed server will use, but as of MySQL 5.5.5, it also creates a pristine “template” data directory named `data` under the installation directory. This directory can be useful when the machine will be used to run multiple instances of MySQL: After an installation has been performed using an MSI package, the template data directory can be copied to set up additional MySQL instances. See [Section 5.3, “Running Multiple MySQL Instances on One Machine”](#).

2.3.2 Choosing An Installation Package

For MySQL 5.5, there are installation package formats to choose from when installing MySQL on Windows:

Note

MySQL Installer and the "Complete Package" methods for installing MySQL are similar, but different. The MySQL Installer is the newer and more advanced option, and it includes all functionality found within the "Complete Package."

- **MySQL Installer:** This package has a file name similar to `mysql-installer-community-5.5.40.0.msi` or `mysql-installer-commercial-5.5.40.0.msi`, and utilizes MSIs

to automatically install MySQL server and other products. It will download and apply updates to itself, and for each of the installed products. It also configures the additional non-server products.

The installed products are configurable, and this includes: documentation with samples and examples, connectors (such as C, C++, J, NET, and ODBC), MySQL Workbench, MySQL Notifier for Microsoft Windows, MySQL for Excel, and the MySQL Server with its components.

MySQL Installer will run on all Windows platforms that are supported by MySQL (see <http://www.mysql.com/support/supportedplatforms/database.html>).

Note

Because MySQL Installer is not a native component of Microsoft Windows and depends on .NET, it will not work on minimal installation options like the "Server Core" version of Windows Server 2008.

For instructions on installing MySQL using MySQL Installer, see [Section 2.3.3, "Installing MySQL on Microsoft Windows Using MySQL Installer"](#).

- **The Complete Package:** This package has a file name similar to `mysql-5.5.40-win32.msi` and contains all files needed for a complete Windows installation, including the Configuration Wizard. This package includes optional components such as the embedded server and benchmark suite.
- **The Noinstall Archive:** This package has a file name similar to `mysql-5.5.40-win32.zip` and contains all the files found in the Complete install package, with the exception of the Configuration Wizard. This package does not include an automated installer, and must be manually installed and configured.

MySQL Installer is recommended for most users. Both MySQL Installer and the alternative "Complete distribution" versions are available as `.msi` files for use with installations on Windows. The Noinstall distribution is packaged as a Zip archive. To use a Zip archive, you must have a tool that can unpack `.zip` files.

Your choice of install package affects the installation process you must follow. If you choose to install using MySQL Installer, see [Section 2.3.3, "Installing MySQL on Microsoft Windows Using MySQL Installer"](#). If you choose to install a standard MSI package, see [Section 2.3.5, "Installing MySQL on Microsoft Windows Using an MSI Package"](#). If you choose to install a Noinstall archive, see [Section 2.3.7, "Installing MySQL on Microsoft Windows Using a noinstall Zip Archive"](#).

2.3.3 Installing MySQL on Microsoft Windows Using MySQL Installer

MySQL Installer is an application that simplifies the installation and updating process for a wide range of MySQL products, including [MySQL Notifier for Microsoft Windows](#), [MySQL Workbench](#), and [MySQL for Excel](#). From this central application, you can see which MySQL products are already installed, configure them, and update or remove them if necessary. The installer can also install plugins, documentation, tutorials, and example databases. The MySQL Installer is only available for Microsoft Windows, and includes both a GUI and command-line interface.

Installer package types

- **Full:** Bundles all of the MySQL products (including MySQL Server). The file size is over 160MB, and its name has the form `mysql-installer-community-VERSION.N.msi` where `VERSION` is the MySQL Server version number such as 5.6 and `N` is the package number, which begins at 0.
- **Web:** Only contains the Installer and configuration files, and it only downloads the MySQL products you choose to install. The size of this file is about 2MB; the name of the file has the form `mysql-`

`installer-community-web-VERSION.N.msi` where `VERSION` is the MySQL Server version number such as 5.6 and `N` is the package number, which begins at 0.

Installer editions

- **Community edition:** Downloadable at <http://dev.mysql.com/downloads/installer/>. It installs the community edition of all MySQL products.
- **Commercial edition:** Downloadable at either [My Oracle Support \(MOS\)](#) or <https://edelivery.oracle.com/>. It installs the commercial version of all MySQL products, including Workbench SE. It also integrates with your MOS account, so enter in your MOS credentials to automatically receive updates for your commercial MySQL products.

For notes detailing the changes in each release of MySQL Installer, see [MySQL Installer Release Notes](#).

MySQL Installer is compatible with pre-existing installations, and adds them to its list of installed components. While the MySQL Installer is bundled with a specific version of MySQL Server, a single MySQL Installer instance can install and manage multiple MySQL Server versions. For example, a single MySQL Installer instance can install versions 5.1, 5.5, and 5.6. It can also manage either commercial or community editions of the MySQL Server.

Note

A single host can not have both community and commercial editions of MySQL Server installed. For example, if you want both MySQL Server 5.5 and 5.6 installed on a single host, then both must be the same commercial or community edition.

MySQL Installer handles the initial configuration and setup of the applications. For example:

1. It will create MySQL Server connections in MySQL Workbench.
2. It creates the configuration file (`my.ini`) that is used to configure the MySQL Server. The values written to this file are influenced by choices you make during the installation process.
3. It imports example databases.
4. It creates MySQL Server user accounts with configurable permissions based on general roles, such as DB Administrator, DB Designer, and Backup Admin. It optionally creates a Windows user named `MysqISys` with limited privileges, which would then run the MySQL Server.

This feature is only available during the initial installation of the MySQL Server, and not during future updates. User accounts may also be added with MySQL Workbench.

5. If the "Advanced Configuration" option is checked, then the **Logging Options** are also configured. This includes defining file paths for the error log, general log, slow query log (including the configuration of seconds it requires to execute a query), and the binary log.

MySQL Installer can optionally check for updated components and download them for you automatically.

2.3.3.1 MySQL Installer GUI

After installation of the GUI version, the installer will have add its own Start Menu item under MySQL.

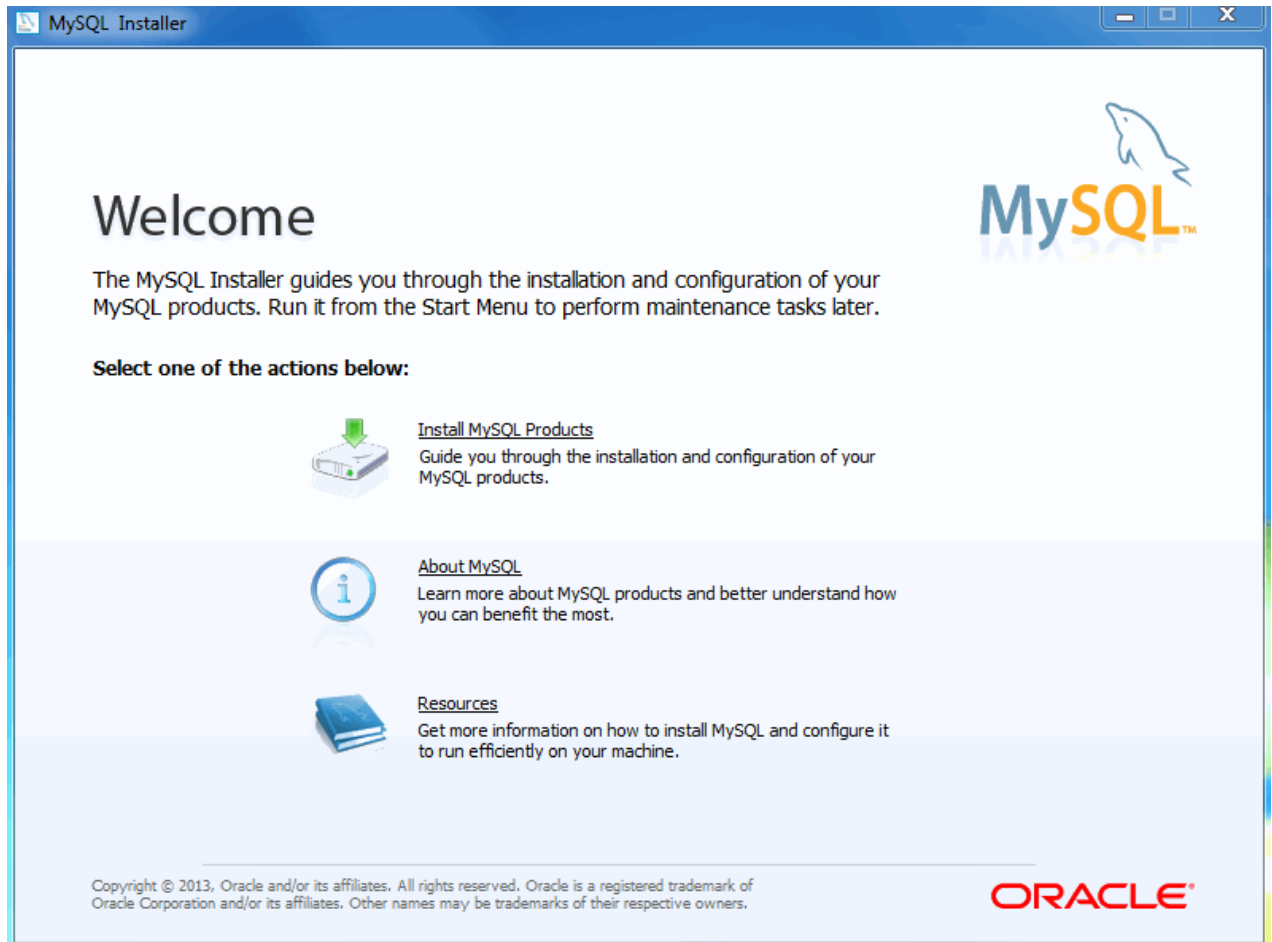

Note

Files that are generated by MySQL Installer grant full permissions to the user that executes MySQL Installer, including `my.ini`. This does not apply to files

and directories for specific products such as the MySQL Server data directory in `ProgramData`, that is owned by `SYSTEM`.

After the installer itself has been installed and started, the following screen is displayed:

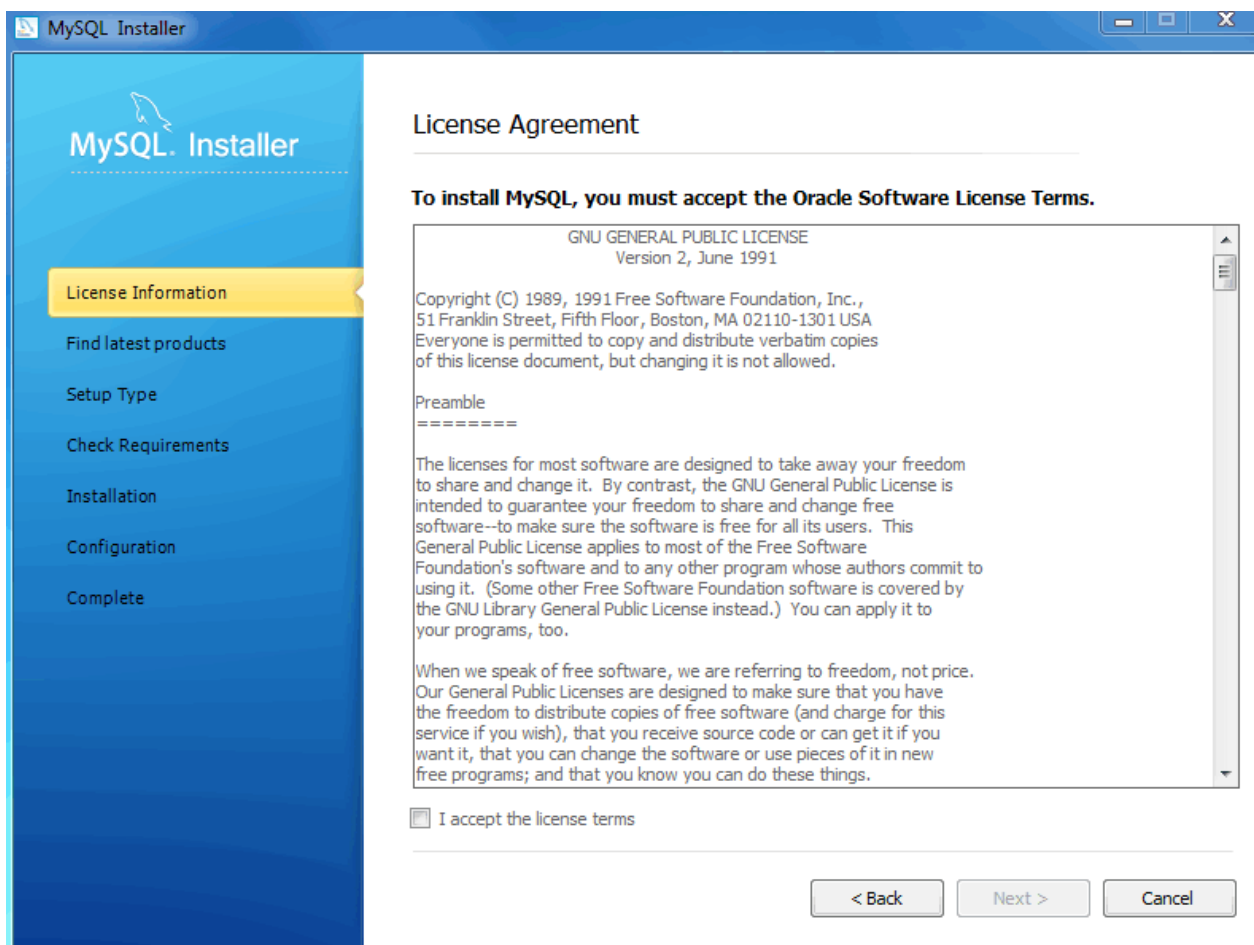

Figure 2.7 MySQL Installer - Welcome Screen

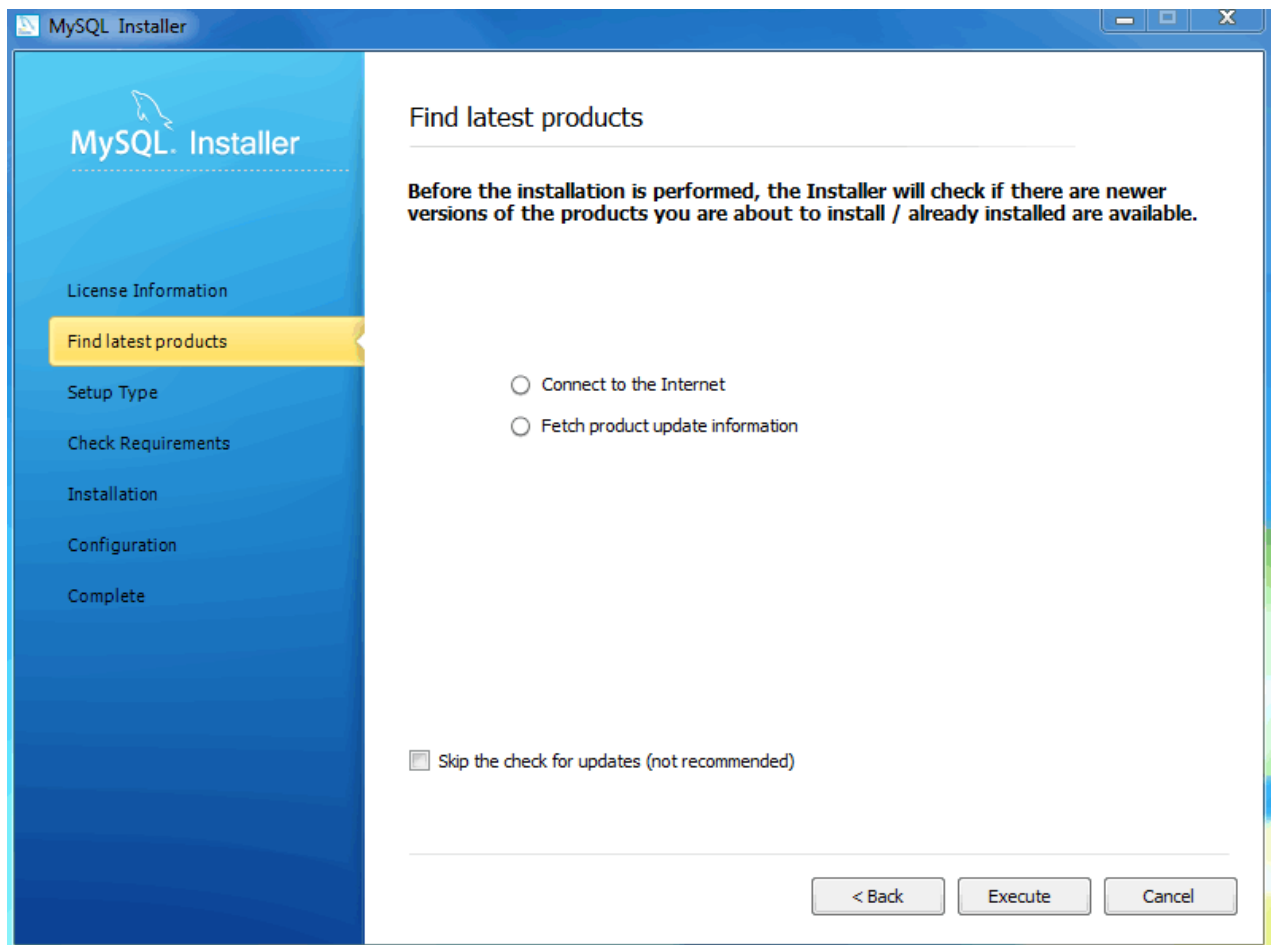

There are three main options:

1. Install MySQL Products - The Installation Wizard.
2. About MySQL - Learn about MySQL products and features.
3. Resources - Information to help install and configure MySQL.

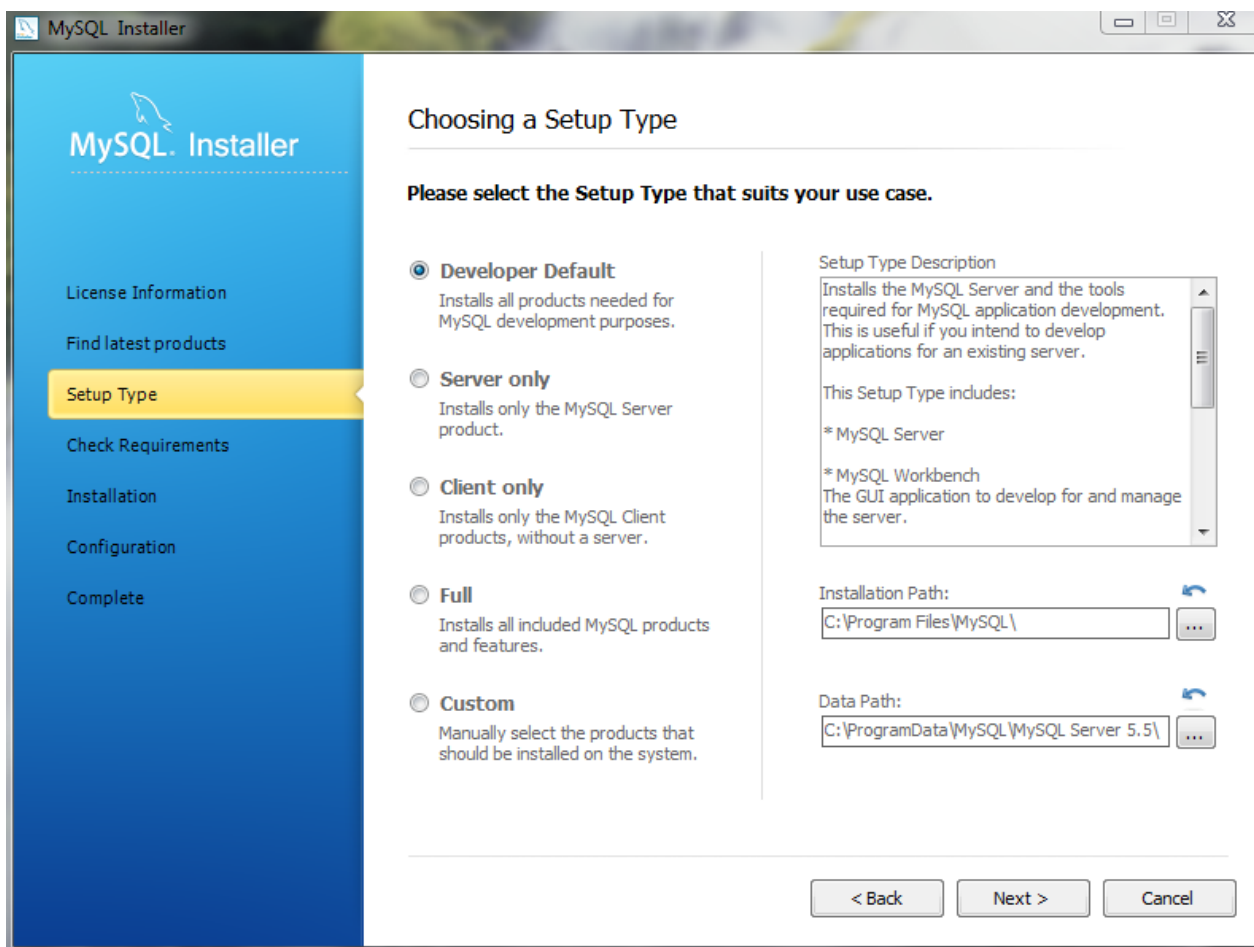

To **Install MySQL Products** after executing MySQL Installer for the first time, you must accept the license agreement before proceeding with the installation process.

Figure 2.8 MySQL Installer - License Agreement

If you are connected to the Internet, then the Installer will search for the latest MySQL components and add them to the installation bundle. Click **Connect to the Internet** to complete this step, or otherwise check the **Skip** checkbox and then **Continue**.

Figure 2.9 MySQL Installer - Find latest products

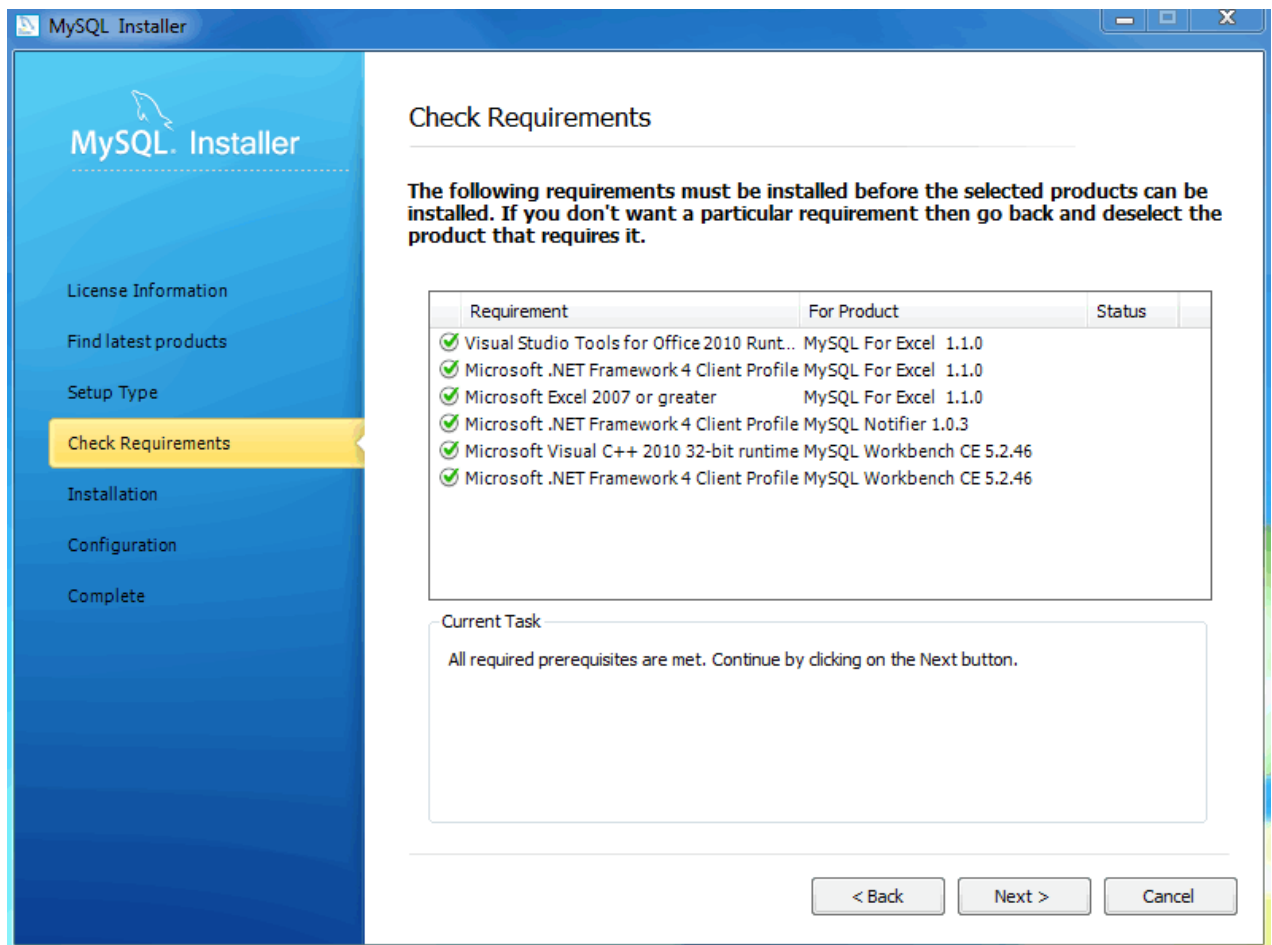

If you chose "Connect to the Internet," the next page will show the progress of MySQL Installer's search for available updates. When the search is complete (or if you opted to skip the search), you will be taken to the **Choose Setup Type** page:

Figure 2.10 MySQL Installer - Choosing a Setup Type

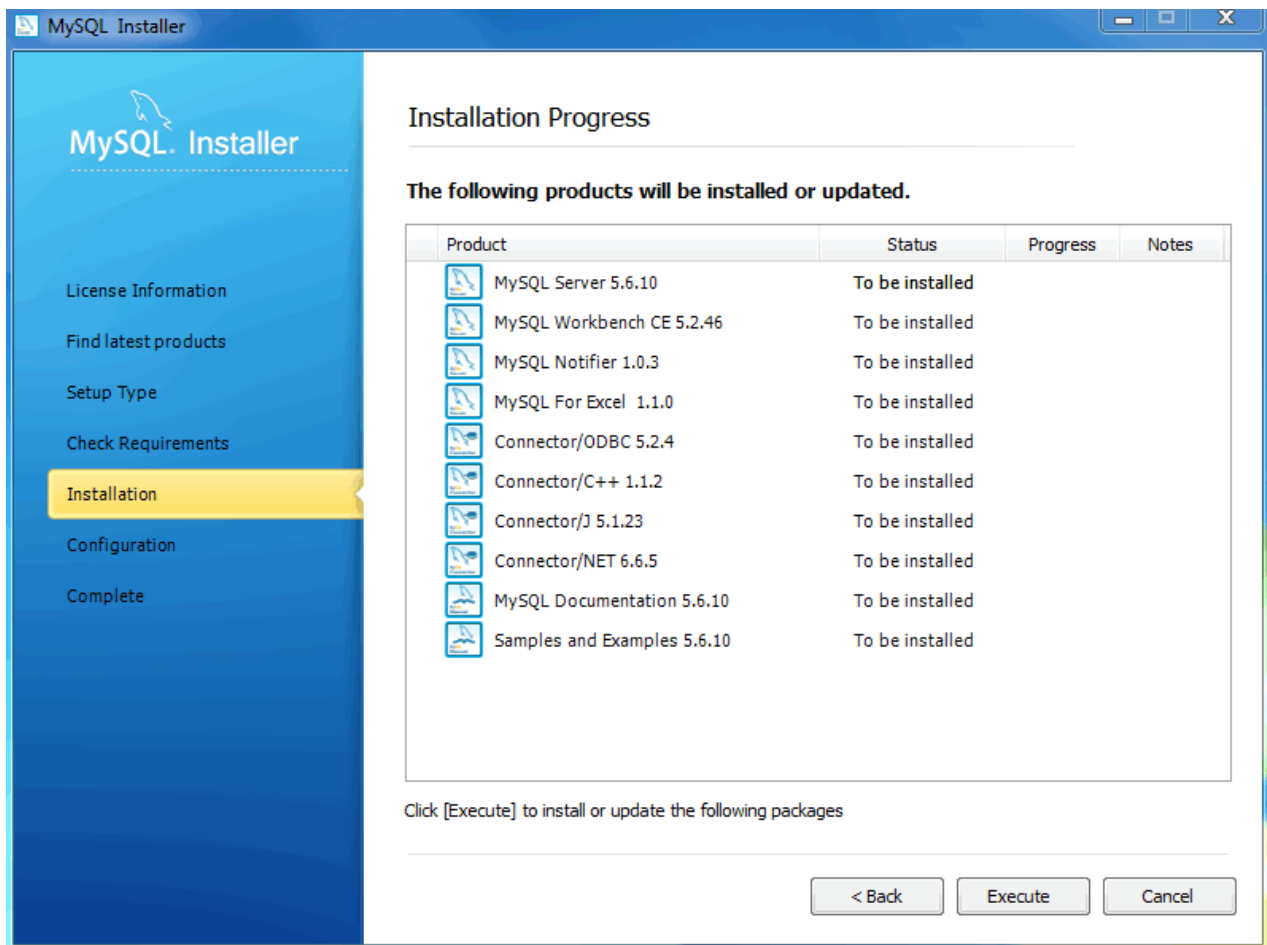

Determine the option most compatible with your preferences by reading the **Setup Type Description** descriptions.

The Installation and Data paths are also defined here, and a caution flag will notify you if the data path you define already exists.

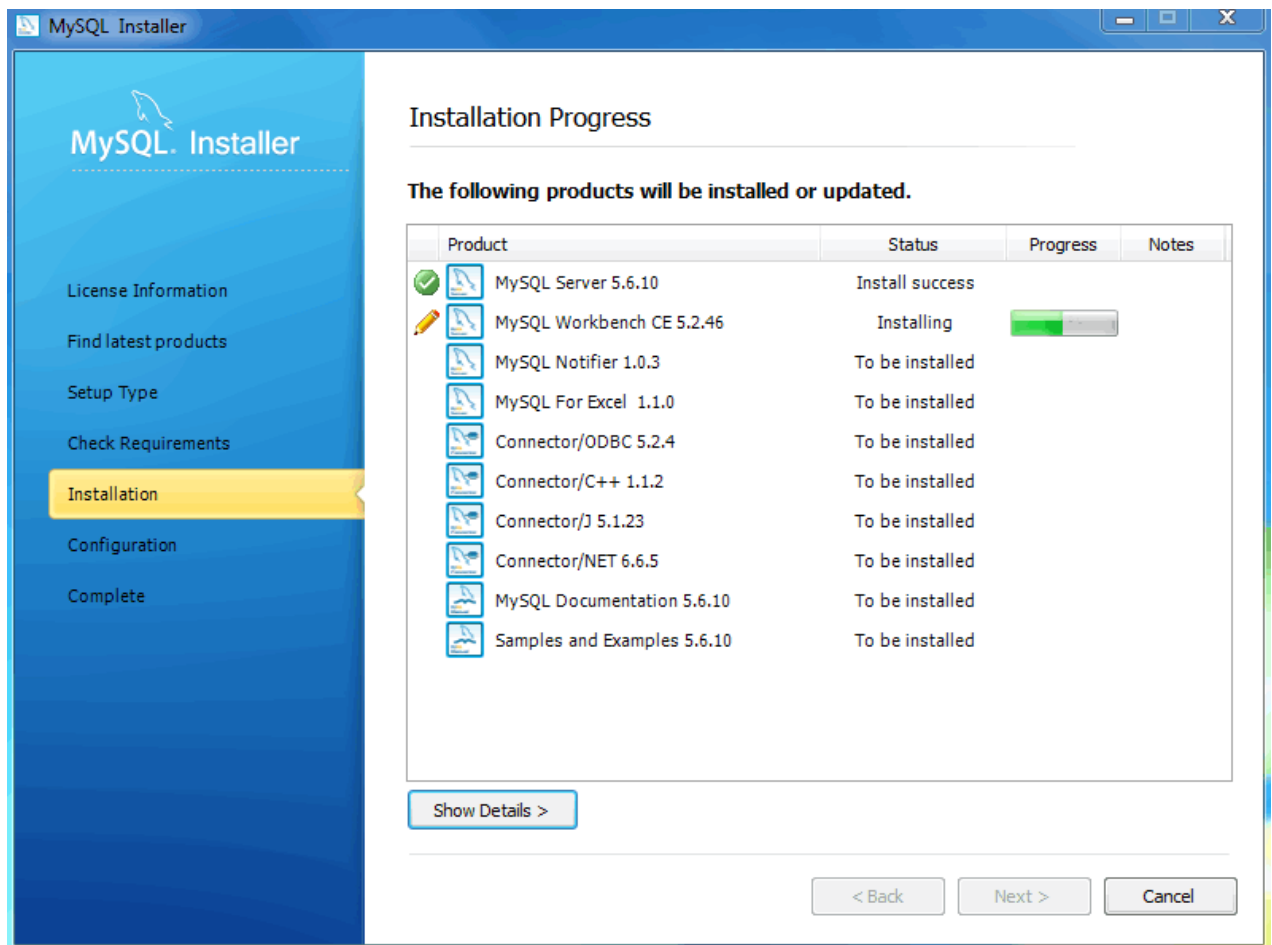

After you select a setup type, the MySQL Installer will check your system for the necessary external requirements and download then install missing components onto your system.

Figure 2.11 MySQL Installer - Check Requirements

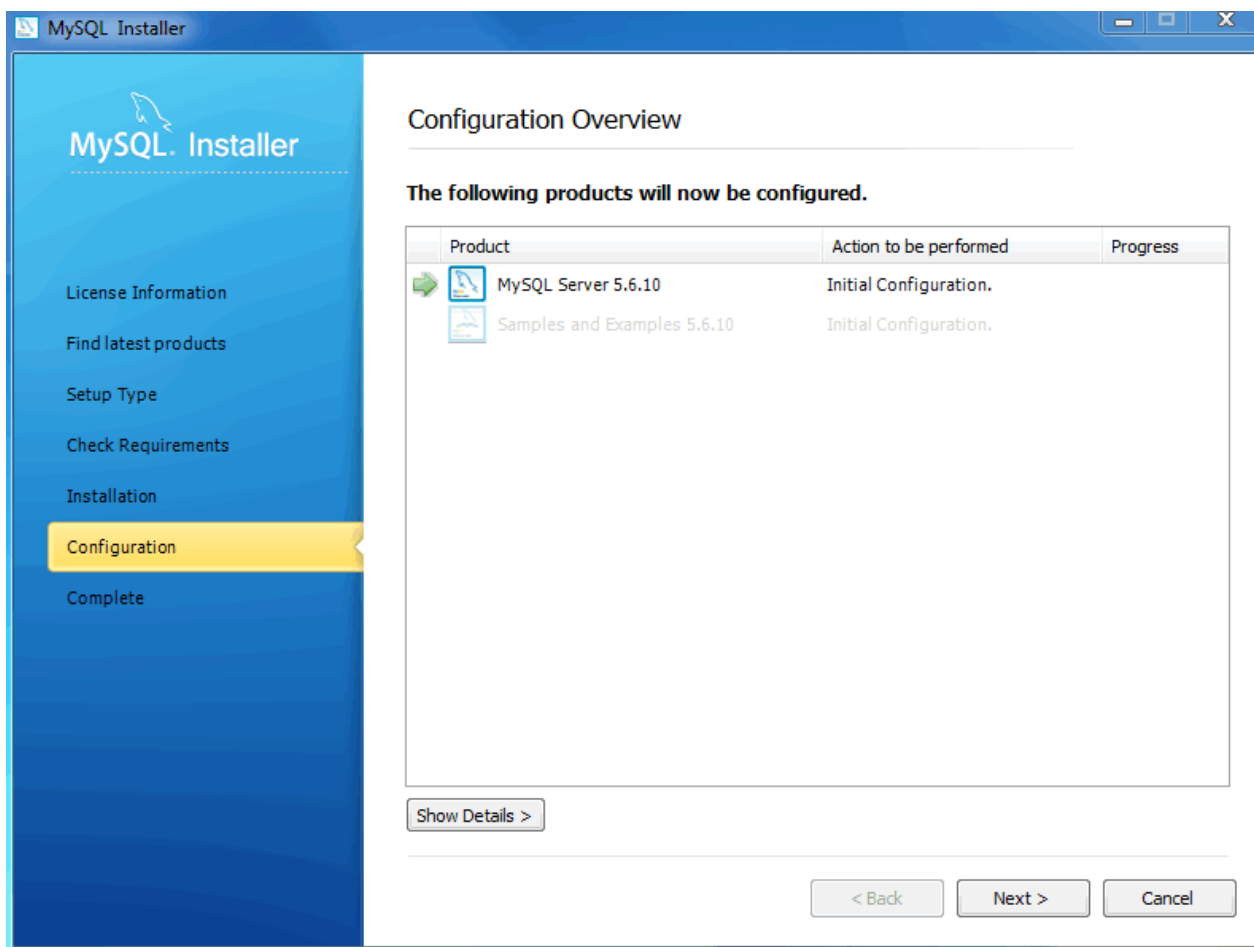

The next window lists the MySQL products that are scheduled to be installed:

Figure 2.12 MySQL Installer - Installation Progress

As components are installed, you'll see their status change from "to be installed" to "install success."

Figure 2.13 MySQL Installer - Installation Progress status

After all components are installed, the next step involves configuring the products. The [Configuration Overview](#) window displays the progress and then loads a configuration window if it is required.

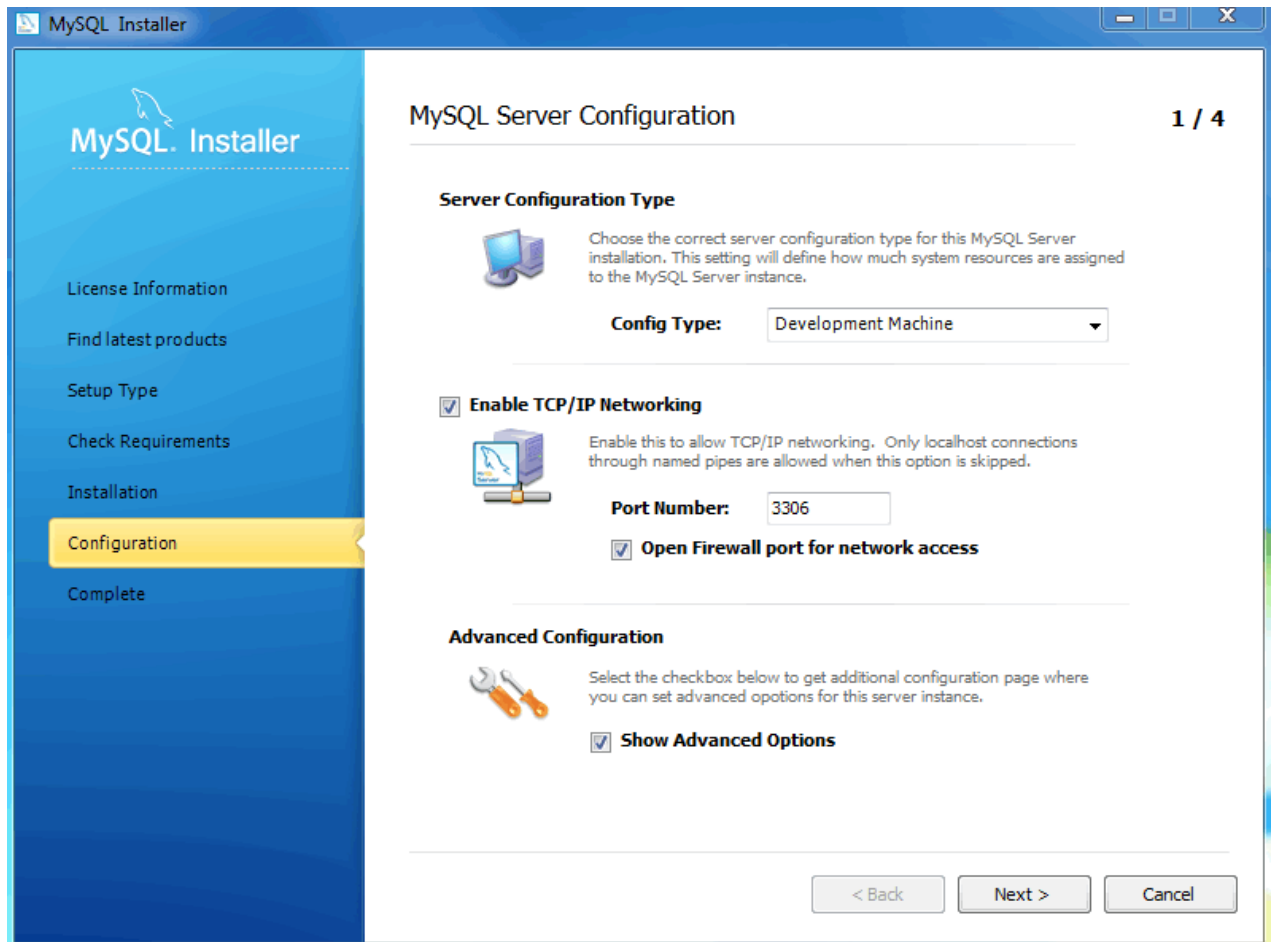

Figure 2.14 MySQL Installer - Configuration Overview

The ideal MySQL Server configuration depends on your intended use, as explained in the next window. Choose the description that most closely applies to your machine.

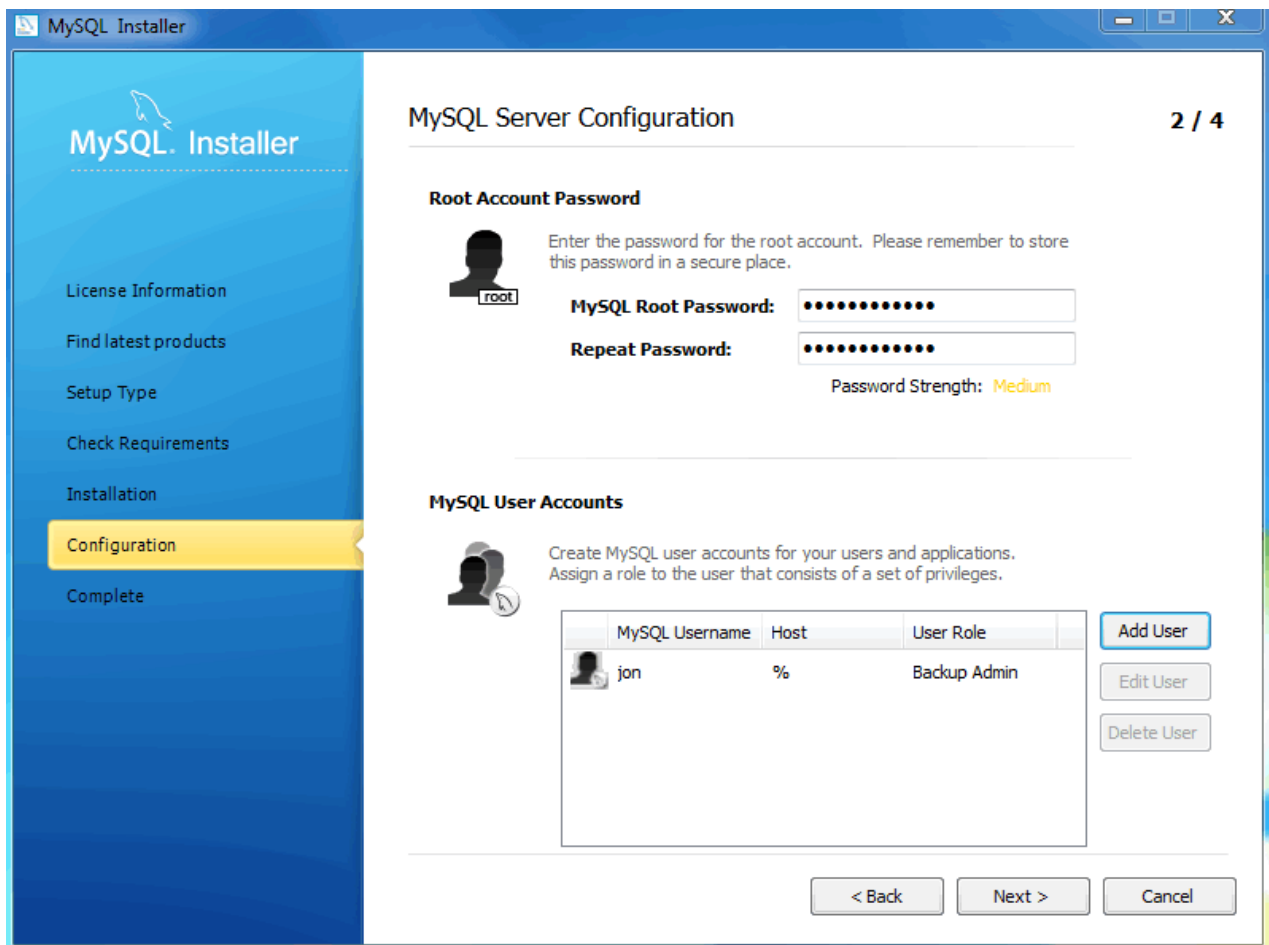

You may enable TCP/IP Networking here as otherwise only localhost connections are allowed.

Checking the "Advanced Configuration" option provides additional **Logging Options** to configure. This includes defining file paths for the error log, general log, slow query log (including the configuration of seconds it requires to execute a query), and the binary log.

Figure 2.15 MySQL Installer - MySQL Server Configuration: Define platform, networking, and logging options

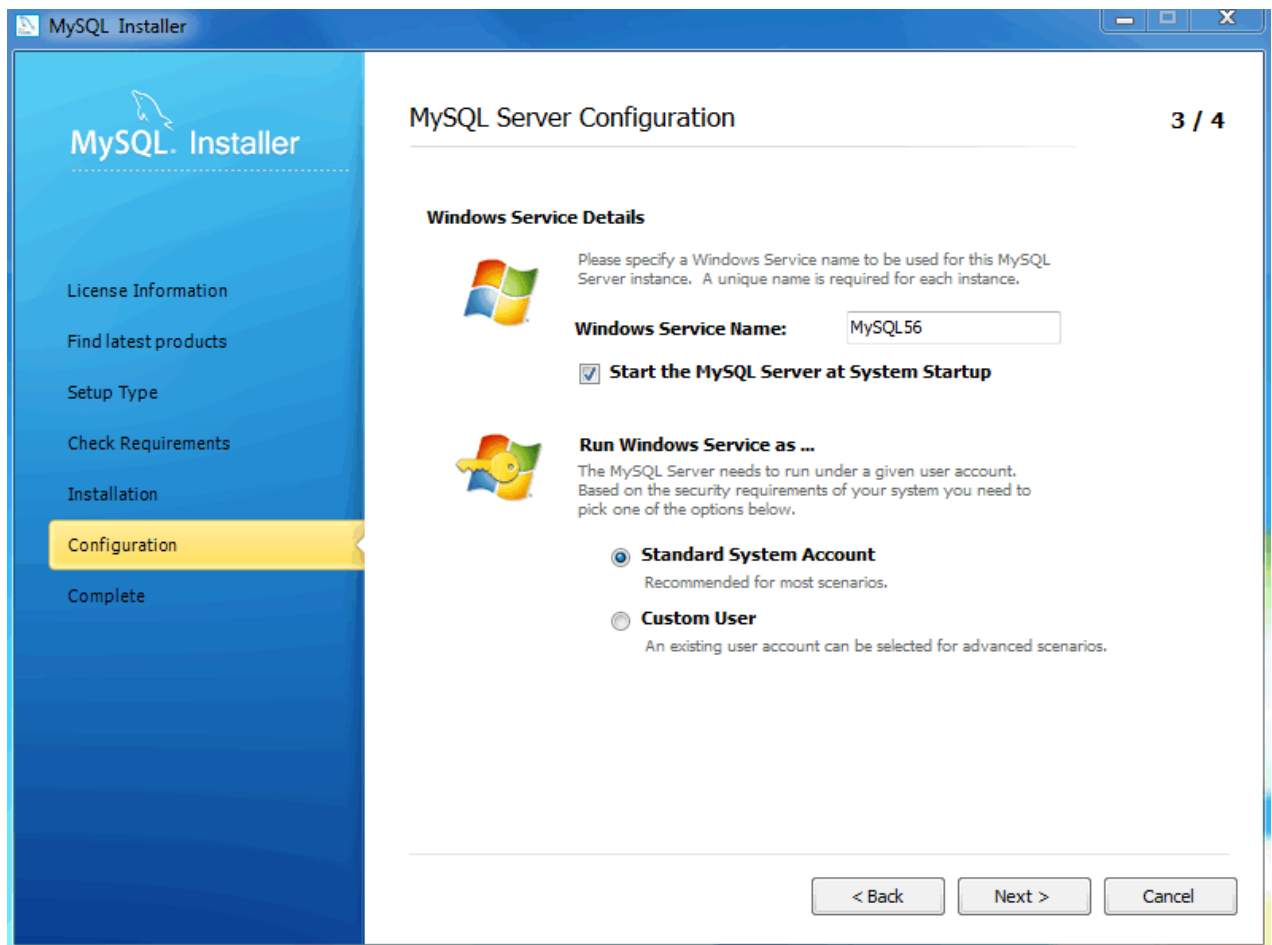

Next, choose your account information. Defining a root password is required, whereas it's optional to create additional users. There are several different predefined user roles that each have different permission levels. For example, a "DB Admin" will have more privileges than a "DB Designer."

Figure 2.16 MySQL Installer - MySQL Server Configuration: User accounts**Note**

If the MySQL Server is already installed, then the **Current Root Password** will also be needed.

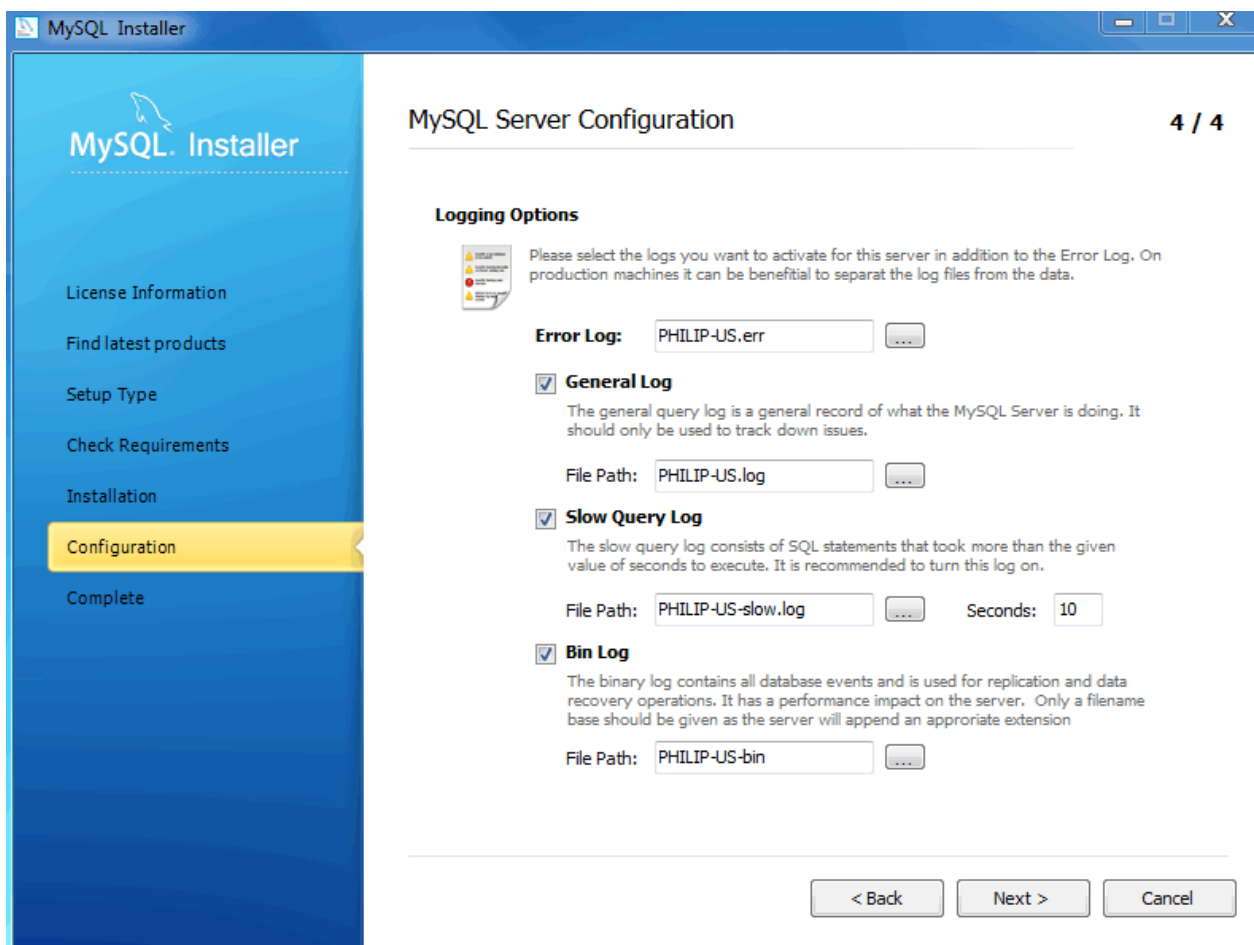

Next, configure the **Windows Service Details**. This includes the service name, how the MySQL Server should be loaded at startup, and how the Windows Service for MySQL Server will be run.

Figure 2.17 MySQL Installer - MySQL Server Configuration: Windows service details**Note**

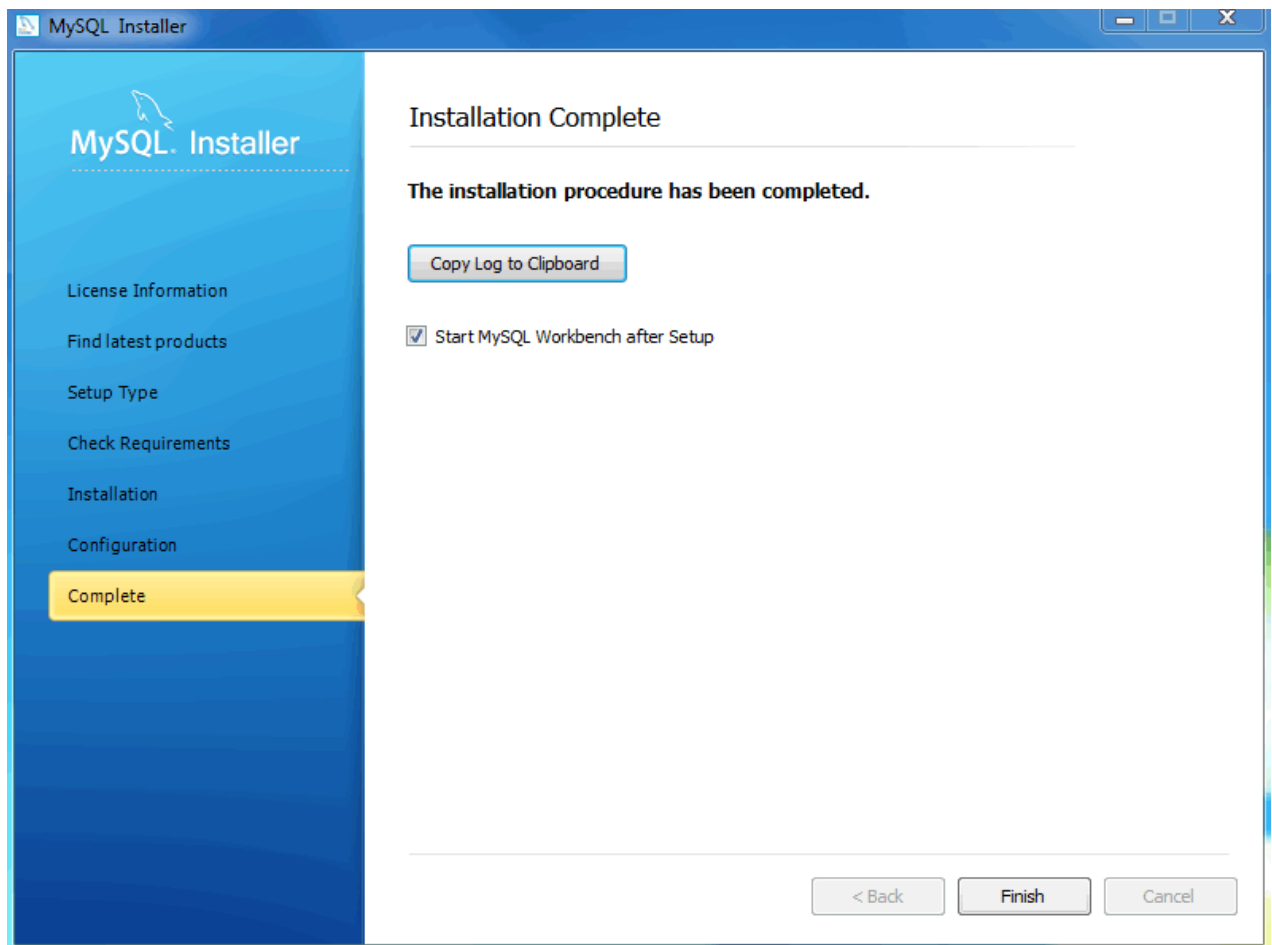

When configuring **Run Windows Services as ...** using a **Custom User**, the custom user must have privileges to log on to Windows as a service. And the **Next** button will be disabled until this user is given these user rights.

On Microsoft Windows 7, this is configured by loading the [Start Menu](#), [Control Panel](#), [Administrative Tools](#), [Local Security Policy](#), [Local Policies](#), [User Rights Assignment](#), then [Log On As A Service](#). Choose [Add User or Group](#) here to add the custom user, and then **OK**, **OK** to save.

The final configuration step is available if the **Advanced Configuration** option was checked, and it includes configuration options related to log file names:

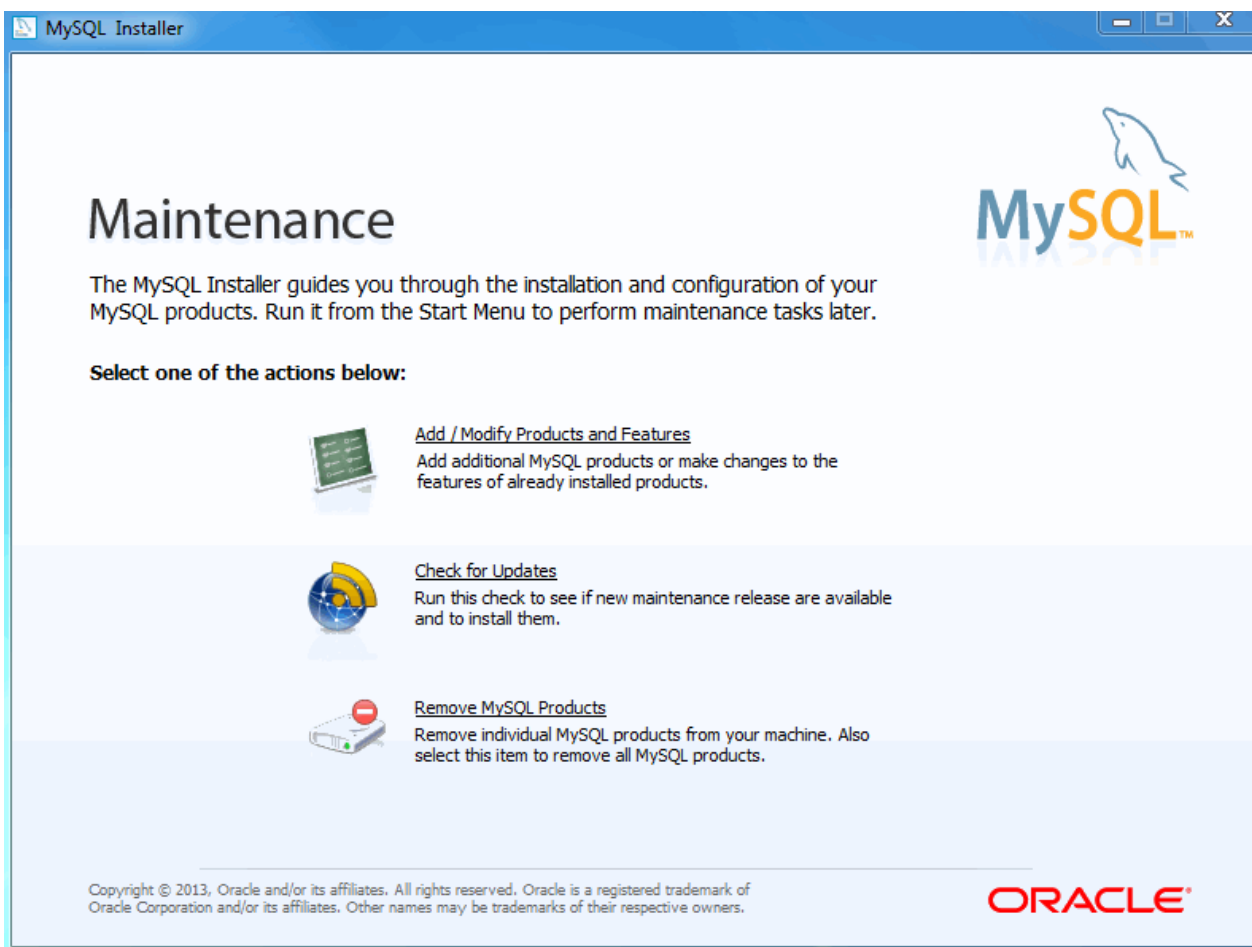

Figure 2.18 MySQL Installer - MySQL Server Configuration: Logging options

After the MySQL Installer configuration process is completed, you may save the installation log, and then load MySQL Workbench if the **Start MySQL Workbench after Setup** option is checked:

Figure 2.19 MySQL Installer - Installation Complete

You can now open MySQL Installer from the Microsoft Windows Start menu under the [MySQL](#) group, which will load the MySQL Installer [Maintenance Screen](#). This is used to add, update, and remove features.

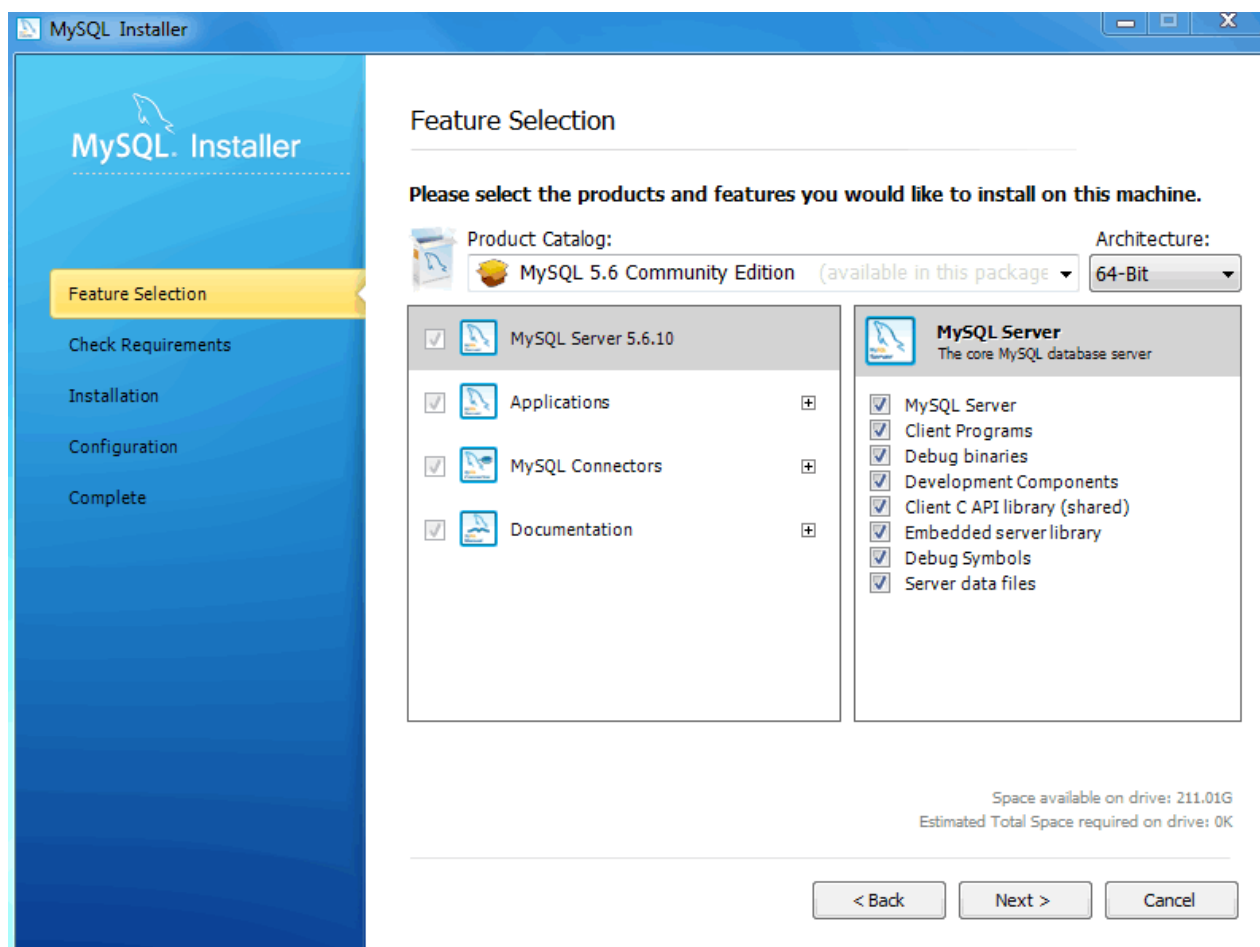

Figure 2.20 MySQL Installer - Maintenance Screen

Note

An [Update Screen](#) screen is shown if MySQL Installer is used on a machine with older products installed, as opposed to the [Maintenance Screen](#) shown above. However, the functionality remains the same.

Add/Modify Products and Features will list all installed and available MySQL products.

Figure 2.21 MySQL Installer - Add/Modify Products and Features

The installation is now complete. MySQL Server should be running, and most MySQL products installed and available for use.

See also the MySQL Workbench documentation (<http://dev.mysql.com/doc/workbench/en/>).

2.3.3.2 MySQL Installer Console

`MySQLInstallerConsole` provides functionality similar to the GUI version of MySQL Installer, but from the command-line. It is installed when MySQL Installer is initially executed, and then available within the `MySQL Installer` directory. Typically that is in `C:\Program Files (x86)\MySQL\MySQL Installer\`, and the console must be executed with administrative privileges.

To use, invoke the Command Prompt with administrative privileges by choosing **Start**, **Accessories**, then right-click on **Command Prompt** and choose **Run as administrator**. And from the command-line, optionally change the directory to where `MySQLInstallerConsole` is located:

```
C:\> cd "C:\Program Files (x86)\MySQL\MySQL Installer"
```

`MySQLInstallerConsole` supports the following options, which are specified on the command line:

- `--help`, `-h`, or `-?`

Displays a help message with usage examples, and then exits.

```
C:\> MySQLInstallerConsole --help
```

- `--updates` (or `-u`)

Checks for new products before any further action is taken. Disabled by default.

- `--nowait`

Skips the final pause when the program finishes. Otherwise, a "Press Enter to continue." dialogue is generated. It is used in conjunction with other options.

- `--catalog=catalog_name` (or `-c`)

Sets the default catalog. Use `--list` to view a list of available catalogs.

- `--type=installation_type` (or `-t`)

Sets the installation type.

The possible values for `installation_type` are: developer, server, client, full, and custom.

- `--action=action_name`

The action being performed.

The possible values are: install, remove, upgrade, list, and status.

- **install**: Installs a product or products, as defined by `--products`
- **upgrade**: Upgrades a product or products, as defined by `--products`.
- **remove**: Removes a product or products, as defined by `--products`.
- **list**: Lists the product manifest, both installed and available products.
- **status**: Shows the status after another action is performed.
- `--product=product_name[:feature1],[feature2], [...]` (or `-p`)

Set the feature list of a product. Use `--list` to view available products, or pass in `--product=*` (an asterisk) to install all available products.

- `--config=product_name:passwd=root_password[;parameter1=value], [;parameter2=value], ...`

The configuration parameters for the most recently listed products.

- `--user=product_name:name=username,host:hostname,role=rolename,password=password` or `--user=product_name:name=username,host:hostname,role=rolename,tokens=tokens`

Creates a new user.

Requires: name, host, role, and the password or tokens. Tokens are separated by pipe (|) characters.

2.3.4 MySQL Notifier for Microsoft Windows

The MySQL Notifier for Microsoft Windows is a tool that enables you to monitor and adjust the status of your local and remote MySQL Server instances through an indicator that resides in the system tray. The MySQL Notifier for Microsoft Windows also gives quick access to several MySQL GUI tools (such as MySQL Workbench) through its context menu.

The MySQL Notifier for Microsoft Windows is installed by MySQL Installer, and (by default) will start-up when Microsoft Windows is started.

Note

To install, download and execute the [MySQL Installer](#), be sure the MySQL Notifier for Microsoft Windows product is selected, then proceed with the installation. See the [MySQL Installer manual](#) for additional details.

For notes detailing the changes in each release of MySQL Notifier for Microsoft Windows, see the [MySQL Notifier Release Notes](#).

Visit the [MySQL Notifier forum](#) for additional MySQL Notifier for Microsoft Windows help and support.

Features include:

- Start, Stop, and Restart instances of the MySQL Server.
- Automatically detects (and adds) new MySQL Server services. These are listed under **Manage Monitored Items**, and may also be configured.
- The Tray icon changes, depending on the status. It's green if all monitored MySQL Server instances are running, or red if at least one service is stopped. The **Update MySQL Notifier tray icon based on service status** option, which dictates this behavior, is enabled by default for each service.
- Links to other applications like MySQL Workbench, MySQL Installer, and the MySQL Utilities. For example, choosing **Configure Instance** will load the MySQL Workbench Server Administration window for that particular instance.
- If MySQL Workbench is also installed, then the **Configure Instance** and **SQL Editor** options are available for local (but not remote) MySQL instances.
- Monitoring of both local and remote MySQL instances.

Note

Remote monitoring is available since MySQL Notifier for Microsoft Windows 1.1.0.

The MySQL Notifier for Microsoft Windows resides in the system tray and provides visual status information for your MySQL Server instances. A green icon is displayed at the top left corner of the tray icon if the current MySQL Server is running, or a red icon if the service is stopped.

The MySQL Notifier for Microsoft Windows automatically adds discovered MySQL Services on the local machine, and each service is saved and configurable. By default, the **Automatically add new services whose name contains** option is enabled and set to `mysql`. Related **Notifications Options** include being

notified when new services are either discovered or experience status changes, and are also enabled by default. And uninstalling a service will also remove the service from the MySQL Notifier for Microsoft Windows.

Note

The **Automatically add new services whose name contains** option default changed from ".*mysqld.*" to "mysql" in Notifier 1.1.0.

Clicking the system tray icon will reveal several options, as seen in the screenshots below:

The Service Instance menu is the main MySQL Notifier for Microsoft Windows window, and enables you to Stop, Start, and Restart the MySQL Server.

Figure 2.22 MySQL Notifier for Microsoft Windows Service Instance menu

The **Actions** menu includes several links to external applications (if they are installed), and a **Refresh Status** option to manually refresh the status of all monitored services (in both local and remote computers) and MySQL instances.

Note

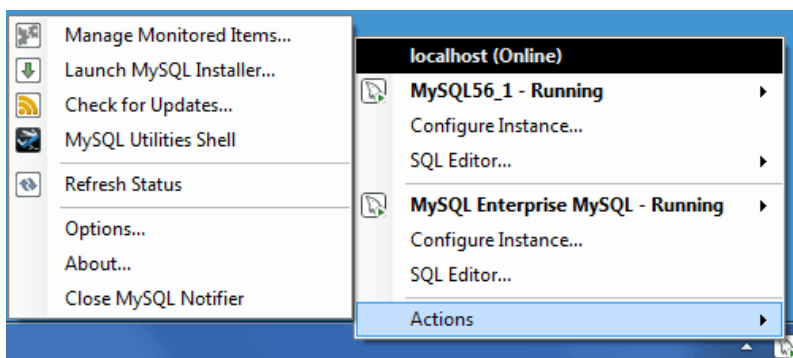

The main menu will not show the **Actions** menu when there are no services being monitored by MySQL Notifier for Microsoft Windows.

Note

The **Refresh Status** feature is available since MySQL Notifier for Microsoft Windows 1.1.0.

Figure 2.23 MySQL Notifier for Microsoft Windows Actions menu

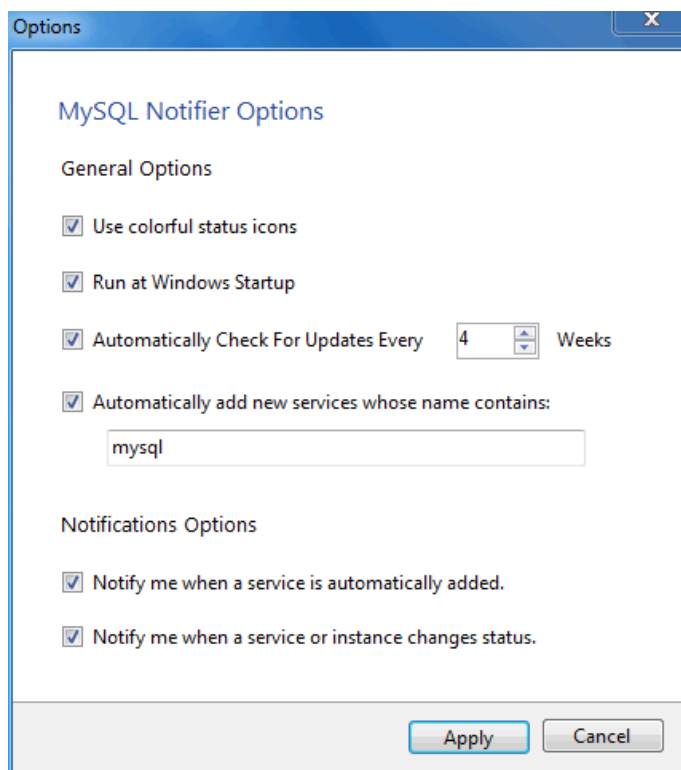

The [Actions](#), [Options](#) menu configures MySQL Notifier for Microsoft Windows and includes options to:

- **Use colorful status icons**: Enables a colorful style of icons for the tray of the MySQL Notifier for Microsoft Windows.
- **Run at Windows Startup**: Allows the application to be loaded when Microsoft Windows starts.
- **Automatically Check For Updates Every # Weeks**: Checks for a new version of MySQL Notifier for Microsoft Windows, and runs this check every # weeks.
- **Automatically add new services whose name contains**: The text used to filter services and add them automatically to the monitored list of the local computer running MySQL Notifier, and on remote computers already monitoring Windows services. monitored services, and also filters the list of the Microsoft Windows services for the **Add New Service** dialog.

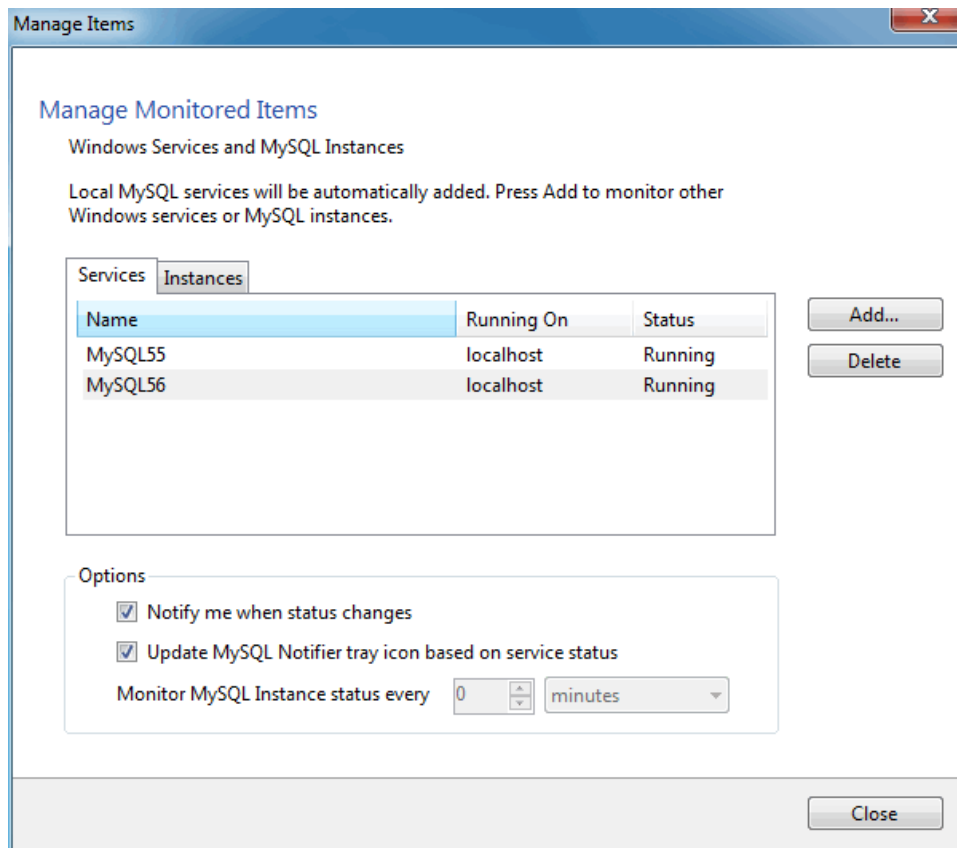

Prior to version 1.1.0, this option was named "Automatically add new services that match this pattern."

- **Notify me when a service is automatically added**: Will display a balloon notification from the taskbar when a newly discovered service is added to the monitored services list.
- **Notify me when a service changes status**: Will display a balloon notification from the taskbar when a monitored service changes its status.

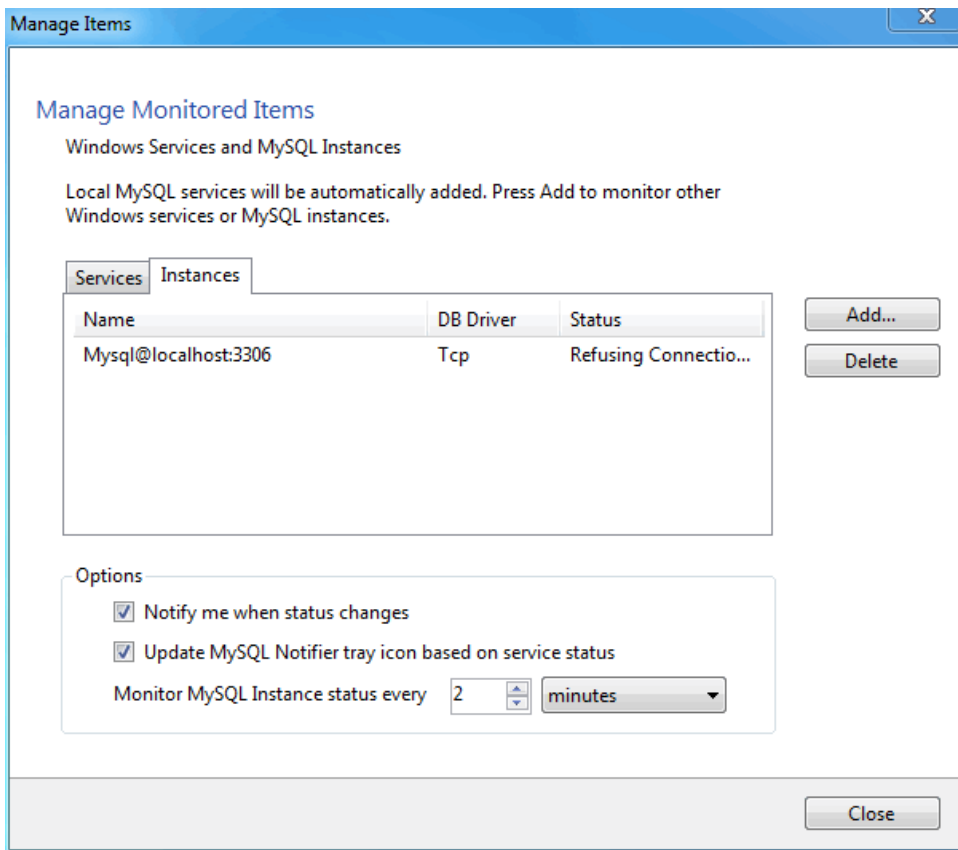

Figure 2.24 MySQL Notifier for Microsoft Windows Options menu

The [Actions](#), [Manage Monitored Items](#) menu enables you to configure the monitored services and MySQL instances. First, with the **Services** tab open:

Figure 2.25 MySQL Notifier for Microsoft Windows Manage Services menu

The **Instances** tab is similar:

Figure 2.26 MySQL Notifier for Microsoft Windows Manage Instances menu

Adding a service or instance (after clicking **Add** in the **Manage Monitored Items** window) enables you to select a running Microsoft Windows service or instance connection, and configure MySQL Notifier for Microsoft Windows to monitor it. Add a new service or instance by clicking service name from the list, then **OK** to accept. Multiple services and instances may be selected.

Figure 2.27 MySQL Notifier for Microsoft Windows Adding new services

And instances:

Figure 2.28 MySQL Notifier for Microsoft Windows Adding new instances**Note**

The **Instances** tab available since MySQL Notifier for Microsoft Windows 1.1.0.

2.3.4.1 Remote monitoring set up and installation instructions

The MySQL Notifier for Microsoft Windows uses Windows Management Instrumentation (WMI) to manage and monitor services in remote computers running Windows XP or later. This guide explains how it works, and how to set up your system to monitor remote MySQL instances.

**Note**

Remote monitoring is available since MySQL Notifier for Microsoft Windows 1.1.0.

In order to configure WMI, it is important to understand that the underlying Distributed Component Object Model (DCOM) architecture is doing the WMI work. Specifically, MySQL Notifier for Microsoft Windows is using asynchronous notification queries on remote Microsoft Windows hosts as .NET events. These events send an asynchronous callback to the computer running the MySQL Notifier for Microsoft Windows so it knows when a service status has changed on the remote computer. Asynchronous notifications offer the best performance compared to semisynchronous notifications or synchronous notifications that use timers.

Asynchronous notifications requires the remote computer to send a callback to the client computer (thus opening a reverse connection), so the Windows Firewall and DCOM settings must be properly configured for the communication to function properly.

Figure 2.29 MySQL Notifier for Microsoft Windows Distributed Component Object Model (DCOM)

Most of the common errors thrown by asynchronous WMI notifications are related to Windows Firewall blocking the communication, or to DCOM / WMI settings not being set up properly. For a list of common errors with solutions, see [Common Errors](#).

The following steps are required to make WMI function. These steps are divided between two machines. A single host computer that runs MySQL Notifier for Microsoft Windows (Computer A), and multiple remote machines that are being monitored (Computer B).

Computer running MySQL Notifier for Microsoft Windows (Computer A)

1. Allow for remote administration by either editing the **Group Policy Editor**, or using [NETSH](#):

Using the **Group Policy Editor**:

- a. Click **Start**, click **Run**, type `GPEDIT.MSC`, and then click **OK**.
- b. Under the **Local Computer Policy** heading, double-click **Computer Configuration**.
- c. Double-click **Administrative Templates**, then **Network**, **Network Connections**, and then **Windows Firewall**.
- d. If the computer is in the domain, then double-click **Domain Profile**; otherwise, double-click **Standard Profile**.
- e. Click **Windows Firewall: Allow inbound remote administration exception**.
- f. On the Action menu either select **Edit**, or double-click the selection from the previous step.
- g. Check the **Enabled** radio button, and then click **OK**.

Using the [NETSH](#) command:

- a. Open a command prompt window with Administrative rights (you can right-click the Command Prompt icon and click **Run as Administrator**).
- b. Execute the following command:

```
NETSH firewall set service RemoteAdmin enable
```

2. Open the DCOM port TCP 135:

- a. Open a command prompt window with Administrative rights (you can right-click the Command Prompt icon and click **Run as Administrator**) .
- b. Execute the following command:

```
NETSH firewall add portopening protocol=tcp port=135 name=DCOM_TCP135
```

3. Add the client application which contains the sink for the callback (`MySQLNotifier.exe`) to the Windows Firewall Exceptions List (use either the Windows Firewall configuration or `NETSH`):

Using the Windows Firewall configuration:

- a. In the Control Panel, double-click **Windows Firewall**.
- b. In the Windows Firewall window's left panel, click **Allow a program or feature through Windows Firewall**.
- c. In the Allowed Programs window, click **Change Settings**.
- d. If `MySQLNotifier.exe` is in the Allowed programs and features list, make sure it is checked for the type of networks the computer connects to (Private, Public or both).
- e. If `MySQLNotifier.exe` is not in the list, click **Allow another program...**
- f. In the **Add a Program** window, select the `MySQLNotifier.exe` if it exists in the Programs list, otherwise click **Browse...** and go to the directory where `MySQLNotifier.exe` was installed to select it, then click **Add**.
- g. Make sure `MySQLNotifier.exe` is checked for the type of networks the computer connects to (Private, Public or both).

Using the `NETSH` command:

- a. Open a command prompt window with Administrative rights (you can right-click the Command Prompt icon and click **Run as Administrator**).
- b. Execute the following command, where you change "`[YOUR_INSTALL_DIRECTORY]`":

```
NETSH firewall add allowedprogram program=[YOUR_INSTALL_DIRECTORY]\MySQLNotifier.exe name=MySQLNotif
```

4. If Computer B is either a member of `WORKGROUP` or is in a different domain that is untrusted by Computer A, then the callback connection (Connection 2) is created as an Anonymous connection. To grant Anonymous connections DCOM Remote Access permissions:
 - a. Click **Start**, click **Run**, type `DCOMCNFG`, and then click **OK**.
 - b. In the Component Services dialog box, expand Component Services, expand Computers, and then right-click **My Computer** and click **Properties**.
 - c. In the My Computer Properties dialog box, click the **COM Security** tab.
 - d. Under Access Permissions, click **Edit Limits**.

- e. In the Access Permission dialog box, select **ANONYMOUS LOGON name** in the Group or user names box. In the Allow column under Permissions for User, select **Remote Access**, and then click **OK**.

Monitored Remote Computer (Computer B)

If the user account that is logged into the computer running the MySQL Notifier for Microsoft Windows (Computer A) is a local administrator on the remote computer (Computer B), such that the same account is an administrator on Computer B, you can skip to the "Allow for remote administration" step.

Setting DCOM security to allow a non-administrator user to access a computer remotely:

1. Grant "DCOM remote launch" and activation permissions for a user or group:
 - a. Click **Start**, click **Run**, type **DCOMCNFG**, and then click **OK**.
 - b. In the Component Services dialog box, expand Component Services, expand Computers, and then right-click **My Computer** and click **Properties**.
 - c. In the My Computer Properties dialog box, click the **COM Security** tab.
 - d. Under Access Permissions, click **Edit Limits**.
 - e. In the **Launch Permission** dialog box, follow these steps if your name or your group does not appear in the Groups or user names list:
 - i. In the **Launch Permission** dialog box, click **Add**.
 - ii. In the Select Users, Computers, or Groups dialog box, add your name and the group in the "Enter the object names to select" box, and then click **OK**.
 - f. In the **Launch Permission** dialog box, select your user and group in the Group or user names box. In the Allow column under Permissions for User, select **Remote Launch**, select **Remote Activation**, and then click **OK**.

Grant DCOM remote access permissions:

- a. Click **Start**, click **Run**, type **DCOMCNFG**, and then click **OK**.
 - b. In the Component Services dialog box, expand Component Services, expand Computers, and then right-click **My Computer** and click **Properties**.
 - c. In the My Computer Properties dialog box, click the **COM Security** tab.
 - d. Under Access Permissions, click **Edit Limits**.
 - e. In the Access Permission dialog box, select **ANONYMOUS LOGON name** in the Group or user names box. In the Allow column under Permissions for User, select **Remote Access**, and then click **OK**.
2. Allowing non-administrator users access to a specific WMI namespace:
 - a. In the Control Panel, double-click **Administrative Tools**.
 - b. In the Administrative Tools window, double-click **Computer Management**.

- c. In the Computer Management window, expand the **Services and Applications** tree and double-click the **WMI Control**.
 - d. Right-click the WMI Control icon and select **Properties**.
 - e. In the WMI Control Properties window, click the **Security** tab.
 - f. In the Security tab, select the namespace and click **Security**.
 - g. Locate the appropriate account and check **Remote Enable in the Permissions list**.
3. Allow for remote administration by either editing the **Group Policy Editor** or using **NETSH**:

Using the **Group Policy Editor**:

- a. Click **Start**, click **Run**, type **GPEDIT.MSC**, and then click **OK**.
- b. Under the Local Computer Policy heading, double-click **Computer Configuration**.
- c. Double-click **Administrative Templates**, then **Network**, **Network Connections**, and then **Windows Firewall**.
- d. If the computer is in the domain, then double-click **Domain Profile**; otherwise, double-click **Standard Profile**.
- e. Click **Windows Firewall: Allow inbound remote administration exception**.
- f. On the Action menu either select **Edit**, or double-click the selection from the previous step.
- g. Check the **Enabled** radio button, and then click **OK**.

Using the **NETSH** command:

- a. Open a command prompt window with Administrative rights (you can right-click the Command Prompt icon and click Run as Administrator).
- b. Execute the following command:

```
NETSH firewall set service RemoteAdmin enable
```

4. Now, be sure the user you are logging in with uses the **Name** value and not the **Full Name** value:
 - a. In the **Control Panel**, double-click **Administrative Tools**.
 - b. In the **Administrative Tools** window, double-click **Computer Management**.
 - c. In the **Computer Management** window, expand the **System Tools then Local Users and Groups**.
 - d. Click the **Users** node, and on the right side panel locate your user and make sure it uses the **Name** value to connect, and not the **Full Name** value.
5. If the remote computer is running on **Windows XP Professional**, make sure that remote logins are not being forcefully changed to the guest account user (also known as **ForceGuest**), which is enabled by default on computers that are not attached to a domain.
 - a. Click **Start**, click **Run**, type **SECPOL.MSC**, and then click **OK**.

- b. Under the **Local Policies** node, double-click **Security Options**.
- c. Select **Network Access: Sharing and security model for local accounts** and save.

Common Errors

- 0x80070005
 - DCOM Security was not configured properly (see Computer B, the [Setting DCOM security...](#) step).
 - The remote computer (Computer B) is a member of WORKGROUP or is in a domain that is untrusted by the client computer (Computer A) (see Computer A, the [Grant Anonymous connections DCOM Remote Access permissions](#) step).
- 0x8007000E
 - The remote computer (Computer B) is a member of WORKGROUP or is in a domain that is untrusted by the client computer (Computer A) (see Computer A, the [Grant Anonymous connections DCOM Remote Access permissions](#) step).
- 0x80041003
 - Access to the remote WMI namespace was not configured properly (see Computer B, the [Allowing non-administrator users access to a specific WMI namespace](#) step).
- 0x800706BA
 - The DCOM port is not open on the client computers (Computer A) firewall. See the [Open the DCOM port TCP 135](#) step for Computer A.
 - The remote computer (Computer B) is inaccessible because its network location is set to Public. Make sure you can access it through the Windows Explorer.

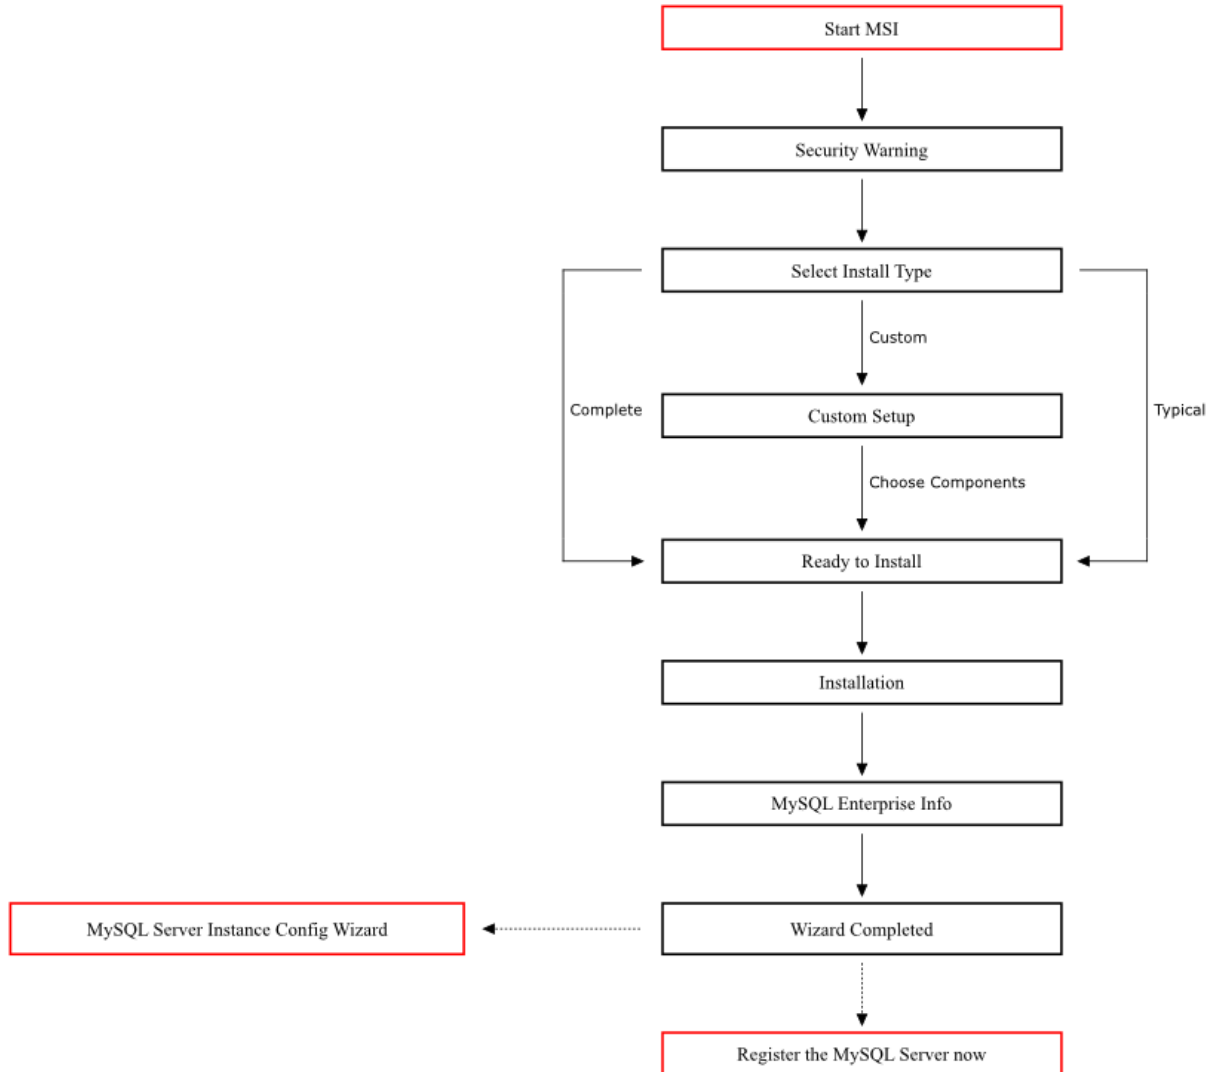

2.3.5 Installing MySQL on Microsoft Windows Using an MSI Package

The MSI package is designed to install and configure MySQL in such a way that you can immediately get started using MySQL.

The MySQL Installation Wizard and MySQL Configuration Wizard are available in the Complete install package, which is recommended for most standard MySQL installations. Exceptions include users who need to install multiple instances of MySQL on a single server host and advanced users who want complete control of server configuration.

- For information on installing using the GUI MSI installer process, see [Section 2.3.5.1, “Using the MySQL Installation Wizard”](#).
- For information on installing using the command line using the MSI package, see [Section 2.3.5.2, “Automating MySQL Installation on Microsoft Windows Using the MSI Package”](#).
- If you have previously installed MySQL using the MSI package and want to remove MySQL, see [Section 2.3.5.3, “Removing MySQL When Installed from the MSI Package”](#).

The workflow sequence for using the installer is shown in the figure below:

Figure 2.30 Installation Workflow for Windows Using MSI Installer**Note**

Microsoft Windows XP and later include a firewall which specifically blocks ports. If you plan on using MySQL through a network port then you should open and create an exception for this port before performing the installation. To check and if necessary add an exception to the firewall settings:

1. First ensure that you are logged in as an Administrator or a user with Administrator privileges.
2. Go to the **Control Panel**, and double click the **Windows Firewall** icon.
3. Choose the **Allow a program through Windows Firewall** option and click the **Add port** button.
4. Enter **MySQL** into the **Name** text box and **3306** (or the port of your choice) into the **Port number** text box.

5. Also ensure that the **TCP** protocol radio button is selected.
6. If you wish, you can also limit access to the MySQL server by choosing the **Change scope** button.
7. Confirm your choices by clicking the **OK** button.

Additionally, when running the MySQL Installation Wizard on Windows Vista or newer, ensure that you are logged in as a user with administrative rights.

Note

When using Windows Vista or newer, you may want to disable User Account Control (UAC) before performing the installation. If you do not do so, then MySQL may be identified as a security risk, which will mean that you need to enable MySQL. You can disable the security checking by following these instructions:

1. Open **Control Panel**.
2. Under the **User Accounts and Family Safety**, select **Add or remove user accounts**.
3. Click the **Got to the main User Accounts page** link.
4. Click on **Turn User Account Control on or off**. You may be prompted to provide permission to change this setting. Click **Continue**.
5. Deselect or uncheck the check box next to **Use User Account Control (UAC) to help protect your computer**. Click **OK** to save the setting.

You will need to restart to complete the process. Click **Restart Now** to reboot the machine and apply the changes. You can then follow the instructions below for installing Windows.

2.3.5.1 Using the MySQL Installation Wizard

MySQL Installation Wizard is an installer for the MySQL server that uses the latest installer technologies for Microsoft Windows. The MySQL Installation Wizard, in combination with the MySQL Configuration Wizard, enables a user to install and configure a MySQL server that is ready for use immediately after installation.

The MySQL Installation Wizard is the standard installer for all MySQL server distributions, version 4.1.5 and higher. Users of previous versions of MySQL need to shut down and remove their existing MySQL installations manually before installing MySQL with the MySQL Installation Wizard. See [Upgrading MySQL with the Installation Wizard](#), for more information on upgrading from a previous version.

Microsoft has included an improved version of their Microsoft Windows Installer (MSI) in the recent versions of Windows. MSI has become the de-facto standard for application installations on Windows 2000, Windows XP, and Windows Server 2003. The MySQL Installation Wizard makes use of this technology to provide a smoother and more flexible installation process.

The Microsoft Windows Installer Engine was updated with the release of Windows XP; those using a previous version of Windows can reference [this Microsoft Knowledge Base article](#) for information on upgrading to the latest version of the Windows Installer Engine.

In addition, Microsoft has introduced the WiX (Windows Installer XML) toolkit recently. This is the first highly acknowledged Open Source project from Microsoft. We have switched to WiX because it is an Open Source project and it enables us to handle the complete Windows installation process in a flexible manner using scripts.

Improving the MySQL Installation Wizard depends on the support and feedback of users like you. If you find that the MySQL Installation Wizard is lacking some feature important to you, or if you discover a bug, please report it in our bugs database using the instructions given in [Section 1.7, “How to Report Bugs or Problems”](#).

Downloading and Starting the MySQL Installation Wizard

The MySQL installation packages can be downloaded from <http://dev.mysql.com/downloads/>. If the package you download is contained within a Zip archive, you need to extract the archive first.

Note

If you are installing on Windows Vista or newer, it is best to open a network port before beginning the installation. To do this, first ensure that you are logged in as an Administrator, go to the [Control Panel](#), and double-click the [Windows Firewall](#) icon. Choose the [Allow a program through Windows Firewall](#) option and click the [Add port](#) button. Enter [MySQL](#) into the **Name** text box and [3306](#) (or the port of your choice) into the **Port number** text box. Also ensure that the **TCP** protocol radio button is selected. If you wish, you can also limit access to the MySQL server by choosing the **Change scope** button. Confirm your choices by clicking the [OK](#) button. If you do not open a port prior to installation, you cannot configure the MySQL server immediately after installation. Additionally, when running the MySQL Installation Wizard on Windows Vista or newer, ensure that you are logged in as a user with administrative rights.

The process for starting the wizard depends on the contents of the installation package you download. If there is a [setup.exe](#) file present, double-click it to start the installation process. If there is an [.msi](#) file present, double-click it to start the installation process.

Choosing an Install Type

There are three installation types available: **Typical**, **Complete**, and **Custom**.

The **Typical** installation type installs the MySQL server, the [mysql](#) command-line client, and the command-line utilities. The command-line clients and utilities include [mysqldump](#), [myisamchk](#), and several other tools to help you manage the MySQL server.

The **Complete** installation type installs all components included in the installation package. The full installation package includes components such as the embedded server library, the benchmark suite, support scripts, and documentation.

The **Custom** installation type gives you complete control over which packages you wish to install and the installation path that is used. See [The Custom Install Dialog](#), for more information on performing a custom install.

If you choose the **Typical** or **Complete** installation types and click the [Next](#) button, you advance to the confirmation screen to verify your choices and begin the installation. If you choose the **Custom** installation type and click the [Next](#) button, you advance to the custom installation dialog, described in [The Custom Install Dialog](#).

The Custom Install Dialog

If you wish to change the installation path or the specific components that are installed by the MySQL Installation Wizard, choose the **Custom** installation type.

A tree view on the left side of the custom install dialog lists all available components. Components that are not installed have a red X icon; components that are installed have a gray icon. To change whether a component is installed, click that component's icon and choose a new option from the drop-down list that appears.

You can change the default installation path by clicking the **Change...** button to the right of the displayed installation path.

After choosing your installation components and installation path, click the **Next** button to advance to the confirmation dialog.

The Confirmation Dialog

Once you choose an installation type and optionally choose your installation components, you advance to the confirmation dialog. Your installation type and installation path are displayed for you to review.

To install MySQL if you are satisfied with your settings, click the **Install** button. To change your settings, click the **Back** button. To exit the MySQL Installation Wizard without installing MySQL, click the **Cancel** button.

The final screen of the installer provides a summary of the installation and gives you the option to launch the MySQL Configuration Wizard, which you can use to create a configuration file, install the MySQL service, and configure security settings.

Changes Made by MySQL Installation Wizard

Once you click the **Install** button, the MySQL Installation Wizard begins the installation process and makes certain changes to your system which are described in the sections that follow.

Changes to the Registry

The MySQL Installation Wizard creates one Windows registry key in a typical install situation, located in `HKEY_LOCAL_MACHINE\SOFTWARE\MySQL AB`.

The MySQL Installation Wizard creates a key named after the major version of the server that is being installed, such as `MySQL Server 5.5`. It contains two string values, `Location` and `Version`. The `Location` string contains the path to the installation directory. In a default installation it contains `C:\Program Files\MySQL\MySQL Server 5.5\`. The `Version` string contains the release number. For example, for an installation of MySQL Server 5.5.40, the key contains a value of `5.5.40`.

These registry keys are used to help external tools identify the installed location of the MySQL server, preventing a complete scan of the hard-disk to determine the installation path of the MySQL server. The registry keys are not required to run the server, and if you install MySQL using the `noinstall` Zip archive, the registry keys are not created.

Changes to the Start Menu

The MySQL Installation Wizard creates a new entry in the Windows **Start** menu under a common MySQL menu heading named after the major version of MySQL that you have installed. For example, if you install MySQL 5.5, the MySQL Installation Wizard creates a MySQL Server 5.5 section in the **Start** menu.

The following entries are created within the new **Start** menu section:

- **MySQL Command-Line Client:** This is a shortcut to the `mysql` command-line client and is configured to connect as the `root` user. The shortcut prompts for a `root` user password when you connect.
- **MySQL Server Instance Config Wizard:** This is a shortcut to the MySQL Configuration Wizard. Use this shortcut to configure a newly installed server, or to reconfigure an existing server.
- **MySQL Documentation:** This is a link to the MySQL server documentation that is stored locally in the MySQL server installation directory.

Changes to the File System

The MySQL Installation Wizard by default installs the MySQL 5.5 server to `C:\Program Files\MySQL\MySQL Server 5.5`, where *Program Files* is the default location for applications in your system, and *5.5* is the major version of your MySQL server. This is the recommended location for the MySQL server, replacing the former default location `C:\mysql`.

By default, all MySQL applications are stored in a common directory at `C:\Program Files\MySQL`, where *Program Files* is the default location for applications in your Windows installation. A typical MySQL installation on a developer machine might look like this:

```
C:\Program Files\MySQL\MySQL Server 5.5
C:\Program Files\MySQL\MySQL Workbench 5.1 OSS
```

This approach makes it easier to manage and maintain all MySQL applications installed on a particular system.

The default location of the data directory is the `AppData` directory configured for the user that installed the MySQL application.

Upgrading MySQL with the Installation Wizard

The MySQL Installation Wizard can perform server upgrades automatically using the upgrade capabilities of MSI. That means you do not need to remove a previous installation manually before installing a new release. The installer automatically shuts down and removes the previous MySQL service before installing the new version.

Automatic upgrades are available only when upgrading between installations that have the same major and minor version numbers. For example, you can upgrade automatically from MySQL 5.5.5 to MySQL 5.5.6, but not from MySQL 5.1 to MySQL 5.5.

See [Section 2.3.9, “Upgrading MySQL on Windows”](#).

2.3.5.2 Automating MySQL Installation on Microsoft Windows Using the MSI Package

The Microsoft Installer (MSI) supports both a *quiet* and a *passive* mode that can be used to install MySQL automatically without requiring intervention. You can use this either in scripts to automatically install MySQL or through a terminal connection such as Telnet where you do not have access to the standard Windows user interface. The MSI packages can also be used in combination with Microsoft's Group Policy system (part of Windows Server 2003 and Windows Server 2008) to install MySQL across multiple machines.

To install MySQL from one of the MSI packages automatically from the command line (or within a script), you need to use the `msiexec.exe` tool. For example, to perform a quiet installation (which shows no dialog boxes or progress):

```
shell> msiexec /i mysql-5.5.40.msi /quiet
```

The `/i` indicates that you want to perform an installation. The `/quiet` option indicates that you want no interactive elements.

To provide a dialog box showing the progress during installation, and the dialog boxes providing information on the installation and registration of MySQL, use `/passive` mode instead of `/quiet`:

```
shell> msiexec /i mysql-5.5.40.msi /passive
```

Regardless of the mode of the installation, installing the package in this manner performs a 'Typical' installation, and installs the default components into the standard location.

You can also use this method to uninstall MySQL by using the `/uninstall` or `/x` options:

```
shell> msiexec /x mysql-5.5.40.msi /uninstall
```

To install MySQL and configure a MySQL instance from the command line, see [Section 2.3.6.13, “MySQL Server Instance Config Wizard: Creating an Instance from the Command Line”](#).

For information on using MSI packages to install software automatically using Group Policy, see [How to use Group Policy to remotely install software in Windows Server 2003](#).

2.3.5.3 Removing MySQL When Installed from the MSI Package

To uninstall a MySQL where you have used the MSI packages, you must use the **Add/Remove Programs** tool within **Control Panel**. To do this:

1. Right-click the **start** menu and choose **Control Panel**.
2. If the Control Panel is set to category mode (you will see **Pick a category** at the top of the **Control Panel** window), double-click **Add or Remove Programs**. If the Control is set to classic mode, double-click the **Add or Remove Programs** icon.
3. Find MySQL in the list of installed software. MySQL Server is installed against major version numbers (MySQL 5.1, MySQL 5.5, etc.). Select the version that you want to remove and click **Remove**.
4. You will be prompted to confirm the removal. Click **Yes** to remove MySQL.

When MySQL is removed using this method, only the installed components are removed. Any database information (including the tables and data), import or export files, log files, and binary logs produced during execution are kept in their configured location.

If you try to install MySQL again the information will be retained and you will be prompted to enter the password configured with the original installation.

If you want to delete MySQL completely:

- Delete the associated data directory. On Windows XP and Windows Server 2003, the default data directory is the configured AppData directory, which is `C:\Documents and Settings\All Users\Application Data\MySQL` by default.
- On Windows 7 and Windows Server 2008, the default data directory location is `C:\ProgramData\MySQL`.

Note

The `C:\ProgramData` directory is hidden by default. You must change your folder options to view the hidden file. Choose **Organize**, Folder and search options, **Show hidden folders**.

2.3.6 MySQL Server Instance Configuration Wizard

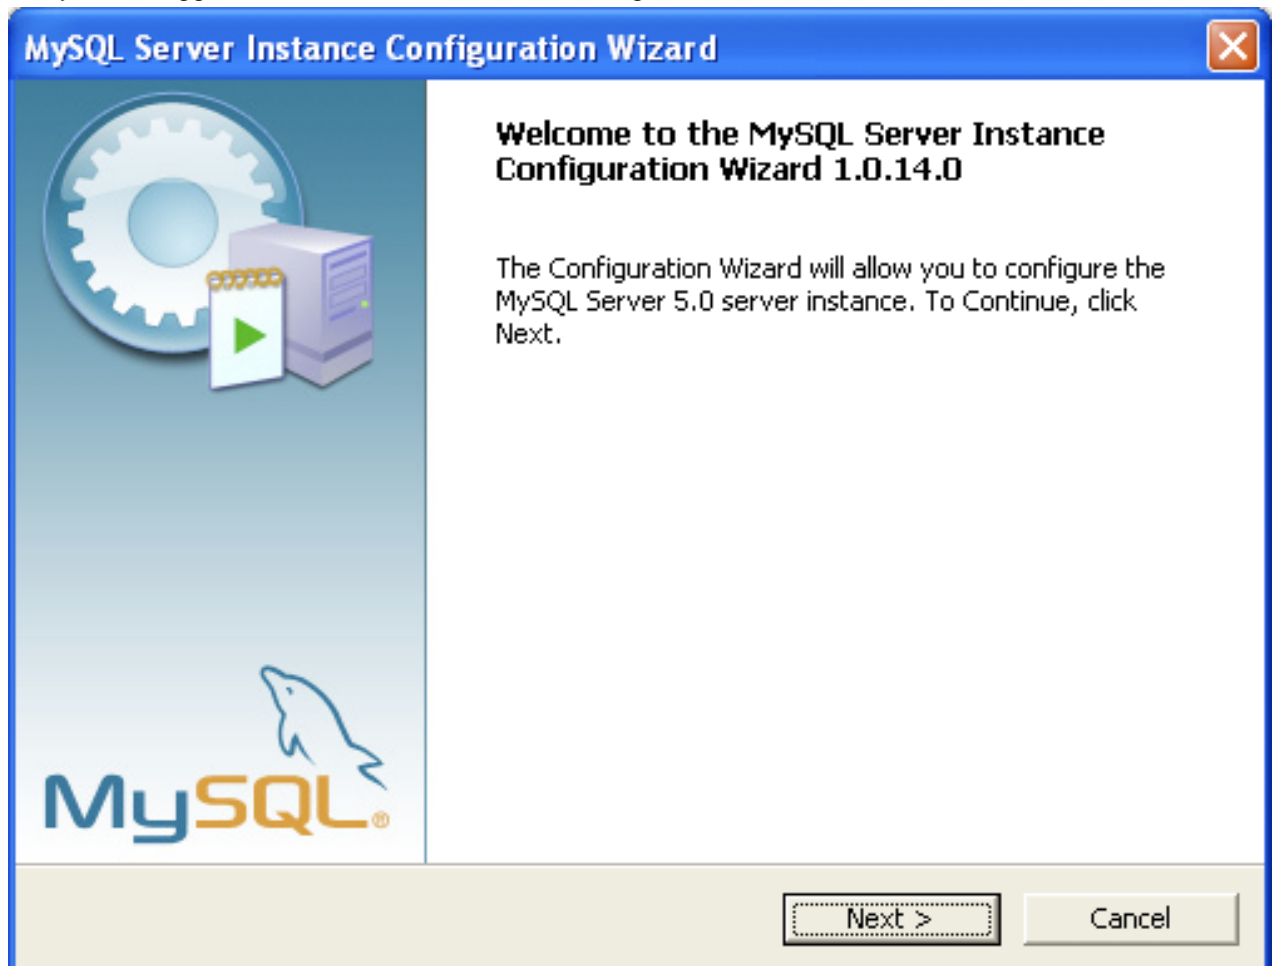

The MySQL Server Instance Configuration Wizard helps automate the process of configuring your server. It creates a custom MySQL configuration file (`my.ini` or `my.cnf`) by asking you a series of questions and then applying your responses to a template to generate the configuration file that is tuned to your installation.

The MySQL Server Instance Configuration Wizard is included with the MySQL 5.5 server. The MySQL Server Instance Configuration Wizard is only available for Windows.

2.3.6.1 Starting the MySQL Server Instance Configuration Wizard

The MySQL Server Instance Configuration Wizard is normally started as part of the installation process. You should only need to run the MySQL Server Instance Configuration Wizard again when you need to change the configuration parameters of your server.

If you chose not to open a port prior to installing MySQL on Windows Vista or newer, you can choose to use the MySQL Server Configuration Wizard after installation. However, you must open a port in the Windows Firewall. To do this see the instructions given in [Downloading and Starting the MySQL Installation Wizard](#). Rather than opening a port, you also have the option of adding MySQL as a program that bypasses the Windows Firewall. One or the other option is sufficient—you need not do both. Additionally, when running the MySQL Server Configuration Wizard on Windows Vista or newer, ensure that you are logged in as a user with administrative rights.

You can launch the MySQL Configuration Wizard by clicking the MySQL Server Instance Config Wizard entry in the MySQL section of the Windows **Start** menu.

Alternatively, you can navigate to the `bin` directory of your MySQL installation and launch the `MySQLInstanceConfig.exe` file directly.

The MySQL Server Instance Configuration Wizard places the `my.ini` file in the installation directory for the MySQL server. This helps associate configuration files with particular server instances.

To ensure that the MySQL server knows where to look for the `my.ini` file, an argument similar to this is passed to the MySQL server as part of the service installation:

```
--defaults-file="C:\Program Files\MySQL\MySQL Server 5.5\my.ini"
```

Here, `C:\Program Files\MySQL\MySQL Server 5.5` is replaced with the installation path to the MySQL Server. The `--defaults-file` option instructs the MySQL server to read the specified file for configuration options when it starts.

Apart from making changes to the `my.ini` file by running the MySQL Server Instance Configuration Wizard again, you can modify it by opening it with a text editor and making any necessary changes. You can also modify the server configuration with the <http://www.mysql.com/products/administrator/> utility. For more information about server configuration, see [Section 5.1.3, "Server Command Options"](#).

MySQL clients and utilities such as the `mysql` and `mysqldump` command-line clients are not able to locate the `my.ini` file located in the server installation directory. To configure the client and utility applications, create a new `my.ini` file in the Windows installation directory (for example, `C:\WINDOWS`).

Under Windows Server 2003, Windows Server 2000, Windows XP, and Windows Vista, MySQL Server Instance Configuration Wizard will configure MySQL to work as a Windows service. To start and stop MySQL you use the [Services](#) application that is supplied as part of the Windows Administrator Tools.

2.3.6.2 Choosing a Maintenance Option

If the MySQL Server Instance Configuration Wizard detects an existing configuration file, you have the option of either reconfiguring your existing server, or removing the server instance by deleting the configuration file and stopping and removing the MySQL service.

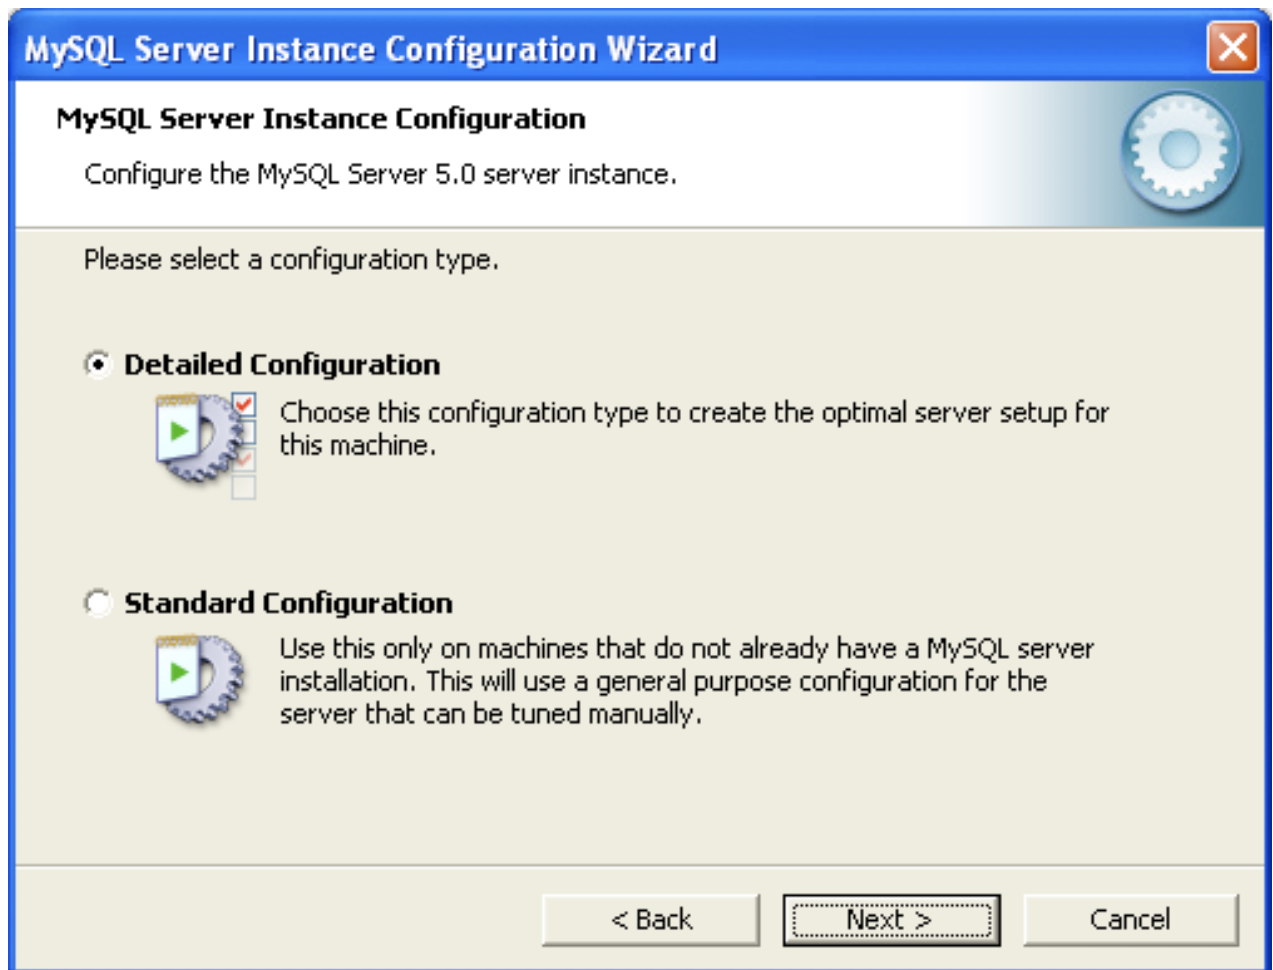

To reconfigure an existing server, choose the Re-configure Instance option and click the **Next** button. Any existing configuration file is not overwritten, but renamed (within the same directory) using a timestamp (Windows) or sequential number (Linux). To remove the existing server instance, choose the Remove Instance option and click the **Next** button.

If you choose the Remove Instance option, you advance to a confirmation window. Click the **Execute** button. The MySQL Server Configuration Wizard stops and removes the MySQL service, and then deletes the configuration file. The server installation and its `data` folder are not removed.

If you choose the Re-configure Instance option, you advance to the [Configuration Type](#) dialog where you can choose the type of installation that you wish to configure.

2.3.6.3 Choosing a Configuration Type

When you start the MySQL Server Instance Configuration Wizard for a new MySQL installation, or choose the Re-configure Instance option for an existing installation, you advance to the [Configuration Type](#) dialog.

There are two configuration types available: Detailed Configuration and Standard Configuration. The Standard Configuration option is intended for new users who want to get started with MySQL quickly without having to make many decisions about server configuration. The Detailed Configuration option is intended for advanced users who want more fine-grained control over server configuration.

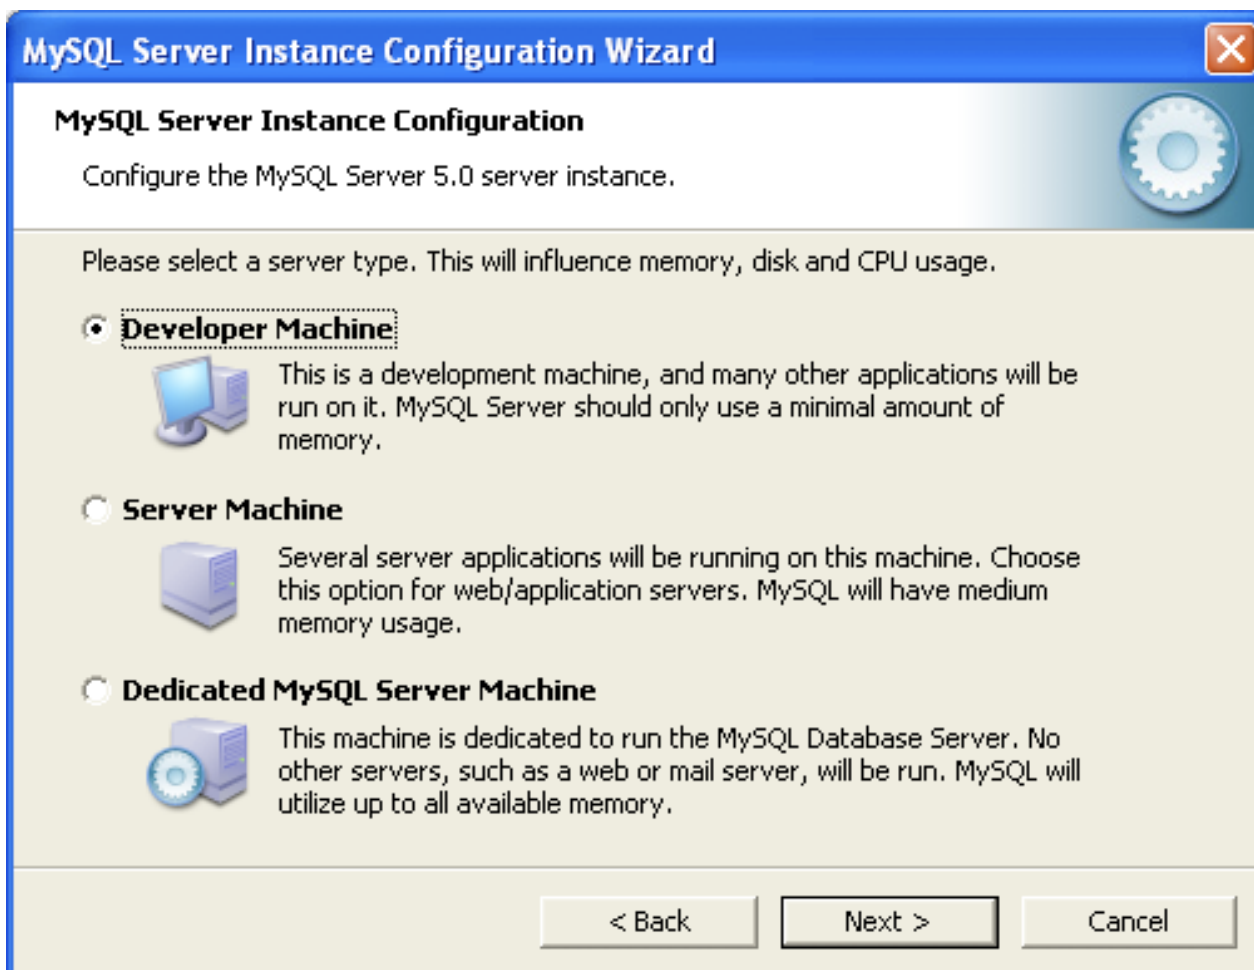

If you are new to MySQL and need a server configured as a single-user developer machine, the Standard Configuration should suit your needs. Choosing the Standard Configuration option causes the MySQL Configuration Wizard to set all configuration options automatically with the exception of Service Options and Security Options.

The Standard Configuration sets options that may be incompatible with systems where there are existing MySQL installations. If you have an existing MySQL installation on your system in addition to the installation you wish to configure, the Detailed Configuration option is recommended.

To complete the Standard Configuration, please refer to the sections on Service Options and Security Options in [Section 2.3.6.10, “The Service Options Dialog”](#), and [Section 2.3.6.11, “The Security Options Dialog”](#), respectively.

2.3.6.4 The Server Type Dialog

There are three different server types available to choose from. The server type that you choose affects the decisions that the MySQL Server Instance Configuration Wizard makes with regard to memory, disk, and processor usage.

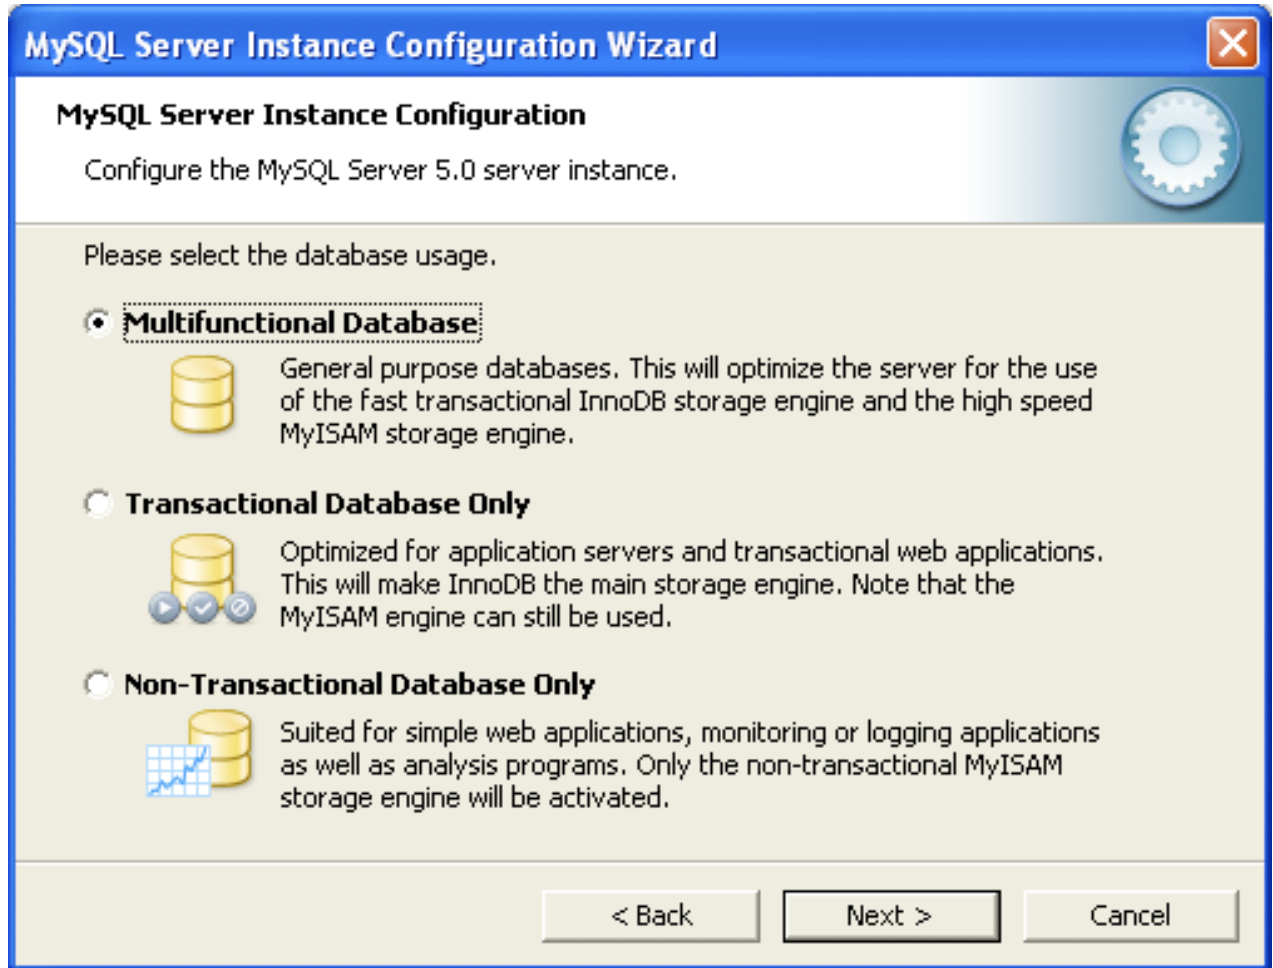

- **Developer Machine:** Choose this option for a typical desktop workstation where MySQL is intended only for personal use. It is assumed that many other desktop applications are running. The MySQL server is configured to use minimal system resources.
- **Server Machine:** Choose this option for a server machine where the MySQL server is running alongside other server applications such as FTP, email, and Web servers. The MySQL server is configured to use a moderate portion of the system resources.
- **Dedicated MySQL Server Machine:** Choose this option for a server machine that is intended to run only the MySQL server. It is assumed that no other applications are running. The MySQL server is configured to use all available system resources.

**Note**

By selecting one of the preconfigured configurations, the values and settings of various options in your `my.cnf` or `my.ini` will be altered accordingly. The default values and options as described in the reference manual may therefore be different to the options and values that were created during the execution of the configuration wizard.

2.3.6.5 The Database Usage Dialog

The Database Usage dialog enables you to indicate the storage engines that you expect to use when creating MySQL tables. The option you choose determines whether the [InnoDB](#) storage engine is available and what percentage of the server resources are available to [InnoDB](#).

- **Multifunctional Database:** This option enables both the [InnoDB](#) and [MyISAM](#) storage engines and divides resources evenly between the two. This option is recommended for users who use both storage engines on a regular basis.
- **Transactional Database Only:** This option enables both the [InnoDB](#) and [MyISAM](#) storage engines, but dedicates most server resources to the [InnoDB](#) storage engine. This option is recommended for users who use [InnoDB](#) almost exclusively and make only minimal use of [MyISAM](#).
- **Non-Transactional Database Only:** This option disables the [InnoDB](#) storage engine completely and dedicates all server resources to the [MyISAM](#) storage engine. This option is recommended for users who do not use [InnoDB](#).

The Configuration Wizard uses a template to generate the server configuration file. The Database Usage dialog sets one of the following option strings:

```
Multifunctional Database:      MIXED
Transactional Database Only:   INNODB
Non-Transactional Database Only: MYISAM
```

When these options are processed through the default template (my-template.ini) the result is:

```
Multifunctional Database:
default-storage-engine=InnoDB
_myisam_pct=50

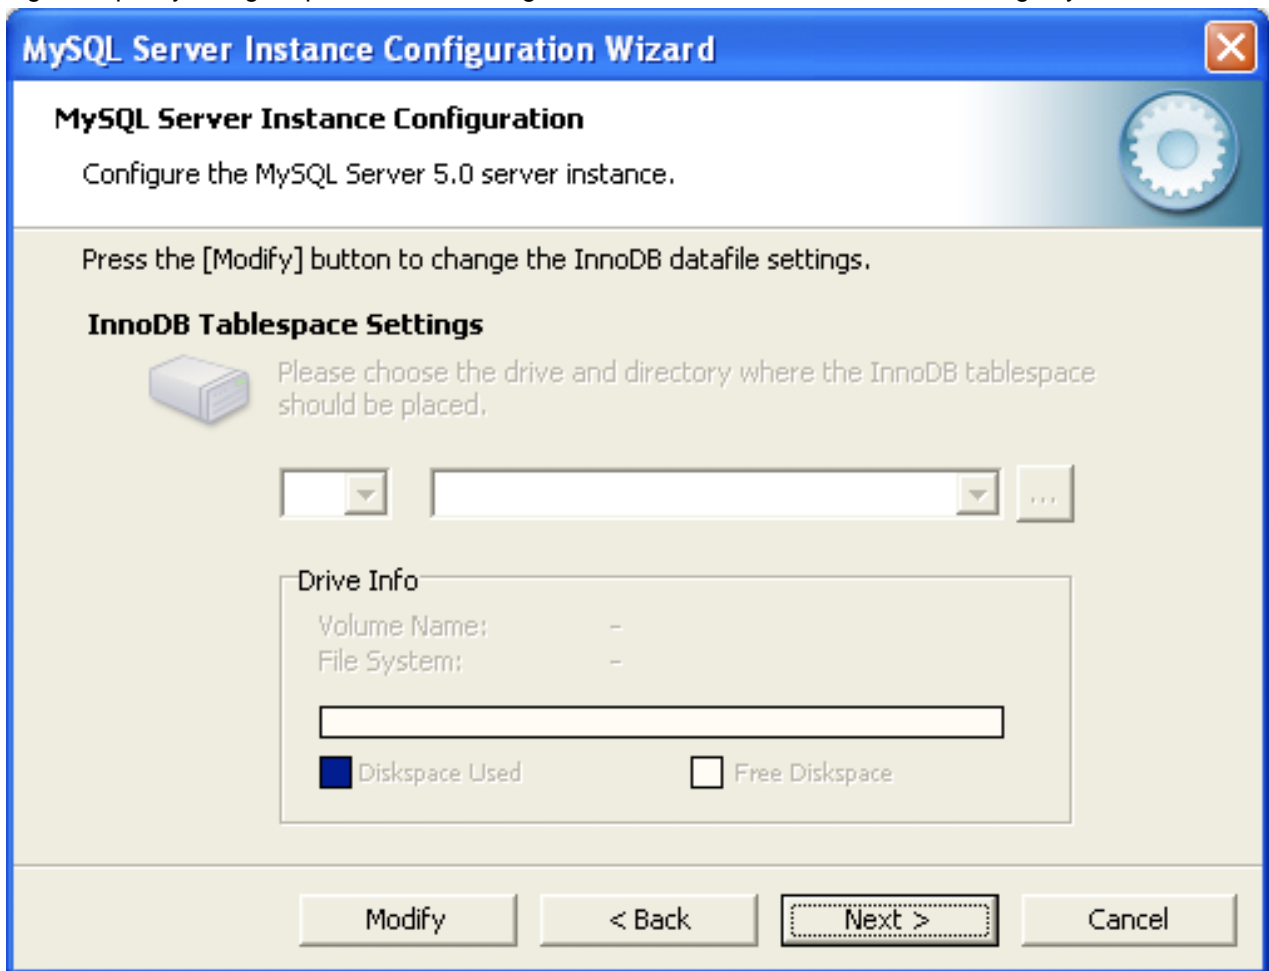

Transactional Database Only:
default-storage-engine=InnoDB
_myisam_pct=5

Non-Transactional Database Only:
default-storage-engine=MyISAM
_myisam_pct=100
skip-innodb
```

The `_myisam_pct` value is used to calculate the percentage of resources dedicated to [MyISAM](#). The remaining resources are allocated to [InnoDB](#).

2.3.6.6 The InnoDB Tablespace Dialog

Some users may want to locate the [InnoDB](#) tablespace files in a different location than the MySQL server data directory. Placing the tablespace files in a separate location can be desirable if your system has a higher capacity or higher performance storage device available, such as a RAID storage system.

To change the default location for the [InnoDB](#) tablespace files, choose a new drive from the drop-down list of drive letters and choose a new path from the drop-down list of paths. To create a custom path, click the [...](#) button.

If you are modifying the configuration of an existing server, you must click the [Modify](#) button before you change the path. In this situation you must move the existing tablespace files to the new location manually before starting the server.

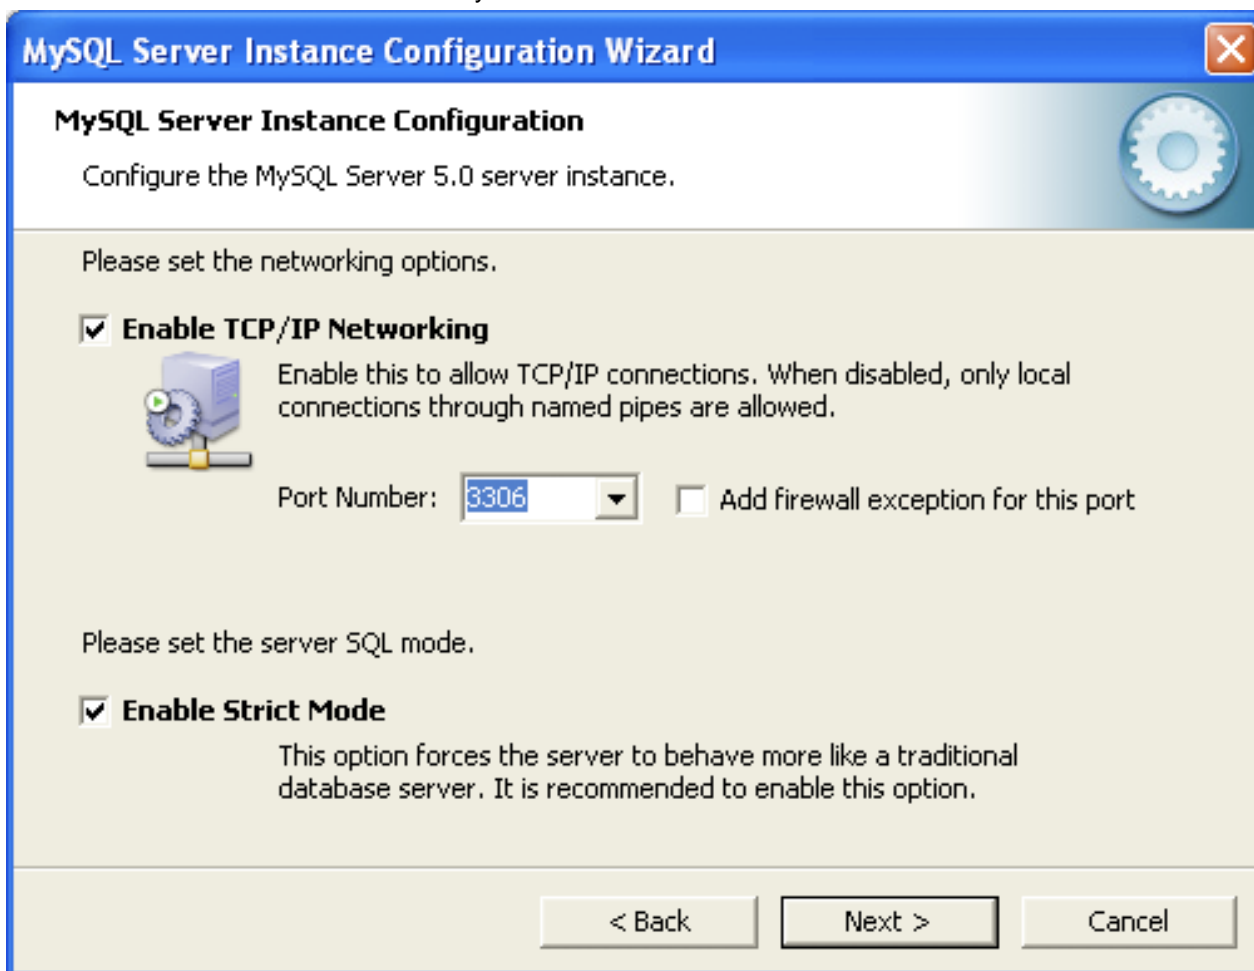

2.3.6.7 The Concurrent Connections Dialog

To prevent the server from running out of resources, it is important to limit the number of concurrent connections to the MySQL server that can be established. The [Concurrent Connections](#) dialog enables you to choose the expected usage of your server, and sets the limit for concurrent connections accordingly. It is also possible to set the concurrent connection limit manually.

- **Decision Support (DSS)/OLAP:** Choose this option if your server does not require a large number of concurrent connections. The maximum number of connections is set at 100, with an average of 20 concurrent connections assumed.
- **Online Transaction Processing (OLTP):** Choose this option if your server requires a large number of concurrent connections. The maximum number of connections is set at 500.
- **Manual Setting:** Choose this option to set the maximum number of concurrent connections to the server manually. Choose the number of concurrent connections from the drop-down box provided, or enter the maximum number of connections into the drop-down box if the number you desire is not listed.

2.3.6.8 The Networking and Strict Mode Options Dialog

Use the [Networking Options](#) dialog to enable or disable TCP/IP networking and to configure the port number that is used to connect to the MySQL server.

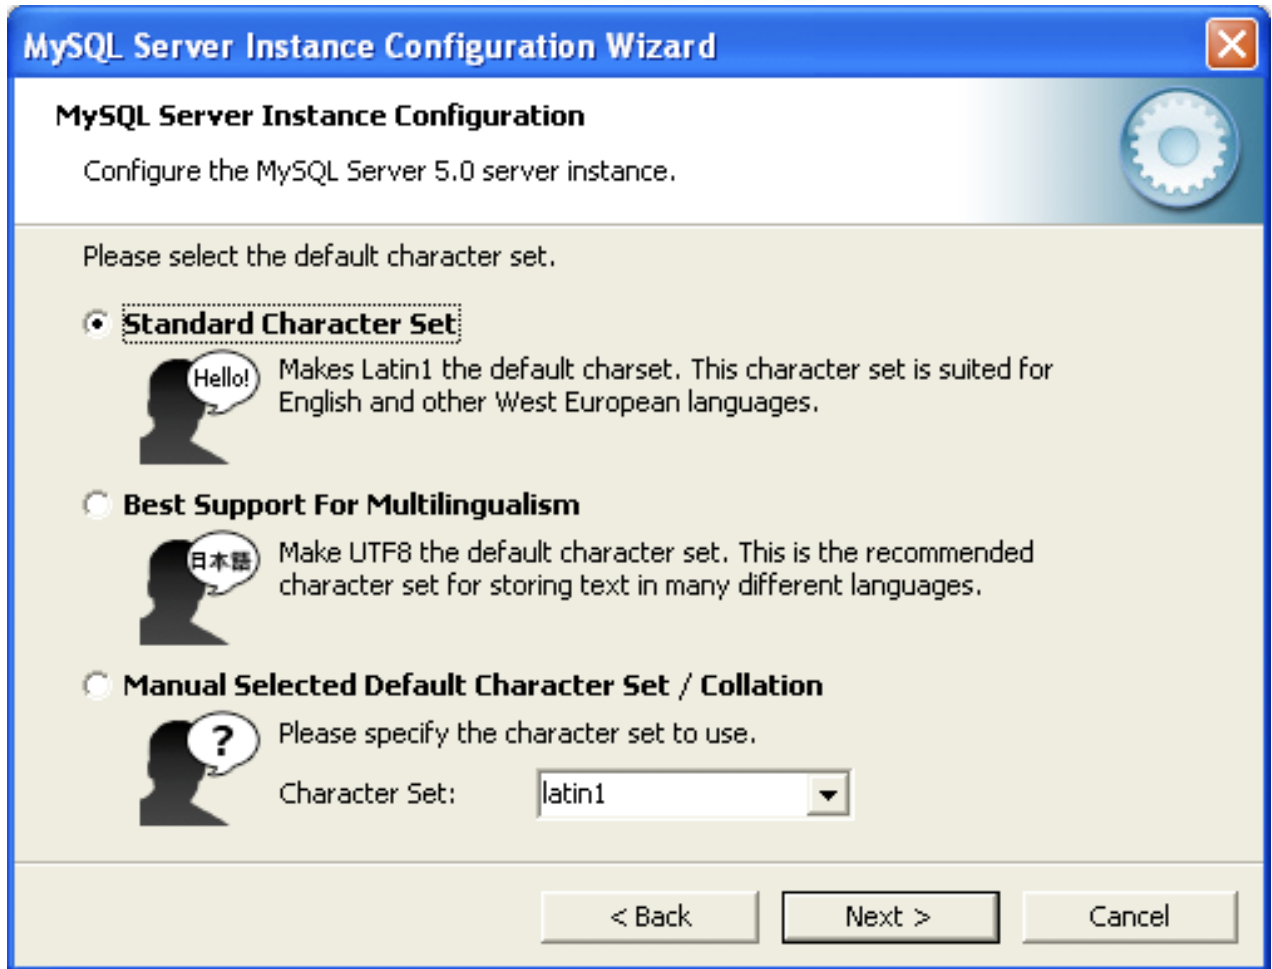

TCP/IP networking is enabled by default. To disable TCP/IP networking, uncheck the box next to the Enable TCP/IP Networking option.

Port 3306 is used by default. To change the port used to access MySQL, choose a new port number from the drop-down box or type a new port number directly into the drop-down box. If the port number you choose is in use, you are prompted to confirm your choice of port number.

Set the [Server SQL Mode](#) to either enable or disable strict mode. Enabling strict mode (default) makes MySQL behave more like other database management systems. *If you run applications that rely on MySQL's old "forgiving" behavior, make sure to either adapt those applications or to disable strict mode.* For more information about strict mode, see [Section 5.1.7, "Server SQL Modes"](#).

2.3.6.9 The Character Set Dialog

The MySQL server supports multiple character sets and it is possible to set a default server character set that is applied to all tables, columns, and databases unless overridden. Use the [Character Set](#) dialog to change the default character set of the MySQL server.

- **Standard Character Set:** Choose this option if you want to use `latin1` as the default server character set. `latin1` is used for English and many Western European languages.
- **Best Support For Multilingualism:** Choose this option if you want to use `utf8` as the default server character set. This is a Unicode character set that can store characters from many different languages.
- **Manual Selected Default Character Set / Collation:** Choose this option if you want to pick the server's default character set manually. Choose the desired character set from the provided drop-down list.

2.3.6.10 The Service Options Dialog

On Windows platforms, the MySQL server can be installed as a Windows service. When installed this way, the MySQL server can be started automatically during system startup, and even restarted automatically by Windows in the event of a service failure.

The MySQL Server Instance Configuration Wizard installs the MySQL server as a service by default, using the service name `MySQL`. If you do not wish to install the service, uncheck the box next to the **Install As Windows Service** option. You can change the service name by picking a new service name from the drop-down box provided or by entering a new service name into the drop-down box.

Note

Service names can include any legal character except forward (/) or backward (\) slashes, and must be less than 256 characters long.

**Warning**

If you are installing multiple versions of MySQL onto the same machine, you *must* choose a different service name for each version that you install. If you do not choose a different service for each installed version then the service manager information will be inconsistent and this will cause problems when you try to uninstall a previous version.

If you have already installed multiple versions using the same service name, you must manually edit the contents of the `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services` parameters within the Windows registry to update the association of the service name with the correct server version.

Typically, when installing multiple versions you create a service name based on the version information. For example, you might install MySQL 5.x as `mysql5`, or specific versions such as MySQL 5.5.0 as `mysql50500`.

To install the MySQL server as a service but not have it started automatically at startup, uncheck the box next to the Launch the MySQL Server Automatically option.

2.3.6.11 The Security Options Dialog

The content of the security options portion of the MySQL Server Instance Configuration Wizard will depend on whether this is a new installation, or modifying an existing installation.

- **Setting the root password for a new installation**

It is strongly recommended that you set a `root` password for your MySQL server, and the MySQL Server Instance Config Wizard requires by default that you do so. If you do not wish to set a `root` password, uncheck the box next to the Modify Security Settings option.

The image shows a screenshot of the 'MySQL Server Instance Configuration Wizard' window. The title bar is blue with the text 'MySQL Server Instance Configuration Wizard' and a close button. Below the title bar, the main heading is 'MySQL Server Instance Configuration' with a subtitle 'Configure the MySQL Server 5.0 server instance.' and a gear icon. The main content area has a light beige background and contains the instruction 'Please set the security options.' followed by two sections. The first section, 'Modify Security Settings', is checked and includes a 'root' user icon, a 'New root password:' field, a 'Confirm:' field, and an unchecked checkbox for 'Enable root access from remote machines'. The second section, 'Create An Anonymous Account', is unchecked and includes a question mark icon and a warning text. At the bottom, there are three buttons: '< Back', 'Next >', and 'Cancel'.

MySQL Server Instance Configuration Wizard

MySQL Server Instance Configuration
Configure the MySQL Server 5.0 server instance.

Please set the security options.

☒ **Modify Security Settings**

 New root password: Enter the root password.

Confirm: Retype the password.

☐ Enable root access from remote machines

☐ **Create An Anonymous Account**

 This option will create an anonymous account on this server. Please note that this can lead to an insecure system.

< Back Next > Cancel

- To set the `root` password, enter the desired password into both the New root password and Confirm boxes.

Setting the root password for an existing installation

If you are modifying the configuration of an existing configuration, or you are installing an upgrade and the MySQL Server Instance Configuration Wizard has detected an existing MySQL system, then you must enter the existing password for `root` before changing the configuration information.

The image shows a screenshot of the 'MySQL Server Instance Configuration Wizard' window. The title bar is blue with the text 'MySQL Server Instance Configuration Wizard' and a close button. The main area has a light blue header with the title 'MySQL Server Instance Configuration' and a subtitle 'Configure the MySQL Server 5.1 server instance.' Below this, it says 'Please set the security options.' There are two main sections. The first section is 'Modify Security Settings', which is checked. It contains three password fields: 'Current root password:', 'New root password:', and 'Confirm:'. To the left of these fields is a silhouette of a person with the label 'root'. To the right of each field is a prompt: 'Enter the current password.', 'Enter the root password.', and 'Retype the password.' respectively. Below these fields is a checkbox labeled 'Enable root access from remote machines'. The second section is 'Create An Anonymous Account', which is unchecked. It contains a silhouette of a person with a question mark and a text box that says 'This option will create an anonymous account on this server. Please note that this can lead to an insecure system.' At the bottom of the window are three buttons: '< Back', 'Next >', and 'Cancel'.

MySQL Server Instance Configuration Wizard

MySQL Server Instance Configuration

Configure the MySQL Server 5.1 server instance.

Please set the security options.

☒ **Modify Security Settings**

 Current root password: Enter the current password.

New root password: Enter the root password.

Confirm: Retype the password.

☐ Enable root access from remote machines

☐ **Create An Anonymous Account**

 This option will create an anonymous account on this server. Please note that this can lead to an insecure system.

< Back Next > Cancel

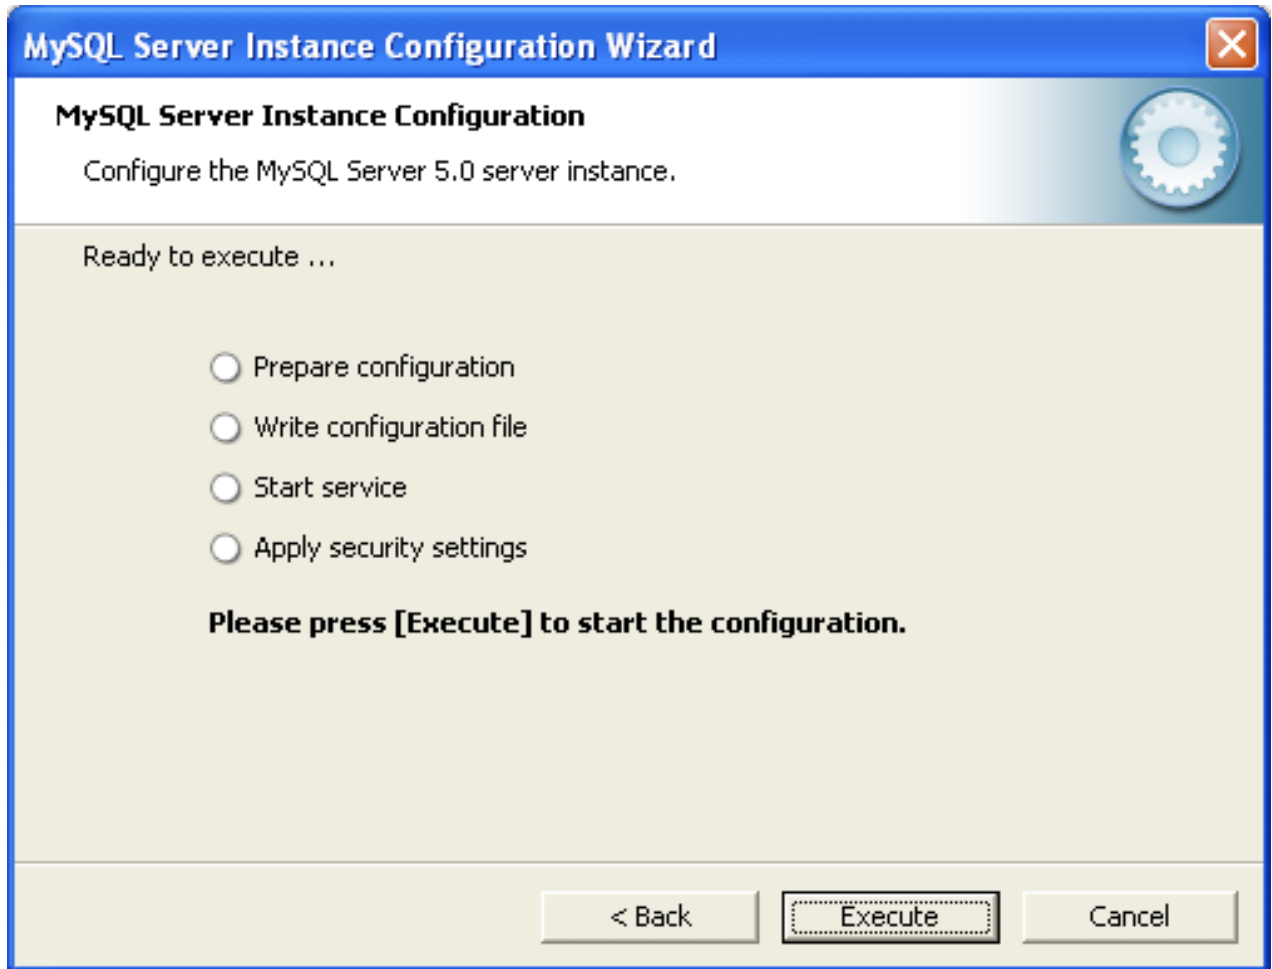

If you want to change the current `root` password, enter the desired new password into both the New root password and Confirm boxes.

To permit `root` logins from across the network, check the box next to the Enable root access from remote machines option. This decreases the security of your `root` account.

To create an anonymous user account, check the box next to the Create An Anonymous Account option. Creating an anonymous account can decrease server security and cause login and permission difficulties. For this reason, it is not recommended.

2.3.6.12 The Confirmation Dialog

The final dialog in the MySQL Server Instance Configuration Wizard is the Confirmation Dialog. To start the configuration process, click the Execute button. To return to a previous dialog, click the Back button. To exit the MySQL Server Instance Configuration Wizard without configuring the server, click the Cancel button.

After you click the **Execute** button, the MySQL Server Instance Configuration Wizard performs a series of tasks and displays the progress onscreen as the tasks are performed.

The MySQL Server Instance Configuration Wizard first determines configuration file options based on your choices using a template prepared by MySQL developers and engineers. This template is named `my-template.ini` and is located in your server installation directory.

The MySQL Configuration Wizard then writes these options to the corresponding configuration file.

If you chose to create a service for the MySQL server, the MySQL Server Instance Configuration Wizard creates and starts the service. If you are reconfiguring an existing service, the MySQL Server Instance Configuration Wizard restarts the service to apply your configuration changes.

If you chose to set a `root` password, the MySQL Configuration Wizard connects to the server, sets your new `root` password, and applies any other security settings you may have selected.

After the MySQL Server Instance Configuration Wizard has completed its tasks, it displays a summary. Click the **Finish** button to exit the MySQL Server Configuration Wizard.

2.3.6.13 MySQL Server Instance Config Wizard: Creating an Instance from the Command Line

In addition to using the GUI interface to the MySQL Server Instance Config Wizard, you can also create instances automatically from the command line.

To use the MySQL Server Instance Config Wizard on the command line, you need to use the `MySQLInstanceConfig.exe` command that is installed with MySQL in the `bin` directory within the installation directory. `MySQLInstanceConfig.exe` takes a number of command-line arguments that set the properties that would normally be selected through the GUI interface, and then creates a new configuration file (`my.ini`) by combining these selections with a template configuration file to produce the working configuration file.

The main command line options are provided in the table below. Some of the options are required, while some options are optional.

Table 2.5 MySQL Server Instance Config Wizard Command Line Options

Option	Description
Required Parameters	
<code>-nPRODUCTNAME</code>	The name of the instance when installed
<code>-pPATH</code>	Path of the base directory for installation. This is equivalent to the directory when using the <code>basedir</code> configuration parameter
<code>-vVERSION</code>	The version tag to use for this installation
Action to Perform	
<code>-i</code>	Install an instance
<code>-r</code>	Remove an instance
<code>-s</code>	Stop an existing instance
<code>-q</code>	Perform the operation quietly
<code>-lFILENAME</code>	Save the installation progress in a logfile
Config File to Use	
<code>-tFILENAME</code>	Path to the template config file that will be used to generate the installed configuration file
<code>-cFILENAME</code>	Path to a config file to be generated

The `-t` and `-c` options work together to set the configuration parameters for a new instance. The `-t` option specifies the template configuration file to use as the basic configuration, which are then merged with the configuration parameters generated by the MySQL Server Instance Config Wizard into the configuration file specified by the `-c` option.

A sample template file, `my-template.ini` is provided in the toplevel MySQL installation directory. The file contains elements that are replaced automatically by the MySQL Server Instance Config Wizard during configuration.

If you specify a configuration file that already exists, the existing configuration file will be saved in the file with the original, with the date and time added. For example, the `mysql.ini` will be copied to `mysql 2009-10-27 1646.ini.bak`.

The parameters that you can specify on the command line are listed in the table below.

Table 2.6 MySQL Server Instance Config Wizard Parameters

Parameter	Description
<code>ServiceName=\$</code>	Specify the name of the service to be created
<code>AddBinToPath={yes no}</code>	Specifies whether to add the binary directory of MySQL to the standard <code>PATH</code> environment variable

Parameter	Description
<code>ServerType={DEVELOPMENT SERVER DEDICATED}</code>	Specify the server type. For more information, see Section 2.3.6.4, “The Server Type Dialog”
<code>DatabaseType={MIXED INNODB MYISAM}</code>	Specify the default database type. For more information, see Section 2.3.6.5, “The Database Usage Dialog”
<code>ConnectionUsage={DSS OLTP}</code>	Specify the type of connection support, this automates the setting for the number of concurrent connections (see the <code>ConnectionCount</code> parameter). For more information, see Section 2.3.6.7, “The Concurrent Connections Dialog”
<code>ConnectionCount=#</code>	Specify the number of concurrent connections to support. For more information, see Section 2.3.6.4, “The Server Type Dialog”
<code>SkipNetworking={yes no}</code>	Specify whether network support should be supported. Specifying <code>yes</code> disables network access altogether
<code>Port=#</code>	Specify the network port number to use for network connections. For more information, see Section 2.3.6.8, “The Networking and Strict Mode Options Dialog”
<code>StrictMode={yes no}</code>	Specify whether to use the <code>strict</code> SQL mode. For more information, see Section 2.3.6.8, “The Networking and Strict Mode Options Dialog”
<code>Charset=\$</code>	Specify the default character set. For more information, see Section 2.3.6.9, “The Character Set Dialog”
<code>RootPassword=\$</code>	Specify the root password
<code>RootCurrentPassword=\$</code>	Specify the current root password then stopping or reconfiguring an existing service

**Note**

When specifying options on the command line, you can enclose the entire command-line option and the value you are specifying using double quotation marks. This enables you to use spaces in the options. For example, `"-cC:\mysql.ini"`.

The following command installs a MySQL Server 5.5 instance from the directory `C:\Program Files\MySQL\MySQL Server 5.5` using the service name `MySQL55` and setting the root password to 1234.

```
shell> MySQLInstanceConfig.exe -i -q "-lC:\mysql_install_log.txt" »
"-nMySQL Server 5.5" "-pC:\Program Files\MySQL\MySQL Server 5.5" -v5.5.40 »
"-tmy-template.ini" "-cC:\mytest.ini" ServerType=DEVELOPMENT DatabaseType=MIXED »
ConnectionUsage=DSS Port=3311 ServiceName=MySQL55 RootPassword=1234
```

In the above example, a log file will be generated in `mysql_install_log.txt` containing the information about the instance creation process. The log file generated by the above example is shown below:

```
Welcome to the MySQL Server Instance Configuration Wizard 1.0.16.0
Date: 2009-10-27 17:07:21

Installing service ...

Product Name:      MySQL Server 5.5
Version:           5.5.40
Installation Path:  C:\Program Files\MySQL\MySQL Server 5.5\
```

```
Creating configuration file C:\mytest.ini using template my-template.ini.
Options:
DEVELOPMENT
MIXED
DSS
STRICTMODE

Variables:
port: 3311
default-character-set: latin1
basedir: "C:/Program Files/MySQL/MySQL Server 5.5/"
datadir: "C:/Program Files/MySQL/MySQL Server 5.5/Data/"

Creating Windows service entry.
Service name: "MySQL55"
Parameters: "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysqld" --defaults-file="C:\mytest.ini" MySQL55.
Windows service MySQL55 installed.
```

When using the command line, the return values in the following table indicate an error performing the specified option.

Table 2.7 Return Value from MySQL Server Instance Config Wizard

Value	Description
2	Configuration template file cannot be found
3	The Windows service entry cannot be created
4	Could not connect to the Service Control Manager
5	The MySQL service cannot be started
6	The MySQL service cannot be stopped
7	The security settings cannot be applied
8	The configuration file cannot be written
9	The Windows service entry cannot be removed

You can perform an installation of MySQL automatically using the MSI package. For more information, see [Section 2.3.5.2, “Automating MySQL Installation on Microsoft Windows Using the MSI Package”](#).

2.3.7 Installing MySQL on Microsoft Windows Using a `noinstall` Zip Archive

Users who are installing from the `noinstall` package can use the instructions in this section to manually install MySQL. The process for installing MySQL from a Zip archive is as follows:

1. Extract the archive to the desired install directory
2. Create an option file
3. Choose a MySQL server type
4. Start the MySQL server
5. Secure the default user accounts

This process is described in the sections that follow.

2.3.7.1 Extracting the Install Archive

To install MySQL manually, do the following:

1. If you are upgrading from a previous version please refer to [Section 2.3.9, “Upgrading MySQL on Windows”](#), before beginning the upgrade process.
2. Make sure that you are logged in as a user with administrator privileges.
3. Choose an installation location. Traditionally, the MySQL server is installed in `C:\mysql`. The MySQL Installation Wizard installs MySQL under `C:\Program Files\MySQL`. If you do not install MySQL at `C:\mysql`, you must specify the path to the install directory during startup or in an option file. See [Section 2.3.7.2, “Creating an Option File”](#).
4. Extract the install archive to the chosen installation location using your preferred Zip archive tool. Some tools may extract the archive to a folder within your chosen installation location. If this occurs, you can move the contents of the subfolder into the chosen installation location.

2.3.7.2 Creating an Option File

If you need to specify startup options when you run the server, you can indicate them on the command line or place them in an option file. For options that are used every time the server starts, you may find it most convenient to use an option file to specify your MySQL configuration. This is particularly true under the following circumstances:

- The installation or data directory locations are different from the default locations (`C:\Program Files\MySQL\MySQL Server 5.5` and `C:\Program Files\MySQL\MySQL Server 5.5\data`).
- You need to tune the server settings, such as memory, cache, or InnoDB configuration information.

When the MySQL server starts on Windows, it looks for option files in several locations, such as the Windows directory, `C:\`, and the MySQL installation directory (for the full list of locations, see [Section 4.2.6, “Using Option Files”](#)). The Windows directory typically is named something like `C:\WINDOWS`. You can determine its exact location from the value of the `WINDIR` environment variable using the following command:

```
C:\> echo %WINDIR%
```

MySQL looks for options in each location first in the `my.ini` file, and then in the `my.cnf` file. However, to avoid confusion, it is best if you use only one file. If your PC uses a boot loader where `C:` is not the boot drive, your only option is to use the `my.ini` file. Whichever option file you use, it must be a plain text file.

Note

When using the MySQL Installer to install MySQL Server, it will create the `my.ini` at the default location. And as of MySQL Server 5.5.27, the user running MySQL Installer is granted full permissions to this new `my.ini`.

In other words, be sure that the MySQL Server user has permission to read the `my.ini` file.

You can also make use of the example option files included with your MySQL distribution; see [Section 5.1.2, “Server Configuration Defaults”](#).

An option file can be created and modified with any text editor, such as Notepad. For example, if MySQL is installed in `E:\mysql` and the data directory is in `E:\mydata\data`, you can create an option file containing a `[mysqld]` section to specify values for the `basedir` and `datadir` options:

```
[mysqld]
# set basedir to your installation path
basedir=E:/mysql
# set datadir to the location of your data directory
```

```
datadir=E:/mydata/data
```

Note that Windows path names are specified in option files using (forward) slashes rather than backslashes. If you do use backslashes, double them:

```
[mysqld]
# set basedir to your installation path
basedir=E:\\mysql
# set datadir to the location of your data directory
datadir=E:\\mydata\\data
```

The rules for use of backslash in option file values are given in [Section 4.2.6, “Using Option Files”](#).

The data directory is located within the `AppData` directory for the user running MySQL.

If you would like to use a data directory in a different location, you should copy the entire contents of the `data` directory to the new location. For example, if you want to use `E:\\mydata` as the data directory instead, you must do two things:

1. Move the entire `data` directory and all of its contents from the default location (for example `C:\\Program Files\\MySQL\\MySQL Server 5.5\\data`) to `E:\\mydata`.
2. Use a `--datadir` option to specify the new data directory location each time you start the server.

2.3.7.3 Selecting a MySQL Server Type

The following table shows the available servers for Windows in MySQL 5.5.

Binary	Description
<code>mysqld</code>	Optimized binary with named-pipe support
<code>mysqld-debug</code>	Like <code>mysqld</code> , but compiled with full debugging and automatic memory allocation checking

All of the preceding binaries are optimized for modern Intel processors, but should work on any Intel i386-class or higher processor.

Each of the servers in a distribution support the same set of storage engines. The `SHOW ENGINES` statement displays which engines a given server supports.

All Windows MySQL 5.5 servers have support for symbolic linking of database directories.

MySQL supports TCP/IP on all Windows platforms. MySQL servers on Windows also support named pipes, if you start the server with the `--enable-named-pipe` option. It is necessary to use this option explicitly because some users have experienced problems with shutting down the MySQL server when named pipes were used. The default is to use TCP/IP regardless of platform because named pipes are slower than TCP/IP in many Windows configurations.

2.3.7.4 Starting the Server for the First Time

This section gives a general overview of starting the MySQL server. The following sections provide more specific information for starting the MySQL server from the command line or as a Windows service.

The information here applies primarily if you installed MySQL using the `Noinstall` version, or if you wish to configure and test MySQL manually rather than with the GUI tools.

The examples in these sections assume that MySQL is installed under the default location of `C:\\Program Files\\MySQL\\MySQL Server 5.5`. Adjust the path names shown in the examples if you have MySQL installed in a different location.

Clients have two options. They can use TCP/IP, or they can use a named pipe if the server supports named-pipe connections.

MySQL for Windows also supports shared-memory connections if the server is started with the `--shared-memory` option. Clients can connect through shared memory by using the `--protocol=MEMORY` option.

For information about which server binary to run, see [Section 2.3.7.3, “Selecting a MySQL Server Type”](#).

Testing is best done from a command prompt in a console window (or “DOS window”). In this way you can have the server display status messages in the window where they are easy to see. If something is wrong with your configuration, these messages make it easier for you to identify and fix any problems.

To start the server, enter this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysqld" --console
```

For a server that includes [InnoDB](#) support, you should see the messages similar to those following as it starts (the path names and sizes may differ):

```
InnoDB: The first specified datafile c:\ibdata\ibdata1 did not exist:
InnoDB: a new database to be created!
InnoDB: Setting file c:\ibdata\ibdata1 size to 209715200
InnoDB: Database physically writes the file full: wait...
InnoDB: Log file c:\iblogs\ib_logfile0 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile0 size to 31457280
InnoDB: Log file c:\iblogs\ib_logfile1 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile1 size to 31457280
InnoDB: Log file c:\iblogs\ib_logfile2 did not exist: new to be created
InnoDB: Setting log file c:\iblogs\ib_logfile2 size to 31457280
InnoDB: Doublewrite buffer not found: creating new
InnoDB: Doublewrite buffer created
InnoDB: creating foreign key constraint system tables
InnoDB: foreign key constraint system tables created
011024 10:58:25 InnoDB: Started
```

When the server finishes its startup sequence, you should see something like this, which indicates that the server is ready to service client connections:

```
mysqld: ready for connections
Version: '5.5.40' socket: '' port: 3306
```

The server continues to write to the console any further diagnostic output it produces. You can open a new console window in which to run client programs.

If you omit the `--console` option, the server writes diagnostic output to the error log in the data directory (`C:\Program Files\MySQL\MySQL Server 5.5\data` by default). The error log is the file with the `.err` extension, or may be specified by passing in the `--log-error` option.

Note

The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in [Section 2.10.2, “Securing the Initial MySQL Accounts”](#).

2.3.7.5 Starting MySQL from the Windows Command Line

The MySQL server can be started manually from the command line. This can be done on any version of Windows.

To start the `mysqld` server from the command line, you should start a console window (or “DOS window”) and enter this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysqld"
```

The path to `mysqld` may vary depending on the install location of MySQL on your system.

You can stop the MySQL server by executing this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysqladmin" -u root shutdown
```

Note

If the MySQL `root` user account has a password, you need to invoke `mysqladmin` with the `-p` option and supply the password when prompted.

This command invokes the MySQL administrative utility `mysqladmin` to connect to the server and tell it to shut down. The command connects as the MySQL `root` user, which is the default administrative account in the MySQL grant system. Note that users in the MySQL grant system are wholly independent from any login users under Windows.

If `mysqld` doesn't start, check the error log to see whether the server wrote any messages there to indicate the cause of the problem. By default, the error log is located in the `C:\Program Files\MySQL\MySQL Server 5.5\data` directory. It is the file with a suffix of `.err`, or may be specified by passing in the `--log-error` option. Alternatively, you can try to start the server as `mysqld --console`; in this case, you may get some useful information on the screen that may help solve the problem.

The last option is to start `mysqld` with the `--standalone` and `--debug` options. In this case, `mysqld` writes a log file `C:\mysqld.trace` that should contain the reason why `mysqld` doesn't start. See [Section 24.4.3, “The DBUG Package”](#).

Use `mysqld --verbose --help` to display all the options that `mysqld` supports.

2.3.7.6 Customizing the PATH for MySQL Tools

To make it easier to invoke MySQL programs, you can add the path name of the MySQL `bin` directory to your Windows system `PATH` environment variable:

- On the Windows desktop, right-click the My Computer icon, and select Properties.
- Next select the Advanced tab from the System Properties menu that appears, and click the Environment Variables button.
- Under **System Variables**, select Path, and then click the Edit button. The Edit System Variable dialogue should appear.
- Place your cursor at the end of the text appearing in the space marked **Variable Value**. (Use the **End** key to ensure that your cursor is positioned at the very end of the text in this space.) Then enter the complete path name of your MySQL `bin` directory (for example, `C:\Program Files\MySQL\MySQL Server 5.5\bin`)

Note

There must be a semicolon separating this path from any values present in this field.

Dismiss this dialogue, and each dialogue in turn, by clicking **OK** until all of the dialogues that were opened have been dismissed. You should now be able to invoke any MySQL executable program by

typing its name at the DOS prompt from any directory on the system, without having to supply the path. This includes the servers, the `mysql` client, and all MySQL command-line utilities such as `mysqladmin` and `mysqldump`.

You should not add the MySQL `bin` directory to your Windows `PATH` if you are running multiple MySQL servers on the same machine.

Warning

You must exercise great care when editing your system `PATH` by hand; accidental deletion or modification of any portion of the existing `PATH` value can leave you with a malfunctioning or even unusable system.

2.3.7.7 Starting MySQL as a Windows Service

On Windows, the recommended way to run MySQL is to install it as a Windows service, so that MySQL starts and stops automatically when Windows starts and stops. A MySQL server installed as a service can also be controlled from the command line using `NET` commands, or with the graphical `Services` utility. Generally, to install MySQL as a Windows service you should be logged in using an account that has administrator rights.

The `Services` utility (the Windows `Service Control Manager`) can be found in the Windows Control Panel (under Administrative Tools on Windows 2000, XP, Vista, and Server 2003). To avoid conflicts, it is advisable to close the `Services` utility while performing server installation or removal operations from the command line.

Installing the service

Before installing MySQL as a Windows service, you should first stop the current server if it is running by using the following command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysqladmin"  
-u root shutdown
```

Note

If the MySQL `root` user account has a password, you need to invoke `mysqladmin` with the `-p` option and supply the password when prompted.

This command invokes the MySQL administrative utility `mysqladmin` to connect to the server and tell it to shut down. The command connects as the MySQL `root` user, which is the default administrative account in the MySQL grant system. Note that users in the MySQL grant system are wholly independent from any login users under Windows.

Install the server as a service using this command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysqld" --install
```

The service-installation command does not start the server. Instructions for that are given later in this section.

To make it easier to invoke MySQL programs, you can add the path name of the MySQL `bin` directory to your Windows system `PATH` environment variable:

- On the Windows desktop, right-click the My Computer icon, and select Properties.
- Next select the Advanced tab from the `System Properties` menu that appears, and click the `Environment Variables` button.

- Under **System Variables**, select Path, and then click the **Edit** button. The **Edit System Variable** dialogue should appear.
- Place your cursor at the end of the text appearing in the space marked **Variable Value**. (Use the **End** key to ensure that your cursor is positioned at the very end of the text in this space.) Then enter the complete path name of your MySQL `bin` directory (for example, `C:\Program Files\MySQL\MySQL Server 5.5\bin`). Note that there should be a semicolon separating this path from any values present in this field. Dismiss this dialogue, and each dialogue in turn, by clicking **OK** until all of the dialogues that were opened have been dismissed. You should now be able to invoke any MySQL executable program by typing its name at the DOS prompt from any directory on the system, without having to supply the path. This includes the servers, the `mysql` client, and all MySQL command-line utilities such as `mysqladmin` and `mysqldump`.

You should not add the MySQL `bin` directory to your Windows `PATH` if you are running multiple MySQL servers on the same machine.

Warning

You must exercise great care when editing your system `PATH` by hand; accidental deletion or modification of any portion of the existing `PATH` value can leave you with a malfunctioning or even unusable system.

The following additional arguments can be used when installing the service:

- You can specify a service name immediately following the `--install` option. The default service name is `MySQL`.
- If a service name is given, it can be followed by a single option. By convention, this should be `--defaults-file=file_name` to specify the name of an option file from which the server should read options when it starts.

The use of a single option other than `--defaults-file` is possible but discouraged. `--defaults-file` is more flexible because it enables you to specify multiple startup options for the server by placing them in the named option file.

- You can also specify a `--local-service` option following the service name. This causes the server to run using the `LocalService` Windows account that has limited system privileges. This account is available only for Windows XP or newer. If both `--defaults-file` and `--local-service` are given following the service name, they can be in any order.

For a MySQL server that is installed as a Windows service, the following rules determine the service name and option files that the server uses:

- If the service-installation command specifies no service name or the default service name (`MySQL`) following the `--install` option, the server uses the a service name of `MySQL` and reads options from the `[mysqld]` group in the standard option files.
- If the service-installation command specifies a service name other than `MySQL` following the `--install` option, the server uses that service name. It reads options from the `[mysqld]` group and the group that has the same name as the service in the standard option files. This enables you to use the `[mysqld]` group for options that should be used by all MySQL services, and an option group with the service name for use by the server installed with that service name.
- If the service-installation command specifies a `--defaults-file` option after the service name, the server reads options the same way as described in the previous item, except that it reads options only from the named file and ignores the standard option files.

As a more complex example, consider the following command:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysqld"  
--install MySQL --defaults-file=C:\my-opts.cnf
```

Here, the default service name (MySQL) is given after the `--install` option. If no `--defaults-file` option had been given, this command would have the effect of causing the server to read the `[mysqld]` group from the standard option files. However, because the `--defaults-file` option is present, the server reads options from the `[mysqld]` option group, and only from the named file.

**Note**

On Windows, if the server is started with the `--defaults-file` and `--install` options, `--install` must be first. Otherwise, `mysqld.exe` will attempt to start the MySQL server.

You can also specify options as Start parameters in the Windows [Services](#) utility before you start the MySQL service.

Starting the service

Once a MySQL server has been installed as a service, Windows starts the service automatically whenever Windows starts. The service also can be started immediately from the [Services](#) utility, or by using a `NET START MySQL` command. The `NET` command is not case sensitive.

When run as a service, `mysqld` has no access to a console window, so no messages can be seen there. If `mysqld` does not start, check the error log to see whether the server wrote any messages there to indicate the cause of the problem. The error log is located in the MySQL data directory (for example, `C:\Program Files\MySQL\MySQL Server 5.5\data`). It is the file with a suffix of `.err`.

When a MySQL server has been installed as a service, and the service is running, Windows stops the service automatically when Windows shuts down. The server also can be stopped manually by using the [Services](#) utility, the `NET STOP MySQL` command, or the `mysqladmin shutdown` command.

You also have the choice of installing the server as a manual service if you do not wish for the service to be started automatically during the boot process. To do this, use the `--install-manual` option rather than the `--install` option:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysqld" --install-manual
```

Removing the service

To remove a server that is installed as a service, first stop it if it is running by executing `NET STOP MySQL`. Then use the `--remove` option to remove it:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysqld" --remove
```

If `mysqld` is not running as a service, you can start it from the command line. For instructions, see [Section 2.3.7.5, “Starting MySQL from the Windows Command Line”](#).

Please see [Section 2.3.8, “Troubleshooting a Microsoft Windows MySQL Server Installation”](#), if you encounter difficulties during installation.

2.3.7.8 Testing The MySQL Installation

You can test whether the MySQL server is working by executing any of the following commands:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysqlshow"
```

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysqlshow" -u root mysql
C:\> "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysqladmin" version status proc
C:\> "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysql" test
```

If `mysqld` is slow to respond to TCP/IP connections from client programs, there is probably a problem with your DNS. In this case, start `mysqld` with the `--skip-name-resolve` option and use only `localhost` and IP addresses in the `Host` column of the MySQL grant tables.

You can force a MySQL client to use a named-pipe connection rather than TCP/IP by specifying the `--pipe` or `--protocol=PIPE` option, or by specifying `.` (period) as the host name. Use the `--socket` option to specify the name of the pipe if you do not want to use the default pipe name.

Note that if you have set a password for the `root` account, deleted the anonymous account, or created a new user account, then to connect to the MySQL server you must use the appropriate `-u` and `-p` options with the commands shown previously. See [Section 4.2.2, “Connecting to the MySQL Server”](#).

For more information about `mysqlshow`, see [Section 4.5.6, “mysqlshow — Display Database, Table, and Column Information”](#).

2.3.8 Troubleshooting a Microsoft Windows MySQL Server Installation

When installing and running MySQL for the first time, you may encounter certain errors that prevent the MySQL server from starting. The purpose of this section is to help you diagnose and correct some of these errors.

Your first resource when troubleshooting server issues is the [error log](#). The MySQL server uses the error log to record information relevant to the error that prevents the server from starting. The error log is located in the [data directory](#) specified in your `my.ini` file. The default data directory location is `C:\Program Files\MySQL\MySQL Server 5.5\data`, or `C:\ProgramData\MySQL` on Windows 7 and Windows Server 2008. The `C:\ProgramData` directory is hidden by default. You need to change your folder options to see the directory and contents. For more information on the error log and understanding the content, see [Section 5.2.2, “The Error Log”](#).

Another source of information regarding possible errors is the console messages displayed when the MySQL service is starting. Use the `NET START MySQL` command from the command line after installing `mysqld` as a service to see any error messages regarding the starting of the MySQL server as a service. See [Section 2.3.7.7, “Starting MySQL as a Windows Service”](#).

The following examples show other common error messages you may encounter when installing MySQL and starting the server for the first time:

- If the MySQL server cannot find the `mysql` privileges database or other critical files, you may see these messages:

```
System error 1067 has occurred.
Fatal error: Can't open privilege tables: Table 'mysql.host' doesn't exist
```

These messages often occur when the MySQL base or data directories are installed in different locations than the default locations (`C:\Program Files\MySQL\MySQL Server 5.5` and `C:\Program Files\MySQL\MySQL Server 5.5\data`, respectively).

This situation may occur when MySQL is upgraded and installed to a new location, but the configuration file is not updated to reflect the new location. In addition, there may be old and new configuration files that conflict. Be sure to delete or rename any old configuration files when upgrading MySQL.

If you have installed MySQL to a directory other than `C:\Program Files\MySQL\MySQL Server 5.5`, you need to ensure that the MySQL server is aware of this through the use of a configuration

(`my.ini`) file. The `my.ini` file needs to be located in your Windows directory, typically `C:\WINDOWS`. You can determine its exact location from the value of the `WINDIR` environment variable by issuing the following command from the command prompt:

```
C:\> echo %WINDIR%
```

An option file can be created and modified with any text editor, such as Notepad. For example, if MySQL is installed in `E:\mysql` and the data directory is `D:\MySQLdata`, you can create the option file and set up a `[mysqld]` section to specify values for the `basedir` and `datadir` options:

```
[mysqld]
# set basedir to your installation path
basedir=E:/mysql
# set datadir to the location of your data directory
datadir=D:/MySQLdata
```

Note that Windows path names are specified in option files using (forward) slashes rather than backslashes. If you do use backslashes, double them:

```
[mysqld]
# set basedir to your installation path
basedir=C:\\Program Files\\MySQL\\MySQL Server 5.5
# set datadir to the location of your data directory
datadir=D:\\MySQLdata
```

The rules for use of backslash in option file values are given in [Section 4.2.6, “Using Option Files”](#).

If you change the `datadir` value in your MySQL configuration file, you must move the contents of the existing MySQL data directory before restarting the MySQL server.

See [Section 2.3.7.2, “Creating an Option File”](#).

- If you reinstall or upgrade MySQL without first stopping and removing the existing MySQL service and install MySQL using the MySQL Configuration Wizard, you may see this error:

```
Error: Cannot create Windows service for MySql. Error: 0
```

This occurs when the Configuration Wizard tries to install the service and finds an existing service with the same name.

One solution to this problem is to choose a service name other than `mysql` when using the configuration wizard. This enables the new service to be installed correctly, but leaves the outdated service in place. Although this is harmless, it is best to remove old services that are no longer in use.

To permanently remove the old `mysql` service, execute the following command as a user with administrative privileges, on the command-line:

```
C:\> sc delete mysql
[SC] DeleteService SUCCESS
```

If the `sc` utility is not available for your version of Windows, download the `delsrv` utility from <http://www.microsoft.com/windows2000/techinfo/reskit/tools/existing/delsrv-o.asp> and use the `delsrv mysql` syntax.

2.3.9 Upgrading MySQL on Windows

To upgrade MySQL on Windows, follow these steps:

1. Review [Section 2.11.1, “Upgrading MySQL”](#), for additional information on upgrading MySQL that is not specific to Windows.
2. You should always back up your current MySQL installation before performing an upgrade. See [Section 7.2, “Database Backup Methods”](#).
3. Download the latest Windows distribution of MySQL from <http://dev.mysql.com/downloads/>.
4. Before upgrading MySQL, you must stop the server. If the server is installed as a service, stop the service with the following command from the command prompt:

```
C:\> NET STOP MySQL
```

If you are not running the MySQL server as a service, use `mysqladmin` to stop it. For example, before upgrading from MySQL 5.1 to 5.5, use `mysqladmin` from MySQL 5.1 as follows:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.1\bin\mysqladmin" -u root shutdown
```

Note

If the MySQL `root` user account has a password, you need to invoke `mysqladmin` with the `-p` option and enter the password when prompted.

5. Before upgrading a MySQL service from MySQL 5.1 to 5.5, you should stop the 5.1 server and remove the instance. Run the MySQL Instance Configuration Wizard, choose the Remove Instance option and in the next screen, confirm removal. After that it is safe to uninstall MySQL Server 5.1.
6. Before upgrading to MySQL 5.5 from a version previous to 4.1.5, or from a version of MySQL installed from a Zip archive to a version of MySQL installed with the MySQL Installation Wizard, you must first manually remove the previous installation and MySQL service (if the server is installed as a service).

To remove the MySQL service, use the following command:

```
C:\> C:\mysql\bin\mysqld --remove
```

If you do not remove the existing service, the MySQL Installation Wizard may fail to properly install the new MySQL service.

7. If you are using the MySQL Installation Wizard, start the wizard as described in [Section 2.3.5.1, “Using the MySQL Installation Wizard”](#).
8. If you are installing MySQL from a Zip archive, extract the archive. You may either overwrite your existing MySQL installation (usually located at `C:\mysql`), or install it into a different directory, such as `C:\mysql5`. Overwriting the existing installation is recommended.
9. If you were running MySQL as a Windows service and you had to remove the service earlier in this procedure, reinstall the service. (See [Section 2.3.7.7, “Starting MySQL as a Windows Service”](#).)
10. Restart the server. For example, use `NET START MySQL` if you run MySQL as a service, or invoke `mysqld` directly otherwise.
11. As Administrator, run `mysql_upgrade` to check your tables, attempt to repair them if necessary, and update your grant tables if they have changed so that you can take advantage of any new capabilities. See [Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”](#).

12. If you encounter errors, see [Section 2.3.8, “Troubleshooting a Microsoft Windows MySQL Server Installation”](#).

2.3.10 Windows Postinstallation Procedures

On Windows, you need not create the data directory and the grant tables. MySQL Windows distributions include the grant tables with a set of preinitialized accounts in the `mysql` database under the data directory. Regarding passwords, if you installed MySQL using the Windows Installation Wizard, you may have already assigned passwords to the accounts. (See [Section 2.3.5.1, “Using the MySQL Installation Wizard”](#).) Otherwise, use the password-assignment procedure given in [Section 2.10.2, “Securing the Initial MySQL Accounts”](#).

Before setting up passwords, you might want to try running some client programs to make sure that you can connect to the server and that it is operating properly. Make sure that the server is running (see [Section 2.3.7.4, “Starting the Server for the First Time”](#)), and then issue the following commands to verify that you can retrieve information from the server. You may need to specify directory different from `C:\mysql\bin` on the command line. If you used the Windows Installation Wizard, the default directory is `C:\Program Files\MySQL\MySQL Server 5.5`, and the `mysql` and `mysqlshow` client programs are in `C:\Program Files\MySQL\MySQL Server 5.5\bin`. See [Section 2.3.5.1, “Using the MySQL Installation Wizard”](#), for more information.

Use `mysqlshow` to see what databases exist:

```
C:\> C:\mysql\bin\mysqlshow

+-----+
| Databases |
+-----+
| information_schema |
| mysql |
| test |
+-----+
```

The list of installed databases may vary, but will always include the minimum of `mysql` and `information_schema`. In most cases, the `test` database will also be installed automatically.

The preceding command (and commands for other MySQL programs such as `mysql`) may not work if the correct MySQL account does not exist. For example, the program may fail with an error, or you may not be able to view all databases. If you installed using the MSI packages and used the MySQL Server Instance Config Wizard, then the `root` user will have been created automatically with the password you supplied. In this case, you should use the `-u root` and `-p` options. (You will also need to use the `-u root` and `-p` options if you have already secured the initial MySQL accounts.) With `-p`, you will be prompted for the `root` password. For example:

```
C:\> C:\mysql\bin\mysqlshow -u root -p
Enter password: (enter root password here)

+-----+
| Databases |
+-----+
| information_schema |
| mysql |
| test |
+-----+
```

If you specify a database name, `mysqlshow` displays a list of the tables within the database:

```
C:\> C:\mysql\bin\mysqlshow mysql
Database: mysql
+-----+
|          Tables          |
+-----+
| columns_priv             |
| db                       |
| event                   |
| func                    |
| help_category            |
| help_keyword             |
| help_relation            |
| help_topic               |
| host                    |
| plugin                  |
| proc                    |
| procs_priv               |
| servers                  |
| tables_priv              |
| time_zone                |
| time_zone_leap_second    |
| time_zone_name           |
| time_zone_transition     |
| time_zone_transition_type |
| user                     |
+-----+
```

Use the `mysql` program to select information from a table in the `mysql` database:

```
C:\> C:\mysql\bin\mysql -e "SELECT Host,Db,User FROM mysql.db"
+-----+-----+-----+
| host | db      | user |
+-----+-----+-----+
| %    | test   |      |
| %    | test_% |      |
+-----+-----+-----+
```

For more information about `mysqlshow` and `mysql`, see [Section 4.5.6, “mysqlshow — Display Database, Table, and Column Information”](#), and [Section 4.5.1, “mysql — The MySQL Command-Line Tool”](#).

If you are running a version of Windows that supports services, you can set up the MySQL server to run automatically when Windows starts. See [Section 2.3.7.7, “Starting MySQL as a Windows Service”](#).

2.4 Installing MySQL on Mac OS X

For a list of supported Mac OS X versions that the MySQL server supports, see <http://www.mysql.com/support/supportedplatforms/database.html>.

MySQL for Mac OS X is available in a number of different forms:

- Native Package Installer format, which uses the native Mac OS X installer (DMG) to walk you through the installation of MySQL. For more information, see [Section 2.4.2, “Installing MySQL on Mac OS X Using Native Packages”](#). You can use the package installer with Mac OS X 10.6 and later, and the package is available for both 32-bit and 64-bit architectures. The user you use to perform the installation must have administrator privileges.
- Tar package format, which uses a file packaged using the Unix `tar` and `gzip` commands. To use this method, you will need to open a `Terminal` window. You do not need administrator privileges using this method, as you can install the MySQL server anywhere using this method. For more information on using this method, you can use the generic instructions for using a tarball, [Section 2.2, “Installing MySQL](#)

on [Unix/Linux Using Generic Binaries](#)". You can use the package installer with Mac OS X 10.6 and later, and available for both 32-bit and 64-bit architectures.

In addition to the core installation, the Package Installer also includes [Section 2.4.3, "Installing the MySQL Startup Item"](#) and [Section 2.4.4, "Installing and Using the MySQL Preference Pane"](#), both of which simplify the management of your installation.

- Mac OS X server includes a version of MySQL as standard. If you want to use a more recent version than that supplied with the Mac OS X server release, you can make use of the package or tar formats. For more information on using the MySQL bundled with Mac OS X, see [Section 2.4.5, "Using the Bundled MySQL on Mac OS X Server"](#).

For additional information on using MySQL on Mac OS X, see [Section 2.4.1, "General Notes on Installing MySQL on Mac OS X"](#).

2.4.1 General Notes on Installing MySQL on Mac OS X

You should keep the following issues and notes in mind:

- The default location for the MySQL Unix socket is different on Mac OS X and Mac OS X Server depending on the installation type you chose. The following table shows the default locations by installation type.

Table 2.8 MySQL Unix Socket Locations on Mac OS X by Installation Type

Installation Type	Socket Location
Package Installer from MySQL	<code>/tmp/mysql.sock</code>
Tarball from MySQL	<code>/tmp/mysql.sock</code>
MySQL Bundled with Mac OS X Server	<code>/var/mysql/mysql.sock</code>

To prevent issues, you should either change the configuration of the socket used within your application (for example, changing `php.ini`), or you should configure the socket location using a MySQL configuration file and the `socket` option. For more information, see [Section 5.1.3, "Server Command Options"](#).

- You may need (or want) to create a specific `mysql` user to own the MySQL directory and data. You can do this through the [Directory Utility](#), and the `mysql` user should already exist. For use in single user mode, an entry for `_mysql` (note the underscore prefix) should already exist within the system `/etc/passwd` file.
- If you get an "insecure startup item disabled" error when MySQL launches, use the following procedure. Adjust the pathnames appropriately for your system.

1. Modify the `mysql.script` using this command (enter it on a single line):

```
shell> sudo /Applications/TextEdit.app/Contents/MacOS/TextEdit
/usr/local/mysql/support-files/mysql.server
```

2. Locate the option file that defines the `basedir` value and modify it to contain these lines:

```
basedir=/usr/local/mysql
datadir=/usr/local/mysql/data
```

In the `/Library/StartupItems/MySQLCOM/` directory, make the following group ID changes from `staff` to `wheel`:

```
shell> sudo chgrp wheel MySQLCOM StartupParameters.plist
```

3. Start the server from System Preferences or Terminal.app.

- Because the MySQL package installer installs the MySQL contents into a version and platform specific directory, you can use this to upgrade and migrate your database between versions. You will need to either copy the `data` directory from the old version to the new version, or alternatively specify an alternative `datadir` value to set location of the data directory.
- You might want to add aliases to your shell's resource file to make it easier to access commonly used programs such as `mysql` and `mysqladmin` from the command line. The syntax for `bash` is:

```
alias mysql=/usr/local/mysql/bin/mysql
alias mysqladmin=/usr/local/mysql/bin/mysqladmin
```

For `tcsh`, use:

```
alias mysql /usr/local/mysql/bin/mysql
alias mysqladmin /usr/local/mysql/bin/mysqladmin
```

Even better, add `/usr/local/mysql/bin` to your `PATH` environment variable. You can do this by modifying the appropriate startup file for your shell. For more information, see [Section 4.2.1, "Invoking MySQL Programs"](#).

- After you have copied over the MySQL database files from the previous installation and have successfully started the new server, you should consider removing the old installation files to save disk space. Additionally, you should also remove older versions of the Package Receipt directories located in `/Library/Receipts/mysql-VERSION.pkg`.

2.4.2 Installing MySQL on Mac OS X Using Native Packages

The package is located inside a disk image (`.dmg`) file that you first need to mount by double-clicking its icon in the Finder. It should then mount the image and display its contents.

Note

Before proceeding with the installation, be sure to stop all running MySQL server instances by using either the MySQL Manager Application (on Mac OS X Server) or `mysqladmin shutdown` on the command line.

When installing from the package version, you should also install the MySQL Preference Pane, which will enable you to control the startup and execution of your MySQL server from System Preferences. For more information, see [Section 2.4.4, "Installing and Using the MySQL Preference Pane"](#).

When installing using the package installer, the files are installed into a directory within `/usr/local` matching the name of the installation version and platform. For example, the installer file `mysql-5.5-osx10.7-x86_64.dmg` installs MySQL into `/usr/local/mysql-5.5-osx10.7-x86_64/`. The following table shows the layout of the installation directory.

Table 2.9 MySQL Installation Layout on Mac OS X

Directory	Contents of Directory
<code>bin</code>	Client programs and the <code>mysqld</code> server

Directory	Contents of Directory
data	Log files, databases
docs	Helper documents, like the Release Notes and build information
include	Include (header) files
lib	Libraries
man	Unix manual pages
mysql-test	MySQL test suite
scripts	mysql_install_db
share	Miscellaneous support files, including error messages, sample configuration files, SQL for database installation
sql-bench	Benchmarks
support-files	Scripts and sample configuration files
/tmp/mysql.sock	Location of the MySQL Unix socket

During the package installer process, a symbolic link from `/usr/local/mysql` to the version/platform specific directory created during installation will be created automatically.

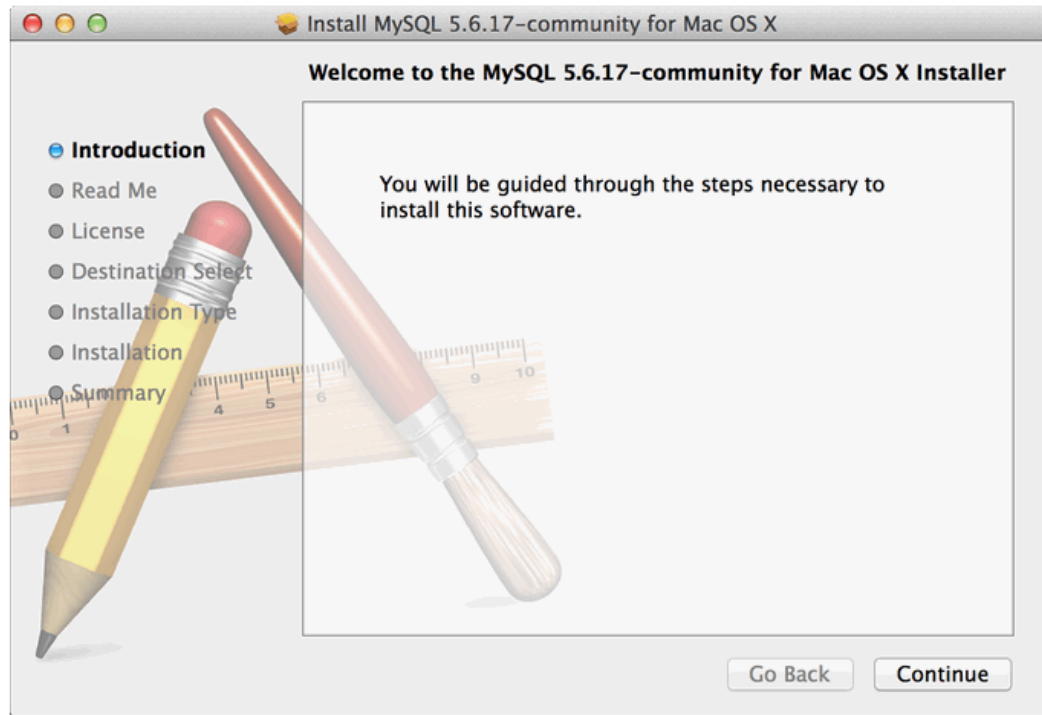

1. Download and open the MySQL package installer, which is provided on a disk image (`.dmg`) that includes the main MySQL installation package, the `MySQLStartupItem.pkg` installation package, and the `MySQL.prefPane`. Double-click the disk image to open it.

Figure 2.31 MySQL Package Installer: DMG Contents

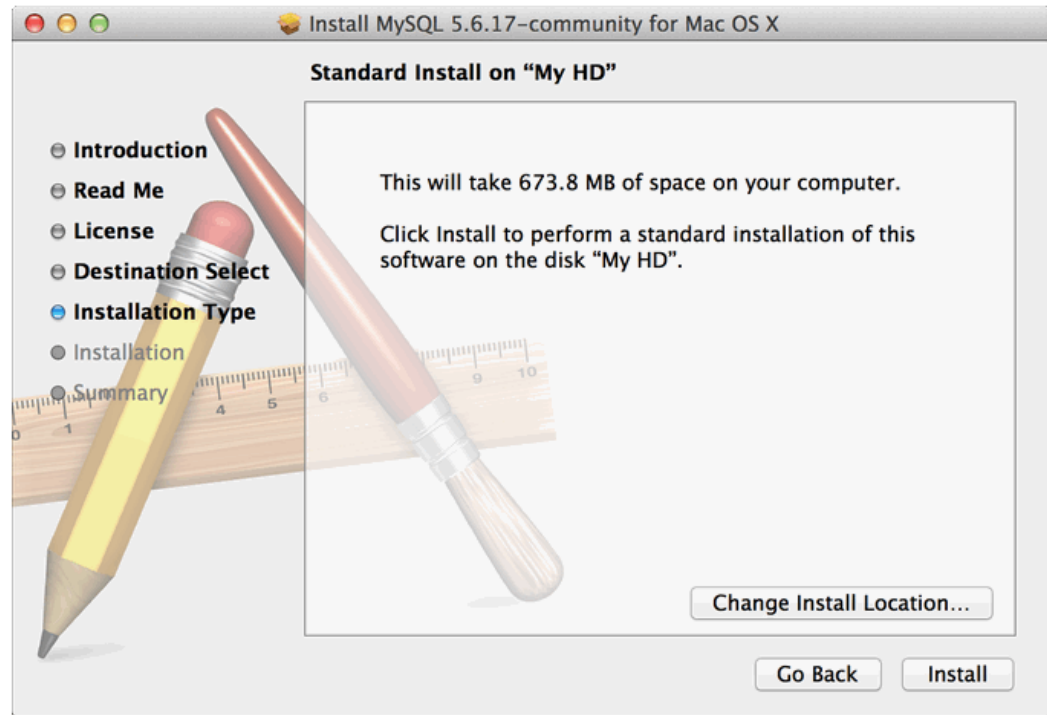

2. Double-click the MySQL installer package. It will be named according to the version of MySQL you have downloaded. For example, if you have downloaded MySQL server 5.5.40, double-click `mysql-5.5.40-osx-10.7-x86_64.pkg`.
3. You will be presented with the opening installer dialog. Click **Continue** to begin installation.

Figure 2.32 MySQL Package Installer: Introduction

4. A copy of the installation instructions and other important information relevant to this installation are displayed. Click **Continue** .
5. If you have downloaded the community version of MySQL, you will be shown a copy of the relevant GNU General Public License. Click **Continue** .
6. Select the drive you want to use to install the MySQL Startup Item. The drive must have a valid, bootable, Mac OS X operating system installed. Click **Continue**.

Figure 2.33 MySQL Package Installer: Choose your Hard drive

7. You will be asked to confirm the details of the installation, including the space required for the installation. To change the drive on which the MySQL server is installed, click either **Go Back** or **Change Install Location...**. To install the MySQL server, click **Install**.
8. Once the installation has been completed successfully, you will be shown an **Install Succeeded** message.

For convenience, you may also want to install the startup item and preference pane. See [Section 2.4.3, “Installing the MySQL Startup Item”](#), and [Section 2.4.4, “Installing and Using the MySQL Preference Pane”](#).

2.4.3 Installing the MySQL Startup Item

The MySQL Installation Package includes a startup item that can be used to automatically start and stop MySQL.

To install the MySQL Startup Item:

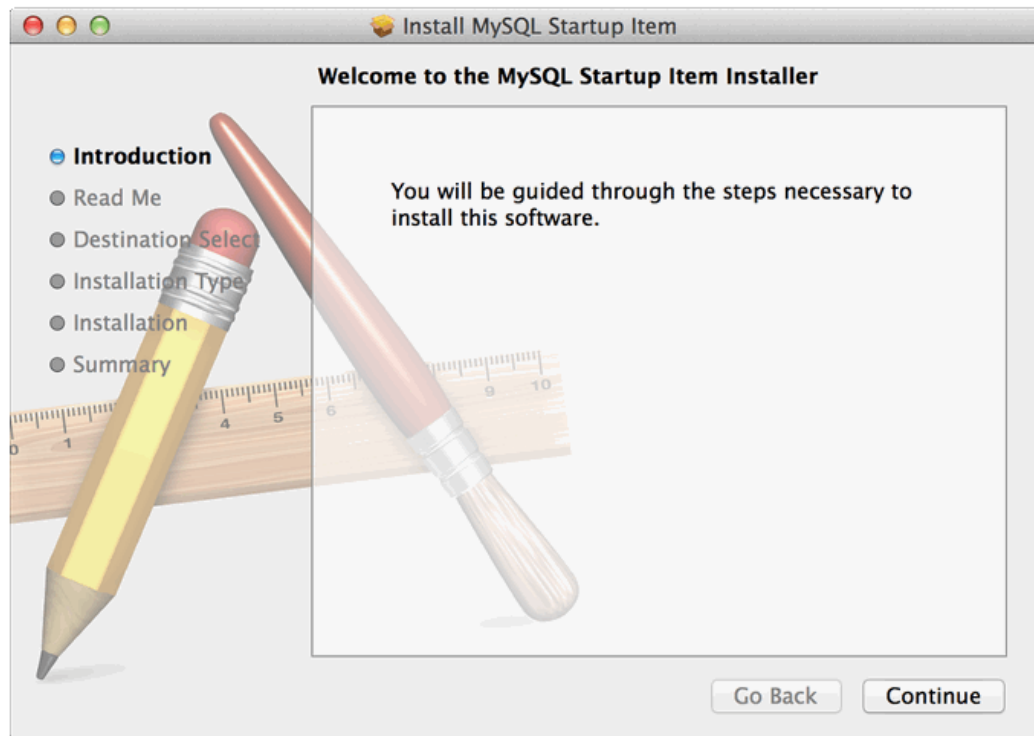

1. Download and open the MySQL package installer, which is provided on a disk image ([.dmg](#)) that includes the main MySQL installation package, the [MySQLStartupItem.pkg](#) installation package, and the [MySQL.prefPane](#). Double-click the disk image to open it.

Figure 2.34 MySQL Package Installer: DMG Contents

2. Double-click the `MySQLStartupItem.pkg` file to start the installation process.
3. You will be presented with the **Install MySQL Startup Item** dialog.

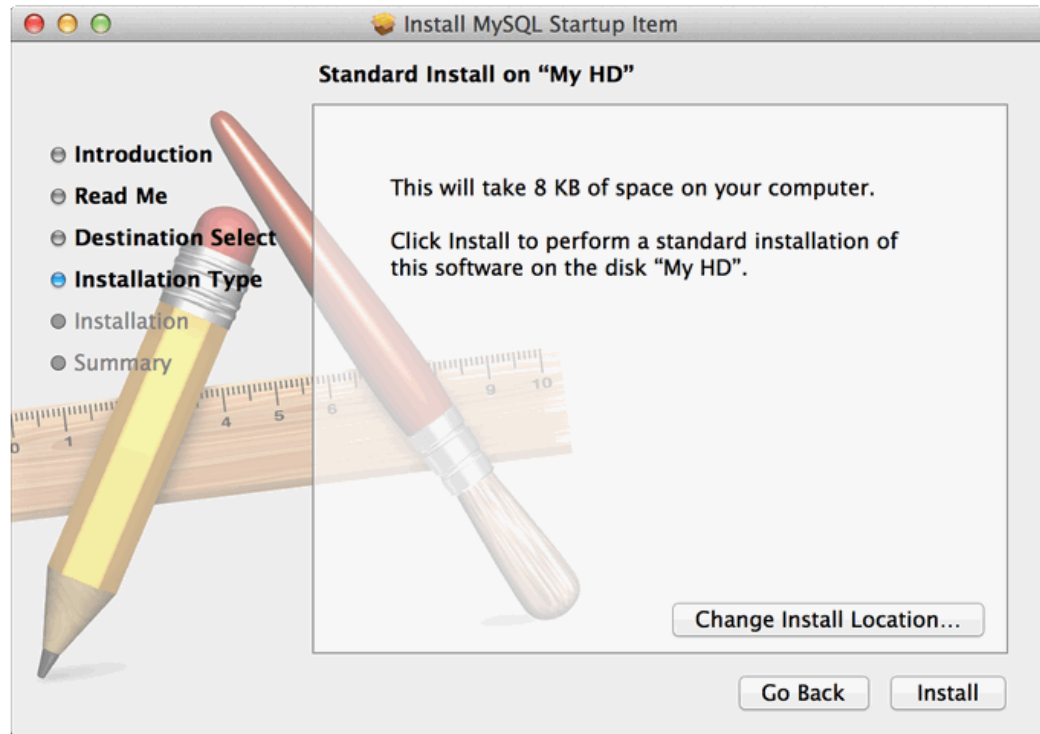

Figure 2.35 MySQL Startup Item Installer: Introduction

Click **Continue** to continue the installation process.

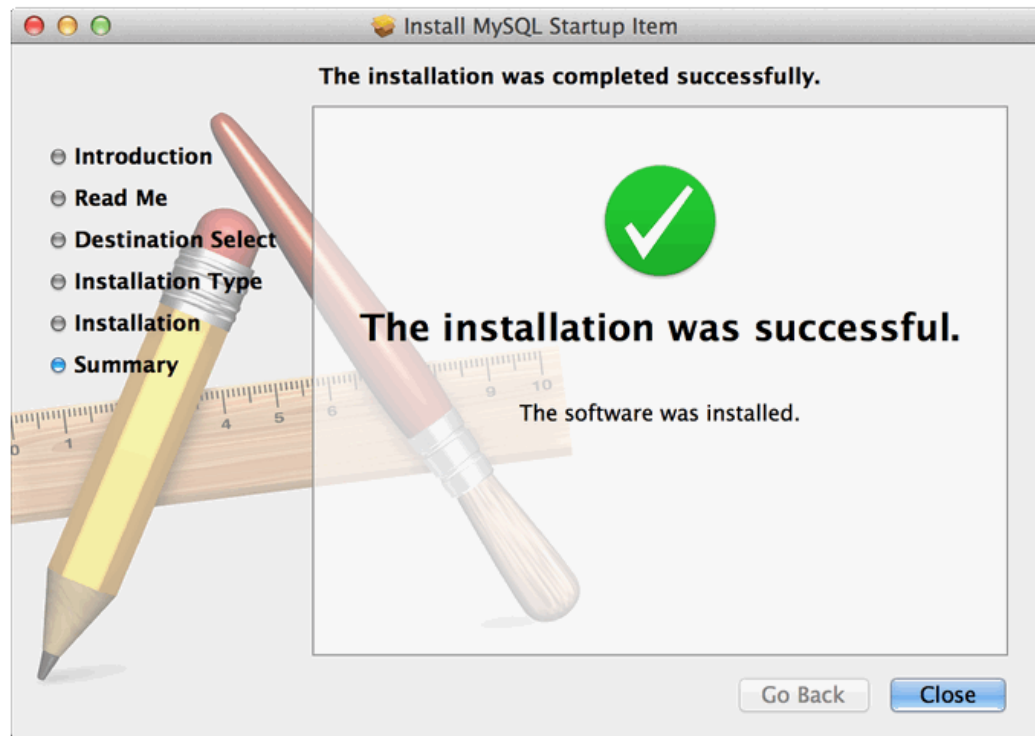

4. A copy of the installation instructions and other important information relevant to this installation are displayed. Click **Continue**.
5. Select the drive you want to use to install the MySQL Startup Item. The drive must have a valid, bootable, Mac OS X operating system installed. Click **Continue**.

Figure 2.36 MySQL Startup Item Installer: Choose Your Hard drive

6. You will be asked to confirm the details of the installation. To change the drive on which the startup item is installed, click either Go Back or Change Install Location.... To install the startup item, click Install.
7. Once the installation has been completed successfully, you will be shown an **Install Succeeded** message.

Figure 2.37 MySQL Startup Item Installer: Summary

The Startup Item for MySQL is installed into `/Library/StartupItems/MySQLCOM`. The Startup Item installation adds a variable `MYSQLCOM=-YES-` to the system configuration file `/etc/hostconfig`. If you want to disable the automatic startup of MySQL, change this variable to `MYSQLCOM=-NO-`.

**Note**

Deselecting **Automatically Start MySQL Server on Startup** from the [MySQL Preference Pane](#) sets the `MYSQLCOM` variable to `-NO-`.

After the installation, you can start and stop the MySQL server from the [MySQL Preference Pane](#) (preferred), or by running the following commands in a terminal window. You must have administrator privileges to perform these tasks, and you may be prompted for your password.

If you have installed the Startup Item, use this command to start the server:

```
shell> sudo /Library/StartupItems/MySQLCOM/MySQLCOM start
```

If you have installed the Startup Item, use this command to stop the server:

```
shell> sudo /Library/StartupItems/MySQLCOM/MySQLCOM stop
```

2.4.4 Installing and Using the MySQL Preference Pane

The MySQL Package installer disk image also includes a custom MySQL Preference Pane that enables you to start, stop, and control automated startup during boot of your MySQL installation.

To install the MySQL Preference Pane:

1. Download and open the MySQL package installer package, which is provided on a disk image (`.dmg`) that includes the main MySQL installation package, the `MySQLStartupItem.pkg` installation package, and the `MySQL.prefPane`. Double-click the disk image to open it.

Figure 2.38 MySQL Package Installer: DMG Contents

2. Double-click the `MySQL.prefPane`. The MySQL System Preferences will open.
3. If this is the first time you have installed the preference pane, you will be asked to confirm installation and whether you want to install the preference pane for all users, or only the current user. To install the preference pane for all users you will need administrator privileges. If necessary, you will be prompted for the username and password for a user with administrator privileges.
4. If you already have the MySQL Preference Pane installed, you will be asked to confirm whether you want to overwrite the existing MySQL Preference Pane.

Note

The MySQL Preference Pane only starts and stops MySQL installation installed from the MySQL package installation that have been installed in the default location.

Once the MySQL Preference Pane has been installed, you can control your MySQL server instance using the preference pane. To use the preference pane, open the **System Preferences...** from the Apple menu. Select the MySQL preference pane by clicking the MySQL logo within the **Other** section of the preference panes list.

Figure 2.39 MySQL Preference Pane: Location

The MySQL Preference Pane shows the current status of the MySQL server, showing **stopped** (in red) if the server is not running and **running** (in green) if the server has already been started. The preference pane also shows the current setting for whether the MySQL server has been set to start automatically.

- **To start the MySQL server using the preference pane:**

Click **Start MySQL Server**. You may be prompted for the username and password of a user with administrator privileges to start the MySQL server.

- **To stop the MySQL server using the preference pane:**

Click **Stop MySQL Server**. You may be prompted for the username and password of a user with administrator privileges to stop the MySQL server.

- **To automatically start the MySQL server when the system boots:**

Check the check box next to **Automatically Start MySQL Server on Startup**.

- **To disable automatic MySQL server startup when the system boots:**

Uncheck the check box next to **Automatically Start MySQL Server on Startup**.

You can close the [System Preferences...](#) window once you have completed your settings.

2.4.5 Using the Bundled MySQL on Mac OS X Server

If you are running Mac OS X Server, a version of MySQL should already be installed. The following table shows the versions of MySQL that ship with Mac OS X Server versions.

Table 2.10 MySQL Versions Preinstalled with Mac OS X Server

Mac OS X Server Version	MySQL Version
10.2-10.2.2	3.23.51
10.2.3-10.2.6	3.23.53
10.3	4.0.14
10.3.2	4.0.16
10.4.0	4.1.10a
10.5.0	5.0.45
10.6.0	5.0.82

The following table shows the installation layout of MySQL on Mac OS X Server.

Table 2.11 MySQL Directory Layout for Preinstalled MySQL Installations on Mac OS X Server

Directory	Contents of Directory
/usr/bin	Client programs
/var/mysql	Log files, databases
/usr/libexec	The <code>mysqld</code> server
/usr/share/man	Unix manual pages
/usr/share/mysql/mysql-test	MySQL test suite
/usr/share/mysql	Miscellaneous support files, including error messages, character set files, sample configuration files, SQL for database installation
/var/mysql/mysql.sock	Location of the MySQL Unix socket

Additional Resources

- For more information on managing the bundled MySQL instance in Mac OS X Server 10.5, see [Mac OS X Server: Web Technologies Administration For Version 10.5 Leopard](#).
- For more information on managing the bundled MySQL instance in Mac OS X Server 10.6, see [Mac OS X Server: Web Technologies Administration Version 10.6 Snow Leopard](#).
- The MySQL server bundled with Mac OS X Server does not include the MySQL client libraries and header files required to access and use MySQL from a third-party driver, such as Perl DBI or PHP.

For more information on obtaining and installing MySQL libraries, see [Mac OS X Server version 10.5: MySQL libraries available for download](#). Alternatively, you can ignore the bundled MySQL server and install MySQL from the package or tarball installation.

2.5 Installing MySQL on Linux

Linux supports a number of different solutions for installing MySQL. The recommended method is to use one of the distributions from Oracle. If you choose this method, there are several options available:

- Installing from a generic binary package in `.tar.gz` format. See [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#) for more information.
- Extracting and compiling MySQL from a source distribution. For detailed instructions, see [Section 2.9, “Installing MySQL from Source”](#).
- Installing using a precompiled RPM package. For more information, see [Section 2.5.1, “Installing MySQL on Linux Using RPM Packages”](#).
- Installing using a precompiled Debian package. For more information, see [Section 2.5.2, “Installing MySQL on Linux Using Debian Packages”](#).
- Installing using Oracle's Unbreakable Linux Network (ULN). For more information, see [Section 2.6, “Installing MySQL Using Unbreakable Linux Network \(ULN\)”](#).

As an alternative, you can use the native package manager within your Linux distribution to automatically download and install MySQL for you. Native package installations can take care of the download and dependencies required to run MySQL, but the MySQL version will often be some versions behind the currently available release. You will also normally be unable to install development releases, as these are not usually made available in the native repository. For more information on using the native package installers, see [Section 2.5.3, “Installing MySQL on Linux Using Native Package Managers”](#).

Note

For many Linux installations, you will want to set up MySQL to be started automatically when your machine starts. Many of the native package installations perform this operation for you, but for source, binary and RPM solutions you may need to set this up separately. The required script, `mysql.server`, can be found in the `support-files` directory under the MySQL installation directory or in a MySQL source tree. You can install it as `/etc/init.d/mysql` for automatic MySQL startup and shutdown. See [Section 2.10.1.2, “Starting and Stopping MySQL Automatically”](#).

2.5.1 Installing MySQL on Linux Using RPM Packages

Note

To install or upgrade to MySQL 5.5.31, be sure to read the special instructions at the end of this section.

The recommended way to install MySQL on RPM-based Linux distributions is by using the RPM packages. The RPMs that we provide to the community should work on all versions of Linux that support RPM packages and use `glibc` 2.3. To obtain RPM packages, see [Section 2.1.3, “How to Get MySQL”](#).

For non-RPM Linux distributions, you can install MySQL using a `.tar.gz` package. See [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#).

Installations created from our Linux RPM distributions result in files under the system directories shown in the following table.

Table 2.12 MySQL Installation Layout for Linux RPM Packages

Directory	Contents of Directory
<code>/usr/bin</code>	Client programs and scripts
<code>/usr/sbin</code>	The <code>mysqld</code> server
<code>/var/lib/mysql</code>	Log files, databases
<code>/usr/share/info</code>	Manual in Info format
<code>/usr/share/man</code>	Unix manual pages
<code>/usr/include/mysql</code>	Include (header) files
<code>/usr/lib/mysql</code>	Libraries
<code>/usr/share/mysql</code>	Miscellaneous support files, including error messages, character set files, sample configuration files, SQL for database installation
<code>/usr/share/sql-bench</code>	Benchmarks

Note

RPM distributions of MySQL are also provided by other vendors. Be aware that they may differ from those built by us in features, capabilities, and conventions (including communication setup), and that the instructions in this manual do not necessarily apply to installing them. The vendor's instructions should be consulted instead. Because of these differences, RPM packages built by us check whether such RPMs built by other vendors are installed. If so, the RPM does not install and produces a message explaining this.

Conflicts can arise when an RPM from another vendor is already installed, such as when a vendor's convention about which files belong with the server and which belong with the client library differ from the breakdown used for Oracle packages. In such cases, attempts to install an Oracle RPM with `rpm -i` may result in messages that files in the RPM to be installed conflict with files from an installed package (denoted `mysql-libs` in the following paragraphs).

We provide a `MySQL-shared-compat` package with each MySQL release. This package is meant to replace `mysql-libs` and provides a replacement-compatible client library for older MySQL series. `MySQL-shared-compat` is set up to make `mysql-libs` obsolete, but `rpm` explicitly refuses to replace obsoleted packages when invoked with `-i` (unlike `-U`), which is why installation with `rpm -i` produces a conflict.

`MySQL-shared-compat` can safely be installed alongside `mysql-libs` because libraries are installed to different locations. Therefore, it is possible to install `shared-compat` first, then manually remove `mysql-libs` before continuing with the installation. After `mysql-libs` is removed, the dynamic linker stops looking for the client library in the location where `mysql-libs` puts it, and the library provided by the `MySQL-shared-compat` package takes over.

Another alternative is to install packages using `yum`. In a directory containing all RPM packages for a MySQL release, `yum install MySQL*rpm` installs them in the correct order and removes `mysql-libs` in one step without conflicts.

In most cases, you need to install only the [MySQL-server](#) and [MySQL-client](#) packages to get a functional MySQL installation. The other packages are not required for a standard installation.

RPMs for MySQL Cluster. Standard MySQL server RPMs built by MySQL do not provide support for the [NDBCLUSTER](#) storage engine.

Important

When upgrading a MySQL Cluster RPM installation, you must upgrade *all* installed RPMs, including the [Server](#) and [Client](#) RPMs.

For more information about installing MySQL Cluster from RPMs, see [Section 18.2, “MySQL Cluster Installation and Upgrades”](#).

For upgrades, if your installation was originally produced by installing multiple RPM packages, it is best to upgrade all the packages, not just some. For example, if you previously installed the server and client RPMs, do not upgrade just the server RPM.

If the data directory exists at RPM installation time, the installation process does not modify existing data. This has the effect, for example, that accounts in the grant tables are not initialized to the default set of accounts.

If you get a dependency failure when trying to install MySQL packages (for example, `error: removing these packages would break dependencies: libmysqlclient.so.10 is needed by ...`), you should also install the [MySQL-shared-compat](#) package, which includes the shared libraries for older releases for backward compatibility.

The RPM packages shown in the following list are available. The names shown here use a suffix of [.glibc23.i386.rpm](#), but particular packages can have different suffixes, described later.

- [MySQL-server-VERSION.glibc23.i386.rpm](#)

The MySQL server. You need this unless you only want to connect to a MySQL server running on another machine.

- [MySQL-client-VERSION.glibc23.i386.rpm](#)

The standard MySQL client programs. You probably always want to install this package.

- [MySQL-devel-VERSION.glibc23.i386.rpm](#)

The libraries and include files that are needed if to compile other MySQL clients, such as the Perl modules. Install this RPM if you intend to compile C API applications.

- [MySQL-shared-VERSION.glibc23.i386.rpm](#)

This package contains the shared libraries ([libmysqlclient.so*](#)) that certain languages and applications need to dynamically load and use MySQL. It contains single-threaded and thread-safe libraries. Install this RPM if you intend to compile or run C API applications that depend on the shared client library. Prior to MySQL 5.5.6, if you install this package, do not install the [MySQL-shared-compat](#) package.

- [MySQL-shared-compat-VERSION.glibc23.i386.rpm](#)

This package includes the shared libraries for older releases. It contains single-threaded and thread-safe libraries. Install this package if you have applications installed that are dynamically linked against older versions of MySQL but you want to upgrade to the current version without breaking the library

dependencies. Before MySQL 5.5.6, `MySQL-shared-compat` also includes the libraries for the current release, so if you install it, you should not also install `MySQL-shared`. As of 5.5.6, `MySQL-shared-compat` does not include the current library version, so there is no conflict.

As of MySQL 5.5.23, the `MySQL-shared-compat` RPM package enables users of Red Hat-provided `mysql-*5.1` RPM packages to migrate to Oracle-provided `MySQL-*5.5` packages. `MySQL-shared-compat` replaces the Red Hat `mysql-libs` package by replacing `libmysqlclient.so` files of the latter package, thus satisfying dependencies of other packages on `mysql-libs`. This change affects only users of Red Hat (or Red Hat-compatible) RPM packages. Nothing is different for users of Oracle RPM packages.

- `MySQL-embedded-VERSION.glibc23.i386.rpm`

The embedded MySQL server library.

- `MySQL-test-VERSION.glibc23.i386.rpm`

This package includes the MySQL test suite.

- `MySQL-VERSION.src.rpm`

This contains the source code for all of the previous packages. It can also be used to rebuild the RPMs on other architectures (for example, Alpha or SPARC).

The suffix of RPM package names (following the `VERSION` value) has the following syntax:

```
.PLATFORM.CPU.rpm
```

The `PLATFORM` and `CPU` values indicate the type of system for which the package is built. `PLATFORM` indicates the platform and `CPU` indicates the processor type or family.

All packages are dynamically linked against `glibc` 2.3. The `PLATFORM` value indicates whether the package is platform independent or intended for a specific platform, as shown in the following table.

Table 2.13 MySQL Linux Installation Packages

<code>PLATFORM</code> Value	Intended Use
<code>glibc23</code>	Platform independent, should run on any Linux distribution that supports <code>glibc</code> 2.3
<code>rhel4</code> , <code>rhel5</code>	Red Hat Enterprise Linux 4 or 5
<code>el6</code>	Enterprise Linux 6
<code>sles10</code> , <code>sles11</code>	SuSE Linux Enterprise Server 10 or 11

In MySQL 5.5, only `glibc23` packages are available currently.

The `CPU` value indicates the processor type or family for which the package is built.

Table 2.14 MySQL Installation Packages for Linux CPU Identifiers

<code>CPU</code> Value	Intended Processor Type or Family
<code>i386</code> , <code>i586</code> , <code>i686</code>	Pentium processor or better, 32 bit
<code>x86_64</code>	64-bit x86 processor

CPU Value	Intended Processor Type or Family
ia64	Itanium (IA-64) processor

To see all files in an RPM package (for example, a `MySQL-server` RPM), run a command like this:

```
shell> rpm -qpl MySQL-server-VERSION.glibc23.i386.rpm
```

To perform a standard minimal installation, install the server and client RPMs:

```
shell> rpm -i MySQL-server-VERSION.glibc23.i386.rpm
shell> rpm -i MySQL-client-VERSION.glibc23.i386.rpm
```

To install only the client programs, install just the client RPM:

```
shell> rpm -i MySQL-client-VERSION.glibc23.i386.rpm
```

RPM provides a feature to verify the integrity and authenticity of packages before installing them. To learn more about this feature, see [Section 2.1.4, “Verifying Package Integrity Using MD5 Checksums or GnuPG”](#).

The server RPM places data under the `/var/lib/mysql` directory. The RPM also creates a login account for a user named `mysql` (if one does not exist) to use for running the MySQL server, and creates the appropriate entries in `/etc/init.d/` to start the server automatically at boot time. (This means that if you have performed a previous installation and have made changes to its startup script, you may want to make a copy of the script so that you do not lose it when you install a newer RPM.) See [Section 2.10.1.2, “Starting and Stopping MySQL Automatically”](#), for more information on how MySQL can be started automatically on system startup.

In MySQL 5.5.5 and later, during a new installation, the server boot scripts are installed, but the MySQL server is not started at the end of the installation, since the status of the server during an unattended installation is not known.

In MySQL 5.5.5 and later, during an upgrade installation using the RPM packages, if the MySQL server is running when the upgrade occurs, the MySQL server is stopped, the upgrade occurs, and the MySQL server is restarted. If the MySQL server is not already running when the RPM upgrade occurs, the MySQL server is not started at the end of the installation.

If something goes wrong, you can find more information in the binary installation section. See [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#).

Note

The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in [Section 2.10, “Postinstallation Setup and Testing”](#).

During RPM installation, a user named `mysql` and a group named `mysql` are created on the system. This is done using the `useradd`, `groupadd`, and `usermod` commands. Those commands require appropriate administrative privileges, which is required for locally managed users and groups (as listed in the `/etc/passwd` and `/etc/group` files) by the RPM installation process being run by `root`.

If you log in as the `mysql` user, you may find that MySQL displays “Invalid (old?) table or database name” errors that mention `.mysqlgui`, `lost+found`, `.mysqlgui`, `.bash_history`, `.fonts.cache-1`, `.lessht`, `.mysql_history`, `.profile`, `.viminfo`, and similar files created by MySQL or operating system utilities. You can safely ignore these error messages or remove the files or directories that cause them if you do not need them.

For nonlocal user management (LDAP, NIS, and so forth), the administrative tools may require additional authentication (such as a password), and will fail if the installing user does not provide this authentication. Even if they fail, the RPM installation will not abort but succeed, and this is intentional. If they failed, some of the intended transfer of ownership may be missing, and it is recommended that the system administrator then manually ensures some appropriate user and group exists and manually transfers ownership following the actions in the RPM spec file.

In MySQL 5.5.31, the RPM spec file has been updated, which has the following consequences:

- For a non-upgrade installation (no existing MySQL version installed), it is possible to install MySQL using [yum](#).
- For upgrades, it is necessary to clean up any earlier MySQL installations. In effect, the update is performed by removing the old installations and installing the new one.

Additional details follow.

For a non-upgrade installation of MySQL 5.5.31, it is possible to install using [yum](#):

```
shell> yum install MySQL-server-NEWVERSION.glibc23.i386.rpm
```

For upgrades to MySQL 5.5.31, the upgrade is performed by removing the old installation and installing the new one. To do this, use the following procedure:

1. Remove the existing 5.5.*X* installation. *OLDVERSION* is the version to remove.

```
shell> rpm -e MySQL-server-OLDVERSION.glibc23.i386.rpm
```

Repeat this step for all installed MySQL RPMs.

2. Install the new version. *NEWVERSION* is the version to install.

```
shell> rpm -ivh MySQL-server-NEWVERSION.glibc23.i386.rpm
```

Alternatively, the removal and installation can be done using [yum](#):

```
shell> yum remove MySQL-server-OLDVERSION.glibc23.i386.rpm
shell> yum install MySQL-server-NEWVERSION.glibc23.i386.rpm
```

2.5.2 Installing MySQL on Linux Using Debian Packages

Oracle provides Debian packages for installation on Debian or Debian-like Linux systems. To obtain a package, see [Section 2.1.3, “How to Get MySQL”](#).

Note

Debian distributions of MySQL are also provided by other vendors. Be aware that they may differ from those built by us in features, capabilities, and conventions (including communication setup), and that the instructions in this manual do not necessarily apply to installing them. The vendor's instructions should be consulted instead.

Debian package files have names in `mysql-MVER-DVER-CPU.deb` format. *MVER* is the MySQL version and *DVER* is the Debian version. The *CPU* value indicates the processor type or family for which the package is built, as shown in the following table.

Table 2.15 MySQL Installation Packages for Linux CPU Identifiers

<i>CPU</i> Value	Intended Processor Type or Family
i686	Pentium processor or better, 32 bit
x86_64	64-bit x86 processor

After downloading a Debian package, use the following command to install it;

```
shell> dpkg -i mysql-MVER-DVER-CPU.deb
```

The Debian package installs files in the `/opt/mysql/server-5.5` directory.

You may also need to install the `libaio` library if it is not already present on your system:

```
shell> apt-get install libaio1
```

2.5.3 Installing MySQL on Linux Using Native Package Managers

Many Linux distributions include a version of the MySQL server, client tools, and development components into the standard package management system built into distributions such as Fedora, Debian, Ubuntu, and Gentoo. This section provides basic instructions for installing MySQL using these systems.

Important

Native package installations can take care of the download and dependencies required to run MySQL, but the MySQL version will often be some way behind the currently available release. You will also normally be unable to install development releases, as these are not usually made available in the native repository.

Distribution specific instructions are shown below:

- **Red Hat Linux, Fedora, CentOS**

For Red Hat and similar distributions, the MySQL distribution is divided into a number of separate packages, `mysql` for the client tools, `mysql-server` for the server and associated tools, and `mysql-libs` for the libraries. The libraries are required if you want to provide connectivity from different languages and environments such as Perl, Python and others.

To install, use the `yum` command to specify the packages that you want to install. For example:

```
root-shell> yum install mysql mysql-server mysql-libs mysql-server
Loaded plugins: presto, refresh-packagekit
Setting up Install Process

Dependency Installed:
perl-DBD-MySQL.x86_64 0:4.017-1.fc13

Complete!

```

MySQL and the MySQL server should now be installed. A sample configuration file is installed into `/etc/my.cnf`. An init script, to start and stop the server, will have been installed into `/etc/init.d/mysql`. To start the MySQL server use `service`:

```
root-shell> service mysqld start
```

To enable the server to be started and stopped automatically during boot, use `chkconfig`:

```
root-shell> chkconfig --levels 235 mysqld on
```

Which enables the MySQL server to be started (and stopped) automatically at the specified the run levels.

The database tables will have been automatically created for you, if they do not already exist. You should, however, run `mysql_secure_installation` to set the root passwords on your server.

- **Debian, Ubuntu, Kubuntu**

On Debian and related distributions, there are two packages, `mysql-client` and `mysql-server`, for the client and server components respectively. You should specify an explicit version, for example `mysql-client-5.1`, to ensure that you install the version of MySQL that you want.

To download and install, including any dependencies, use the `apt-get` command, specifying the packages that you want to install.

Note

Before installing, make sure that you update your `apt-get` index files to ensure you are downloading the latest available version.

A sample installation of the MySQL packages might look like this (some sections trimmed for clarity):

```
root-shell> apt-get install mysql-client-5.1 mysql-server-5.1
Reading package lists... Done
Building dependency tree
Reading state information... Done
The following packages were automatically installed and are no longer required:
  linux-headers-2.6.28-11 linux-headers-2.6.28-11-generic
Use 'apt-get autoremove' to remove them.
The following extra packages will be installed:
  bsd-mailx libdbd-mysql-perl libdbi-perl libhtml-template-perl
  libmysqlclient15off libmysqlclient16 libnet-daemon-perl libplrpc-perl mailx
  mysql-common postfix
Suggested packages:
  dbshell libipc-sharedcache-perl tinyca procmail postfix-mysql postfix-pgsql
  postfix-ldap postfix-pcre sasl2-bin resolvconf postfix-cdb
The following NEW packages will be installed
  bsd-mailx libdbd-mysql-perl libdbi-perl libhtml-template-perl
  libmysqlclient15off libmysqlclient16 libnet-daemon-perl libplrpc-perl mailx
  mysql-client-5.1 mysql-common mysql-server-5.1 postfix

```

Note

The `apt-get` command will install a number of packages, including the MySQL server, in order to provide the typical tools and application environment. This can mean that you install a large number of packages in addition to the main MySQL package.

During installation, the initial database will be created, and you will be prompted for the MySQL root password (and confirmation). A configuration file will have been created in `/etc/mysql/my.cnf`. An init script will have been created in `/etc/init.d/mysql`.

The server will already be started. You can manually start and stop the server using:

```
root-shell> service mysql [start|stop]
```

The service will automatically be added to the 2, 3 and 4 run levels, with stop scripts in the single, shutdown and restart levels.

• Gentoo Linux

As a source-based distribution, installing MySQL on Gentoo involves downloading the source, patching the Gentoo specifics, and then compiling the MySQL server and installing it. This process is handled automatically by the `emerge` command. Depending on the version of MySQL that you want to install, you may need to unmask the specific version that you want for your chosen platform.

The MySQL server and client tools are provided within a single package, `dev-db/mysql`. You can obtain a list of the versions available to install by looking at the portage directory for the package:

```
root-shell> ls /usr/portage/dev-db/mysql/mysql-5.1*
mysql-5.1.39-r1.ebuild
mysql-5.1.44-r1.ebuild
mysql-5.1.44-r2.ebuild
mysql-5.1.44-r3.ebuild
mysql-5.1.44.ebuild
mysql-5.1.45-r1.ebuild
mysql-5.1.45.ebuild
mysql-5.1.46.ebuild
```

To install a specific MySQL version, you must specify the entire atom. For example:

```
root-shell> emerge =dev-db/mysql-5.1.46
```

A simpler alternative is to use the `virtual/mysql-5.1` package, which will install the latest version:

```
root-shell> emerge =virtual/mysql-5.1
```

If the package is masked (because it is not tested or certified for the current platform), use the `ACCEPT_KEYWORDS` environment variable. For example:

```
root-shell> ACCEPT_KEYWORDS="~x86" emerge =virtual/mysql-5.1
```

After installation, you should create a new database using `mysql_install_db`, and set the password for the root user on MySQL. You can use the configuration interface to set the password and create the initial database:

```
root-shell> emerge --config =dev-db/mysql-5.1.46
```

A sample configuration file will have been created for you in `/etc/mysql/my.cnf`, and an init script will have been created in `/etc/init.d/mysql`.

To enable MySQL to start automatically at the normal (default) run levels, you can use:

```
root-shell> rc-update add mysql default
```

2.6 Installing MySQL Using Unbreakable Linux Network (ULN)

Linux supports a number of different solutions for installing MySQL, covered in [Section 2.5, “Installing MySQL on Linux”](#). One of the methods, covered in this section, is installing from Oracle's Unbreakable Linux Network (ULN). You can find information about Oracle Linux and ULN under <http://linux.oracle.com/>.

To use ULN, you need to obtain a ULN login and register the machine used for installation with ULN. This is described in detail in the [ULN FAQ](#). The page also describes how to install and update packages. The MySQL packages are in the “MySQL for Oracle Linux 6” channel for your system architecture on ULN.

Note

At the time of writing this (September 2012), ULN provides MySQL 5.5 for Oracle Linux 6.

Once MySQL has been installed using ULN, you can find information on starting and stopping the server, and more, in [this section](#), particularly under [Section 2.5.1, “Installing MySQL on Linux Using RPM Packages”](#).

If you're updating an existing MySQL installation to an installation using ULN, the recommended procedure is to export your data using `mysqldump`, remove the existing installation, install MySQL from ULN, and load the exported data into your freshly installed MySQL.

If the existing MySQL installation you're upgrading from is from a previous release series (prior to MySQL 5.5), make sure to read the section on upgrading MySQL, [Section 2.11.1, “Upgrading MySQL”](#).

2.7 Installing MySQL on Solaris and OpenSolaris

MySQL on Solaris and OpenSolaris is available in a number of different formats.

- For information on installing using the native Solaris PKG format, see [Section 2.7.1, “Installing MySQL on Solaris Using a Solaris PKG”](#).
- On OpenSolaris, the standard package repositories include MySQL packages specially built for OpenSolaris that include entries for the Service Management Framework (SMF) to enable control of the installation using the SMF administration commands. For more information, see [Section 2.7.2, “Installing MySQL on OpenSolaris Using IPS”](#).
- To use a standard `tar` binary installation, use the notes provided in [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#). Check the notes and hints at the end of this section for Solaris specific notes that you may need before or after installation.

To obtain a binary MySQL distribution for Solaris in tarball or PKG format, <http://dev.mysql.com/downloads/mysql/5.5.html>.

Additional notes to be aware of when installing and using MySQL on Solaris:

- If you want to use MySQL with the `mysql` user and group, use the `groupadd` and `useradd` commands:

```
groupadd mysql
useradd -g mysql mysql
```

- If you install MySQL using a binary tarball distribution on Solaris, you may run into trouble even before you get the MySQL distribution unpacked, as the Solaris `tar` cannot handle long file names. This means that you may see errors when you try to unpack MySQL.

If this occurs, you must use GNU `tar` (`gtar`) to unpack the distribution. In Solaris 10 and OpenSolaris `gtar` is normally located in `/usr/sfw/bin/gtar`, but may not be included in the default path definition.

- When using Solaris 10 for x86_64, you should mount any file systems on which you intend to store `InnoDB` files with the `forcedirectio` option. (By default mounting is done without this option.) Failing to do so will cause a significant drop in performance when using the `InnoDB` storage engine on this platform.
- If you would like MySQL to start automatically, you can copy `support-files/mysql.server` to `/etc/init.d` and create a symbolic link to it named `/etc/rc3.d/S99mysql.server`.
- If too many processes try to connect very rapidly to `mysqld`, you should see this error in the MySQL log:

```
Error in accept: Protocol error
```

You might try starting the server with the `--back_log=50` option as a workaround for this.

- To configure the generation of core files on Solaris you should use the `coreadm` command. Because of the security implications of generating a core on a `setuid()` application, by default, Solaris does not support core files on `setuid()` programs. However, you can modify this behavior using `coreadm`. If you enable `setuid()` core files for the current user, they will be generated using the mode 600 and owned by the superuser.

2.7.1 Installing MySQL on Solaris Using a Solaris PKG

You can install MySQL on Solaris and OpenSolaris using a binary package using the native Solaris PKG format instead of the binary tarball distribution.

To use this package, download the corresponding `mysql-VERSION-solaris10-PLATFORM.pkg.gz` file, then uncompress it. For example:

```
shell> gunzip mysql-5.5.40-solaris10-x86_64.pkg.gz
```

To install a new package, use `pkgadd` and follow the onscreen prompts. You must have root privileges to perform this operation:

```
shell> pkgadd -d mysql-5.5.40-solaris10-x86_64.pkg
```

The following packages are available:

```
1  mysql      MySQL Community Server (GPL)
      (i86pc) 5.5.40
```

```
Select package(s) you wish to process (or 'all' to process
all packages). (default: all) [?,??,q]:
```

The PKG installer installs all of the files and tools needed, and then initializes your database if one does not exist. To complete the installation, you should set the root password for MySQL as provided in the instructions at the end of the installation. Alternatively, you can run the `mysql_secure_installation` script that comes with the installation.

By default, the PKG package installs MySQL under the root path `/opt/mysql`. You can change only the installation root path when using `pkgadd`, which can be used to install MySQL in a different Solaris zone. If you need to install in a specific directory, use a binary `tar` file distribution.

The `pkg` installer copies a suitable startup script for MySQL into `/etc/init.d/mysql`. To enable MySQL to startup and shutdown automatically, you should create a link between this file and the init script directories. For example, to ensure safe startup and shutdown of MySQL you could use the following commands to add the right links:

```
shell> ln /etc/init.d/mysql /etc/rc3.d/S91mysql
shell> ln /etc/init.d/mysql /etc/rc0.d/K02mysql
```

To remove MySQL, the installed package name is `mysql`. You can use this in combination with the `pkgrm` command to remove the installation.

To upgrade when using the Solaris package file format, you must remove the existing installation before installing the updated package. Removal of the package does not delete the existing database information, only the server, binaries and support files. The typical upgrade sequence is therefore:

```
shell> mysqladmin shutdown
shell> pkgrm mysql
shell> pkgadd -d mysql-5.5.40-solaris10-x86_64.pkg
shell> mysqld_safe &
shell> mysql_upgrade
```

You should check the notes in [Section 2.11, “Upgrading or Downgrading MySQL”](#) before performing any upgrade.

2.7.2 Installing MySQL on OpenSolaris Using IPS

OpenSolaris includes standard packages for MySQL in the core repository. The MySQL packages are based on a specific release of MySQL and updated periodically. For the latest release you must use either the native Solaris PKG, `tar`, or source installations. The native OpenSolaris packages include SMF files so that you can easily control your MySQL installation, including automatic startup and recovery, using the native service management tools.

To install MySQL on OpenSolaris, use the `pkg` command. You will need to be logged in as root, or use the `pfexec` tool, as shown in the example below:

```
shell> pfexec pkg install SUNWmysql55
```

The package set installs three individual packages, `SUNWmysql55lib`, which contains the MySQL client libraries; `SUNWmysql55r` which contains the root components, including SMF and configuration files; and `SUNWmysql55u` which contains the scripts, binary tools and other files. You can install these packages individually if you only need the corresponding components.

The MySQL files are installed into `/usr/mysql` which symbolic links for the sub directories (`bin`, `lib`, etc.) to a version specific directory. For MySQL 5.5, the full installation is located in `/usr/mysql/5.5`. The default data directory is `/var/mysql/5.5/data`. The configuration file is installed in `/etc/`

`mysql/5.5/my.cnf`. This layout permits multiple versions of MySQL to be installed, without overwriting the data and binaries from other versions.

Once installed, you must run `mysql_install_db` to initialize the database, and use the `mysql_secure_installation` to secure your installation.

Using SMF to manage your MySQL installation

Once installed, you can start and stop your MySQL server using the installed SMF configuration. The service name is `mysql`, or if you have multiple versions installed, you should use the full version name, for example `mysql:version_55`. To start and enable MySQL to be started at boot time:

```
shell> svcadm enable mysql
```

To disable MySQL from starting during boot time, and shut the MySQL server down if it is running, use:

```
shell> svcadm disable mysql
```

To restart MySQL, for example after a configuration file changes, use the `restart` option:

```
shell> svcadm restart mysql
```

You can also use SMF to configure the data directory and enable full 64-bit mode. For example, to set the data directory used by MySQL:

```
shell> svccfg
svc:> select mysql:version_55
svc:/application/database/mysql:version_55> setprop mysql/data=/data0/mysql
```

By default, the 32-bit binaries are used. To enable the 64-bit server on 64-bit platforms, set the `enable_64bit` parameter. For example:

```
svc:/application/database/mysql:version_55> setprop mysql/enable_64bit=1
```

You need to refresh the SMF after settings these options:

```
shell> svcadm refresh mysql
```

2.8 Installing MySQL on FreeBSD

This section provides information about installing MySQL on variants of FreeBSD Unix.

You can install MySQL on FreeBSD by using the binary distribution provided by Oracle. For more information, see [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#).

The easiest (and preferred) way to install MySQL is to use the `mysql-server` and `mysql-client` ports available at <http://www.freebsd.org/>. Using these ports gives you the following benefits:

- A working MySQL with all optimizations enabled that are known to work on your version of FreeBSD.
- Automatic configuration and build.
- Startup scripts installed in `/usr/local/etc/rc.d`.
- The ability to use `pkg_info -L` to see which files are installed.
- The ability to use `pkg_delete` to remove MySQL if you no longer want it on your machine.

The MySQL build process requires GNU make (`gmake`) to work. If GNU `make` is not available, you must install it first before compiling MySQL.

To install using the ports system:

```
# cd /usr/ports/databases/mysql51-server
# make
...
# cd /usr/ports/databases/mysql51-client
# make
...
```

The standard port installation places the server into `/usr/local/libexec/mysqld`, with the startup script for the MySQL server placed in `/usr/local/etc/rc.d/mysql-server`.

Some additional notes on the BSD implementation:

- To remove MySQL after installation using the ports system:

```
# cd /usr/ports/databases/mysql51-server
# make deinstall
...
# cd /usr/ports/databases/mysql51-client
# make deinstall
...
```

- If you get problems with the current date in MySQL, setting the `TZ` variable should help. See [Section 2.12, “Environment Variables”](#).

2.9 Installing MySQL from Source

Building MySQL from the source code enables you to customize build parameters, compiler optimizations, and installation location. For a list of systems on which MySQL is known to run, see <http://www.mysql.com/support/supportedplatforms/database.html>.

Before you proceed with an installation from source, check whether Oracle produces a precompiled binary distribution for your platform and whether it works for you. We put a great deal of effort into ensuring that our binaries are built with the best possible options for optimal performance. Instructions for installing binary distributions are available in [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#).

Note

This section describes how to build MySQL from source using [CMake](#). Before MySQL 5.5, source builds used the GNU autotools on Unix-like systems. Source builds on Windows used [CMake](#), but the process was different from that described here. For source-building instructions for older versions of MySQL, see [Installing MySQL from Source](#), in the MySQL 5.1 Reference Manual. If you are familiar with autotools but not [CMake](#), you might find these transition instructions helpful: [Autotools to CMake Transition Guide](#)

Source Installation Methods

There are two methods for installing MySQL from source:

- Use a standard MySQL source distribution. To obtain a standard distribution, see [Section 2.1.3, “How to Get MySQL”](#). For instructions on building from a standard distribution, see [Section 2.9.2, “Installing MySQL Using a Standard Source Distribution”](#).

Standard distributions are available as compressed `tar` files, Zip archives, or RPM packages. Distribution files have names of the form `mysql-VERSION.tar.gz`, `mysql-VERSION.zip`, or

`mysql-VERSION.rpm`, where `VERSION` is a number like `5.5.40`. File names for source distributions can be distinguished from those for precompiled binary distributions in that source distribution names are generic and include no platform name, whereas binary distribution names include a platform name indicating the type of system for which the distribution is intended (for example, `pc-linux-i686` or `winx64`).

- Use a MySQL development tree. Development trees have not necessarily received the same level of testing as standard release distributions, so this installation method is usually required only if you need the most recent code changes. For information on building from one of the development trees, see [Section 2.9.3, “Installing MySQL Using a Development Source Tree”](#).

Source Installation System Requirements

Installation of MySQL from source requires several development tools. Some of these tools are needed no matter whether you use a standard source distribution or a development source tree. Other tool requirements depend on which installation method you use.

To install MySQL from source, your system must have the following tools, regardless of installation method:

- `CMake`, which is used as the build framework on all platforms. `CMake` can be downloaded from <http://www.cmake.org>.
- A good `make` program. Although some platforms come with their own `make` implementations, it is highly recommended that you use GNU `make` 3.75 or newer. It may already be available on your system as `gmake`. GNU `make` is available from <http://www.gnu.org/software/make/>.
- A working ANSI C++ compiler. GCC 4.2.1 or later, Sun Studio 12 or later, Visual Studio 2008 or later, and many current vendor-supplied compilers are known to work.
- Perl is needed if you intend to run test scripts. Most Unix-like systems include Perl. On Windows, you can use a version such as ActiveState Perl.

To install MySQL from a standard source distribution, one of the following tools is required to unpack the distribution file:

- For a `.tar.gz` compressed `tar` file: GNU `gunzip` to uncompress the distribution and a reasonable `tar` to unpack it. If your `tar` program supports the `z` option, it can both uncompress and unpack the file.

GNU `tar` is known to work. The standard `tar` provided with some operating systems is not able to unpack the long file names in the MySQL distribution. You should download and install GNU `tar`, or if available, use a preinstalled version of GNU `tar`. Usually this is available as `gnutar`, `gtar`, or as `tar` within a GNU or Free Software directory, such as `/usr/sfw/bin` or `/usr/local/bin`. GNU `tar` is available from <http://www.gnu.org/software/tar/>.

- For a `.zip` Zip archive: `WinZip` or another tool that can read `.zip` files.
- For an `.rpm` RPM package: The `rpmbuild` program used to build the distribution unpacks it.

To install MySQL from a development source tree, the following additional tools are required:

- To obtain the source tree, you must have Bazaar installed. The [Bazaar VCS Web site](#) has instructions for downloading and installing Bazaar on different platforms. Bazaar is supported on any platform that supports Python, and is therefore compatible with any Linux, Unix, Windows, or Mac OS X host.
- `bison` is needed to generate `sql_yacc.cc` from `sql_yacc.yy`. You should use the latest version of `bison` where possible. Versions 1.75 and 2.1 are known to work. There have been reported problems with `bison` 1.875. If you experience problems, upgrade to a later, rather than earlier, version.

`bison` is available from <http://www.gnu.org/software/bison/>. `bison` for Windows can be downloaded from <http://gnuwin32.sourceforge.net/packages/bison.htm>. Download the package labeled “Complete package, excluding sources”. On Windows, the default location for `bison` is the `C:\Program Files\GnuWin32` directory. Some utilities may fail to find `bison` because of the space in the directory name. Also, Visual Studio may simply hang if there are spaces in the path. You can resolve these problems by installing into a directory that does not contain a space; for example `C:\GnuWin32`.

- On OpenSolaris and Solaris Express, `m4` must be installed in addition to `bison`. `m4` is available from <http://www.gnu.org/software/m4/>.

**Note**

If you have to install any programs, modify your `PATH` environment variable to include any directories in which the programs are located. See [Section 4.2.10, “Setting Environment Variables”](#).

If you run into problems and need to file a bug report, please use the instructions in [Section 1.7, “How to Report Bugs or Problems”](#).

2.9.1 MySQL Layout for Source Installation

By default, when you install MySQL after compiling it from source, the installation step installs files under `/usr/local/mysql`. The component locations under the installation directory are the same as for binary distributions. See [Table 2.3, “MySQL Installation Layout for Generic Unix/Linux Binary Package”](#), and [Section 2.3.1, “MySQL Installation Layout on Microsoft Windows”](#). To configure installation locations different from the defaults, use the options described at [Section 2.9.4, “MySQL Source-Configuration Options”](#).

2.9.2 Installing MySQL Using a Standard Source Distribution

To install MySQL from a standard source distribution:

1. Verify that your system satisfies the tool requirements listed at [Section 2.9, “Installing MySQL from Source”](#).
2. Obtain a distribution file using the instructions in [Section 2.1.3, “How to Get MySQL”](#).
3. Configure, build, and install the distribution using the instructions in this section.
4. Perform postinstallation procedures using the instructions in [Section 2.10, “Postinstallation Setup and Testing”](#).

In MySQL 5.5, `CMake` is used as the build framework on all platforms. The instructions given here should enable you to produce a working installation. For additional information on using `CMake` to build MySQL, see [How to Build MySQL Server with CMake](#).

If you start from a source RPM, use the following command to make a binary RPM that you can install. If you do not have `rpmbuild`, use `rpm` instead.

```
shell> rpmbuild --rebuild --clean MySQL-VERSION.src.rpm
```

The result is one or more binary RPM packages that you install as indicated in [Section 2.5.1, “Installing MySQL on Linux Using RPM Packages”](#).

The sequence for installation from a compressed `tar` file or Zip archive source distribution is similar to the process for installing from a generic binary distribution (see [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#)), except that it is used on all platforms and includes steps to configure and compile

the distribution. For example, with a compressed `tar` file source distribution on Unix, the basic installation command sequence looks like this:

```
# Preconfiguration setup
shell> groupadd mysql
shell> useradd -r -g mysql mysql
# Beginning of source-build specific instructions
shell> tar zxvf mysql-VERSION.tar.gz
shell> cd mysql-VERSION
shell> cmake .
shell> make
shell> make install
# End of source-build specific instructions
# Postinstallation setup
shell> cd /usr/local/mysql
shell> chown -R mysql .
shell> chgrp -R mysql .
shell> scripts/mysql_install_db --user=mysql
shell> chown -R root .
shell> chown -R mysql data
# Next command is optional
shell> cp support-files/my-medium.cnf /etc/my.cnf
shell> bin/mysqld_safe --user=mysql &
# Next command is optional
shell> cp support-files/mysql.server /etc/init.d/mysql.server
```

A more detailed version of the source-build specific instructions is shown following.

Note

The procedure shown here does not set up any passwords for MySQL accounts. After following the procedure, proceed to [Section 2.10, “Postinstallation Setup and Testing”](#), for postinstallation setup and testing.

Perform Preconfiguration Setup

On Unix, set up the `mysql` user and group that will be used to run and execute the MySQL server and own the database directory. For details, see [Creating a `mysql` System User and Group](#), in [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#). Then perform the following steps as the `mysql` user, except as noted.

Obtain and Unpack the Distribution

Pick the directory under which you want to unpack the distribution and change location into it.

Obtain a distribution file using the instructions in [Section 2.1.3, “How to Get MySQL”](#).

Unpack the distribution into the current directory:

- To unpack a compressed `tar` file, `tar` can uncompress and unpack the distribution if it has `z` option support:

```
shell> tar zxvf mysql-VERSION.tar.gz
```

If your `tar` does not have `z` option support, use `gunzip` to unpack the distribution and `tar` to unpack it:

```
shell> gunzip < mysql-VERSION.tar.gz | tar xvf -
```

Alternatively, `CMake` can uncompress and unpack the distribution:

```
shell> cmake -E tar zxvf mysql-VERSION.tar.gz
```

- To unpack a Zip archive, use [WinZip](#) or another tool that can read `.zip` files.

Unpacking the distribution file creates a directory named `mysql-VERSION`.

Configure the Distribution

Change location into the top-level directory of the unpacked distribution:

```
shell> cd mysql-VERSION
```

Configure the source directory. The minimum configuration command includes no options to override configuration defaults:

```
shell> cmake .
```

On Windows, specify the development environment. For example, the following commands configure MySQL for 32-bit or 64-bit builds, respectively:

```
shell> cmake . -G "Visual Studio 9 2008"
shell> cmake . -G "Visual Studio 9 2008 Win64"
```

On Mac OS X, to use the Xcode IDE:

```
shell> cmake . -G Xcode
```

When you run `cmake`, you might want to add options to the command line. Here are some examples:

- `-DBUILD_CONFIG=mysql_release`: Configure the source with the same build options used by Oracle to produce binary distributions for official MySQL releases.
- `-DCMAKE_INSTALL_PREFIX=dir_name`: Configure the distribution for installation under a particular location.
- `-DCPACK_MONOLITHIC_INSTALL=1`: Cause `make package` to generate a single installation file rather than multiple files.
- `-DWITH_DEBUG=1`: Build the distribution with debugging support.

For a more extensive list of options, see [Section 2.9.4, “MySQL Source-Configuration Options”](#).

To list the configuration options, use one of the following commands:

```
shell> cmake . -L      # overview
shell> cmake . -LH     # overview with help text
shell> cmake . -LAH    # all params with help text
shell> ccmake .        # interactive display
```

If `CMake` fails, you might need to reconfigure by running it again with different options. If you do reconfigure, take note of the following:

- If `CMake` is run after it has previously been run, it may use information that was gathered during its previous invocation. This information is stored in `CMakeCache.txt`. When `CMake` starts up, it looks for that file and reads its contents if it exists, on the assumption that the information is still correct. That assumption is invalid when you reconfigure.

- Each time you run `CMake`, you must run `make` again to recompile. However, you may want to remove old object files from previous builds first because they were compiled using different configuration options.

To prevent old object files or configuration information from being used, run these commands on Unix before re-running `CMake`:

```
shell> make clean
shell> rm CMakeCache.txt
```

Or, on Windows:

```
shell> devenv MySQL.sln /clean
shell> del CMakeCache.txt
```

If you build out of the source tree (as described later), the `CMakeCache.txt` file and all built files are in the build directory, so you can remove that directory to object files and cached configuration information.

If you are going to send mail to a MySQL mailing list to ask for configuration assistance, first check the files in the `CMakeFiles` directory for useful information about the failure. To file a bug report, please use the instructions in [Section 1.7, "How to Report Bugs or Problems"](#).

Build the Distribution

On Unix:

```
shell> make
shell> make VERBOSE=1
```

The second command sets `VERBOSE` to show the commands for each compiled source.

Use `gmake` instead on systems where you are using GNU `make` and it has been installed as `gmake`.

On Windows:

```
shell> devenv MySQL.sln /build RelWithDebInfo
```

It is possible to build out of the source tree to keep the tree clean. If the top-level source directory is named `mysql-src` under your current working directory, you can build in a directory named `bld` at the same level like this:

```
shell> mkdir bld
shell> cd bld
shell> cmake ../mysql-src
```

The build directory need not actually be outside the source tree. For example, to build in a directory, you can build in a directory named `bld` under the top-level source tree, do this, starting with `mysql-src` as your current working directory:

```
shell> mkdir bld
shell> cd bld
shell> cmake ..
```

If you have multiple source trees at the same level (for example, to build multiple versions of MySQL), the second strategy can be advantageous. The first strategy places all build directories at the same level, which requires that you choose a unique name for each. With the second strategy, you can use the same name for the build directory within each source tree.

If you have gotten to the compilation stage, but the distribution does not build, see [Section 2.9.5, “Dealing with Problems Compiling MySQL”](#), for help. If that does not solve the problem, please enter it into our bugs database using the instructions given in [Section 1.7, “How to Report Bugs or Problems”](#). If you have installed the latest versions of the required tools, and they crash trying to process our configuration files, please report that also. However, if you get a `command not found` error or a similar problem for required tools, do not report it. Instead, make sure that all the required tools are installed and that your `PATH` variable is set correctly so that your shell can find them.

Install the Distribution

On Unix:

```
shell> make install
```

This installs the files under the configured installation directory (by default, `/usr/local/mysql`). You might need to run the command as `root`.

To install in a specific directory, add a `DESTDIR` parameter to the command line:

```
shell> make install DESTDIR="/opt/mysql"
```

Alternatively, generate installation package files that you can install where you like:

```
shell> make package
```

This operation produces one or more `.tar.gz` files that can be installed like generic binary distribution packages. See [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#). If you run `CMake` with `-DCPACK_MONOLITHIC_INSTALL=1`, the operation produces a single file. Otherwise, it produces multiple files.

On Windows, generate the data directory, then create a `.zip` archive installation package:

```
shell> devenv MySQL.sln /build RelWithDebInfo /project initial_database
shell> devenv MySQL.sln /build RelWithDebInfo /project package
```

You can install the resulting `.zip` archive where you like. See [Section 2.3.7, “Installing MySQL on Microsoft Windows Using a noinstall Zip Archive”](#).

Perform Postinstallation Setup

The remainder of the installation process involves setting up the configuration file, creating the core databases, and starting the MySQL server. For instructions, see [Section 2.10, “Postinstallation Setup and Testing”](#).

Note

The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in [Section 2.10, “Postinstallation Setup and Testing”](#).

2.9.3 Installing MySQL Using a Development Source Tree

This section discusses how to install MySQL from the latest development source code. Development trees have not necessarily received the same level of testing as standard release distributions, so this installation method is usually required only if you need the most recent code changes. Do not use a development tree

for production systems. If your goal is simply to get MySQL up and running on your system, you should use a standard release distribution (either a binary or source distribution). See [Section 2.1.3, “How to Get MySQL”](#).

MySQL development projects are hosted on [Launchpad](#). MySQL projects, including MySQL Server, MySQL Workbench, and others are available from the [Oracle/MySQL Engineering](#) page. For the repositories related only to MySQL Server, see the [MySQL Server](#) page.

To install MySQL from a development source tree, your system must satisfy the tool requirements listed at [Section 2.9, “Installing MySQL from Source”](#), including the requirements for Bazaar and [bison](#).

To create a local branch of the MySQL development tree on your machine, use this procedure:

1. To obtain a copy of the MySQL source code, you must create a new Bazaar branch. If you do not already have a Bazaar repository directory set up, you must initialize a new directory:

```
shell> mkdir mysql-server
shell> bzr init-repo --trees mysql-server
```

This is a one-time operation.

2. Assuming that you have an initialized repository directory, you can branch from the public MySQL server repositories to create a local source tree. To create a branch of a specific version:

```
shell> cd mysql-server
shell> bzr branch lp:mysql-server/5.5 mysql-5.5
```

This is a one-time operation per source tree. You can branch the source trees for several versions of MySQL under the `mysql-server` directory.

3. The initial download will take some time to complete, depending on the speed of your connection. Please be patient. Once you have downloaded the first tree, additional trees should take significantly less time to download.
4. When building from the Bazaar branch, you may want to create a copy of your active branch so that you can make configuration and other changes without affecting the original branch contents. You can achieve this by branching from the original branch:

```
shell> bzr branch mysql-5.5 mysql-5.5-build
```

5. To obtain changes made after you have set up the branch initially, update it using the `pull` option periodically. Use this command in the top-level directory of the local copy:

```
shell> bzr pull
```

To examine the changeset comments for the tree, use the `log` option to `bzr`:

```
shell> bzr log
```

You can also browse changesets, comments, and source code online at the Launchpad [MySQL Server](#) page.

If you see diffs (changes) or code that you have a question about, do not hesitate to send email to the MySQL [internals](#) mailing list. See [Section 1.6.1, “MySQL Mailing Lists”](#). If you think you have a better idea on how to do something, send an email message to the list with a patch.

After you have the local branch, you can build MySQL server from the source code. For information, see [Section 2.9.2, “Installing MySQL Using a Standard Source Distribution”](#), except that you skip the part about obtaining and unpacking the distribution.

Be careful about installing a build from a distribution source tree on a production machine. The installation command may overwrite your live release installation. If you already have MySQL installed and do not want to overwrite it, run `CMake` with values for the `CMAKE_INSTALL_PREFIX`, `MYSQL_TCP_PORT`, and `MYSQL_UNIX_ADDR` options different from those used by your production server. For additional information about preventing multiple servers from interfering with each other, see [Section 5.3, “Running Multiple MySQL Instances on One Machine”](#).

Play hard with your new installation. For example, try to make new features crash. Start by running `make test`. See [Section 24.1.2, “The MySQL Test Suite”](#).

2.9.4 MySQL Source-Configuration Options

The `CMake` program provides a great deal of control over how you configure a MySQL source distribution. Typically, you do this using options on the `CMake` command line. For information about options supported by `CMake`, run either of these commands in the top-level source directory:

```
shell> cmake . -LH
shell> ccmake .
```

You can also affect `CMake` using certain environment variables. See [Section 2.12, “Environment Variables”](#).

The following table shows the available `CMake` options. In the `Default` column, `PREFIX` stands for the value of the `CMAKE_INSTALL_PREFIX` option, which specifies the installation base directory. This value is used as the parent location for several of the installation subdirectories.

Table 2.16 MySQL Source-Configuration Option Reference (`CMake`)

Formats	Description	Default	Introduced	Removed
<code>BUILD_CONFIG</code>	Use same build options as official releases		5.5.7	
<code>CMAKE_BUILD_TYPE</code>	Type of build to produce	<code>RelWithDebInfo</code>	5.5.7	
<code>CMAKE_C_FLAGS</code>	Flags for C Compiler			
<code>CMAKE_CXX_FLAGS</code>	Flags for C++ Compiler			
<code>CMAKE_INSTALL_PREFIX</code>	Installation base directory	<code>/usr/local/mysql</code>	5.5.8	
<code>COMPILATION_COMMENT</code>	Comment about compilation environment		5.5.7	
<code>CPACK_MONOLITHIC_INSTALL</code>	Whether package build produces single file	<code>OFF</code>	5.5.7	
<code>DEFAULT_CHARSET</code>	The default server character set	<code>latin1</code>	5.5.7	
<code>DEFAULT_COLLATION</code>	The default server collation	<code>latin1_swedish_ci</code>	5.5.7	
<code>ENABLE_DEBUG_SYNC</code>	Whether to enable Debug Sync support	<code>ON</code>	5.5.7	
<code>ENABLE_DOWNLOADS</code>	Whether to download optional files	<code>OFF</code>	5.5.7	

Formats	Description	Default	Introduced	Removed
<code>ENABLE_DTRACE</code>	Whether to include DTrace support		5.5.7	
<code>ENABLE_GCOV</code>	Whether to include gcov support		5.5.14	
<code>ENABLED_LOCAL_INFILE</code>	Whether to enable LOCAL for LOAD DATA INFILE	<code>OFF</code>	5.5.7	
<code>ENABLED_PROFILING</code>	Whether to enable query profiling code	<code>ON</code>	5.5.7	
<code>IGNORE_AIO_CHECK</code>	With - DBUILD_CONFIG=mysql_release, ignore libaio check	<code>OFF</code>	5.5.9	
<code>INSTALL_BINDIR</code>	User executables directory	<code>PREFIX/bin</code>	5.5.7	
<code>INSTALL_DOCDIR</code>	Documentation directory	<code>PREFIX/docs</code>	5.5.7	
<code>INSTALL_DOCREADMEDIR</code>	README file directory	<code>PREFIX</code>	5.5.7	
<code>INSTALL_INCLUDEDIR</code>	Header file directory	<code>PREFIX/include</code>	5.5.7	
<code>INSTALL_INFODIR</code>	Info file directory	<code>PREFIX/docs</code>	5.5.7	
<code>INSTALL_LAYOUT</code>	Select predefined installation layout	<code>STANDALONE</code>	5.5.7	
<code>INSTALL_LIBDIR</code>	Library file directory	<code>PREFIX/lib</code>	5.5.7	
<code>INSTALL_MANDIR</code>	Manual page directory	<code>PREFIX/man</code>	5.5.7	
<code>INSTALL_MYSQLSHAREDIR</code>	Shared data directory	<code>PREFIX/share</code>	5.5.7	
<code>INSTALL_MYSQLTESTDIR</code>	mysql-test directory	<code>PREFIX/mysql-test</code>	5.5.7	
<code>INSTALL_PLUGINDIR</code>	Plugin directory	<code>PREFIX/lib/plugin</code>	5.5.7	
<code>INSTALL_SBINDIR</code>	Server executable directory	<code>PREFIX/bin</code>	5.5.7	
<code>INSTALL_SCRIPTDIR</code>	Scripts directory	<code>PREFIX/scripts</code>	5.5.7	
<code>INSTALL_SHAREDIR</code>	aclocal/mysql.m4 installation directory	<code>PREFIX/share</code>	5.5.7	
<code>INSTALL_SQLBENCHDIR</code>	sql-bench directory	<code>PREFIX</code>	5.5.7	
<code>INSTALL_SUPPORTFILESDIR</code>	Extra support files directory	<code>PREFIX/support-files</code>	5.5.7	
<code>MEMCACHED_HOME</code>	Path to memcached	<code>[none]</code>	5.5.16-ndb-7.2.2	
<code>MYSQL_DATADIR</code>	Data directory		5.5.7	
<code>MYSQL_MAINTAINER_MODE</code>	Whether to enable MySQL maintainer-specific development environment	<code>OFF</code>	5.5.7	
<code>MYSQL_PROJECT_NAME</code>	Windows/Mac OS X project name	<code>3306</code>	5.5.21	
<code>MYSQL_TCP_PORT</code>	TCP/IP port number	<code>3306</code>	5.5.7	
<code>MYSQL_UNIX_ADDR</code>	Unix socket file	<code>/tmp/mysql.sock</code>	5.5.7	

Formats	Description	Default	Introduced	Removed
ODBC_INCLUDES	ODBC includes directory			
ODBC_LIB_DIR	ODBC library directory			
SYSCONFDIR	Option file directory		5.5.7	
TMPDIR	tmpdir default value		5.5.36	
WITH_ASAN	Enable AddressSanitizer	OFF	5.5.35	
WITH_BUNDLED_LIBEVENT	Use bundled libevent when building ndbmemcache	ON	5.5.16-ndb-7.2.2	
WITH_BUNDLED_MEMCACHED	Use bundled memcached when building ndbmemcache	ON	5.5.16-ndb-7.2.2	
WITH_CLASSPATH	Classpath to use when building MySQL Cluster Connector for Java. Default is an empty string.			
WITH_DEBUG	Whether to include debugging support	OFF	5.5.7	
WITH_EMBEDDED_SERVER	Whether to build embedded server	OFF	5.5.7	
WITH_xxx_STORAGE_ENGINE	Compile storage engine xxx statically into server		5.5.7	
WITH_ERROR_INSERT	Enable error injection in the NDB storage engine. Should not be used for building binaries intended for production.	OFF		
WITH_EXTRA_CHARSETS	Which extra character sets to include	all	5.5.7	
WITH_LIBEDIT	Use bundled libedit library	ON	5.5.7	
WITH_LIBWRAP	Whether to include libwrap (TCP wrappers) support	OFF	5.5.7	
WITH_NDB_BINLOG	Enable binary logging by default by mysqld.	ON		
WITH_NDB_DEBUG	Produce a debug build for testing or troubleshooting.	OFF		
WITH_NDB_JAVA	Enable building of Java and ClusterJ support. Enabled by default. Supported in MySQL Cluster only.	ON	5.5.27-ndb-7.2.9	
WITH_NDB_PORT	Default port used by a management server built with this option. If this option was not used to build it, the management server's default port is 1186.	[none]		
WITH_NDB_TEST	Include NDB API test programs.	OFF		

Formats	Description	Default	Introduced	Removed
WITH_NDBCLUSTER_STORAGE_ENGINE	Build the NDB storage engine	ON		
WITH_NDBMTD	Build multi-threaded data node.	ON		
WITH_READLINE	Use bundled readline library	OFF	5.5.7	
WITH_SSL	Type of SSL support	no	5.5.7	
WITH_UNIXODBC	Enable unixODBC support	OFF		
WITH_VALGRIND	Whether to compile in Valgrind header files	OFF	5.5.6	
WITH_ZLIB	Type of zlib support	system	5.5.7	
WITHOUT_xxx_STORAGE_ENGINE	Exclude storage engine xxx from build		5.5.7	
WITHOUT_SERVER	Do not build the server	OFF		

The following sections provide more information about [CMake](#) options.

- [General Options](#)
- [Installation Layout Options](#)
- [Feature Options](#)
- [CMake Options for Compiling MySQL Cluster](#)
- [Compiler Flags](#)

For boolean options, the value may be specified as 1 or [ON](#) to enable the option, or as 0 or [OFF](#) to disable the option.

Many options configure compile-time defaults that can be overridden at server startup. For example, the [CMAKE_INSTALL_PREFIX](#), [MYSQL_TCP_PORT](#), and [MYSQL_UNIX_ADDR](#) options that configure the default installation base directory location, TCP/IP port number, and Unix socket file can be changed at server startup with the [--basedir](#), [--port](#), and [--socket](#) options for [mysqld](#). Where applicable, configuration option descriptions indicate the corresponding [mysqld](#) startup option.

General Options

- [-DBUILD_CONFIG=mysql_release](#)

This option configures a source distribution with the same build options used by Oracle to produce binary distributions for official MySQL releases.

- [-DCMAKE_BUILD_TYPE=type](#)

The type of build to produce:

- [RelWithDebInfo](#): Enable optimizations and generate debugging information. This is the default MySQL build type.
- [Debug](#): Disable optimizations and generate debugging information. This build type is also used if the [WITH_DEBUG](#) option is enabled. That is, [-DWITH_DEBUG=1](#) has the same effect as [-DCMAKE_BUILD_TYPE=Debug](#).
- [-DCPACK_MONOLITHIC_INSTALL=bool](#)

This option affects whether the `make package` operation produces multiple installation package files or a single file. If disabled, the operation produces multiple installation package files, which may be useful if you want to install only a subset of a full MySQL installation. If enabled, it produces a single file for installing everything.

Installation Layout Options

The `CMAKE_INSTALL_PREFIX` option indicates the base installation directory. Other options with names of the form `INSTALL_XXX` that indicate component locations are interpreted relative to the prefix and their values are relative pathnames. Their values should not include the prefix.

- `-DCMAKE_INSTALL_PREFIX=dir_name`

The installation base directory.

This value can be set at server startup with the `--basedir` option.

- `-DINSTALL_BINDIR=dir_name`

Where to install user programs.

- `-DINSTALL_DOCDIR=dir_name`

Where to install documentation.

- `-DINSTALL_DOCREADMEDIR=dir_name`

Where to install `README` files.

- `-DINSTALL_INCLUDEDIR=dir_name`

Where to install header files.

- `-DINSTALL_INFODIR=dir_name`

Where to install Info files.

- `-DINSTALL_LAYOUT=name`

Select a predefined installation layout:

- `STANDALONE`: Same layout as used for `.tar.gz` and `.zip` packages. This is the default.
- `RPM`: Layout similar to RPM packages.
- `SVR4`: Solaris package layout.
- `DEB`: DEB package layout (experimental).

You can select a predefined layout but modify individual component installation locations by specifying other options. For example:

```
shell> cmake . -DINSTALL_LAYOUT=SVR4 -DMYSQL_DATADIR=/var/mysql/data
```

- `-DINSTALL_LIBDIR=dir_name`

Where to install library files.

- `-DINSTALL_MANDIR=dir_name`

Where to install manual pages.

- `-DINSTALL_MYSQLSHAREDIR=dir_name`

Where to install shared data files.

- `-DINSTALL_MYSQLTESTDIR=dir_name`

Where to install the `mysql-test` directory. As of MySQL 5.5.32, to suppress installation of this directory, explicitly set the option to the empty value (`-DINSTALL_MYSQLTESTDIR=`).

- `-DINSTALL_PLUGINDIR=dir_name`

The location of the plugin directory.

This value can be set at server startup with the `--plugin_dir` option.

- `-DINSTALL_SBINDIR=dir_name`

Where to install the `mysqld` server.

- `-DINSTALL_SCRIPTDIR=dir_name`

Where to install `mysql_install_db`.

- `-DINSTALL_SHAREDIR=dir_name`

Where to install `aclocal/mysql.m4`.

- `-DINSTALL_SQLBENCHDIR=dir_name`

Where to install the `sql-bench` directory. To suppress installation of this directory, explicitly set the option to the empty value (`-DINSTALL_SQLBENCHDIR=`).

- `-DINSTALL_SUPPORTFILES DIR=dir_name`

Where to install extra support files.

- `-DMYSQL_DATADIR=dir_name`

The location of the MySQL data directory.

This value can be set at server startup with the `--datadir` option.

- `-DODBC_INCLUDES=dir_name`

The location of the ODBC includes directory, and may be used while configuring Connector/ODBC.

- `-DODBC_LIB_DIR=dir_name`

The location of the ODBC library directory, and may be used while configuring Connector/ODBC.

- `-DSYSCONFDIR=dir_name`

The default `my.cnf` option file directory.

This location cannot be set at server startup, but you can start the server with a given option file using the `--defaults-file=file_name` option, where `file_name` is the full path name to the file.

- `-DTMPDIR=dir_name`

The default location to use for the `tmpdir` system variable. If unspecified, the value defaults to `P_tmpdir` in `<stdio.h>`. This option was added in MySQL 5.6.16.

Storage Engine Options

Storage engines are built as plugins. You can build a plugin as a static module (compiled into the server) or a dynamic module (built as a dynamic library that must be installed into the server using the `INSTALL PLUGIN` statement or the `--plugin-load` option before it can be used). Some plugins might not support static or dynamic building.

The `MyISAM`, `MERGE`, `MEMORY`, and `CSV` engines are mandatory (always compiled into the server) and need not be installed explicitly.

To compile a storage engine statically into the server, use `-DWITH_engine_STORAGE_ENGINE=1`. Some permissible *engine* values are `ARCHIVE`, `BLACKHOLE`, `EXAMPLE`, `FEDERATED`, `INNODB` (`InnoDB`), `NDBCLUSTER` (`NDB`), `PARTITION` (partitioning support), and `PERFSCHEMA` (Performance Schema). Examples:

```
-DWITH_INNODB_STORAGE_ENGINE=1
-DWITH_ARCHIVE_STORAGE_ENGINE=1
-DWITH_BLACKHOLE_STORAGE_ENGINE=1
-DWITH_PERFSCHEMA_STORAGE_ENGINE=1
```

Note

`WITH_NDBCLUSTER_STORAGE_ENGINE` is supported only when building MySQL Cluster using the MySQL Cluster sources. It cannot be used to enable clustering support in other MySQL source trees or distributions. In MySQL Cluster NDB 7.2 source distributions, it is enabled by default. See [Section 18.2.1.3, “Building MySQL Cluster from Source on Linux”](#), and [Section 18.2.2.2, “Compiling and Installing MySQL Cluster from Source on Windows”](#), for more information.

To exclude a storage engine from the build, use `-DWITHOUT_engine_STORAGE_ENGINE=1`. Examples:

```
-DWITHOUT_EXAMPLE_STORAGE_ENGINE=1
-DWITHOUT_FEDERATED_STORAGE_ENGINE=1
-DWITHOUT_PARTITION_STORAGE_ENGINE=1
```

If neither `-DWITH_engine_STORAGE_ENGINE` nor `-DWITHOUT_engine_STORAGE_ENGINE` are specified for a given storage engine, the engine is built as a shared module, or excluded if it cannot be built as a shared module.

Feature Options

- `-DCOMPILATION_COMMENT=string`

A descriptive comment about the compilation environment.

- `-DDEFAULT_CHARSET=charset_name`

The server character set. By default, MySQL uses the `latin1` (cp1252 West European) character set.

charset_name may be one of `binary`, `armscii8`, `ascii`, `big5`, `cp1250`, `cp1251`, `cp1256`, `cp1257`, `cp850`, `cp852`, `cp866`, `cp932`, `dec8`, `eucjpms`, `euckr`, `gb2312`, `gbk`, `geostd8`, `greek`, `hebrew`, `hp8`, `keybcs2`, `koi8r`, `koi8u`, `latin1`, `latin2`, `latin5`, `latin7`, `macce`, `macroman`,

`sjis`, `swe7`, `tis620`, `ucs2`, `ujis`, `utf8`, `utf8mb4`, `utf16`, `utf32`. The permissible character sets are listed in the `cmake/character_sets.cmake` file as the value of `CHARSETS_AVAILABLE`.

This value can be set at server startup with the `--character_set_server` option.

- `-DDEFAULT_COLLATION=collation_name`

The server collation. By default, MySQL uses `latin1_swedish_ci`. Use the `SHOW COLLATION` statement to determine which collations are available for each character set.

This value can be set at server startup with the `--collation_server` option.

- `-DENABLE_DEBUG_SYNC=bool`

Whether to compile the Debug Sync facility into the server. This facility is used for testing and debugging. This option is enabled by default, but has no effect unless MySQL is configured with debugging enabled. If debugging is enabled and you want to disable Debug Sync, use `-DENABLE_DEBUG_SYNC=0`.

When compiled in, Debug Sync is disabled by default at runtime. To enable it, start `mysqld` with the `--debug-sync-timeout=N` option, where *N* is a timeout value greater than 0. (The default value is 0, which disables Debug Sync.) *N* becomes the default timeout for individual synchronization points.

For a description of the Debug Sync facility and how to use synchronization points, see [MySQL Internals: Test Synchronization](#).

- `-DENABLE_DOWNLOADS=bool`

Whether to download optional files. For example, with this option enabled, `CMake` downloads the Google Test distribution that is used by the test suite to run unit tests.

- `-DENABLE_DTRACE=bool`

Whether to include support for DTrace probes. For information about DTrace, see [Section 5.4, “Tracing mysqld Using DTrace”](#)

- `-DENABLE_GCOV=bool`

Whether to include gcov support (Linux only).

- `-DENABLED_LOCAL_INFILE=bool`

Whether to enable `LOCAL` capability in the client library for `LOAD DATA INFILE`.

This option controls client-side `LOCAL` capability, but the capability can be set on the server side at server startup with the `--local-infile` option. See [Section 6.1.6, “Security Issues with LOAD DATA LOCAL”](#).

- `-DENABLED_PROFILING=bool`

Whether to enable query profiling code (for the `SHOW PROFILE` and `SHOW PROFILES` statements).

- `-DIGNORE_AIO_CHECK=bool`

If the `-DBUILD_CONFIG=mysql_release` option is given on Linux, the `libaio` library must be linked in by default. If you do not have `libaio` or do not want to install it, you can suppress the check for it by specifying `-DIGNORE_AIO_CHECK=1`. This option was added in MySQL 5.5.9.

- `-DMYSQL_MAINTAINER_MODE=bool`

Whether to enable a MySQL maintainer-specific development environment. If enabled, this option causes compiler warnings to become errors.

- `-DMYSQL_PROJECT_NAME=name`

For Windows or Mac OS X, the project name to incorporate into the project file name. This option was added in MySQL 5.5.21.

- `-DMYSQL_TCP_PORT=port_num`

The port number on which the server listens for TCP/IP connections. The default is 3306.

This value can be set at server startup with the `--port` option.

- `-DMYSQL_UNIX_ADDR=file_name`

The Unix socket file path on which the server listens for socket connections. This must be an absolute path name. The default is `/tmp/mysql.sock`.

This value can be set at server startup with the `--socket` option.

- `-DWITH_ASAN=bool`

Whether to enable AddressSanitizer, for compilers that support it. The default is off. This option was added in MySQL 5.5.35.

- `-DWITH_DEBUG=bool`

Whether to include debugging support.

Configuring MySQL with debugging support enables you to use the `--debug="d,parser_debug"` option when you start the server. This causes the Bison parser that is used to process SQL statements to dump a parser trace to the server's standard error output. Typically, this output is written to the error log.

- `-DWITH_EMBEDDED_SERVER=bool`

Whether to build the `libmysqld` embedded server library.

- `-DWITH_EXTRA_CHARSETS=name`

Which extra character sets to include:

- `all`: All character sets. This is the default.
- `complex`: Complex character sets.
- `none`: No extra character sets.

- `-DWITH_LIBEDIT=bool`

Whether to use the `libedit` library bundled with the distribution.

- `-DWITH_LIBWRAP=bool`

Whether to include `libwrap` (TCP wrappers) support.

- `-DWITH_READLINE=bool`

Whether to use the `readline` library bundled with the distribution.

- `-DWITH_SSL=ssl_type`

The type of SSL support to include, if any:

- `no`: No SSL support. This is the default.
- `yes`: Use the system SSL library if present, else the library bundled with the distribution.
- `bundled`: Use the SSL library bundled with the distribution.
- `system`: Use the system SSL library.

For information about using SSL support, see [Section 6.3.9, “Using SSL for Secure Connections”](#).

- `-DWITH_UNIXODBC=1`

Enables unixODBC support, for Connector/ODBC.

- `-DWITH_VALGRIND=bool`

Whether to compile in the Valgrind header files, which exposes the Valgrind API to MySQL code. The default is `OFF`.

To generate a Valgrind-aware debug build, `-DWITH_VALGRIND=1` normally is combined with `-DWITH_DEBUG=1`. See [Building Debug Configurations](#).

- `-DWITH_ZLIB=zlib_type`

Some features require that the server be built with compression library support, such as the `COMPRESS()` and `UNCOMPRESS()` functions, and compression of the client/server protocol. The `WITH_ZLIB` indicates the source of `zlib` support:

- `bundled`: Use the `zlib` library bundled with the distribution.
- `system`: Use the system `zlib` library. This is the default.

- `-DWITHOUT_SERVER=bool`

Whether to build without the MySQL server. The default is `OFF`, which does build the server.

Compiler Flags

- `-DCMAKE_C_FLAGS="flags"`

Flags for the C Compiler.

- `-DCMAKE_CXX_FLAGS="flags"`

Flags for the C++ Compiler.

To specify your own C and C++ compiler flags, for flags that do not affect optimization, use the `CMAKE_C_FLAGS` and `CMAKE_CXX_FLAGS` CMake options.

When providing your own compiler flags, you might want to specify `CMAKE_BUILD_TYPE` as well.

For example, to create a 32-bit release build on a 64-bit Linux machine, do this:

```
shell> mkdir bld
shell> cd bld
shell> cmake .. -DCMAKE_C_FLAGS=-m32 \
               -DCMAKE_CXX_FLAGS=-m32 \
               -DCMAKE_BUILD_TYPE=RelWithDebInfo
```

If you set flags that affect optimization (*-Onumber*), you must set the `CMAKE_C_FLAGS_build_type` and/or `CMAKE_CXX_FLAGS_build_type` options, where *build_type* corresponds to the `CMAKE_BUILD_TYPE` value. To specify a different optimization for the default build type (`RelWithDebInfo`) set the `CMAKE_C_FLAGS_RELWITHDEBINFO` and `CMAKE_CXX_FLAGS_RELWITHDEBINFO` options. For example, to compile on Linux with `-O3` and with debug symbols, do this:

```
shell> cmake .. -DCMAKE_C_FLAGS_RELWITHDEBINFO="-O3 -g" \
               -DCMAKE_CXX_FLAGS_RELWITHDEBINFO="-O3 -g"
```

CMake Options for Compiling MySQL Cluster

The following options are for use when building MySQL Cluster NDB 7.2 or later. These options are supported only with the MySQL Cluster NDB 7.2 and later MySQL Cluster sources; they are not supported when using sources from the MySQL 5.5 Server tree.

- `-DMEMCACHED_HOME=path`

Perform the build using the memcached (version 1.6 or later) installed in the system directory indicated by *path*. Files from this installation that are used in the build include the memcached binary, header files, and libraries, as well as the `memcached_utilities` library and the header file `engine_testapp.h`.

You must leave this option unset when building `ndbmemcache` using the bundled memcached sources (`WITH_BUNDLED_MEMCACHED` option); in other words, the bundled sources are used by default).

This option was added in MySQL Cluster NDB 7.2.2.

While additional CMake options—such as for SASL authorization and for providing `dtrace` support—are available for use when compiling `memcached` from external sources, these options are currently not enabled for the `memcached` sources bundled with MySQL Cluster.

- `-DWITH_BUNDLED_LIBEVENT={ON|OFF}`

Use the `libevent` included in the MySQL Cluster sources when building MySQL Cluster with `ndbmemcached` support (MySQL Cluster NDB 7.2.2 and later). Enabled by default. OFF causes the system's `libevent` to be used instead.

- `-DWITH_BUNDLED_MEMCACHED={ON|OFF}`

Build the memcached sources included in the MySQL Cluster source tree (MySQL Cluster NDB 7.2.3 and later), then use the resulting memcached server when building the `ndbmemcache` engine. In this case, `make install` places the `memcached` binary in the installation `bin` directory, and the `ndbmemcache` engine shared object file `ndb_engine.so` in the installation `lib` directory.

This option is ON by default.

- `-DWITH_CLASSPATH=path`

Sets the classpath for building MySQL Cluster Connector for Java. The default is empty. In MySQL Cluster NDB 7.2.9 and later, this option is ignored if `-DWITH_NDB_JAVA=OFF` is used.

- `-DWITH_ERROR_INSERT={ON|OFF}`

Enables error injection in the `NDB` kernel. For testing only; not intended for use in building production binaries. The default is `OFF`.

- `-DWITH_NDBCLUSTER_STORAGE_ENGINE={ON|OFF}`

Build and link in support for the `NDB` (`NDBCLUSTER`) storage engine in `mysqld`. The default is `ON`.

- `-DWITH_NDBCLUSTER={ON|OFF}`

This is an alias for `WITH_NDBCLUSTER_STORAGE_ENGINE`.

- `-DWITH_NDBMTD={ON|OFF}`

Build the multi-threaded data node executable `ndbmt`. The default is `ON`.

- `-DWITH_NDB_BINLOG={ON|OFF}`

Enable binary logging by default in the `mysqld` built using this option. `ON` by default.

- `-DWITH_NDB_DEBUG={ON|OFF}`

Enable building the debug versions of the MySQL Cluster binaries. `OFF` by default.

- `-DWITH_NDB_JAVA={ON|OFF}`

Enable building MySQL Cluster with Java support, including `ClusterJ`.

This option was added in MySQL Cluster NDB 7.2.9, and is `ON` by default. If you do not wish to compile MySQL Cluster with Java support, you must disable it explicitly by specifying `-DWITH_NDB_JAVA=OFF` when running `CMake`. Otherwise, if Java cannot be found, configuration of the build fails.

- `-DWITH_NDB_PORT=port`

Causes the MySQL Cluster management server (`ndb_mgmd`) that is built to use this `port` by default. If this option is unset, the resulting management server tries to use port 1186 by default.

- `-DWITH_NDB_TEST={ON|OFF}`

If enabled, include a set of NDB API test programs. The default is `OFF`.

2.9.5 Dealing with Problems Compiling MySQL

The solution to many problems involves reconfiguring. If you do reconfigure, take note of the following:

- If `CMake` is run after it has previously been run, it may use information that was gathered during its previous invocation. This information is stored in `CMakeCache.txt`. When `CMake` starts up, it looks for that file and reads its contents if it exists, on the assumption that the information is still correct. That assumption is invalid when you reconfigure.
- Each time you run `CMake`, you must run `make` again to recompile. However, you may want to remove old object files from previous builds first because they were compiled using different configuration options.

To prevent old object files or configuration information from being used, run the following commands before re-running `CMake`:

On Unix:

```
shell> make clean
shell> rm CMakeCache.txt
```

On Windows:

```
shell> devenv MySQL.sln /clean
shell> del CMakeCache.txt
```

If you build outside of the source tree, remove and recreate your build directory before re-running `CMake`. For instructions on building outside of the source tree, see [How to Build MySQL Server with CMake](#).

On some systems, warnings may occur due to differences in system include files. The following list describes other problems that have been found to occur most often when compiling MySQL:

- To define which C and C++ compilers to use, you can define the `CC` and `CXX` environment variables. For example:

```
shell> CC=gcc
shell> CXX=g++
shell> export CC CXX
```

To specify your own C and C++ compiler flags, use the `CMAKE_C_FLAGS` and `CMAKE_CXX_FLAGS` CMake options. See [Compiler Flags](#).

To see what flags you might need to specify, invoke `mysql_config` with the `--cflags` option.

- To see what commands are executed during the compile stage, after using `CMake` to configure MySQL, run `make VERBOSE=1` rather than just `make`.
- If compilation fails, check whether the `MYSQL_MAINTAINER_MODE` option is enabled. This mode causes compiler warnings to become errors, so disabling it may enable compilation to proceed.
- If your compile fails with errors such as any of the following, you must upgrade your version of `make` to GNU `make`:

```
make: Fatal error in reader: Makefile, line 18:
Badly formed macro assignment
```

Or:

```
make: file `Makefile' line 18: Must be a separator (:
```

Or:

```
pthread.h: No such file or directory
```

Solaris and FreeBSD are known to have troublesome `make` programs.

GNU `make` 3.75 is known to work.

- The `sql_yacc.cc` file is generated from `sql_yacc.yy`. Normally, the build process does not need to create `sql_yacc.cc` because MySQL comes with a pregenerated copy. However, if you do need to re-create it, you might encounter this error:

```
"sql_yacc.yy", line xxx fatal: default action causes potential...
```

This is a sign that your version of `yacc` is deficient. You probably need to install a recent version of `bison` (the GNU version of `yacc`) and use that instead.

Versions of `bison` older than 1.75 may report this error:

```
sql_yacc.yy:#####: fatal error: maximum table size (32767) exceeded
```

The maximum table size is not actually exceeded; the error is caused by bugs in older versions of `bison`.

For information about acquiring or updating tools, see the system requirements in [Section 2.9, “Installing MySQL from Source”](#).

2.9.6 MySQL Configuration and Third-Party Tools

Third-party tools that need to determine the MySQL version from the MySQL source can read the `VERSION` file in the top-level source directory. The file lists the pieces of the version separately. For example, if the version is MySQL 5.7.4-m14, the file looks like this:

```
MYSQL_VERSION_MAJOR=5
MYSQL_VERSION_MINOR=7
MYSQL_VERSION_PATCH=4
MYSQL_VERSION_EXTRA=-m14
```

If the source is not for a General Availability (GA) release, the `MYSQL_VERSION_EXTRA` value will be nonempty. For the example, the value corresponds to Milestone 14.

To construct a five-digit number from the version components, use this formula:

```
MYSQL_VERSION_MAJOR*10000 + MYSQL_VERSION_MINOR*100 + MYSQL_VERSION_PATCH
```

2.10 Postinstallation Setup and Testing

This section discusses post-installation items for Unix-like systems. If you are using Windows, see [Section 2.3.10, “Windows Postinstallation Procedures”](#).

After installing MySQL, there are some items that you should address. For example:

- You should initialize the data directory and create the MySQL grant tables, as describe in [Section 2.10.1, “Postinstallation Procedures for Unix-like Systems”](#).
- An important security concern is that the initial accounts in the grant tables have no passwords. You should assign passwords to prevent unauthorized access to the MySQL server. For instructions, see [Section 2.10.2, “Securing the Initial MySQL Accounts”](#).
- Optionally, you can create time zone tables to enable recognition of named time zones. For instructions, see [Section 4.4.6, “mysql_tzinfo_to_sql — Load the Time Zone Tables”](#).
- If you have trouble getting the server to start, see [Section 2.10.1.3, “Starting and Troubleshooting the MySQL Server”](#).
- When you are ready to create additional user accounts, you can find information on the MySQL access control system and account management in [Section 6.2, “The MySQL Access Privilege System”](#), and [Section 6.3, “MySQL User Account Management”](#).

2.10.1 Postinstallation Procedures for Unix-like Systems

After installing MySQL on a Unix-like system, you must initialize the grant tables, start the server, and make sure that the server works satisfactorily. You may also wish to arrange for the server to be started and stopped automatically when your system starts and stops. You should also assign passwords to the accounts in the grant tables.

On a Unix-like system, the grant tables are set up by the `mysql_install_db` program. For some installation methods, this program is run for you automatically if an existing database cannot be found.

- If you install MySQL on Linux using RPM distributions, the server RPM runs `mysql_install_db`.
- Using the native packaging system on many platforms, including Debian Linux, Ubuntu Linux, Gentoo Linux and others, the `mysql_install_db` command is run for you.
- If you install MySQL on Mac OS X using a DMG distribution, the installer runs `mysql_install_db`.

For other platforms and installation types, including generic binary and source installs, you will need to run `mysql_install_db` yourself.

The following procedure describes how to initialize the grant tables (if that has not previously been done) and start the server. It also suggests some commands that you can use to test whether the server is accessible and working properly. For information about starting and stopping the server automatically, see [Section 2.10.1.2, “Starting and Stopping MySQL Automatically”](#).

After you complete the procedure and have the server running, you should assign passwords to the accounts created by `mysql_install_db` and perhaps restrict access to test databases. For instructions, see [Section 2.10.2, “Securing the Initial MySQL Accounts”](#).

In the examples shown here, the server runs under the user ID of the `mysql` login account. This assumes that such an account exists. Either create the account if it does not exist, or substitute the name of a different existing login account that you plan to use for running the server. For information about creating the account, see [Creating a `mysql` System User and Group](#), in [Section 2.2, “Installing MySQL on Unix/Linux Using Generic Binaries”](#).

1. Change location into the top-level directory of your MySQL installation, represented here by `BASEDIR`:

```
shell> cd BASEDIR
```

`BASEDIR` is the installation directory for your MySQL instance. It is likely to be something like `/usr/local/mysql` or `/usr/local`. The following steps assume that you have changed location to this directory.

You will find several files and subdirectories in the `BASEDIR` directory. The most important for installation purposes are the `bin` and `scripts` subdirectories:

- The `bin` directory contains client programs and the server. You should add the full path name of this directory to your `PATH` environment variable so that your shell finds the MySQL programs properly. See [Section 2.12, “Environment Variables”](#).
 - The `scripts` directory contains the `mysql_install_db` script used to initialize the `mysql` database containing the grant tables that store the server access permissions.
2. If necessary, ensure that the distribution contents are accessible to `mysql`. If you installed the distribution as `mysql`, no further action is required. If you installed the distribution as `root`, its contents

will be owned by `root`. Change its ownership to `mysql` by executing the following commands as `root` in the installation directory. The first command changes the owner attribute of the files to the `mysql` user. The second changes the group attribute to the `mysql` group.

```
shell> chown -R mysql .
shell> chgrp -R mysql .
```

3. If necessary, run the `mysql_install_db` program to set up the initial MySQL grant tables containing the privileges that determine how users are permitted to connect to the server. You will need to do this if you used a distribution type for which the installation procedure does not run the program for you.

```
shell> scripts/mysql_install_db --user=mysql
```

Typically, `mysql_install_db` needs to be run only the first time you install MySQL, so you can skip this step if you are upgrading an existing installation. However, `mysql_install_db` does not overwrite any existing privilege tables, so it should be safe to run in any circumstances.

It might be necessary to specify other options such as `--basedir` or `--datadir` if `mysql_install_db` does not identify the correct locations for the installation directory or data directory. For example:

```
shell> scripts/mysql_install_db --user=mysql \
      --basedir=/opt/mysql/mysql \
      --datadir=/opt/mysql/mysql/data
```

The `mysql_install_db` script creates the server's data directory with `mysql` as the owner. Under the data directory, it creates directories for the `mysql` database that holds the grant tables and the `test` database that you can use to test MySQL. The script also creates privilege table entries for `root` and anonymous-user accounts. The accounts have no passwords initially. [Section 2.10.2, "Securing the Initial MySQL Accounts"](#), describes the initial privileges. Briefly, these privileges permit the MySQL `root` user to do anything, and permit anybody to create or use databases with a name of `test` or starting with `test_`. See [Section 6.2, "The MySQL Access Privilege System"](#), for a complete listing and description of the grant tables.

It is important to make sure that the database directories and files are owned by the `mysql` login account so that the server has read and write access to them when you run it later. To ensure this if you run `mysql_install_db` as `root`, include the `--user` option as shown. Otherwise, you should execute the script while logged in as `mysql`, in which case you can omit the `--user` option from the command.

If you do not want to have the `test` database, you can remove it after starting the server, using the instructions in [Section 2.10.2, "Securing the Initial MySQL Accounts"](#).

If you have trouble with `mysql_install_db` at this point, see [Section 2.10.1.1, "Problems Running mysql_install_db"](#).

4. Most of the MySQL installation can be owned by `root` if you like. The exception is that the data directory must be owned by `mysql`. To accomplish this, run the following commands as `root` in the installation directory:

```
shell> chown -R root .
shell> chown -R mysql data
```

5. If the plugin directory (the directory named by the `plugin_dir` system variable) is writable by the server, it may be possible for a user to write executable code to a file in the directory using

`SELECT ... INTO DUMPFILE`. This can be prevented by making `plugin_dir` read only to the server or by setting `--secure-file-priv` to a directory where `SELECT` writes can be made safely.

6. If you installed MySQL using a source distribution, you may want to optionally copy one of the provided configuration files from the `support-files` directory into your `/etc` directory. There are different sample configuration files for different use cases, server types, and CPU and RAM configurations. If you want to use one of these standard files, you should copy it to `/etc/my.cnf`, or `/etc/mysql/my.cnf` and edit and check the configuration before starting your MySQL server for the first time.

If you do not copy one of the standard configuration files, the MySQL server will be started with the default settings.

If you want MySQL to start automatically when you boot your machine, you can copy `support-files/mysql.server` to the location where your system has its startup files. More information can be found in the `mysql.server` script itself, and in [Section 2.10.1.2, “Starting and Stopping MySQL Automatically”](#).

7. Start the MySQL server:

```
shell> bin/mysqld_safe --user=mysql &
```

It is important that the MySQL server be run using an unprivileged (non-`root`) login account. To ensure this if you run `mysqld_safe` as `root`, include the `--user` option as shown. Otherwise, you should execute the script while logged in as `mysql`, in which case you can omit the `--user` option from the command.

For further instructions for running MySQL as an unprivileged user, see [Section 6.1.5, “How to Run MySQL as a Normal User”](#).

If the command fails immediately and prints `mysqld ended`, look for information in the error log (which by default is the `host_name.err` file in the data directory).

If you neglected to create the grant tables by running `mysql_install_db` before proceeding to this step, the following message appears in the error log file when you start the server:

```
mysqld: Can't find file: 'host.frm'
```

This error also occurs if you run `mysql_install_db` as `root` without the `--user` option. Remove the `data` directory and run `mysql_install_db` with the `--user` option as described previously.

If you have other problems starting the server, see [Section 2.10.1.3, “Starting and Troubleshooting the MySQL Server”](#). For more information about `mysqld_safe`, see [Section 4.3.2, “mysqld_safe — MySQL Server Startup Script”](#).

8. Use `mysqladmin` to verify that the server is running. The following commands provide simple tests to check whether the server is up and responding to connections:

```
shell> bin/mysqladmin version
shell> bin/mysqladmin variables
```

The output from `mysqladmin version` varies slightly depending on your platform and version of MySQL, but should be similar to that shown here:

```
shell> bin/mysqladmin version
mysqladmin Ver 14.12 Distrib 5.5.40, for pc-linux-gnu on i686
```

```
...
Server version          5.5.40
Protocol version        10
Connection              Localhost via UNIX socket
UNIX socket             /var/lib/mysql/mysql.sock
Uptime:                 14 days 5 hours 5 min 21 sec

Threads: 1  Questions: 366  Slow queries: 0
Opens: 0  Flush tables: 1  Open tables: 19
Queries per second avg: 0.000
```

To see what else you can do with `mysqladmin`, invoke it with the `--help` option.

9. Verify that you can shut down the server:

```
shell> bin/mysqladmin -u root shutdown
```

10. Verify that you can start the server again. Do this by using `mysqld_safe` or by invoking `mysqld` directly. For example:

```
shell> bin/mysqld_safe --user=mysql &
```

If `mysqld_safe` fails, see [Section 2.10.1.3, “Starting and Troubleshooting the MySQL Server”](#).

11. Run some simple tests to verify that you can retrieve information from the server. The output should be similar to what is shown here:

```
shell> bin/mysqlshow
+-----+
|      Databases      |
+-----+
| information_schema |
| mysql              |
| test               |
+-----+

shell> bin/mysqlshow mysql
Database: mysql
+-----+
|      Tables      |
+-----+
| columns_priv      |
| db                 |
| event             |
| func              |
| help_category      |
| help_keyword       |
| help_relation      |
| help_topic         |
| host               |
| plugin             |
| proc               |
| procs_priv         |
| servers            |
| tables_priv        |
| time_zone          |
| time_zone_leap_second |
| time_zone_name     |
| time_zone_transition |
| time_zone_transition_type |
| user               |
+-----+
```

```
shell> bin/mysql -e "SELECT Host,Db,User FROM db" mysql
```

host	db	user
%	test	
%	test_%	

12. There is a benchmark suite in the `sql-bench` directory (under the MySQL installation directory) that you can use to compare how MySQL performs on different platforms. The benchmark suite is written in Perl. It requires the Perl DBI module that provides a database-independent interface to the various databases, and some other additional Perl modules:

```
DBI
DBD::mysql
Data::Dumper
Data::ShowTable
```

These modules can be obtained from CPAN (<http://www.cpan.org/>). See also [Section 2.13.1, “Installing Perl on Unix”](#).

The `sql-bench/Results` directory contains the results from many runs against different databases and platforms. To run all tests, execute these commands:

```
shell> cd sql-bench
shell> perl run-all-tests
```

If you do not have the `sql-bench` directory, you probably installed MySQL using RPM files other than the source RPM. (The source RPM includes the `sql-bench` benchmark directory.) In this case, you must first install the benchmark suite before you can use it. There are separate benchmark RPM files named `mysql-bench-VERSION.i386.rpm` that contain benchmark code and data.

If you have a source distribution, there are also tests in its `tests` subdirectory that you can run. For example, to run `auto_increment.tst`, execute this command from the top-level directory of your source distribution:

```
shell> mysql -vtf test < ./tests/auto_increment.tst
```

The expected result of the test can be found in the `./tests/auto_increment.res` file.

13. At this point, you should have the server running. However, none of the initial MySQL accounts have a password, and the server permits permissive access to test databases. To tighten security, follow the instructions in [Section 2.10.2, “Securing the Initial MySQL Accounts”](#).

The MySQL 5.5 installation procedure creates time zone tables in the `mysql` database but does not populate them. To do so, use the instructions in [Section 10.6, “MySQL Server Time Zone Support”](#).

To make it more convenient to invoke programs installed in the `bin` directory under the installation directory, you can add that directory to your `PATH` environment variable setting. That enables you to run a program by typing only its name, not its entire path name. See [Section 4.2.10, “Setting Environment Variables”](#).

You can set up new accounts using the `bin/mysql_setpermission` script if you install the `DBI` and `DBD::mysql` Perl modules. See [Section 4.6.13, “mysql_setpermission — Interactively Set Permissions in Grant Tables”](#). For Perl module installation instructions, see [Section 2.13, “Perl Installation Notes”](#).

If you would like to use `mysqlaccess` and have the MySQL distribution in some nonstandard location, you must change the location where `mysqlaccess` expects to find the `mysql` client. Edit the `bin/mysqlaccess` script at approximately line 18. Search for a line that looks like this:

```
$MYSQL = '/usr/local/bin/mysql'; # path to mysql executable
```

Change the path to reflect the location where `mysql` actually is stored on your system. If you do not do this, a `Broken pipe` error will occur when you run `mysqlaccess`.

2.10.1.1 Problems Running `mysql_install_db`

The purpose of the `mysql_install_db` script is to generate new MySQL privilege tables. It does not overwrite existing MySQL privilege tables, and it does not affect any other data.

If you want to re-create your privilege tables, first stop the `mysqld` server if it is running. Then rename the `mysql` directory under the data directory to save it, and then run `mysql_install_db`. Suppose that your current directory is the MySQL installation directory and that `mysql_install_db` is located in the `bin` directory and the data directory is named `data`. To rename the `mysql` database and re-run `mysql_install_db`, use these commands.

```
shell> mv data/mysql data/mysql.old
shell> scripts/mysql_install_db --user=mysql
```

When you run `mysql_install_db`, you might encounter the following problems:

- **`mysql_install_db` fails to install the grant tables**

You may find that `mysql_install_db` fails to install the grant tables and terminates after displaying the following messages:

```
Starting mysqld daemon with databases from XXXXXX
mysqld ended
```

In this case, you should examine the error log file very carefully. The log should be located in the directory `XXXXXX` named by the error message and should indicate why `mysqld` did not start. If you do not understand what happened, include the log when you post a bug report. See [Section 1.7, “How to Report Bugs or Problems”](#).

- **There is a `mysqld` process running**

This indicates that the server is running, in which case the grant tables have probably been created already. If so, there is no need to run `mysql_install_db` at all because it needs to be run only once (when you install MySQL the first time).

- **Installing a second `mysqld` server does not work when one server is running**

This can happen when you have an existing MySQL installation, but want to put a new installation in a different location. For example, you might have a production installation, but you want to create a second installation for testing purposes. Generally the problem that occurs when you try to run a second server is that it tries to use a network interface that is in use by the first server. In this case, you should see one of the following error messages:

```
Can't start server: Bind on TCP/IP port:
Address already in use
Can't start server: Bind on unix socket...
```

For instructions on setting up multiple servers, see [Section 5.3, “Running Multiple MySQL Instances on One Machine”](#).

- **You do not have write access to the `/tmp` directory**

If you do not have write access to create temporary files or a Unix socket file in the default location (the `/tmp` directory) or the `TMP_DIR` environment variable, if it has been set, an error occurs when you run `mysql_install_db` or the `mysqld` server.

You can specify different locations for the temporary directory and Unix socket file by executing these commands prior to starting `mysql_install_db` or `mysqld`, where *some_tmp_dir* is the full path name to some directory for which you have write permission:

```
shell> TMPDIR=/some_tmp_dir/
shell> MYSQL_UNIX_PORT=/some_tmp_dir/mysql.sock
shell> export TMPDIR MYSQL_UNIX_PORT
```

Then you should be able to run `mysql_install_db` and start the server with these commands:

```
shell> scripts/mysql_install_db --user=mysql
shell> bin/mysqld_safe --user=mysql &
```

If `mysql_install_db` is located in the `scripts` directory, modify the first command to `scripts/mysql_install_db`.

See [Section B.5.4.5, “How to Protect or Change the MySQL Unix Socket File”](#), and [Section 2.12, “Environment Variables”](#).

There are some alternatives to running the `mysql_install_db` script provided in the MySQL distribution:

- If you want the initial privileges to be different from the standard defaults, you can modify `mysql_install_db` before you run it. However, it is preferable to use `GRANT` and `REVOKE` to change the privileges *after* the grant tables have been set up. In other words, you can run `mysql_install_db`, and then use `mysql -u root mysql` to connect to the server as the MySQL `root` user so that you can issue the necessary `GRANT` and `REVOKE` statements.

If you want to install MySQL on several machines with the same privileges, you can put the `GRANT` and `REVOKE` statements in a file and execute the file as a script using `mysql` after running `mysql_install_db`. For example:

```
shell> scripts/mysql_install_db --user=mysql
shell> bin/mysql -u root < your_script_file
```

By doing this, you can avoid having to issue the statements manually on each machine.

- It is possible to re-create the grant tables completely after they have previously been created. You might want to do this if you are just learning how to use `GRANT` and `REVOKE` and have made so many modifications after running `mysql_install_db` that you want to wipe out the tables and start over.

To re-create the grant tables, remove all the `.frm`, `.MYI`, and `.MYD` files in the `mysql` database directory. Then run the `mysql_install_db` script again.

- You can start `mysqld` manually using the `--skip-grant-tables` option and add the privilege information yourself using `mysql`:

```
shell> bin/mysqld_safe --user=mysql --skip-grant-tables &  
shell> bin/mysql mysql
```

From `mysql`, manually execute the SQL commands contained in `mysql_install_db`. Make sure that you run `mysqladmin flush-privileges` or `mysqladmin reload` afterward to tell the server to reload the grant tables.

Note that by not using `mysql_install_db`, you not only have to populate the grant tables manually, you also have to create them first.

2.10.1.2 Starting and Stopping MySQL Automatically

Generally, you start the `mysqld` server in one of these ways:

- Invoke `mysqld` directly. This works on any platform.
- Invoke `mysqld_safe`, which tries to determine the proper options for `mysqld` and then runs it with those options. This script is used on Unix and Unix-like systems. See [Section 4.3.2, “mysqld_safe — MySQL Server Startup Script”](#).
- Invoke `mysql.server`. This script is used primarily at system startup and shutdown on systems that use System V-style run directories (that is, `/etc/init.d` and run-level specific directories), where it usually is installed under the name `mysql`. The `mysql.server` script starts the server by invoking `mysqld_safe`. See [Section 4.3.3, “mysql.server — MySQL Server Startup Script”](#).
- On Mac OS X, install a separate MySQL Startup Item package to enable the automatic startup of MySQL on system startup. The Startup Item starts the server by invoking `mysql.server`. See [Section 2.4.3, “Installing the MySQL Startup Item”](#), for details. A MySQL Preference Pane also provides control for starting and stopping MySQL through the System Preferences, see [Section 2.4.4, “Installing and Using the MySQL Preference Pane”](#).
- Use the Solaris/OpenSolaris service management framework (SMF) system to initiate and control MySQL startup. For more information, see [Section 2.7.2, “Installing MySQL on OpenSolaris Using IPS”](#).

The `mysqld_safe` and `mysql.server` scripts, Solaris/OpenSolaris SMF, and the Mac OS X Startup Item (or MySQL Preference Pane) can be used to start the server manually, or automatically at system startup time. `mysql.server` and the Startup Item also can be used to stop the server.

To start or stop the server manually using the `mysql.server` script, invoke it with `start` or `stop` arguments:

```
shell> mysql.server start  
shell> mysql.server stop
```

Before `mysql.server` starts the server, it changes location to the MySQL installation directory, and then invokes `mysqld_safe`. If you want the server to run as some specific user, add an appropriate `user` option to the `[mysqld]` group of the `/etc/my.cnf` option file, as shown later in this section. (It is possible that you will need to edit `mysql.server` if you've installed a binary distribution of MySQL in a nonstandard location. Modify it to change location into the proper directory before it runs `mysqld_safe`. If you do this, your modified version of `mysql.server` may be overwritten if you upgrade MySQL in the future, so you should make a copy of your edited version that you can reinstall.)

`mysql.server stop` stops the server by sending a signal to it. You can also stop the server manually by executing `mysqladmin shutdown`.

To start and stop MySQL automatically on your server, you need to add start and stop commands to the appropriate places in your `/etc/rc*` files.

If you use the Linux server RPM package (`MySQL-server-VERSION.rpm`), or a native Linux package installation, the `mysql.server` script may be installed in the `/etc/init.d` directory with the name `mysql`. See [Section 2.5.1, “Installing MySQL on Linux Using RPM Packages”](#), for more information on the Linux RPM packages.

Some vendors provide RPM packages that install a startup script under a different name such as `mysqld`.

If you install MySQL from a source distribution or using a binary distribution format that does not install `mysql.server` automatically, you can install it manually. The script can be found in the `support-files` directory under the MySQL installation directory or in a MySQL source tree.

To install `mysql.server` manually, copy it to the `/etc/init.d` directory with the name `mysql`, and then make it executable. Do this by changing location into the appropriate directory where `mysql.server` is located and executing these commands:

```
shell> cp mysql.server /etc/init.d/mysql
shell> chmod +x /etc/init.d/mysql
```

**Note**

Older Red Hat systems use the `/etc/rc.d/init.d` directory rather than `/etc/init.d`. Adjust the preceding commands accordingly. Alternatively, first create `/etc/init.d` as a symbolic link that points to `/etc/rc.d/init.d`:

```
shell> cd /etc
shell> ln -s rc.d/init.d .
```

After installing the script, the commands needed to activate it to run at system startup depend on your operating system. On Linux, you can use `chkconfig`:

```
shell> chkconfig --add mysql
```

On some Linux systems, the following command also seems to be necessary to fully enable the `mysql` script:

```
shell> chkconfig --level 345 mysql on
```

On FreeBSD, startup scripts generally should go in `/usr/local/etc/rc.d/`. The `rc(8)` manual page states that scripts in this directory are executed only if their basename matches the `*.sh` shell file name pattern. Any other files or directories present within the directory are silently ignored. In other words, on FreeBSD, you should install the `mysql.server` script as `/usr/local/etc/rc.d/mysql.server.sh` to enable automatic startup.

As an alternative to the preceding setup, some operating systems also use `/etc/rc.local` or `/etc/init.d/boot.local` to start additional services on startup. To start up MySQL using this method, you could append a command like the one following to the appropriate startup file:

```
/bin/sh -c 'cd /usr/local/mysql; ./bin/mysqld_safe --user=mysql &'
```

For other systems, consult your operating system documentation to see how to install startup scripts.

You can add options for `mysql.server` in a global `/etc/my.cnf` file. A typical `/etc/my.cnf` file might look like this:

```
[mysqld]
datadir=/usr/local/mysql/var
```

```
socket=/var/tmp/mysql.sock
port=3306
user=mysql

[mysql.server]
basedir=/usr/local/mysql
```

The `mysql.server` script supports the following options: `basedir`, `datadir`, and `pid-file`. If specified, they *must* be placed in an option file, not on the command line. `mysql.server` supports only `start` and `stop` as command-line arguments.

The following table shows which option groups the server and each startup script read from option files.

Table 2.17 MySQL Startup scripts and supported server option groups

Script	Option Groups
<code>mysqld</code>	<code>[mysqld]</code> , <code>[server]</code> , <code>[mysqld-major_version]</code>
<code>mysqld_safe</code>	<code>[mysqld]</code> , <code>[server]</code> , <code>[mysqld_safe]</code>
<code>mysql.server</code>	<code>[mysqld]</code> , <code>[mysql.server]</code> , <code>[server]</code>

`[mysqld-major_version]` means that groups with names like `[mysqld-5.1]` and `[mysqld-5.5]` are read by servers having versions 5.1.x, 5.5.x, and so forth. This feature can be used to specify options that can be read only by servers within a given release series.

For backward compatibility, `mysql.server` also reads the `[mysql_server]` group and `mysqld_safe` also reads the `[safe_mysqld]` group. However, you should update your option files to use the `[mysql.server]` and `[mysqld_safe]` groups instead when using MySQL 5.5.

For more information on MySQL configuration files and their structure and contents, see [Section 4.2.6, “Using Option Files”](#).

2.10.1.3 Starting and Troubleshooting the MySQL Server

This section provides troubleshooting suggestions for problems starting the server on a Unix-like system. If you are using Windows, see [Section 2.3.8, “Troubleshooting a Microsoft Windows MySQL Server Installation”](#).

If you have problems starting the server, here are some things to try:

- Check the error log to see why the server does not start.
- Specify any special options needed by the storage engines you are using.
- Make sure that the server knows where to find the data directory.
- Make sure that the server can access the data directory. The ownership and permissions of the data directory and its contents must be set such that the server can read and modify them.
- Verify that the network interfaces the server wants to use are available.

Some storage engines have options that control their behavior. You can create a `my.cnf` file and specify startup options for the engines that you plan to use. If you are going to use storage engines that support transactional tables ([InnoDB](#), [NDB](#)), be sure that you have them configured the way you want before starting the server:

If you are using [InnoDB](#) tables, see [Section 14.6, “InnoDB Configuration”](#).

Storage engines will use default option values if you specify none, but it is recommended that you review the available options and specify explicit values for those for which the defaults are not appropriate for your installation.

When the `mysqld` server starts, it changes location to the data directory. This is where it expects to find databases and where it expects to write log files. The server also writes the pid (process ID) file in the data directory.

The data directory location is hardwired in when the server is compiled. This is where the server looks for the data directory by default. If the data directory is located somewhere else on your system, the server will not work properly. You can determine what the default path settings are by invoking `mysqld` with the `--verbose` and `--help` options.

If the default locations do not match the MySQL installation layout on your system, you can override them by specifying options to `mysqld` or `mysqld_safe` on the command line or in an option file.

To specify the location of the data directory explicitly, use the `--datadir` option. However, normally you can tell `mysqld` the location of the base directory under which MySQL is installed and it looks for the data directory there. You can do this with the `--basedir` option.

To check the effect of specifying path options, invoke `mysqld` with those options followed by the `--verbose` and `--help` options. For example, if you change location into the directory where `mysqld` is installed and then run the following command, it shows the effect of starting the server with a base directory of `/usr/local`:

```
shell> ./mysqld --basedir=/usr/local --verbose --help
```

You can specify other options such as `--datadir` as well, but `--verbose` and `--help` must be the last options.

Once you determine the path settings you want, start the server without `--verbose` and `--help`.

If `mysqld` is currently running, you can find out what path settings it is using by executing this command:

```
shell> mysqladmin variables
```

Or:

```
shell> mysqladmin -h host_name variables
```

`host_name` is the name of the MySQL server host.

If you get `Errcode 13` (which means `Permission denied`) when starting `mysqld`, this means that the privileges of the data directory or its contents do not permit server access. In this case, you change the permissions for the involved files and directories so that the server has the right to use them. You can also start the server as `root`, but this raises security issues and should be avoided.

Change location into the data directory and check the ownership of the data directory and its contents to make sure the server has access. For example, if the data directory is `/usr/local/mysql/var`, use this command:

```
shell> ls -la /usr/local/mysql/var
```

If the data directory or its files or subdirectories are not owned by the login account that you use for running the server, change their ownership to that account. If the account is named `mysql`, use these commands:

```
shell> chown -R mysql /usr/local/mysql/var
shell> chgrp -R mysql /usr/local/mysql/var
```

If it possible that even with correct ownership, MySQL may fail to start up if there is other security software running on your system that manages application access to various parts of the file system. In this case, you may need to reconfigure that software to enable `mysqld` to access the directories it uses during normal operation.

If the server fails to start up correctly, check the error log. Log files are located in the data directory (typically `C:\Program Files\MySQL\MySQL Server 5.5\data` on Windows, `/usr/local/mysql/data` for a Unix/Linux binary distribution, and `/usr/local/var` for a Unix/Linux source distribution). Look in the data directory for files with names of the form `host_name.err` and `host_name.log`, where `host_name` is the name of your server host. Then examine the last few lines of these files. You can use `tail` to display them:

```
shell> tail host_name.err
shell> tail host_name.log
```

The error log should contain information that indicates why the server could not start.

If either of the following errors occur, it means that some other program (perhaps another `mysqld` server) is using the TCP/IP port or Unix socket file that `mysqld` is trying to use:

```
Can't start server: Bind on TCP/IP port: Address already in use
Can't start server: Bind on unix socket...
```

Use `ps` to determine whether you have another `mysqld` server running. If so, shut down the server before starting `mysqld` again. (If another server is running, and you really want to run multiple servers, you can find information about how to do so in [Section 5.3, "Running Multiple MySQL Instances on One Machine"](#).)

If no other server is running, try to execute the command `telnet your_host_name tcp_ip_port_number`. (The default MySQL port number is 3306.) Then press Enter a couple of times. If you do not get an error message like `telnet: Unable to connect to remote host: Connection refused`, some other program is using the TCP/IP port that `mysqld` is trying to use. You will need to track down what program this is and disable it, or else tell `mysqld` to listen to a different port with the `--port` option. In this case, you will also need to specify the port number for client programs when connecting to the server using TCP/IP.

Another reason the port might be inaccessible is that you have a firewall running that blocks connections to it. If so, modify the firewall settings to permit access to the port.

If the server starts but you cannot connect to it, you should make sure that you have an entry in `/etc/hosts` that looks like this:

```
127.0.0.1      localhost
```

If you cannot get `mysqld` to start, you can try to make a trace file to find the problem by using the `--debug` option. See [Section 24.4.3, "The DBUG Package"](#).

2.10.2 Securing the Initial MySQL Accounts

Part of the MySQL installation process is to set up the `mysql` database that contains the grant tables:

- Windows distributions contain preinitialized grant tables.
- On Unix, the `mysql_install_db` program populates the grant tables. Some installation methods run this program for you. Others require that you execute it manually. For details, see [Section 2.10.1, "Postinstallation Procedures for Unix-like Systems"](#).

The `mysql.user` grant table defines the initial MySQL user accounts and their access privileges:

- Some accounts have the user name `root`. These are superuser accounts that have all privileges and can do anything. The initial `root` account passwords are empty, so anyone can connect to the MySQL server as `root` without a password and be granted all privileges.
- On Windows, `root` accounts are created that permit connections from the local host only. Connections can be made by specifying the host name `localhost`, the IP address `127.0.0.1`, or the IPv6 address `::1`. If the user selects the **Enable root access from remote machines** option during installation, the Windows installer creates another `root` account that permits connections from any host.
- On Unix, each `root` account permits connections from the local host. Connections can be made by specifying the host name `localhost`, the IP address `127.0.0.1`, the IPv6 address `::1`, or the actual host name or IP address.

An attempt to connect to the host `127.0.0.1` normally resolves to the `localhost` account. However, this fails if the server is run with the `--skip-name-resolve` option, so the `127.0.0.1` account is useful in that case. The `::1` account is used for IPv6 connections.

- Some accounts are for anonymous users. These have an empty user name. The anonymous accounts have no password, so anyone can use them to connect to the MySQL server.
- On Windows, there is one anonymous account that permits connections from the local host. Connections can be made by specifying a host name of `localhost`.
- On Unix, each anonymous account permits connections from the local host. Connections can be made by specifying a host name of `localhost` for one of the accounts, or the actual host name or IP address for the other.

To display which accounts exist in the `mysql.user` table and check whether their passwords are empty, use the following statement:

```
mysql> SELECT User, Host, Password FROM mysql.user;
```

User	Host	Password
root	localhost	
root	myhost.example.com	
root	127.0.0.1	
root	::1	
	localhost	
	myhost.example.com	

This output indicates that there are several `root` and anonymous-user accounts, none of which have passwords. The output might differ on your system, but the presence of accounts with empty passwords means that your MySQL installation is unprotected until you do something about it:

- You should assign a password to each MySQL `root` account.
- If you want to prevent clients from connecting as anonymous users without a password, you should either assign a password to each anonymous account or else remove the accounts.

In addition, the `mysql.db` table contains rows that permit all accounts to access the `test` database and other databases with names that start with `test_`. This is true even for accounts that otherwise have no special privileges such as the default anonymous accounts. This is convenient for testing but inadvisable on production servers. Administrators who want database access restricted only to accounts that have permissions granted explicitly for that purpose should remove these `mysql.db` table rows.

The following instructions describe how to set up passwords for the initial MySQL accounts, first for the `root` accounts, then for the anonymous accounts. The instructions also cover how to remove the anonymous accounts, should you prefer not to permit anonymous access at all, and describe how to remove permissive access to test databases. Replace `newpwd` in the examples with the password that you want to use. Replace `host_name` with the name of the server host. You can determine this name from the output of the preceding `SELECT` statement. For the output shown, `host_name` is `myhost.example.com`.

Note

For additional information about setting passwords, see [Section 6.3.5, “Assigning Account Passwords”](#). If you forget your `root` password after setting it, see [Section B.5.4.1, “How to Reset the Root Password”](#).

You might want to defer setting the passwords until later, to avoid the need to specify them while you perform additional setup or testing. However, be sure to set them before using your installation for production purposes.

To set up additional accounts, see [Section 6.3.2, “Adding User Accounts”](#).

Assigning `root` Account Passwords

The `root` account passwords can be set several ways. The following discussion demonstrates three methods:

- Use the `SET PASSWORD` statement
- Use the `UPDATE` statement
- Use the `mysqladmin` command-line client program

To assign passwords using `SET PASSWORD`, connect to the server as `root` and issue a `SET PASSWORD` statement for each `root` account listed in the `mysql.user` table. Be sure to encrypt the password using the `PASSWORD()` function.

For Windows, do this:

```
shell> mysql -u root
mysql> SET PASSWORD FOR 'root'@'localhost' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR 'root'@'127.0.0.1' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR 'root'@':::1' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR 'root'@'%' = PASSWORD('newpwd');
```

The last statement is unnecessary if the `mysql.user` table has no `root` account with a host value of `%`.

For Unix, do this:

```
shell> mysql -u root
mysql> SET PASSWORD FOR 'root'@'localhost' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR 'root'@'127.0.0.1' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR 'root'@':::1' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR 'root'@'host_name' = PASSWORD('newpwd');
```

You can also use a single statement that assigns a password to all `root` accounts by using `UPDATE` to modify the `mysql.user` table directly. This method works on any platform:

```
shell> mysql -u root
mysql> UPDATE mysql.user SET Password = PASSWORD('newpwd')
```

```
-> WHERE User = 'root';
mysql> FLUSH PRIVILEGES;
```

The `FLUSH` statement causes the server to reread the grant tables. Without it, the password change remains unnoticed by the server until you restart it.

To assign passwords to the `root` accounts using `mysqladmin`, execute the following commands:

```
shell> mysqladmin -u root password "newpwd"
shell> mysqladmin -u root -h host_name password "newpwd"
```

Those commands apply both to Windows and to Unix. The double quotation marks around the password are not always necessary, but you should use them if the password contains spaces or other characters that are special to your command interpreter.

The `mysqladmin` method of setting the `root` account passwords does not work for the `'root'@'127.0.0.1'` or `'root'@':::1'` account. Use the `SET PASSWORD` method shown earlier.

After the `root` passwords have been set, you must supply the appropriate password whenever you connect as `root` to the server. For example, to shut down the server with `mysqladmin`, use this command:

```
shell> mysqladmin -u root -p shutdown
Enter password: (enter root password here)
```

Assigning Anonymous Account Passwords

The `mysql` commands in the following instructions include a `-p` option based on the assumption that you have set the `root` account passwords using the preceding instructions and must specify that password when connecting to the server.

To assign passwords to the anonymous accounts, connect to the server as `root`, then use either `SET PASSWORD` or `UPDATE`. Be sure to encrypt the password using the `PASSWORD()` function.

To use `SET PASSWORD` on Windows, do this:

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> SET PASSWORD FOR ''@'localhost' = PASSWORD('newpwd');
```

To use `SET PASSWORD` on Unix, do this:

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> SET PASSWORD FOR ''@'localhost' = PASSWORD('newpwd');
mysql> SET PASSWORD FOR ''@'host_name' = PASSWORD('newpwd');
```

To set the anonymous-user account passwords with a single `UPDATE` statement, do this (on any platform):

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> UPDATE mysql.user SET Password = PASSWORD('newpwd')
-> WHERE User = '';
mysql> FLUSH PRIVILEGES;
```

The `FLUSH` statement causes the server to reread the grant tables. Without it, the password change remains unnoticed by the server until you restart it.

Removing Anonymous Accounts

If you prefer to remove any anonymous accounts rather than assigning them passwords, do so as follows on Windows:

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> DROP USER '@'localhost';
```

On Unix, remove the anonymous accounts like this:

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> DROP USER '@'localhost';
mysql> DROP USER '@'host_name';
```

Securing Test Databases

By default, the `mysql.db` table contains rows that permit access by any user to the `test` database and other databases with names that start with `test_`. (These rows have an empty `User` column value, which for access-checking purposes matches any user name.) This means that such databases can be used even by accounts that otherwise possess no privileges. If you want to remove any-user access to test databases, do so as follows:

```
shell> mysql -u root -p
Enter password: (enter root password here)
mysql> DELETE FROM mysql.db WHERE Db LIKE 'test%';
mysql> FLUSH PRIVILEGES;
```

The `FLUSH` statement causes the server to reread the grant tables. Without it, the privilege change remains unnoticed by the server until you restart it.

With the preceding change, only users who have global database privileges or privileges granted explicitly for the `test` database can use it. However, if you do not want the database to exist at all, drop it:

```
mysql> DROP DATABASE test;
```

Note

On Windows, you can also perform the process described in this section using the Configuration Wizard (see [Section 2.3.6.11, “The Security Options Dialog”](#)). On all platforms, the MySQL distribution includes `mysql_secure_installation`, a command-line utility that automates much of the process of securing a MySQL installation.

2.11 Upgrading or Downgrading MySQL

2.11.1 Upgrading MySQL

As a general rule, to upgrade from one release series to another, go to the next series rather than skipping a series. To upgrade from a release series previous to MySQL 5.1, upgrade to each successive release series in turn until you have reached MySQL 5.1, and then proceed with the upgrade to MySQL 5.5. For example, if you currently are running MySQL 5.0 and wish to upgrade to a newer series, upgrade to MySQL 5.1 first before upgrading to 5.5, and so forth. For information on upgrading to MySQL 5.1, see the *MySQL 5.1 Reference Manual*.

There is a special case for upgrading to MySQL 5.5, which is that there was a short-lived MySQL 5.4 development series. This series is no longer being worked on, but to accommodate users of both series, this section includes one subsection for users upgrading from MySQL 5.1 to 5.5 and another for users upgrading from MySQL 5.4 to 5.5.

To upgrade to MySQL 5.5, use the items in the following checklist as a guide:

- Before any upgrade, back up your databases, including the `mysql` database that contains the grant tables. See [Section 7.2, “Database Backup Methods”](#).
- Read *all* the notes in [Section 2.11.1.1, “Upgrading from MySQL 5.1 to 5.5”](#), or [Section 2.11.1.2, “Upgrading from MySQL 5.4 to 5.5”](#), depending on whether you currently use MySQL 5.1 or 5.4. These notes enable you to identify upgrade issues that apply to your current MySQL installation. Some incompatibilities discussed in that section require your attention *before* upgrading. Others should be dealt with *after* upgrading.
- Read the [Release Notes](#) as well, which provide information about features that are new in MySQL 5.5 or differ from those found in earlier MySQL releases.
- After upgrading to a new version of MySQL, run `mysql_upgrade` (see [Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”](#)). This program checks your tables, and attempts to repair them if necessary. It also updates your grant tables to make sure that they have the current structure so that you can take advantage of any new capabilities. (Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features.)

`mysql_upgrade` does not upgrade the contents of the help tables. For upgrade instructions, see [Section 5.1.10, “Server-Side Help”](#).

- If you run MySQL Server on Windows, see [Section 2.3.9, “Upgrading MySQL on Windows”](#).
- If you use replication, see [Section 17.4.3, “Upgrading a Replication Setup”](#), for information on upgrading your replication setup.
- If you use InnoDB, consider setting `innodb_fast_shutdown` to 0 before shutting down and upgrading your server. When you set `innodb_fast_shutdown` to 0, InnoDB does a slow shutdown, a full purge and an insert buffer merge before shutting down, which ensures that all data files are fully prepared in case the upgrade process modifies the file format.
- If you upgrade an installation originally produced by installing multiple RPM packages, it is best to upgrade all the packages, not just some. For example, if you previously installed the server and client RPMs, do not upgrade just the server RPM.
- If you have created a user-defined function (UDF) with a given name and upgrade MySQL to a version that implements a new built-in function with the same name, the UDF becomes inaccessible. To correct this, use `DROP FUNCTION` to drop the UDF, and then use `CREATE FUNCTION` to re-create the UDF with a different nonconflicting name. The same is true if the new version of MySQL implements a built-in function with the same name as an existing stored function. See [Section 9.2.4, “Function Name Parsing and Resolution”](#), for the rules describing how the server interprets references to different kinds of functions.

For upgrades between versions of a MySQL release series that has reached General Availability status, you can move the MySQL format files and data files between different versions on systems with the same architecture. For upgrades to a version of a MySQL release series that is in development status, that is not necessarily true. Use of development releases is at your own risk.

If you are cautious about using new versions, you can always rename your old `mysqld` before installing a newer one. For example, if you are using a version of MySQL 5.1 and want to upgrade to 5.5, rename your

current server from `mysqld` to `mysqld-5.1`. If your new `mysqld` then does something unexpected, you can simply shut it down and restart with your old `mysqld`.

If problems occur, such as that the new `mysqld` server does not start or that you cannot connect without a password, verify that you do not have an old `my.cnf` file from your previous installation. You can check this with the `--print-defaults` option (for example, `mysqld --print-defaults`). If this command displays anything other than the program name, you have an active `my.cnf` file that affects server or client operation.

If, after an upgrade, you experience problems with compiled client programs, such as `Commands out of sync` or unexpected core dumps, you probably have used old header or library files when compiling your programs. In this case, you should check the date for your `mysql.h` file and `libmysqlclient.a` library to verify that they are from the new MySQL distribution. If not, recompile your programs with the new headers and libraries. Recompile might also be necessary for programs compiled against the shared client library if the library major version number has changed (for example from `libmysqlclient.so.15` to `libmysqlclient.so.16`).

If your MySQL installation contains a large amount of data that might take a long time to convert after an in-place upgrade, you might find it useful to create a “dummy” database instance for assessing what conversions might be needed and the work involved to perform them. Make a copy of your MySQL instance that contains a full copy of the `mysql` database, plus all other databases without data. Run your upgrade procedure on this dummy instance to see what actions might be needed so that you can better evaluate the work involved when performing actual data conversion on your original database instance.

It is a good idea to rebuild and reinstall the Perl `DBD:mysql` module whenever you install a new release of MySQL. The same applies to other MySQL interfaces as well, such as PHP `mysql` extensions and the Python `MySQLdb` module.

2.11.1.1 Upgrading from MySQL 5.1 to 5.5

Note

It is good practice to back up your data before installing any new version of software. Although MySQL works very hard to ensure a high level of quality, you should protect your data by making a backup.

To upgrade to 5.5 from any previous version, MySQL recommends that you dump your tables with `mysqldump` before upgrading and reload the dump file after upgrading. Use the `--all-databases` option to include all databases in the dump. If your databases include stored programs, use the `--routines` and `--events` options as well.

In general, you should do the following when upgrading from MySQL 5.1 to 5.5:

- Read *all* the items in these sections to see whether any of them might affect your applications:
 - [Section 2.11.1, “Upgrading MySQL”](#), has general update information.
 - The items in the change lists provided later in this section enable you to identify upgrade issues that apply to your current MySQL installation. Some incompatibilities discussed there require your attention *before* upgrading. Others should be dealt with *after* upgrading.
 - The MySQL 5.5 [Release Notes](#) describe significant new features you can use in 5.5 or that differ from those found in earlier MySQL releases. Some of these changes may result in incompatibilities.

Note particularly any changes that are marked **Known issue** or **Incompatible change**. These incompatibilities with earlier versions of MySQL may require your attention *before you upgrade*. Our aim

is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases. If any upgrade issue applicable to your installation involves an incompatibility that requires special handling, follow the instructions given in the incompatibility description. Sometimes this involves dumping and reloading tables, or use of a statement such as `CHECK TABLE` or `REPAIR TABLE`.

For dump and reload instructions, see [Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”](#). Any procedure that involves `REPAIR TABLE` with the `USE_FRM` option *must* be done before upgrading. Use of this statement with a version of MySQL different from the one used to create the table (that is, using it after upgrading) may damage the table. See [Section 13.7.2.5, “REPAIR TABLE Syntax”](#).

- Before upgrading to a new version of MySQL, [Section 2.11.3, “Checking Whether Tables or Indexes Must Be Rebuilt”](#), to see whether changes to table formats or to character sets or collations were made between your current version of MySQL and the version to which you are upgrading. If so and these changes result in an incompatibility between MySQL versions, you will need to upgrade the affected tables using the instructions in [Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”](#).
- After upgrading to a new version of MySQL, run `mysql_upgrade` (see [Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”](#)). This program checks your tables, and attempts to repair them if necessary. It also updates your grant tables to make sure that they have the current structure so that you can take advantage of any new capabilities. (Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features.)

`mysql_upgrade` does not upgrade the contents of the help tables. For upgrade instructions, see [Section 5.1.10, “Server-Side Help”](#).

- If you run MySQL Server on Windows, see [Section 2.3.9, “Upgrading MySQL on Windows”](#).
- If you use replication, see [Section 17.4.3, “Upgrading a Replication Setup”](#), for information on upgrading your replication setup.

If your MySQL installation contains a large amount of data that might take a long time to convert after an in-place upgrade, you might find it useful to create a “dummy” database instance for assessing what conversions might be needed and the work involved to perform them. Make a copy of your MySQL instance that contains a full copy of the `mysql` database, plus all other databases without data. Run your upgrade procedure on this dummy instance to see what actions might be needed so that you can better evaluate the work involved when performing actual data conversion on your original database instance.

The following lists describe changes that may affect applications and that you should watch out for when upgrading from MySQL 5.1 to 5.5.

Configuration Changes

- **Incompatible change:** The `InnoDB Plugin` is included in MySQL 5.5 releases. It becomes the built-in version of `InnoDB` in MySQL Server, replacing the version previously included as the built-in `InnoDB` engine. `InnoDB Plugin` is also available in MySQL 5.1 as of 5.1.38, but it is an optional storage engine that must be enabled explicitly using two server options:

```
[mysqld]
ignore-builtin-innodb
plugin-load=innodb=ha_innodb_plugin.so
```

If you were using `InnoDB Plugin` in MySQL 5.1 by means of those options, you must remove them after an upgrade to 5.5 or the server will fail to start.

In addition, in `InnoDB Plugin`, the `innodb_file_io_threads` system variable has been removed and replaced with `innodb_read_io_threads` and `innodb_write_io_threads`. If you

upgrade from MySQL 5.1 to MySQL 5.5 and previously explicitly set `innodb_file_io_threads` at server startup, you must change your configuration. Either remove any reference to `innodb_file_io_threads` or replace it with references to `innodb_read_io_threads` and `innodb_write_io_threads`.

- **Incompatible change:** In MySQL 5.5, the server includes a plugin services interface that complements the plugin API. The services interface enables server functionality to be exposed as a “service” that plugins can access through a function-call interface. The `libmysqservices` library provides access to the available services and dynamic plugins now must be linked against this library (use the `–
lmysqservices` flag). For an example showing how to configure for CMake, see [Section 24.2.5, “MySQL Services for Plugins”](#).

Server Changes

- **Known issue:** As of MySQL 5.5.32, for new installations, the `url` columns in the `mysql` database help tables are now created as type `TEXT` to accommodate longer URLs. For upgrades, `mysql_upgrade` does *not* update the columns. Modify them manually using these statements:

```
ALTER TABLE mysql.help_category MODIFY url TEXT NOT NULL;
ALTER TABLE mysql.help_topic MODIFY url TEXT NOT NULL;
```

- **Incompatible change:** As of MySQL 5.5.3, due to work done for Bug #989, `FLUSH TABLES` is not permitted when there is an active `LOCK TABLES ... READ`. To provide a workaround for this restriction, `FLUSH TABLES` has a new variant, `FLUSH TABLES tbl_list WITH READ LOCK`, that enables tables to be flushed and locked in a single operation. As a result of this change, applications that previously used this statement sequence to lock and flush tables will fail:

```
LOCK TABLES tbl_list READ;
FLUSH TABLES tbl_list;
```

Such applications should now use this statement instead:

```
FLUSH TABLES tbl_list WITH READ LOCK;
```

- **Incompatible change:** As of MySQL 5.5.7, the server requires that a new grant table, `proxies_priv`, be present in the `mysql` database. If you are upgrading to 5.5.7 from a previous MySQL release rather than performing a new installation, the server will find that this table is missing and exit during startup with the following message:

```
Table 'mysql.proxies_priv' doesn't exist
```

To create the `proxies_priv` table, start the server with the `--skip-grant-tables` option to cause it to skip the normal grant table checks, then run `mysql_upgrade`. For example:

```
shell> mysqld --skip-grant-tables &
shell> mysql_upgrade
```

Then stop the server and restart it normally.

You can specify other options on the `mysqld` command line if necessary. Alternatively, if your installation is configured so that the server normally reads options from an option file, use the `--defaults-file` option to specify the file (enter each command on a single line):

```
shell> mysqld --defaults-file=/usr/local/mysql/etc/my.cnf
```

```
--skip-grant-tables &
shell> mysql_upgrade
```

With the `--skip-grant-tables` option, the server does no password or privilege checking, so any client can connect and effectively have all privileges. For additional security, use the `--skip-networking` option as well to prevent remote clients from connecting.

Note

This problem is fixed in MySQL 5.5.8; the server treats a missing `proxies_priv` table as equivalent to an empty table. However, after starting the server, you should still run `mysql_upgrade` to create the table.

- **Incompatible change:** As of MySQL 5.5.7, InnoDB always uses the fast truncation technique, equivalent to `DROP TABLE` and `CREATE TABLE`. It no longer performs a row-by-row delete for tables with parent-child foreign key relationships. `TRUNCATE TABLE` returns an error for such tables. Modify your SQL to issue `DELETE FROM table_name` for such tables instead.
- **Incompatible change:** Prior to MySQL 5.5.7, if you flushed the logs using `FLUSH LOGS` or `mysqladmin flush-logs` and `mysqld` was writing the error log to a file (for example, if it was started with the `--log-error` option), it renames the current log file with the suffix `-old`, then created a new empty log file. This had the problem that a second log-flushing operation thus caused the original error log file to be lost unless you saved it under a different name. For example, you could use the following commands to save the file:

```
shell> mysqladmin flush-logs
shell> mv host_name.err-old backup-directory
```

To avoid the preceding file-loss problem, no renaming occurs as of MySQL 5.5.7; the server merely closes and reopens the log file. To rename the file, you can do so manually before flushing. Then flushing the logs reopens a new file with the original file name. For example, you can rename the file and create a new one using the following commands:

```
shell> mv host_name.err host_name.err-old
shell> mysqladmin flush-logs
shell> mv host_name.err-old backup-directory
```

- **Incompatible change:** As of MySQL 5.5.6, handling of `CREATE TABLE IF NOT EXISTS ... SELECT` statements has been changed for the case that the destination table already exists:
 - Previously, for `CREATE TABLE IF NOT EXISTS ... SELECT`, MySQL produced a warning that the table exists, but inserted the rows and wrote the statement to the binary log anyway. By contrast, `CREATE TABLE ... SELECT` (without `IF NOT EXISTS`) failed with an error, but MySQL inserted no rows and did not write the statement to the binary log.
 - MySQL now handles both statements the same way when the destination table exists, in that neither statement inserts rows or is written to the binary log. The difference between them is that MySQL produces a warning when `IF NOT EXISTS` is present and an error when it is not.

This change in handling of `IF NOT EXISTS` results in an incompatibility for statement-based replication from a MySQL 5.1 master with the original behavior and a MySQL 5.5 slave with the new behavior. Suppose that `CREATE TABLE IF NOT EXISTS ... SELECT` is executed on the master and the destination table exists. The result is that rows are inserted on the master but not on the slave. (Row-based replication does not have this problem.)

To address this issue, statement-based binary logging for `CREATE TABLE IF NOT EXISTS ... SELECT` is changed in MySQL 5.1 as of 5.1.51:

- If the destination table does not exist, there is no change: The statement is logged as is.
- If the destination table does exist, the statement is logged as the equivalent pair of `CREATE TABLE IF NOT EXISTS` and `INSERT ... SELECT` statements. (If the `SELECT` in the original statement is preceded by `IGNORE` or `REPLACE`, the `INSERT` becomes `INSERT IGNORE` or `REPLACE`, respectively.)

This change provides forward compatibility for statement-based replication from MySQL 5.1 to 5.5 because when the destination table exists, the rows will be inserted on both the master and slave. To take advantage of this compatibility measure, the 5.1 server must be at least 5.1.51 and the 5.5 server must be at least 5.5.6.

To upgrade an existing 5.1-to-5.5 replication scenario, upgrade the master first to 5.1.51 or higher. Note that this differs from the usual replication upgrade advice of upgrading the slave first.

A workaround for applications that wish to achieve the original effect (rows inserted regardless of whether the destination table exists) is to use `CREATE TABLE IF NOT EXISTS` and `INSERT ... SELECT` statements rather than `CREATE TABLE IF NOT EXISTS ... SELECT` statements.

Along with the change just described, the following related change was made: Previously, if an existing view was named as the destination table for `CREATE TABLE IF NOT EXISTS ... SELECT`, rows were inserted into the underlying base table and the statement was written to the binary log. As of MySQL 5.1.51 and 5.5.6, nothing is inserted or logged.

- **Incompatible change:** Prior to MySQL 5.5.6, if the server was started with `character_set_server` set to `utf16`, it crashed during full-text stopword initialization. Now the stopword file is loaded and searched using `latin1` if `character_set_server` is `ucs2`, `utf16`, or `utf32`. If any table was created with `FULLTEXT` indexes while the server character set was `ucs2`, `utf16`, or `utf32`, it should be repaired using this statement:

```
REPAIR TABLE tbl_name QUICK;
```

- **Incompatible change:** As of MySQL 5.5.5, all numeric operators and functions on integer, floating-point and `DECIMAL` values throw an “out of range” error (`ER_DATA_OUT_OF_RANGE`) rather than returning an incorrect value or `NULL`, when the result is out of the supported range for the corresponding data type. See [Section 11.2.6, “Out-of-Range and Overflow Handling”](#).
- **Incompatible change:** In very old versions of MySQL (prior to 4.1), the `TIMESTAMP` data type supported a display width, which was silently ignored beginning with MySQL 4.1. This is deprecated in MySQL 5.1, and removed altogether in MySQL 5.5. These changes in behavior can lead to two problem scenarios when trying to use `TIMESTAMP(N)` columns with a MySQL 5.5 or later server:
 - When importing a dump file (for example, one created using `mysqldump`) created in a MySQL 5.0 or earlier server into a server from a newer release series, a `CREATE TABLE` or `ALTER TABLE` statement containing `TIMESTAMP(N)` causes the import to fail with a syntax error.
To fix this problem, edit the dump file in a text editor to replace any instances of `TIMESTAMP(N)` with `TIMESTAMP` prior to importing the file. Be sure to use a plain text editor for this, and not a word processor; otherwise, the result is almost certain to be unusable for importing into the MySQL server.
 - When trying replicate any `CREATE TABLE` or `ALTER TABLE` statement containing `TIMESTAMP(N)` from a master MySQL server that supports the `TIMESTAMP(N)` syntax to a MySQL 5.5.3 or newer slave, the statement causes replication to fail. Similarly, when you try to restore from a binary log

written by a server that supports `TIMESTAMP(N)` to a MySQL 5.5.3 or newer server, any `CREATE TABLE` or `ALTER TABLE` statement containing `TIMESTAMP(N)` causes the backup to fail. This holds true regardless of the logging format.

It may be possible to fix such issues using a hex editor, by replacing any width arguments used with `TIMESTAMP`, and the parentheses containing them, with space characters (hexadecimal 20). Be sure to use a programmer's binary hex editor and not a regular text editor or word processor for this; otherwise, the result is almost certain to be a corrupted binary log file. To guard against accidental corruption of the binary log, you should always work on a copy of the file rather than the original.

You should try to handle potential issues of these types proactively by updating with `ALTER TABLE` any `TIMESTAMP(N)` columns in your databases so that they use `TIMESTAMP` instead, before performing any upgrades.

- **Incompatible change:** As of MySQL 5.5.3, the Unicode implementation has been extended to provide support for supplementary characters that lie outside the Basic Multilingual Plane (BMP). Noteworthy features:
 - `utf16` and `utf32` character sets have been added. These correspond to the UTF-16 and UTF-32 encodings of the Unicode character set, and they both support supplementary characters.
 - The `utf8mb4` character set has been added. This is similar to `utf8`, but its encoding allows up to four bytes per character to enable support for supplementary characters.
 - The `ucs2` character set is essentially unchanged except for the inclusion of some newer BMP characters.

In most respects, upgrading to MySQL 5.5 should present few problems with regard to Unicode usage, although there are some potential areas of incompatibility. These are the primary areas of concern:

- For the variable-length character data types (`VARCHAR` and the `TEXT` types), the maximum length in characters is less for `utf8mb4` columns than for `utf8` columns.
- For all character data types (`CHAR`, `VARCHAR`, and the `TEXT` types), the maximum number of characters that can be indexed is less for `utf8mb4` columns than for `utf8` columns.

Consequently, if you want to upgrade tables from `utf8` to `utf8mb4` to take advantage of supplementary-character support, it may be necessary to change some column or index definitions.

For additional details about the new Unicode character sets and potential incompatibilities, see [Section 10.1.10, “Unicode Support”](#), and [Section 10.1.11, “Upgrading from Previous to Current Unicode Support”](#).

- **Incompatible change:** As of MySQL 5.5.3, the server includes `dtoa`, a library for conversion between strings and numbers by David M. Gay. In MySQL, this library provides the basis for improved conversion between string or `DECIMAL` values and approximate-value (`FLOAT` or `DOUBLE`) numbers.

Because the conversions produced by this library differ in some cases from previous results, the potential exists for incompatibilities in applications that rely on previous results. For example, applications that depend on a specific exact result from previous conversions might need adjustment to accommodate additional precision.

For additional information about the properties of `dtoa` conversions, see [Section 12.2, “Type Conversion in Expression Evaluation”](#).

- **Incompatible change:** In MySQL 5.5, several changes were made regarding the language and character set of error messages:

- The `--language` option for specifying the directory for the error message file is now deprecated. The new `lc_messages_dir` and `lc_messages` system variables should be used instead, and the server treats `--language` as an alias for `lc_messages_dir`.
- The `language` system variable has been removed and replaced with the new `lc_messages_dir` and `lc_messages` system variables. `lc_messages_dir` has only a global value and is read only. `lc_messages` has global and session values and can be modified at runtime, so the error message language can be changed while the server is running, and individual clients each can have a different error message language by changing their session `lc_messages` value to a different locale name.
- Error messages previously were constructed in a mix of character sets. This issue is resolved by constructing error messages internally within the server using UTF-8 and returning them to the client in the character set specified by the `character_set_results` system variable. The content of error messages therefore may in some cases differ from the messages returned previously.

For more information, see [Section 10.2, “Setting the Error Message Language”](#), and [Section 10.1.6, “Character Set for Error Messages”](#).

- **Incompatible change:** MySQL 5.5 implements new functions used to calculate row placement for tables partitioned by `KEY` and `LINEAR KEY`. Tables that were created using `KEY` or `LINEAR KEY` partitioning in MySQL 5.1 can be upgraded in MySQL 5.5.31 and later using `ALTER TABLE ... PARTITION BY ALGORITHM=2 [LINEAR] KEY (...)`. (Bug #14521864, Bug #66462)

SQL Changes

- **Incompatible change:** Previously, the parser accepted an `INTO` clause in nested `SELECT` statements, which is invalid because such statements must return their results to the outer context. As of MySQL 5.5.3, this syntax is no longer permitted and statements that use it must be changed.
- **Incompatible change:** In MySQL 5.5.3, several changes were made to alias resolution in multiple-table `DELETE` statements so that it is no longer possible to have inconsistent or ambiguous table aliases.
- In MySQL 5.1.23, alias declarations outside the `table_references` part of the statement were disallowed for the `USING` variant of multiple-table `DELETE` syntax, to reduce the possibility of ambiguous aliases that could lead to ambiguous statements that have unexpected results such as deleting rows from the wrong table.

As of MySQL 5.5.3, alias declarations outside `table_references` are disallowed for all multiple-table `DELETE` statements. Alias declarations are permitted only in the `table_references` part.

Incorrect:

```
DELETE FROM t1 AS a2 USING t1 AS a1 INNER JOIN t2 AS a2;
DELETE t1 AS a2 FROM t1 AS a1 INNER JOIN t2 AS a2;
```

Correct:

```
DELETE FROM t1 USING t1 AS a1 INNER JOIN t2 AS a2;
DELETE t1 FROM t1 AS a1 INNER JOIN t2 AS a2;
```

- Previously, for alias references in the list of tables from which to delete rows in a multiple-table delete, the default database is used unless one is specified explicitly. For example, if the default database is `db1`, the following statement does not work because the unqualified alias reference `a2` is interpreted as having a database of `db1`:

```
DELETE a1, a2 FROM db1.t1 AS a1 INNER JOIN db2.t2 AS a2
WHERE a1.id=a2.id;
```

To correctly match an alias that refers to a table outside the default database, you must explicitly qualify the reference with the name of the proper database:

```
DELETE a1, db2.a2 FROM db1.t1 AS a1 INNER JOIN db2.t2 AS a2
WHERE a1.id=a2.id;
```

As of MySQL 5.5.3, alias resolution does not require qualification and alias references should not be qualified with the database name. Qualified names are interpreted as referring to tables, not aliases.

Statements containing alias constructs that are no longer permitted must be rewritten.

- Some keywords may be reserved in MySQL 5.5 that were not reserved in MySQL 5.1. See [Section 9.3, “Reserved Words”](#).

2.11.1.2 Upgrading from MySQL 5.4 to 5.5

This section is for the special case of upgrading to MySQL 5.5 from the short-lived MySQL 5.4 development series, which is no longer being worked on.

Note

It is good practice to back up your data before installing any new version of software. Although MySQL works very hard to ensure a high level of quality, you should protect your data by making a backup.

To upgrade to 5.5 from any previous version, MySQL recommends that you dump your tables with `mysqldump` before upgrading and reload the dump file after upgrading. Use the `--all-databases` option to include all databases in the dump. If your databases include stored programs, use the `--routines` and `--events` options as well.

In general, you should do the following when upgrading from MySQL 5.4 to 5.5:

- Read *all* the items in these sections to see whether any of them might affect your applications:
 - [Section 2.11.1, “Upgrading MySQL”](#), has general update information.
 - The items in the change lists provided later in this section enable you to identify upgrade issues that apply to your current MySQL installation. Some incompatibilities discussed there require your attention *before* upgrading. Others should be dealt with *after* upgrading.
 - The MySQL 5.5 [Release Notes](#) describe significant new features you can use in 5.5 or that differ from those found in earlier MySQL releases. Some of these changes may result in incompatibilities.

Note particularly any changes that are marked **Known issue** or **Incompatible change**. These incompatibilities with earlier versions of MySQL may require your attention *before you upgrade*. Our aim is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases. If any upgrade issue applicable to your installation involves an incompatibility that requires special handling, follow the instructions given in the incompatibility description. Sometimes this involves dumping and reloading tables, or use of a statement such as `CHECK TABLE` or `REPAIR TABLE`.

For dump and reload instructions, see [Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”](#). Any procedure that involves `REPAIR TABLE` with the `USE_FRM` option *must* be done before upgrading. Use of this statement with a version of MySQL different from the one used to create the table (that is, using it after upgrading) may damage the table. See [Section 13.7.2.5, “REPAIR TABLE Syntax”](#).

- Before upgrading to a new version of MySQL, [Section 2.11.3, “Checking Whether Tables or Indexes Must Be Rebuilt”](#), to see whether changes to table formats or to character sets or collations were made between your current version of MySQL and the version to which you are upgrading. If so and these changes result in an incompatibility between MySQL versions, you will need to upgrade the affected tables using the instructions in [Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”](#).
- After upgrading to a new version of MySQL, run `mysql_upgrade` (see [Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”](#)). This program checks your tables, and attempts to repair them if necessary. It also updates your grant tables to make sure that they have the current structure so that you can take advantage of any new capabilities. (Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features.)

`mysql_upgrade` does not upgrade the contents of the help tables. For upgrade instructions, see [Section 5.1.10, “Server-Side Help”](#).

- If you run MySQL Server on Windows, see [Section 2.3.9, “Upgrading MySQL on Windows”](#).
- If you use replication, see [Section 17.4.3, “Upgrading a Replication Setup”](#), for information on upgrading your replication setup.

If your MySQL installation contains a large amount of data that might take a long time to convert after an in-place upgrade, you might find it useful to create a “dummy” database instance for assessing what conversions might be needed and the work involved to perform them. Make a copy of your MySQL instance that contains a full copy of the `mysql` database, plus all other databases without data. Run your upgrade procedure on this dummy instance to see what actions might be needed so that you can better evaluate the work involved when performing actual data conversion on your original database instance.

The following lists describe changes that may affect applications and that you should watch out for when upgrading from MySQL 5.4 to 5.5.

Configuration Changes

- **Incompatible change:** In MySQL 5.5, the server includes a plugin services interface that complements the plugin API. The services interface enables server functionality to be exposed as a “service” that plugins can access through a function-call interface. The `libmysqlservices` library provides access to the available services and dynamic plugins now must be linked against this library (use the `-lmysqlservices` flag). For an example showing how to configure for `CMake`, see [Section 24.2.5, “MySQL Services for Plugins”](#).

Server Changes

- **Incompatible change:** As of MySQL 5.5.7, the server requires that a new grant table, `proxies_priv`, be present in the `mysql` database. If you are upgrading from a previous MySQL release rather than performing a new installation, the server will find that this table is missing and exit during startup with the following message:

```
Table 'mysql.proxies_priv' doesn't exist
```

To create the `proxies_priv` table, start the server with the `--skip-grant-tables` option to cause it to skip the normal grant table checks, then run `mysql_upgrade`. For example:

```
shell> mysqld --skip-grant-tables &  
shell> mysql_upgrade
```

Then stop the server and restart it normally.

You can specify other options on the `mysqld` command line if necessary. Alternatively, if your installation is configured so that the server normally reads options from an option file, use the `--defaults-file` option to specify the file (enter each command on a single line):

```
shell> mysqld --defaults-file=/usr/local/mysql/etc/my.cnf  
--skip-grant-tables &  
shell> mysql_upgrade
```

With the `--skip-grant-tables` option, the server does no password or privilege checking, so any client can connect and effectively have all privileges. For additional security, use the `--skip-networking` option as well to prevent remote clients from connecting.

- **Incompatible change:** As of MySQL 5.5.3, the Unicode implementation has been extended to provide support for supplementary characters that lie outside the Basic Multilingual Plane (BMP). Noteworthy features:
 - `utf16` and `utf32` character sets have been added. These correspond to the UTF-16 and UTF-32 encodings of the Unicode character set, and they both support supplementary characters.
 - The `utf8mb4` character set has been added. This is similar to `utf8`, but its encoding allows up to four bytes per character to enable support for supplementary characters.
 - The `ucs2` character set is essentially unchanged except for the inclusion of some newer BMP characters.

In most respects, upgrading to MySQL 5.5 should present few problems with regard to Unicode usage, although there are some potential areas of incompatibility. These are the primary areas of concern:

- For the variable-length character data types (`VARCHAR` and the `TEXT` types), the maximum length in characters is less for `utf8mb4` columns than for `utf8` columns.
- For all character data types (`CHAR`, `VARCHAR`, and the `TEXT` types), the maximum number of characters that can be indexed is less for `utf8mb4` columns than for `utf8` columns.

Consequently, if you want to upgrade tables from `utf8` to `utf8mb4` to take advantage of supplementary-character support, it may be necessary to change some column or index definitions.

For additional details about the new Unicode character sets and potential incompatibilities, see [Section 10.1.10, “Unicode Support”](#), and [Section 10.1.11, “Upgrading from Previous to Current Unicode Support”](#).

- **Incompatible change:** As of MySQL 5.5.3, the server includes `dtoa`, a library for conversion between strings and numbers by David M. Gay. In MySQL, this library provides the basis for improved conversion between string or `DECIMAL` values and approximate-value (`FLOAT/DOUBLE`) numbers.

Because the conversions produced by this library differ in some cases from previous results, the potential exists for incompatibilities in applications that rely on previous results. For example, applications that depend on a specific exact result from previous conversions might need adjustment to accommodate additional precision.

For additional information about the properties of `dt oa` conversions, see [Section 12.2, “Type Conversion in Expression Evaluation”](#).

- **Incompatible change:** In MySQL 5.5, several changes were made regarding the language and character set of error messages:
 - The `--language` option for specifying the directory for the error message file is now deprecated. The new `lc_messages_dir` and `lc_messages` system variables should be used instead, and the server treats `--language` as an alias for `lc_messages_dir`.
 - The `language` system variable has been removed and replaced with the new `lc_messages_dir` and `lc_messages` system variables. `lc_messages_dir` has only a global value and is read only. `lc_messages` has global and session values and can be modified at runtime, so the error message language can be changed while the server is running, and individual clients each can have a different error message language by changing their session `lc_messages` value to a different locale name.
 - Error messages previously were constructed in a mix of character sets. This issue is resolved by constructing error messages internally within the server using UTF-8 and returning them to the client in the character set specified by the `character_set_results` system variable. The content of error messages therefore may in some cases differ from the messages returned previously.

For more information, see [Section 10.2, “Setting the Error Message Language”](#), and [Section 10.1.6, “Character Set for Error Messages”](#).

- Before MySQL 5.1.36, plugin options were boolean options (see [Section 4.2.5, “Program Option Modifiers”](#)). If you upgrade to MySQL 5.5 from a version older than 5.1.36 and previously used options of the form `--plugin_name=0` or `--plugin_name=1`, the equivalent options are now `--plugin_name=OFF` and `--plugin_name=ON`, respectively. You also have the choice of requiring plugins to start successfully by using `--plugin_name=FORCE` or `--plugin_name=FORCE_PLUS_PERMANENT`.

SQL Changes

- **Incompatible change:** Previously, the parser accepted an `INTO` clause in nested `SELECT` statements, which is invalid because such statements must return their results to the outer context. As of MySQL 5.5.3, this syntax is no longer permitted and statements that use it must be changed.
- Some keywords may be reserved in MySQL 5.5 that were not reserved in MySQL 5.4. See [Section 9.3, “Reserved Words”](#).

2.11.2 Downgrading MySQL

This section describes what you should do to downgrade to an older MySQL version in the unlikely case that the previous version worked better than the new one.

It is always a good idea to make a backup beforehand, in case a downgrade fails and leaves the instance in an unusable state.

To downgrade between General Availability (GA) status versions within the same release series, typically you just install the new binaries on top of the old ones and do not make any changes to the databases.

Downgrades between milestone releases (or from a GA release to a milestone release) within the same release series are not supported and you may encounter issues.

The following items form a checklist of things you should do whenever you perform a downgrade:

- Read the upgrading section for the release series from which you are downgrading to be sure that it does not have any features you really need. See [Section 2.11.1, “Upgrading MySQL”](#).
- If there is a downgrading section for that version, you should read that as well.
- To see which new features were added between the version to which you are downgrading and your current version, see the [Release Notes](#).
- Check [Section 2.11.3, “Checking Whether Tables or Indexes Must Be Rebuilt”](#), to see whether changes to table formats or to character sets or collations were made between your current version of MySQL and the version to which you are downgrading. If so and these changes result in an incompatibility between MySQL versions, you will need to downgrade the affected tables using the instructions in [Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”](#).

In most cases, you can move the MySQL format files and data files between different GA versions on the same architecture as long as you stay within versions for the same release series of MySQL.

If you downgrade from one release series to another, there may be incompatibilities in table storage formats. In this case, use `mysqldump` to dump your tables before downgrading. After downgrading, reload the dump file using `mysql` or `mysqlimport` to re-create your tables. For examples, see [Section 2.11.5, “Copying MySQL Databases to Another Machine”](#).

A typical symptom of a downward-incompatible table format change when you downgrade is that you cannot open tables. In that case, use the following procedure:

1. Stop the older MySQL server that you are downgrading to.
2. Restart the newer MySQL server you are downgrading from.
3. Dump any tables that were inaccessible to the older server by using `mysqldump` to create a dump file.
4. Stop the newer MySQL server and restart the older one.
5. Reload the dump file into the older server. Your tables should be accessible.

It might also be the case that system tables in the `mysql` database have changed and that downgrading introduces some loss of functionality or requires some adjustments. Here are some examples:

- Trigger creation requires the `TRIGGER` privilege as of MySQL 5.1. In MySQL 5.0, there is no `TRIGGER` privilege and `SUPER` is required instead. If you downgrade from MySQL 5.1 to 5.0, you will need to give the `SUPER` privilege to those accounts that had the `TRIGGER` privilege in 5.1.
- Triggers were added in MySQL 5.0, so if you downgrade from 5.0 to 4.1, you cannot use triggers at all.
- The `mysql.proc.comment` column definition changed between MySQL 5.1 and 5.5. After a downgrade from 5.5 to 5.1, this table is seen as corrupt and in need of repair. To workaround this problem, execute `mysql_upgrade` from the version of MySQL to which you downgraded.

2.11.2.1 Downgrading to MySQL 5.1

When downgrading to MySQL 5.1 from MySQL 5.5, you should keep in mind the following issues relating to features found in MySQL 5.5, but not in MySQL 5.1:

- **InnoDB.** MySQL 5.5 uses `InnoDB Plugin` as the built-in version of `InnoDB`. MySQL 5.1 includes `InnoDB Plugin` as of 5.1.38, but as an option that must be enabled explicitly. See the [Release Notes](#) for MySQL 5.1.38.
- **Tables partitioned by `[LINEAR] KEY`.** MySQL 5.5 implements new functions used to calculate row placement for tables partitioned by `KEY` and `LINEAR KEY`. Tables that were created using `KEY`

or `LINEAR KEY` partitioning in MySQL 5.5 cannot be used by a MySQL 5.1 server. In MySQL 5.5.31 and later, you can downgrade such tables with `ALTER TABLE ... PARTITION BY ALGORITHM=1 [LINEAR] KEY (...)` to make them compatible with MySQL 5.1.

2.11.2.2 Downgrading from MySQL Enterprise Edition to MySQL Community Server

This section describes the steps required to downgrade from MySQL Enterprise Edition to MySQL Community Edition. This can be done at any time, and is required at the expiration of a MySQL Enterprise Edition subscription if you wish to continue using MySQL Server.

When you perform such a downgrade, all commercially licensed components of the MySQL Enterprise Edition subscription must be uninstalled. These components and related considerations are described in the rest of this section.

Note

The issues described in this section are in addition to any that may be encountered as a result of any upgrade or downgrade of the MySQL Server version (such as between MySQL 5.5 and 5.1). Information about upgrading and downgrading between MySQL release series can be found elsewhere in this chapter; see [Section 2.11.1, “Upgrading MySQL”](#), and [Section 2.11.2, “Downgrading MySQL”](#).

MySQL Enterprise Database Server. All commercial versions of MySQL Database Server must be uninstalled.

Commercially licensed extensions. All commercially licensed MySQL Enterprise Database Server extensions must be uninstalled. This includes the following commercial extensions:

- *MySQL External Authentication for Windows:* Following uninstallation of this plugin, existing MySQL user accounts must be re-created using local authentication. See [Section 6.3, “MySQL User Account Management”](#), for more information.
- *MySQL External Authentication for PAM:* Following uninstallation of this plugin, existing MySQL user accounts must be re-created using local authentication. See [Section 6.3, “MySQL User Account Management”](#), for more information.
- *MySQL Enterprise Scalability (Thread Pool):* Following uninstallation of this plugin, existing MySQL servers revert to default thread and connection handling.
- *MySQL Enterprise Audit:* Following uninstallation of this plugin, no logging of user logins or query activity occurs.
- *MySQL High Availability:* Following uninstallation of this plugin, automated failover is no longer available.

MySQL Enterprise Backup. MySQL Enterprise Backup must be uninstalled. Uninstalling this application has the effects listed here:

- Automated backup scripts no longer work.
- Existing backup images taken with MySQL Enterprise Backup can no longer be used for recovery.
- Third-party integration with multimedia systems such as NetBackup, Tivoli, and Oracle Secure Backup no longer works.

MySQL Enterprise Monitor, MySQL Query Analyzer, agents. MySQL Enterprise Monitor, MySQL Query Analyzer, and all server-side agents must be uninstalled. Uninstalling these applications and agents has the following effects:

- Automated SNMP and SMTP alerts no longer work.

- All historical MySQL, OS monitoring, query, and performance metrics as well as all trending data are lost.
- All environment-specific monitoring templates, custom advisors, graphs and scripts are also lost.

2.11.3 Checking Whether Tables or Indexes Must Be Rebuilt

A binary upgrade or downgrade is one that installs one version of MySQL “in place” over an existing version, without dumping and reloading tables:

1. Stop the server for the existing version if it is running.
2. Install a different version of MySQL. This is an upgrade if the new version is higher than the original version, a downgrade if the version is lower.
3. Start the server for the new version.

In many cases, the tables from the previous version of MySQL can be used without problem by the new version. However, sometimes changes occur that require tables or table indexes to be rebuilt, as described in this section. If you have tables that are affected by any of the issues described here, rebuild the tables or indexes as necessary using the instructions given in [Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”](#).

Table Incompatibilities

After a binary upgrade to MySQL 5.1 from a MySQL 5.0 installation that contains [ARCHIVE](#) tables, accessing those tables causes the server to crash, even if you have run `mysql_upgrade` or `CHECK TABLE ... FOR UPGRADE`. To work around this problem, use `mysqldump` to dump all [ARCHIVE](#) tables before upgrading, and reload them into MySQL 5.1 after upgrading. The same problem occurs for binary downgrades from MySQL 5.1 to 5.0.

The upgrade problem is fixed in MySQL 5.6.4: The server can open [ARCHIVE](#) tables created in MySQL 5.0. However, it remains the recommended upgrade procedure to dump 5.0 [ARCHIVE](#) tables before upgrading and reload them after upgrading.

Index Incompatibilities

In MySQL 5.6.3, the length limit for index prefix keys is increased from 767 bytes to 3072 bytes, for [InnoDB](#) tables using `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`. See [Section 14.9.7, “Limits on InnoDB Tables”](#) for details. This change is also backported to MySQL 5.5.14. If you downgrade from one of these releases or higher, to an earlier release with a lower length limit, the index prefix keys could be truncated at 767 bytes or the downgrade could fail. This issue could only occur if the configuration option `innodb_large_prefix` was enabled on the server being downgraded.

If you perform a binary upgrade without dumping and reloading tables, you cannot upgrade directly from MySQL 4.1 to 5.1 or higher. This occurs due to an incompatible change in the [MyISAM](#) table index format in MySQL 5.0. Upgrade from MySQL 4.1 to 5.0 and repair all [MyISAM](#) tables. Then upgrade from MySQL 5.0 to 5.1 and check and repair your tables.

Modifications to the handling of character sets or collations might change the character sort order, which causes the ordering of entries in any index that uses an affected character set or collation to be incorrect. Such changes result in several possible problems:

- Comparison results that differ from previous results
- Inability to find some index values due to misordered index entries
- Misordered `ORDER BY` results

- Tables that `CHECK TABLE` reports as being in need of repair

The solution to these problems is to rebuild any indexes that use an affected character set or collation, either by dropping and re-creating the indexes, or by dumping and reloading the entire table. In some cases, it is possible to alter affected columns to use a different collation. For information about rebuilding indexes, see [Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”](#).

To check whether a table has indexes that must be rebuilt, consult the following list. It indicates which versions of MySQL introduced character set or collation changes that require indexes to be rebuilt. Each entry indicates the version in which the change occurred and the character sets or collations that the change affects. If the change is associated with a particular bug report, the bug number is given.

The list applies both for binary upgrades and downgrades. For example, Bug #27877 was fixed in MySQL 5.1.24, so it applies to upgrades from versions older than 5.1.24 to 5.1.24 or newer, and to downgrades from 5.1.24 or newer to versions older than 5.1.24.

In many cases, you can use `CHECK TABLE ... FOR UPGRADE` to identify tables for which index rebuilding is required. It will report this message:

```
Table upgrade required.
Please do "REPAIR TABLE `tbl_name`" or dump/reload to fix it!
```

In these cases, you can also use `mysqlcheck --check-upgrade` or `mysql_upgrade`, which execute `CHECK TABLE`. However, the use of `CHECK TABLE` applies only after upgrades, not downgrades. Also, `CHECK TABLE` is not applicable to all storage engines. For details about which storage engines `CHECK TABLE` supports, see [Section 13.7.2.2, “CHECK TABLE Syntax”](#).

These changes cause index rebuilding to be necessary:

- MySQL 5.1.24 (Bug #27877)

Affects indexes that use the `utf8_general_ci` or `ucs2_general_ci` collation for columns that contain 'ß' LATIN SMALL LETTER SHARP S (German). The bug fix corrected an error in the original collations but introduced an incompatibility such that 'ß' compares equal to characters with which it previously compared different.

Affected tables can be detected by `CHECK TABLE ... FOR UPGRADE` as of MySQL 5.1.30 (see Bug #40053).

A workaround for this issue is implemented as of MySQL 5.1.62, 5.5.21, and 5.6.5. The workaround involves altering affected columns to use the `utf8_general_mysql500_ci` and `ucs2_general_mysql500_ci` collations, which preserve the original pre-5.1.24 ordering of `utf8_general_ci` and `ucs2_general_ci`.

- MySQL 5.0.48, 5.1.23 (Bug #27562)

Affects indexes that use the `ascii_general_ci` collation for columns that contain any of these characters: `` GRAVE ACCENT, '[' LEFT SQUARE BRACKET, '\ ' REVERSE SOLIDUS, ']' RIGHT SQUARE BRACKET, '~' TILDE

Affected tables can be detected by `CHECK TABLE ... FOR UPGRADE` as of MySQL 5.1.29 (see Bug #39585).

- MySQL 5.0.48, 5.1.21 (Bug #29461)

Affects indexes for columns that use any of these character sets: `eucjpms`, `euc_kr`, `gb2312`, `latin7`, `macce`, `ujis`

Affected tables can be detected by `CHECK TABLE ... FOR UPGRADE` as of MySQL 5.1.29 (see Bug #39585).

2.11.4 Rebuilding or Repairing Tables or Indexes

This section describes how to rebuild a table. This can be necessitated by changes to MySQL such as how data types are handled or changes to character set handling. For example, an error in a collation might have been corrected, necessitating a table rebuild to update the indexes for character columns that use the collation. (For examples, see [Section 2.11.3, “Checking Whether Tables or Indexes Must Be Rebuilt”](#).) It might also be that a table repair or upgrade should be done as indicated by a table check operation such as that performed by `CHECK TABLE`, `mysqlcheck`, or `mysql_upgrade`.

Methods for rebuilding a table include dumping and reloading it, or using `ALTER TABLE` or `REPAIR TABLE`. `REPAIR TABLE` only applies to `MyISAM`, `ARCHIVE`, and `CSV` tables.

Note

If you are rebuilding tables because a different version of MySQL will not handle them after a binary (in-place) upgrade or downgrade, you must use the dump-and-reload method. Dump the tables *before* upgrading or downgrading using your original version of MySQL. Then reload the tables *after* upgrading or downgrading.

If you use the dump-and-reload method of rebuilding tables only for the purpose of rebuilding indexes, you can perform the dump either before or after upgrading or downgrading. Reloading still must be done afterward.

To rebuild a table by dumping and reloading it, use `mysqldump` to create a dump file and `mysql` to reload the file:

```
shell> mysqldump db_name t1 > dump.sql
shell> mysql db_name < dump.sql
```

To rebuild all the tables in a single database, specify the database name without any following table name:

```
shell> mysqldump db_name > dump.sql
shell> mysql db_name < dump.sql
```

To rebuild all tables in all databases, use the `--all-databases` option:

```
shell> mysqldump --all-databases > dump.sql
shell> mysql < dump.sql
```

To rebuild a table with `ALTER TABLE`, use a “null” alteration; that is, an `ALTER TABLE` statement that “changes” the table to use the storage engine that it already has. For example, if `t1` is an `InnoDB` table, use this statement:

```
mysql> ALTER TABLE t1 ENGINE = InnoDB;
```

If you are not sure which storage engine to specify in the `ALTER TABLE` statement, use `SHOW CREATE TABLE` to display the table definition.

If you need to rebuild an `InnoDB` table because a `CHECK TABLE` operation indicates that a table upgrade is required, use `mysqldump` to create a dump file and `mysql` to reload the file, as described earlier. If the `CHECK TABLE` operation indicates that there is a corruption or causes `InnoDB` to fail,

refer to [Section 14.21.2, “Starting InnoDB on a Corrupted Database”](#) for information about using the `innodb_force_recovery` option to restart InnoDB. To understand the type of problem that `CHECK TABLE` may be encountering, refer to the InnoDB notes in [Section 13.7.2.2, “CHECK TABLE Syntax”](#).

For MyISAM, ARCHIVE, or CSV tables, you can use `REPAIR TABLE` if the table checking operation indicates that there is a corruption or that an upgrade is required. For example, to repair a MyISAM table, use this statement:

```
mysql> REPAIR TABLE t1;
```

`mysqlcheck --repair` provides command-line access to the `REPAIR TABLE` statement. This can be a more convenient means of repairing tables because you can use the `--databases` or `--all-databases` option to repair all tables in specific databases or all databases, respectively:

```
shell> mysqlcheck --repair --databases db_name ...
shell> mysqlcheck --repair --all-databases
```

For incompatibilities introduced in MySQL 5.1.24 by the fix for Bug #27877 that corrected the `utf8_general_ci` and `ucs2_general_ci` collations, a workaround is implemented as of MySQL 5.1.62, 5.5.21, and 5.6.5. Upgrade to one of those versions, then convert each affected table using one of the following methods. In each case, the workaround altering affected columns to use the `utf8_general_mysql500_ci` and `ucs2_general_mysql500_ci` collations, which preserve the original pre-5.1.24 ordering of `utf8_general_ci` and `ucs2_general_ci`.

- To convert an affected table after a binary upgrade that leaves the table files in place, alter the table to use the new collation. Suppose that the table `t1` contains one or more problematic `utf8` columns. To convert the table at the table level, use a statement like this:

```
ALTER TABLE t1
CONVERT TO CHARACTER SET utf8 COLLATE utf8_general_mysql500_ci;
```

To apply the change on a column-specific basis, use a statement like this (be sure to repeat the column definition as originally specified except for the `COLLATE` clause):

```
ALTER TABLE t1
MODIFY c1 CHAR(N) CHARACTER SET utf8 COLLATE utf8_general_mysql500_ci;
```

- To upgrade the table using a dump and reload procedure, dump the table using `mysqldump`, modify the `CREATE TABLE` statement in the dump file to use the new collation, and reload the table.

After making the appropriate changes, `CHECK TABLE` should report no error.

2.11.5 Copying MySQL Databases to Another Machine

In cases where you need to transfer databases between different architectures, you can use `mysqldump` to create a file containing SQL statements. You can then transfer the file to the other machine and feed it as input to the `mysql` client.

Note

You can copy the `.frm`, `.MYI`, and `.MYD` files for MyISAM tables between different architectures that support the same floating-point format. (MySQL takes care of any byte-swapping issues.) See [Section 15.3, “The MyISAM Storage Engine”](#).

Use `mysqldump --help` to see what options are available.

The easiest (although not the fastest) way to move a database between two machines is to run the following commands on the machine on which the database is located:

```
shell> mysqladmin -h 'other_hostname' create db_name
shell> mysqldump db_name | mysql -h 'other_hostname' db_name
```

If you want to copy a database from a remote machine over a slow network, you can use these commands:

```
shell> mysqladmin create db_name
shell> mysqldump -h 'other_hostname' --compress db_name | mysql db_name
```

You can also store the dump in a file, transfer the file to the target machine, and then load the file into the database there. For example, you can dump a database to a compressed file on the source machine like this:

```
shell> mysqldump --quick db_name | gzip > db_name.gz
```

Transfer the file containing the database contents to the target machine and run these commands there:

```
shell> mysqladmin create db_name
shell> gunzip < db_name.gz | mysql db_name
```

You can also use `mysqldump` and `mysqlimport` to transfer the database. For large tables, this is much faster than simply using `mysqldump`. In the following commands, `DUMPDIR` represents the full path name of the directory you use to store the output from `mysqldump`.

First, create the directory for the output files and dump the database:

```
shell> mkdir DUMPDIR
shell> mysqldump --tab=DUMPDIR db_name
```

Then transfer the files in the `DUMPDIR` directory to some corresponding directory on the target machine and load the files into MySQL there:

```
shell> mysqladmin create db_name           # create database
shell> cat DUMPDIR/*.sql | mysql db_name   # create tables in database
shell> mysqlimport db_name DUMPDIR/*.txt   # load data into tables
```

Do not forget to copy the `mysql` database because that is where the grant tables are stored. You might have to run commands as the MySQL `root` user on the new machine until you have the `mysql` database in place.

After you import the `mysql` database on the new machine, execute `mysqladmin flush-privileges` so that the server reloads the grant table information.

2.12 Environment Variables

This section lists all the environment variables that are used directly or indirectly by MySQL. Most of these can also be found in other places in this manual.

Note that any options on the command line take precedence over values specified in option files and environment variables, and values in option files take precedence over values in environment variables.

In many cases, it is preferable to use an option file instead of environment variables to modify the behavior of MySQL. See [Section 4.2.6, “Using Option Files”](#).

Variable	Description
CXX	The name of your C++ compiler (for running <code>CMake</code>).
CC	The name of your C compiler (for running <code>CMake</code>).
DBI_USER	The default user name for Perl DBI.
DBI_TRACE	Trace options for Perl DBI.
HOME	The default path for the <code>mysql</code> history file is <code>\$HOME/.mysql_history</code> .
LD_RUN_PATH	Used to specify the location of <code>libmysqlclient.so</code> .
LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN	Enable <code>mysql_clear_password</code> authentication plugin; see Section 6.3.7.5, “The Cleartext Client-Side Authentication Plugin” .
MYSQL_DEBUG	Debug trace options when debugging.
MYSQL_GROUP_SUFFIX	Option group suffix value (like specifying <code>--defaults-group-suffix</code>).
MYSQL_HISTFILE	The path to the <code>mysql</code> history file. If this variable is set, its value overrides the default for <code>\$HOME/.mysql_history</code> .
MYSQL_HOME	The path to the directory in which the server-specific <code>my.cnf</code> file resides.
MYSQL_HOST	The default host name used by the <code>mysql</code> command-line client.
MYSQL_PS1	The command prompt to use in the <code>mysql</code> command-line client.
MYSQL_PWD	The default password when connecting to <code>mysqld</code> . Note that using this is insecure. See Section 6.1.2.1, “End-User Guidelines for Password Security” .
MYSQL_TCP_PORT	The default TCP/IP port number.
MYSQL_UNIX_PORT	The default Unix socket file name; used for connections to <code>localhost</code> .
PATH	Used by the shell to find MySQL programs.
TMPDIR	The directory where temporary files are created.
TZ	This should be set to your local time zone. See Section B.5.4.6, “Time Zone Problems” .
UMASK	The user-file creation mode when creating files. See note following table.
UMASK_DIR	The user-directory creation mode when creating directories. See note following table.
USER	The default user name on Windows when connecting to <code>mysqld</code> .

For information about the `mysql` history file, see [Section 4.5.1.3, “mysql Logging”](#).

The `UMASK` and `UMASK_DIR` variables, despite their names, are used as modes, not masks:

- If `UMASK` is set, `mysqld` uses `($UMASK | 0600)` as the mode for file creation, so that newly created files have a mode in the range from 0600 to 0666 (all values octal).
- If `UMASK_DIR` is set, `mysqld` uses `($UMASK_DIR | 0700)` as the base mode for directory creation, which then is AND-ed with `(~($UMASK & 0666))`, so that newly created directories have a mode in the range from 0700 to 0777 (all values octal). The AND operation may remove read and write permissions from the directory mode, but not execute permissions.

MySQL assumes that the value for `UMASK` or `UMASK_DIR` is in octal if it starts with a zero.

2.13 Perl Installation Notes

The Perl `DBI` module provides a generic interface for database access. You can write a `DBI` script that works with many different database engines without change. To use `DBI`, you must install the `DBI` module, as well as a DataBase Driver (DBD) module for each type of database server you want to access. For MySQL, this driver is the `DBD::mysql` module.

Perl, and the `DBD::MySQL` module for `DBI` must be installed if you want to run the MySQL benchmark scripts; see [Section 8.12.2, “The MySQL Benchmark Suite”](#). They are also required for the MySQL Cluster `ndb_size.pl` utility; see [Section 18.4.23, “ndb_size.pl — NDBCLUSTER Size Requirement Estimator”](#).

Note

Perl support is not included with MySQL distributions. You can obtain the necessary modules from <http://search.cpan.org> for Unix, or by using the ActiveState `ppm` program on Windows. The following sections describe how to do this.

The `DBI/DBD` interface requires Perl 5.6.0, and 5.6.1 or later is preferred. `DBI` *does not work* if you have an older version of Perl. You should use `DBD::mysql` 4.009 or higher. Although earlier versions are available, they do not support the full functionality of MySQL 5.5.

2.13.1 Installing Perl on Unix

MySQL Perl support requires that you have installed MySQL client programming support (libraries and header files). Most installation methods install the necessary files. If you install MySQL from RPM files on Linux, be sure to install the developer RPM as well. The client programs are in the client RPM, but client programming support is in the developer RPM.

The files you need for Perl support can be obtained from the CPAN (Comprehensive Perl Archive Network) at <http://search.cpan.org>.

The easiest way to install Perl modules on Unix is to use the `CPAN` module. For example:

```
shell> perl -MCPAN -e shell
cpan> install DBI
cpan> install DBD::mysql
```

The `DBD::mysql` installation runs a number of tests. These tests attempt to connect to the local MySQL server using the default user name and password. (The default user name is your login name on Unix, and `ODBC` on Windows. The default password is “no password.”) If you cannot connect to the server with those values (for example, if your account has a password), the tests fail. You can use `force install DBD::mysql` to ignore the failed tests.

`DBI` requires the `Data::Dumper` module. It may be installed; if not, you should install it before installing `DBI`.

It is also possible to download the module distributions in the form of compressed `tar` archives and build the modules manually. For example, to unpack and build a `DBI` distribution, use a procedure such as this:

1. Unpack the distribution into the current directory:

```
shell> gunzip < DBI-VERSION.tar.gz | tar xvf -
```

This command creates a directory named `DBI-VERSION`.

2. Change location into the top-level directory of the unpacked distribution:

```
shell> cd DBI-VERSION
```

3. Build the distribution and compile everything:

```
shell> perl Makefile.PL
shell> make
shell> make test
shell> make install
```

The `make test` command is important because it verifies that the module is working. Note that when you run that command during the `DBD:mysql` installation to exercise the interface code, the MySQL server must be running or the test fails.

It is a good idea to rebuild and reinstall the `DBD:mysql` distribution whenever you install a new release of MySQL. This ensures that the latest versions of the MySQL client libraries are installed correctly.

If you do not have access rights to install Perl modules in the system directory or if you want to install local Perl modules, the following reference may be useful: <http://learn.perl.org/faq/perlfaq8.html#How-do-I-keep-my-own-module-library-directory->

2.13.2 Installing ActiveState Perl on Windows

On Windows, you should do the following to install the MySQL `DBD` module with ActiveState Perl:

1. Get ActiveState Perl from <http://www.activestate.com/Products/ActivePerl/> and install it.
2. Open a console window.
3. If necessary, set the `HTTP_proxy` variable. For example, you might try a setting like this:

```
C:\> set HTTP_proxy=my.proxy.com:3128
```

4. Start the PPM program:

```
C:\> C:\perl\bin\ppm.pl
```

5. If you have not previously done so, install `DBI`:

```
ppm> install DBI
```

6. If this succeeds, run the following command:

```
ppm> install DBD-mysql
```

This procedure should work with ActiveState Perl 5.6 or newer.

If you cannot get the procedure to work, you should install the ODBC driver instead and connect to the MySQL server through ODBC:

```
use DBI;
$dbh= DBI->connect("DBI:ODBC:$dsn",$user,$password) ||
die "Got error $DBI::errstr when connecting to $dsn\n";
```

2.13.3 Problems Using the Perl `DBI/DBD` Interface

If Perl reports that it cannot find the `../mysql/mysql.so` module, the problem is probably that Perl cannot locate the `libmysqlclient.so` shared library. You should be able to fix this problem by one of the following methods:

- Copy `libmysqlclient.so` to the directory where your other shared libraries are located (probably `/usr/lib` or `/lib`).
- Modify the `-L` options used to compile `DBD:mysql` to reflect the actual location of `libmysqlclient.so`.
- On Linux, you can add the path name of the directory where `libmysqlclient.so` is located to the `/etc/ld.so.conf` file.
- Add the path name of the directory where `libmysqlclient.so` is located to the `LD_RUN_PATH` environment variable. Some systems use `LD_LIBRARY_PATH` instead.

Note that you may also need to modify the `-L` options if there are other libraries that the linker fails to find. For example, if the linker cannot find `libc` because it is in `/lib` and the link command specifies `-L/usr/lib`, change the `-L` option to `-L/lib` or add `-L/lib` to the existing link command.

If you get the following errors from `DBD:mysql`, you are probably using `gcc` (or using an old binary compiled with `gcc`):

```
/usr/bin/perl: can't resolve symbol '__moddi3'
/usr/bin/perl: can't resolve symbol '__divdi3'
```

Add `-L/usr/lib/gcc-lib/... -lgcc` to the link command when the `mysql.so` library gets built (check the output from `make` for `mysql.so` when you compile the Perl client). The `-L` option should specify the path name of the directory where `libgcc.a` is located on your system.

Another cause of this problem may be that Perl and MySQL are not both compiled with `gcc`. In this case, you can solve the mismatch by compiling both with `gcc`.

3.6.9 Using <code>AUTO_INCREMENT</code>	250
3.7 Using MySQL with Apache	252

This chapter provides a tutorial introduction to MySQL by showing how to use the `mysql` client program to create and use a simple database. `mysql` (sometimes referred to as the “terminal monitor” or just “monitor”) is an interactive program that enables you to connect to a MySQL server, run queries, and view the results. `mysql` may also be used in batch mode: you place your queries in a file beforehand, then tell `mysql` to execute the contents of the file. Both ways of using `mysql` are covered here.

To see a list of options provided by `mysql`, invoke it with the `--help` option:

```
shell> mysql --help
```

This chapter assumes that `mysql` is installed on your machine and that a MySQL server is available to which you can connect. If this is not true, contact your MySQL administrator. (If *you* are the administrator, you need to consult the relevant portions of this manual, such as [Chapter 5, MySQL Server Administration](#).)

This chapter describes the entire process of setting up and using a database. If you are interested only in accessing an existing database, you may want to skip over the sections that describe how to create the database and the tables it contains.

Because this chapter is tutorial in nature, many details are necessarily omitted. Consult the relevant sections of the manual for more information on the topics covered here.

3.1 Connecting to and Disconnecting from the Server

To connect to the server, you will usually need to provide a MySQL user name when you invoke `mysql` and, most likely, a password. If the server runs on a machine other than the one where you log in, you will

also need to specify a host name. Contact your administrator to find out what connection parameters you should use to connect (that is, what host, user name, and password to use). Once you know the proper parameters, you should be able to connect like this:

```
shell> mysql -h host -u user -p
Enter password: *****
```

`host` and `user` represent the host name where your MySQL server is running and the user name of your MySQL account. Substitute appropriate values for your setup. The `*****` represents your password; enter it when `mysql` displays the `Enter password:` prompt.

If that works, you should see some introductory information followed by a `mysql>` prompt:

```
shell> mysql -h host -u user -p
Enter password: *****
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 25338 to server version: 5.5.40-standard

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

The `mysql>` prompt tells you that `mysql` is ready for you to enter commands.

If you are logging in on the same machine that MySQL is running on, you can omit the host, and simply use the following:

```
shell> mysql -u user -p
```

If, when you attempt to log in, you get an error message such as `ERROR 2002 (HY000): Can't connect to local MySQL server through socket '/tmp/mysql.sock' (2)`, it means that the MySQL server daemon (Unix) or service (Windows) is not running. Consult the administrator or see the section of [Chapter 2, Installing and Upgrading MySQL](#) that is appropriate to your operating system.

For help with other problems often encountered when trying to log in, see [Section B.5.2, “Common Errors When Using MySQL Programs”](#).

Some MySQL installations permit users to connect as the anonymous (unnamed) user to the server running on the local host. If this is the case on your machine, you should be able to connect to that server by invoking `mysql` without any options:

```
shell> mysql
```

After you have connected successfully, you can disconnect any time by typing `QUIT` (or `\q`) at the `mysql>` prompt:

```
mysql> QUIT
Bye
```

On Unix, you can also disconnect by pressing Control+D.

Most examples in the following sections assume that you are connected to the server. They indicate this by the `mysql>` prompt.

3.2 Entering Queries

Make sure that you are connected to the server, as discussed in the previous section. Doing so does not in itself select any database to work with, but that is okay. At this point, it is more important to find out a little about how to issue queries than to jump right in creating tables, loading data into them, and retrieving data from them. This section describes the basic principles of entering commands, using several queries you can try out to familiarize yourself with how `mysql` works.

Here is a simple command that asks the server to tell you its version number and the current date. Type it in as shown here following the `mysql>` prompt and press Enter:

```
mysql> SELECT VERSION(), CURRENT_DATE;
+-----+-----+
| VERSION() | CURRENT_DATE |
+-----+-----+
| 5.5.0-m2-log | 2009-05-04 |
+-----+-----+
1 row in set (0.01 sec)
mysql>
```

This query illustrates several things about `mysql`:

- A command normally consists of an SQL statement followed by a semicolon. (There are some exceptions where a semicolon may be omitted. `QUIT`, mentioned earlier, is one of them. We'll get to others later.)
- When you issue a command, `mysql` sends it to the server for execution and displays the results, then prints another `mysql>` prompt to indicate that it is ready for another command.
- `mysql` displays query output in tabular form (rows and columns). The first row contains labels for the columns. The rows following are the query results. Normally, column labels are the names of the columns you fetch from database tables. If you're retrieving the value of an expression rather than a table column (as in the example just shown), `mysql` labels the column using the expression itself.
- `mysql` shows how many rows were returned and how long the query took to execute, which gives you a rough idea of server performance. These values are imprecise because they represent wall clock time (not CPU or machine time), and because they are affected by factors such as server load and network latency. (For brevity, the “rows in set” line is sometimes not shown in the remaining examples in this chapter.)

Keywords may be entered in any lettercase. The following queries are equivalent:

```
mysql> SELECT VERSION(), CURRENT_DATE;
mysql> select version(), current_date;
mysql> SeLeCt vErSiOn(), current_DATE;
```

Here is another query. It demonstrates that you can use `mysql` as a simple calculator:

```
mysql> SELECT SIN(PI()/4), (4+1)*5;
+-----+-----+
| SIN(PI()/4) | (4+1)*5 |
+-----+-----+
| 0.70710678118655 | 25 |
+-----+-----+
1 row in set (0.02 sec)
```

The queries shown thus far have been relatively short, single-line statements. You can even enter multiple statements on a single line. Just end each one with a semicolon:

```
mysql> SELECT VERSION(); SELECT NOW();
+-----+
| VERSION() |
+-----+
| 5.5.0-m2-log |
+-----+
1 row in set (0.00 sec)

+-----+
| NOW() |
+-----+
| 2009-05-04 15:15:00 |
+-----+
1 row in set (0.00 sec)
```

A command need not be given all on a single line, so lengthy commands that require several lines are not a problem. `mysql` determines where your statement ends by looking for the terminating semicolon, not by looking for the end of the input line. (In other words, `mysql` accepts free-format input: it collects input lines but does not execute them until it sees the semicolon.)

Here is a simple multiple-line statement:

```
mysql> SELECT
-> USER()
-> ,
-> CURRENT_DATE;
+-----+
| USER() | CURRENT_DATE |
+-----+
| jon@localhost | 2005-10-11 |
+-----+
```

In this example, notice how the prompt changes from `mysql>` to `->` after you enter the first line of a multiple-line query. This is how `mysql` indicates that it has not yet seen a complete statement and is waiting for the rest. The prompt is your friend, because it provides valuable feedback. If you use that feedback, you can always be aware of what `mysql` is waiting for.

If you decide you do not want to execute a command that you are in the process of entering, cancel it by typing `\c`:

```
mysql> SELECT
-> USER()
-> \c
mysql>
```

Here, too, notice the prompt. It switches back to `mysql>` after you type `\c`, providing feedback to indicate that `mysql` is ready for a new command.

The following table shows each of the prompts you may see and summarizes what they mean about the state that `mysql` is in.

Prompt	Meaning
<code>mysql></code>	Ready for new command.
<code>-></code>	Waiting for next line of multiple-line command.
<code>'></code>	Waiting for next line, waiting for completion of a string that began with a single quote ("').
<code>"></code>	Waiting for next line, waiting for completion of a string that began with a double quote ("").

Prompt	Meaning
`>	Waiting for next line, waiting for completion of an identifier that began with a backtick ("`").
/*>	Waiting for next line, waiting for completion of a comment that began with /*.

Multiple-line statements commonly occur by accident when you intend to issue a command on a single line, but forget the terminating semicolon. In this case, `mysql` waits for more input:

```
mysql> SELECT USER()
->
```

If this happens to you (you think you've entered a statement but the only response is a `->` prompt), most likely `mysql` is waiting for the semicolon. If you don't notice what the prompt is telling you, you might sit there for a while before realizing what you need to do. Enter a semicolon to complete the statement, and `mysql` executes it:

```
mysql> SELECT USER()
-> ;
+-----+
| USER() |
+-----+
| jon@localhost |
+-----+
```

The `'>` and `>>` prompts occur during string collection (another way of saying that MySQL is waiting for completion of a string). In MySQL, you can write strings surrounded by either `"` or `"` characters (for example, `'hello'` or `"goodbye"`), and `mysql` lets you enter strings that span multiple lines. When you see a `'>` or `>>` prompt, it means that you have entered a line containing a string that begins with a `"` or `"` quote character, but have not yet entered the matching quote that terminates the string. This often indicates that you have inadvertently left out a quote character. For example:

```
mysql> SELECT * FROM my_table WHERE name = 'Smith AND age < 30;
'>
```

If you enter this `SELECT` statement, then press **Enter** and wait for the result, nothing happens. Instead of wondering why this query takes so long, notice the clue provided by the `'>` prompt. It tells you that `mysql` expects to see the rest of an unterminated string. (Do you see the error in the statement? The string `'Smith` is missing the second single quotation mark.)

At this point, what do you do? The simplest thing is to cancel the command. However, you cannot just type `\c` in this case, because `mysql` interprets it as part of the string that it is collecting. Instead, enter the closing quote character (so `mysql` knows you've finished the string), then type `\c`:

```
mysql> SELECT * FROM my_table WHERE name = 'Smith AND age < 30;
'> '\c
mysql>
```

The prompt changes back to `mysql>`, indicating that `mysql` is ready for a new command.

The ``>` prompt is similar to the `'>` and `>>` prompts, but indicates that you have begun but not completed a backtick-quoted identifier.

It is important to know what the `'>`, `>>`, and ``>` prompts signify, because if you mistakenly enter an unterminated string, any further lines you type appear to be ignored by `mysql`—including a line containing `QUIT`. This can be quite confusing, especially if you do not know that you need to supply the terminating quote before you can cancel the current command.

3.3 Creating and Using a Database

Once you know how to enter commands, you are ready to access a database.

Suppose that you have several pets in your home (your menagerie) and you would like to keep track of various types of information about them. You can do so by creating tables to hold your data and loading them with the desired information. Then you can answer different sorts of questions about your animals by retrieving data from the tables. This section shows you how to perform the following operations:

- Create a database
- Create a table
- Load data into the table
- Retrieve data from the table in various ways
- Use multiple tables

The menagerie database is simple (deliberately), but it is not difficult to think of real-world situations in which a similar type of database might be used. For example, a database like this could be used by a farmer to keep track of livestock, or by a veterinarian to keep track of patient records. A menagerie distribution containing some of the queries and sample data used in the following sections can be obtained from the MySQL Web site. It is available in both compressed `tar` file and Zip formats at <http://dev.mysql.com/doc/>.

Use the `SHOW` statement to find out what databases currently exist on the server:

```
mysql> SHOW DATABASES;
+-----+
| Database |
+-----+
| mysql    |
| test     |
| tmp      |
+-----+
```

The `mysql` database describes user access privileges. The `test` database often is available as a workspace for users to try things out.

The list of databases displayed by the statement may be different on your machine; `SHOW DATABASES` does not show databases that you have no privileges for if you do not have the `SHOW DATABASES` privilege. See [Section 13.7.5.15, “SHOW DATABASES Syntax”](#).

If the `test` database exists, try to access it:

```
mysql> USE test
Database changed
```

`USE`, like `QUIT`, does not require a semicolon. (You can terminate such statements with a semicolon if you like; it does no harm.) The `USE` statement is special in another way, too: it must be given on a single line.

You can use the `test` database (if you have access to it) for the examples that follow, but anything you create in that database can be removed by anyone else with access to it. For this reason, you should probably ask your MySQL administrator for permission to use a database of your own. Suppose that you want to call yours `menagerie`. The administrator needs to execute a command like this:

```
mysql> GRANT ALL ON menagerie.* TO 'your_mysql_name'@'your_client_host';
```

where `your_mysql_name` is the MySQL user name assigned to you and `your_client_host` is the host from which you connect to the server.

3.3.1 Creating and Selecting a Database

If the administrator creates your database for you when setting up your permissions, you can begin using it. Otherwise, you need to create it yourself:

```
mysql> CREATE DATABASE menagerie;
```

Under Unix, database names are case sensitive (unlike SQL keywords), so you must always refer to your database as `menagerie`, not as `Menagerie`, `MENAGERIE`, or some other variant. This is also true for table names. (Under Windows, this restriction does not apply, although you must refer to databases and tables using the same lettercase throughout a given query. However, for a variety of reasons, the recommended best practice is always to use the same lettercase that was used when the database was created.)

Note

If you get an error such as `ERROR 1044 (42000): Access denied for user 'monty'@'localhost' to database 'menagerie'` when attempting to create a database, this means that your user account does not have the necessary privileges to do so. Discuss this with the administrator or see [Section 6.2, “The MySQL Access Privilege System”](#).

Creating a database does not select it for use; you must do that explicitly. To make `menagerie` the current database, use this command:

```
mysql> USE menagerie
Database changed
```

Your database needs to be created only once, but you must select it for use each time you begin a `mysql` session. You can do this by issuing a `USE` statement as shown in the example. Alternatively, you can select the database on the command line when you invoke `mysql`. Just specify its name after any connection parameters that you might need to provide. For example:

```
shell> mysql -h host -u user -p menagerie
Enter password: *****
```

Important

`menagerie` in the command just shown is **not** your password. If you want to supply your password on the command line after the `-p` option, you must do so with no intervening space (for example, as `-pmypassword`, not as `-p mypassword`). However, putting your password on the command line is not recommended, because doing so exposes it to snooping by other users logged in on your machine.

Note

You can see at any time which database is currently selected using `SELECT DATABASE()`.

3.3.2 Creating a Table

Creating the database is the easy part, but at this point it is empty, as `SHOW TABLES` tells you:

```
mysql> SHOW TABLES;
Empty set (0.00 sec)
```

The harder part is deciding what the structure of your database should be: what tables you need and what columns should be in each of them.

You want a table that contains a record for each of your pets. This can be called the `pet` table, and it should contain, as a bare minimum, each animal's name. Because the name by itself is not very interesting, the table should contain other information. For example, if more than one person in your family keeps pets, you might want to list each animal's owner. You might also want to record some basic descriptive information such as species and sex.

How about age? That might be of interest, but it is not a good thing to store in a database. Age changes as time passes, which means you'd have to update your records often. Instead, it is better to store a fixed value such as date of birth. Then, whenever you need age, you can calculate it as the difference between the current date and the birth date. MySQL provides functions for doing date arithmetic, so this is not difficult. Storing birth date rather than age has other advantages, too:

- You can use the database for tasks such as generating reminders for upcoming pet birthdays. (If you think this type of query is somewhat silly, note that it is the same question you might ask in the context of a business database to identify clients to whom you need to send out birthday greetings in the current week or month, for that computer-assisted personal touch.)
- You can calculate age in relation to dates other than the current date. For example, if you store death date in the database, you can easily calculate how old a pet was when it died.

You can probably think of other types of information that would be useful in the `pet` table, but the ones identified so far are sufficient: name, owner, species, sex, birth, and death.

Use a `CREATE TABLE` statement to specify the layout of your table:

```
mysql> CREATE TABLE pet (name VARCHAR(20), owner VARCHAR(20),
-> species VARCHAR(20), sex CHAR(1), birth DATE, death DATE);
```

`VARCHAR` is a good choice for the `name`, `owner`, and `species` columns because the column values vary in length. The lengths in those column definitions need not all be the same, and need not be 20. You can normally pick any length from 1 to 65535, whatever seems most reasonable to you. If you make a poor choice and it turns out later that you need a longer field, MySQL provides an `ALTER TABLE` statement.

Several types of values can be chosen to represent sex in animal records, such as `'m'` and `'f'`, or perhaps `'male'` and `'female'`. It is simplest to use the single characters `'m'` and `'f'`.

The use of the `DATE` data type for the `birth` and `death` columns is a fairly obvious choice.

Once you have created a table, `SHOW TABLES` should produce some output:

```
mysql> SHOW TABLES;
+-----+
| Tables in menagerie |
+-----+
| pet                  |
+-----+
```

To verify that your table was created the way you expected, use a `DESCRIBE` statement:

```
mysql> DESCRIBE pet;
```

Field	Type	Null	Key	Default	Extra
name	varchar(20)	YES		NULL	
owner	varchar(20)	YES		NULL	
species	varchar(20)	YES		NULL	
sex	char(1)	YES		NULL	
birth	date	YES		NULL	
death	date	YES		NULL	

You can use `DESCRIBE` any time, for example, if you forget the names of the columns in your table or what types they have.

For more information about MySQL data types, see [Chapter 11, Data Types](#).

3.3.3 Loading Data into a Table

After creating your table, you need to populate it. The `LOAD DATA` and `INSERT` statements are useful for this.

Suppose that your pet records can be described as shown here. (Observe that MySQL expects dates in 'YYYY-MM-DD' format; this may be different from what you are used to.)

name	owner	species	sex	birth	death
Fluffy	Harold	cat	f	1993-02-04	
Claws	Gwen	cat	m	1994-03-17	
Buffy	Harold	dog	f	1989-05-13	
Fang	Benny	dog	m	1990-08-27	
Bowser	Diane	dog	m	1979-08-31	1995-07-29
Chirpy	Gwen	bird	f	1998-09-11	
Whistler	Gwen	bird		1997-12-09	
Slim	Benny	snake	m	1996-04-29	

Because you are beginning with an empty table, an easy way to populate it is to create a text file containing a row for each of your animals, then load the contents of the file into the table with a single statement.

You could create a text file `pet.txt` containing one record per line, with values separated by tabs, and given in the order in which the columns were listed in the `CREATE TABLE` statement. For missing values (such as unknown sexes or death dates for animals that are still living), you can use `NULL` values. To represent these in your text file, use `\N` (backslash, capital-N). For example, the record for Whistler the bird would look like this (where the whitespace between values is a single tab character):

```
Whistler      Gwen      bird      \N      1997-12-09      \N
```

To load the text file `pet.txt` into the `pet` table, use this statement:

```
mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet;
```

If you created the file on Windows with an editor that uses `\r\n` as a line terminator, you should use this statement instead:

```
mysql> LOAD DATA LOCAL INFILE '/path/pet.txt' INTO TABLE pet
-> LINES TERMINATED BY '\r\n';
```

(On an Apple machine running OS X, you would likely want to use `LINES TERMINATED BY '\r'.`)

You can specify the column value separator and end of line marker explicitly in the `LOAD DATA` statement if you wish, but the defaults are tab and linefeed. These are sufficient for the statement to read the file `pet.txt` properly.

If the statement fails, it is likely that your MySQL installation does not have local file capability enabled by default. See [Section 6.1.6, “Security Issues with `LOAD DATA LOCAL`”](#), for information on how to change this.

When you want to add new records one at a time, the `INSERT` statement is useful. In its simplest form, you supply values for each column, in the order in which the columns were listed in the `CREATE TABLE` statement. Suppose that Diane gets a new hamster named “Puffball.” You could add a new record using an `INSERT` statement like this:

```
mysql> INSERT INTO pet
-> VALUES ('Puffball','Diane','hamster','f','1999-03-30',NULL);
```

String and date values are specified as quoted strings here. Also, with `INSERT`, you can insert `NULL` directly to represent a missing value. You do not use `\N` like you do with `LOAD DATA`.

From this example, you should be able to see that there would be a lot more typing involved to load your records initially using several `INSERT` statements rather than a single `LOAD DATA` statement.

3.3.4 Retrieving Information from a Table

The `SELECT` statement is used to pull information from a table. The general form of the statement is:

```
SELECT what_to_select
FROM which_table
WHERE conditions_to_satisfy;
```

what_to_select indicates what you want to see. This can be a list of columns, or `*` to indicate “all columns.” *which_table* indicates the table from which you want to retrieve data. The `WHERE` clause is optional. If it is present, *conditions_to_satisfy* specifies one or more conditions that rows must satisfy to qualify for retrieval.

3.3.4.1 Selecting All Data

The simplest form of `SELECT` retrieves everything from a table:

```
mysql> SELECT * FROM pet;
```

name	owner	species	sex	birth	death
Fluffy	Harold	cat	f	1993-02-04	NULL
Claws	Gwen	cat	m	1994-03-17	NULL
Buffy	Harold	dog	f	1989-05-13	NULL
Fang	Benny	dog	m	1990-08-27	NULL
Bowser	Diane	dog	m	1979-08-31	1995-07-29
Chirpy	Gwen	bird	f	1998-09-11	NULL
Whistler	Gwen	bird	NULL	1997-12-09	NULL
Slim	Benny	snake	m	1996-04-29	NULL

Puffball	Diane	hamster	f	1999-03-30	NULL
----------	-------	---------	---	------------	------

This form of `SELECT` is useful if you want to review your entire table, for example, after you've just loaded it with your initial data set. For example, you may happen to think that the birth date for Bowser doesn't seem quite right. Consulting your original pedigree papers, you find that the correct birth year should be 1989, not 1979.

There are at least two ways to fix this:

- Edit the file `pet.txt` to correct the error, then empty the table and reload it using `DELETE` and `LOAD DATA`:

```
mysql> DELETE FROM pet;
mysql> LOAD DATA LOCAL INFILE 'pet.txt' INTO TABLE pet;
```

However, if you do this, you must also re-enter the record for Puffball.

- Fix only the erroneous record with an `UPDATE` statement:

```
mysql> UPDATE pet SET birth = '1989-08-31' WHERE name = 'Bowser';
```

The `UPDATE` changes only the record in question and does not require you to reload the table.

3.3.4.2 Selecting Particular Rows

As shown in the preceding section, it is easy to retrieve an entire table. Just omit the `WHERE` clause from the `SELECT` statement. But typically you don't want to see the entire table, particularly when it becomes large. Instead, you're usually more interested in answering a particular question, in which case you specify some constraints on the information you want. Let's look at some selection queries in terms of questions about your pets that they answer.

You can select only particular rows from your table. For example, if you want to verify the change that you made to Bowser's birth date, select Bowser's record like this:

```
mysql> SELECT * FROM pet WHERE name = 'Bowser';
+-----+-----+-----+-----+-----+-----+
| name  | owner | species | sex  | birth      | death      |
+-----+-----+-----+-----+-----+-----+
| Bowser | Diane | dog     | m    | 1989-08-31 | 1995-07-29 |
+-----+-----+-----+-----+-----+-----+
```

The output confirms that the year is correctly recorded as 1989, not 1979.

String comparisons normally are case-insensitive, so you can specify the name as `'bowser'`, `'BOWSER'`, and so forth. The query result is the same.

You can specify conditions on any column, not just `name`. For example, if you want to know which animals were born during or after 1998, test the `birth` column:

```
mysql> SELECT * FROM pet WHERE birth >= '1998-1-1';
+-----+-----+-----+-----+-----+-----+
| name      | owner | species | sex  | birth      | death      |
+-----+-----+-----+-----+-----+-----+
| Chirpy    | Gwen  | bird    | f    | 1998-09-11 | NULL       |
| Puffball  | Diane | hamster | f    | 1999-03-30 | NULL       |
+-----+-----+-----+-----+-----+-----+
```

You can combine conditions, for example, to locate female dogs:

```
mysql> SELECT * FROM pet WHERE species = 'dog' AND sex = 'f';
```

name	owner	species	sex	birth	death
Buffy	Harold	dog	f	1989-05-13	NULL

The preceding query uses the `AND` logical operator. There is also an `OR` operator:

```
mysql> SELECT * FROM pet WHERE species = 'snake' OR species = 'bird';
```

name	owner	species	sex	birth	death
Chirpy	Gwen	bird	f	1998-09-11	NULL
Whistler	Gwen	bird	NULL	1997-12-09	NULL
Slim	Benny	snake	m	1996-04-29	NULL

`AND` and `OR` may be intermixed, although `AND` has higher precedence than `OR`. If you use both operators, it is a good idea to use parentheses to indicate explicitly how conditions should be grouped:

```
mysql> SELECT * FROM pet WHERE (species = 'cat' AND sex = 'm')
-> OR (species = 'dog' AND sex = 'f');
```

name	owner	species	sex	birth	death
Claws	Gwen	cat	m	1994-03-17	NULL
Buffy	Harold	dog	f	1989-05-13	NULL

3.3.4.3 Selecting Particular Columns

If you do not want to see entire rows from your table, just name the columns in which you are interested, separated by commas. For example, if you want to know when your animals were born, select the `name` and `birth` columns:

```
mysql> SELECT name, birth FROM pet;
```

name	birth
Fluffy	1993-02-04
Claws	1994-03-17
Buffy	1989-05-13
Fang	1990-08-27
Bowser	1989-08-31
Chirpy	1998-09-11
Whistler	1997-12-09
Slim	1996-04-29
Puffball	1999-03-30

To find out who owns pets, use this query:

```
mysql> SELECT owner FROM pet;
```

owner

Harold
Gwen
Harold
Benny
Diane
Gwen
Gwen
Benny
Diane

Notice that the query simply retrieves the `owner` column from each record, and some of them appear more than once. To minimize the output, retrieve each unique output record just once by adding the keyword `DISTINCT`:

```
mysql> SELECT DISTINCT owner FROM pet;
```

owner
Benny
Diane
Gwen
Harold

You can use a `WHERE` clause to combine row selection with column selection. For example, to get birth dates for dogs and cats only, use this query:

```
mysql> SELECT name, species, birth FROM pet
-> WHERE species = 'dog' OR species = 'cat';
```

name	species	birth
Fluffy	cat	1993-02-04
Claws	cat	1994-03-17
Buffy	dog	1989-05-13
Fang	dog	1990-08-27
Bowser	dog	1989-08-31

3.3.4.4 Sorting Rows

You may have noticed in the preceding examples that the result rows are displayed in no particular order. It is often easier to examine query output when the rows are sorted in some meaningful way. To sort a result, use an `ORDER BY` clause.

Here are animal birthdays, sorted by date:

```
mysql> SELECT name, birth FROM pet ORDER BY birth;
```

name	birth
Buffy	1989-05-13
Bowser	1989-08-31
Fang	1990-08-27
Fluffy	1993-02-04
Claws	1994-03-17
Slim	1996-04-29
Whistler	1997-12-09
Chirpy	1998-09-11

```
| Puffball | 1999-03-30 |
+-----+-----+
```

On character type columns, sorting—like all other comparison operations—is normally performed in a case-insensitive fashion. This means that the order is undefined for columns that are identical except for their case. You can force a case-sensitive sort for a column by using `BINARY` like so: `ORDER BY BINARY col_name`.

The default sort order is ascending, with smallest values first. To sort in reverse (descending) order, add the `DESC` keyword to the name of the column you are sorting by:

```
mysql> SELECT name, birth FROM pet ORDER BY birth DESC;
```

```
+-----+-----+
| name   | birth   |
+-----+-----+
| Puffball | 1999-03-30 |
| Chirpy  | 1998-09-11 |
| Whistler | 1997-12-09 |
| Slim    | 1996-04-29 |
| Claws    | 1994-03-17 |
| Fluffy   | 1993-02-04 |
| Fang     | 1990-08-27 |
| Bowser   | 1989-08-31 |
| Buffy    | 1989-05-13 |
+-----+-----+
```

You can sort on multiple columns, and you can sort different columns in different directions. For example, to sort by type of animal in ascending order, then by birth date within animal type in descending order (youngest animals first), use the following query:

```
mysql> SELECT name, species, birth FROM pet
-> ORDER BY species, birth DESC;
```

```
+-----+-----+-----+
| name   | species | birth   |
+-----+-----+-----+
| Chirpy  | bird    | 1998-09-11 |
| Whistler | bird    | 1997-12-09 |
| Claws    | cat     | 1994-03-17 |
| Fluffy   | cat     | 1993-02-04 |
| Fang     | dog     | 1990-08-27 |
| Bowser   | dog     | 1989-08-31 |
| Buffy    | dog     | 1989-05-13 |
| Puffball | hamster | 1999-03-30 |
| Slim     | snake   | 1996-04-29 |
+-----+-----+-----+
```

The `DESC` keyword applies only to the column name immediately preceding it (`birth`); it does not affect the `species` column sort order.

3.3.4.5 Date Calculations

MySQL provides several functions that you can use to perform calculations on dates, for example, to calculate ages or extract parts of dates.

To determine how many years old each of your pets is, use the `TIMESTAMPDIFF()` function. Its arguments are the unit in which you want the result expressed, and the two date for which to take the difference. The following query shows, for each pet, the birth date, the current date, and the age in years. An *alias* (`age`) is used to make the final output column label more meaningful.

```
mysql> SELECT name, birth, CURDATE(),
-> TIMESTAMPDIFF(YEAR,birth,CURDATE()) AS age
-> FROM pet;
```

name	birth	CURDATE()	age
Fluffy	1993-02-04	2003-08-19	10
Claws	1994-03-17	2003-08-19	9
Buffy	1989-05-13	2003-08-19	14
Fang	1990-08-27	2003-08-19	12
Bowser	1989-08-31	2003-08-19	13
Chirpy	1998-09-11	2003-08-19	4
Whistler	1997-12-09	2003-08-19	5
Slim	1996-04-29	2003-08-19	7
Puffball	1999-03-30	2003-08-19	4

The query works, but the result could be scanned more easily if the rows were presented in some order. This can be done by adding an `ORDER BY name` clause to sort the output by name:

```
mysql> SELECT name, birth, CURDATE(),
-> TIMESTAMPDIFF(YEAR,birth,CURDATE()) AS age
-> FROM pet ORDER BY name;
```

name	birth	CURDATE()	age
Bowser	1989-08-31	2003-08-19	13
Buffy	1989-05-13	2003-08-19	14
Chirpy	1998-09-11	2003-08-19	4
Claws	1994-03-17	2003-08-19	9
Fang	1990-08-27	2003-08-19	12
Fluffy	1993-02-04	2003-08-19	10
Puffball	1999-03-30	2003-08-19	4
Slim	1996-04-29	2003-08-19	7
Whistler	1997-12-09	2003-08-19	5

To sort the output by `age` rather than `name`, just use a different `ORDER BY` clause:

```
mysql> SELECT name, birth, CURDATE(),
-> TIMESTAMPDIFF(YEAR,birth,CURDATE()) AS age
-> FROM pet ORDER BY age;
```

name	birth	CURDATE()	age
Chirpy	1998-09-11	2003-08-19	4
Puffball	1999-03-30	2003-08-19	4
Whistler	1997-12-09	2003-08-19	5
Slim	1996-04-29	2003-08-19	7
Claws	1994-03-17	2003-08-19	9
Fluffy	1993-02-04	2003-08-19	10
Fang	1990-08-27	2003-08-19	12
Bowser	1989-08-31	2003-08-19	13
Buffy	1989-05-13	2003-08-19	14

A similar query can be used to determine age at death for animals that have died. You determine which animals these are by checking whether the `death` value is `NULL`. Then, for those with non-`NULL` values, compute the difference between the `death` and `birth` values:

```
mysql> SELECT name, birth, death,
-> TIMESTAMPDIFF(YEAR,birth,death) AS age
-> FROM pet WHERE death IS NOT NULL ORDER BY age;
```

name	birth	death	age
Bowser	1989-08-31	1995-07-29	5

The query uses `death IS NOT NULL` rather than `death <> NULL` because `NULL` is a special value that cannot be compared using the usual comparison operators. This is discussed later. See [Section 3.3.4.6, “Working with NULL Values”](#).

What if you want to know which animals have birthdays next month? For this type of calculation, year and day are irrelevant; you simply want to extract the month part of the `birth` column. MySQL provides several functions for extracting parts of dates, such as `YEAR()`, `MONTH()`, and `DAYOFMONTH()`. `MONTH()` is the appropriate function here. To see how it works, run a simple query that displays the value of both `birth` and `MONTH(birth)`:

```
mysql> SELECT name, birth, MONTH(birth) FROM pet;
```

name	birth	MONTH(birth)
Fluffy	1993-02-04	2
Claws	1994-03-17	3
Buffy	1989-05-13	5
Fang	1990-08-27	8
Bowser	1989-08-31	8
Chirpy	1998-09-11	9
Whistler	1997-12-09	12
Slim	1996-04-29	4
Puffball	1999-03-30	3

Finding animals with birthdays in the upcoming month is also simple. Suppose that the current month is April. Then the month value is `4` and you can look for animals born in May (month `5`) like this:

```
mysql> SELECT name, birth FROM pet WHERE MONTH(birth) = 5;
```

name	birth
Buffy	1989-05-13

There is a small complication if the current month is December. You cannot merely add one to the month number (`12`) and look for animals born in month `13`, because there is no such month. Instead, you look for animals born in January (month `1`).

You can write the query so that it works no matter what the current month is, so that you do not have to use the number for a particular month. `DATE_ADD()` enables you to add a time interval to a given date. If you add a month to the value of `CURDATE()`, then extract the month part with `MONTH()`, the result produces the month in which to look for birthdays:

```
mysql> SELECT name, birth FROM pet
-> WHERE MONTH(birth) = MONTH(DATE_ADD(CURDATE(),INTERVAL 1 MONTH));
```

A different way to accomplish the same task is to add `1` to get the next month after the current one after using the modulo function (`MOD`) to wrap the month value to `0` if it is currently `12`:

```
mysql> SELECT name, birth FROM pet
-> WHERE MONTH(birth) = MOD(MONTH(CURDATE()), 12) + 1;
```

`MONTH()` returns a number between 1 and 12. And `MOD(something,12)` returns a number between 0 and 11. So the addition has to be after the `MOD()`, otherwise we would go from November (11) to January (1).

3.3.4.6 Working with `NULL` Values

The `NULL` value can be surprising until you get used to it. Conceptually, `NULL` means “a missing unknown value” and it is treated somewhat differently from other values.

To test for `NULL`, use the `IS NULL` and `IS NOT NULL` operators, as shown here:

```
mysql> SELECT 1 IS NULL, 1 IS NOT NULL;
+-----+-----+
| 1 IS NULL | 1 IS NOT NULL |
+-----+-----+
| 0 | 1 |
+-----+-----+
```

You cannot use arithmetic comparison operators such as `=`, `<`, or `<>` to test for `NULL`. To demonstrate this for yourself, try the following query:

```
mysql> SELECT 1 = NULL, 1 <> NULL, 1 < NULL, 1 > NULL;
+-----+-----+-----+-----+
| 1 = NULL | 1 <> NULL | 1 < NULL | 1 > NULL |
+-----+-----+-----+-----+
| NULL | NULL | NULL | NULL |
+-----+-----+-----+-----+
```

Because the result of any arithmetic comparison with `NULL` is also `NULL`, you cannot obtain any meaningful results from such comparisons.

In MySQL, 0 or `NULL` means false and anything else means true. The default truth value from a boolean operation is 1.

This special treatment of `NULL` is why, in the previous section, it was necessary to determine which animals are no longer alive using `death IS NOT NULL` instead of `death <> NULL`.

Two `NULL` values are regarded as equal in a `GROUP BY`.

When doing an `ORDER BY`, `NULL` values are presented first if you do `ORDER BY ... ASC` and last if you do `ORDER BY ... DESC`.

A common error when working with `NULL` is to assume that it is not possible to insert a zero or an empty string into a column defined as `NOT NULL`, but this is not the case. These are in fact values, whereas `NULL` means “not having a value.” You can test this easily enough by using `IS [NOT] NULL` as shown:

```
mysql> SELECT 0 IS NULL, 0 IS NOT NULL, '' IS NULL, '' IS NOT NULL;
+-----+-----+-----+-----+
| 0 IS NULL | 0 IS NOT NULL | '' IS NULL | '' IS NOT NULL |
+-----+-----+-----+-----+
| 0 | 1 | 0 | 1 |
+-----+-----+-----+-----+
```

Thus it is entirely possible to insert a zero or empty string into a `NOT NULL` column, as these are in fact `NOT NULL`. See [Section B.5.5.3, “Problems with `NULL` Values”](#).

3.3.4.7 Pattern Matching

MySQL provides standard SQL pattern matching as well as a form of pattern matching based on extended regular expressions similar to those used by Unix utilities such as [vi](#), [grep](#), and [sed](#).

SQL pattern matching enables you to use “[_](#)” to match any single character and “[%](#)” to match an arbitrary number of characters (including zero characters). In MySQL, SQL patterns are case-insensitive by default. Some examples are shown here. You do not use `=` or `<>` when you use SQL patterns; use the [LIKE](#) or [NOT LIKE](#) comparison operators instead.

To find names beginning with “[b](#)”:

```
mysql> SELECT * FROM pet WHERE name LIKE 'b%';
```

name	owner	species	sex	birth	death
Buffy	Harold	dog	f	1989-05-13	NULL
Bowser	Diane	dog	m	1989-08-31	1995-07-29

To find names ending with “[fy](#)”:

```
mysql> SELECT * FROM pet WHERE name LIKE '%fy';
```

name	owner	species	sex	birth	death
Fluffy	Harold	cat	f	1993-02-04	NULL
Buffy	Harold	dog	f	1989-05-13	NULL

To find names containing a “[w](#)”:

```
mysql> SELECT * FROM pet WHERE name LIKE '%w%';
```

name	owner	species	sex	birth	death
Claws	Gwen	cat	m	1994-03-17	NULL
Bowser	Diane	dog	m	1989-08-31	1995-07-29
Whistler	Gwen	bird	NULL	1997-12-09	NULL

To find names containing exactly five characters, use five instances of the “[_](#)” pattern character:

```
mysql> SELECT * FROM pet WHERE name LIKE '_____';
```

name	owner	species	sex	birth	death
Claws	Gwen	cat	m	1994-03-17	NULL
Buffy	Harold	dog	f	1989-05-13	NULL

The other type of pattern matching provided by MySQL uses extended regular expressions. When you test for a match for this type of pattern, use the [REGEXP](#) and [NOT REGEXP](#) operators (or [RLIKE](#) and [NOT RLIKE](#), which are synonyms).

The following list describes some characteristics of extended regular expressions:

- “[.](#)” matches any single character.
- A character class “[[. . .](#)]” matches any character within the brackets. For example, “[[abc](#)]” matches “[a](#)”, “[b](#)”, or “[c](#)”. To name a range of characters, use a dash. “[[a-z](#)]” matches any letter, whereas “[[0-9](#)]” matches any digit.

- “*****” matches zero or more instances of the thing preceding it. For example, “**x***” matches any number of “**x**” characters, “**[0-9]***” matches any number of digits, and “**.***” matches any number of anything.
- A **REGEXP** pattern match succeeds if the pattern matches anywhere in the value being tested. (This differs from a **LIKE** pattern match, which succeeds only if the pattern matches the entire value.)
- To anchor a pattern so that it must match the beginning or end of the value being tested, use “**^**” at the beginning or “**\$**” at the end of the pattern.

To demonstrate how extended regular expressions work, the **LIKE** queries shown previously are rewritten here to use **REGEXP**.

To find names beginning with “**b**”, use “**^**” to match the beginning of the name:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^b';
```

name	owner	species	sex	birth	death
Buffy	Harold	dog	f	1989-05-13	NULL
Bowser	Diane	dog	m	1989-08-31	1995-07-29

If you really want to force a **REGEXP** comparison to be case sensitive, use the **BINARY** keyword to make one of the strings a binary string. This query matches only lowercase “**b**” at the beginning of a name:

```
mysql> SELECT * FROM pet WHERE name REGEXP BINARY '^b';
```

To find names ending with “**fy**”, use “**\$**” to match the end of the name:

```
mysql> SELECT * FROM pet WHERE name REGEXP 'fy$';
```

name	owner	species	sex	birth	death
Fluffy	Harold	cat	f	1993-02-04	NULL
Buffy	Harold	dog	f	1989-05-13	NULL

To find names containing a “**w**”, use this query:

```
mysql> SELECT * FROM pet WHERE name REGEXP 'w';
```

name	owner	species	sex	birth	death
Claws	Gwen	cat	m	1994-03-17	NULL
Bowser	Diane	dog	m	1989-08-31	1995-07-29
Whistler	Gwen	bird	NULL	1997-12-09	NULL

Because a regular expression pattern matches if it occurs anywhere in the value, it is not necessary in the previous query to put a wildcard on either side of the pattern to get it to match the entire value like it would be if you used an SQL pattern.

To find names containing exactly five characters, use “**^**” and “**\$**” to match the beginning and end of the name, and five instances of “**.**” in between:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^.....$';
```

name	owner	species	sex	birth	death
------	-------	---------	-----	-------	-------

Claws	Gwen	cat	m	1994-03-17	NULL
Buffy	Harold	dog	f	1989-05-13	NULL

You could also write the previous query using the `{n}` (“repeat-*n*-times”) operator:

```
mysql> SELECT * FROM pet WHERE name REGEXP '^.{5}$';
```

name	owner	species	sex	birth	death
Claws	Gwen	cat	m	1994-03-17	NULL
Buffy	Harold	dog	f	1989-05-13	NULL

[Section 12.5.2, “Regular Expressions”](#), provides more information about the syntax for regular expressions.

3.3.4.8 Counting Rows

Databases are often used to answer the question, “How often does a certain type of data occur in a table?” For example, you might want to know how many pets you have, or how many pets each owner has, or you might want to perform various kinds of census operations on your animals.

Counting the total number of animals you have is the same question as “How many rows are in the `pet` table?” because there is one record per pet. `COUNT(*)` counts the number of rows, so the query to count your animals looks like this:

```
mysql> SELECT COUNT(*) FROM pet;
```

COUNT(*)
9

Earlier, you retrieved the names of the people who owned pets. You can use `COUNT()` if you want to find out how many pets each owner has:

```
mysql> SELECT owner, COUNT(*) FROM pet GROUP BY owner;
```

owner	COUNT(*)
Benny	2
Diane	2
Gwen	3
Harold	2

The preceding query uses `GROUP BY` to group all records for each `owner`. The use of `COUNT()` in conjunction with `GROUP BY` is useful for characterizing your data under various groupings. The following examples show different ways to perform animal census operations.

Number of animals per species:

```
mysql> SELECT species, COUNT(*) FROM pet GROUP BY species;
```

species	COUNT(*)
bird	2
cat	2

dog	3
hamster	1
snake	1

Number of animals per sex:

```
mysql> SELECT sex, COUNT(*) FROM pet GROUP BY sex;
```

sex	COUNT(*)
NULL	1
f	4
m	4

(In this output, `NULL` indicates that the sex is unknown.)

Number of animals per combination of species and sex:

```
mysql> SELECT species, sex, COUNT(*) FROM pet GROUP BY species, sex;
```

species	sex	COUNT(*)
bird	NULL	1
bird	f	1
cat	f	1
cat	m	1
dog	f	1
dog	m	2
hamster	f	1
snake	m	1

You need not retrieve an entire table when you use `COUNT()`. For example, the previous query, when performed just on dogs and cats, looks like this:

```
mysql> SELECT species, sex, COUNT(*) FROM pet
-> WHERE species = 'dog' OR species = 'cat'
-> GROUP BY species, sex;
```

species	sex	COUNT(*)
cat	f	1
cat	m	1
dog	f	1
dog	m	2

Or, if you wanted the number of animals per sex only for animals whose sex is known:

```
mysql> SELECT species, sex, COUNT(*) FROM pet
-> WHERE sex IS NOT NULL
-> GROUP BY species, sex;
```

species	sex	COUNT(*)
bird	f	1
cat	f	1
cat	m	1
dog	f	1
dog	m	2

hamster	f	1
snake	m	1

If you name columns to select in addition to the `COUNT()` value, a `GROUP BY` clause should be present that names those same columns. Otherwise, the following occurs:

- If the `ONLY_FULL_GROUP_BY` SQL mode is enabled, an error occurs:

```
mysql> SET sql_mode = 'ONLY_FULL_GROUP_BY';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT owner, COUNT(*) FROM pet;
ERROR 1140 (42000): Mixing of GROUP columns (MIN(),MAX(),COUNT()...)
with no GROUP columns is illegal if there is no GROUP BY clause
```

- If `ONLY_FULL_GROUP_BY` is not enabled, the query is processed by treating all rows as a single group, but the value selected for each named column is indeterminate. The server is free to select the value from any row:

```
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT owner, COUNT(*) FROM pet;
+-----+-----+
| owner | COUNT(*) |
+-----+-----+
| Harold |      8 |
+-----+-----+
1 row in set (0.00 sec)
```

See also [Section 12.16.3, “MySQL Extensions to `GROUP BY`”](#).

3.3.4.9 Using More Than one Table

The `pet` table keeps track of which pets you have. If you want to record other information about them, such as events in their lives like visits to the vet or when litters are born, you need another table. What should this table look like? It needs to contain the following information:

- The pet name so that you know which animal each event pertains to.
- A date so that you know when the event occurred.
- A field to describe the event.
- An event type field, if you want to be able to categorize events.

Given these considerations, the `CREATE TABLE` statement for the `event` table might look like this:

```
mysql> CREATE TABLE event (name VARCHAR(20), date DATE,
-> type VARCHAR(15), remark VARCHAR(255));
```

As with the `pet` table, it is easiest to load the initial records by creating a tab-delimited text file containing the following information.

name	date	type	remark
Fluffy	1995-05-15	litter	4 kittens, 3 female, 1 male
Buffy	1993-06-23	litter	5 puppies, 2 female, 3 male

name	date	type	remark
Buffy	1994-06-19	litter	3 puppies, 3 female
Chirpy	1999-03-21	vet	needed beak straightened
Slim	1997-08-03	vet	broken rib
Bowser	1991-10-12	kennel	
Fang	1991-10-12	kennel	
Fang	1998-08-28	birthday	Gave him a new chew toy
Claws	1998-03-17	birthday	Gave him a new flea collar
Whistler	1998-12-09	birthday	First birthday

Load the records like this:

```
mysql> LOAD DATA LOCAL INFILE 'event.txt' INTO TABLE event;
```

Based on what you have learned from the queries that you have run on the `pet` table, you should be able to perform retrievals on the records in the `event` table; the principles are the same. But when is the `event` table by itself insufficient to answer questions you might ask?

Suppose that you want to find out the ages at which each pet had its litters. We saw earlier how to calculate ages from two dates. The litter date of the mother is in the `event` table, but to calculate her age on that date you need her birth date, which is stored in the `pet` table. This means the query requires both tables:

```
mysql> SELECT pet.name,
-> (YEAR(date)-YEAR(birth)) - (RIGHT(date,5)<RIGHT(birth,5)) AS age,
-> remark
-> FROM pet INNER JOIN event
-> ON pet.name = event.name
-> WHERE event.type = 'litter';
```

name	age	remark
Fluffy	2	4 kittens, 3 female, 1 male
Buffy	4	5 puppies, 2 female, 3 male
Buffy	5	3 puppies, 3 female

There are several things to note about this query:

- The `FROM` clause joins two tables because the query needs to pull information from both of them.
- When combining (joining) information from multiple tables, you need to specify how records in one table can be matched to records in the other. This is easy because they both have a `name` column. The query uses an `ON` clause to match up records in the two tables based on the `name` values.

The query uses an `INNER JOIN` to combine the tables. An `INNER JOIN` permits rows from either table to appear in the result if and only if both tables meet the conditions specified in the `ON` clause. In this example, the `ON` clause specifies that the `name` column in the `pet` table must match the `name` column in the `event` table. If a name appears in one table but not the other, the row will not appear in the result because the condition in the `ON` clause fails.

- Because the `name` column occurs in both tables, you must be specific about which table you mean when referring to the column. This is done by prepending the table name to the column name.

You need not have two different tables to perform a join. Sometimes it is useful to join a table to itself, if you want to compare records in a table to other records in that same table. For example, to find breeding pairs among your pets, you can join the `pet` table with itself to produce candidate pairs of males and females of like species:

```
mysql> SELECT p1.name, p1.sex, p2.name, p2.sex, p1.species
-> FROM pet AS p1 INNER JOIN pet AS p2
-> ON p1.species = p2.species AND p1.sex = 'f' AND p2.sex = 'm';
```

name	sex	name	sex	species
Fluffy	f	Claws	m	cat
Buffy	f	Fang	m	dog
Buffy	f	Bowser	m	dog

In this query, we specify aliases for the table name to refer to the columns and keep straight which instance of the table each column reference is associated with.

3.4 Getting Information About Databases and Tables

What if you forget the name of a database or table, or what the structure of a given table is (for example, what its columns are called)? MySQL addresses this problem through several statements that provide information about the databases and tables it supports.

You have previously seen `SHOW DATABASES`, which lists the databases managed by the server. To find out which database is currently selected, use the `DATABASE()` function:

```
mysql> SELECT DATABASE();
```

DATABASE()
menagerie

If you have not yet selected any database, the result is `NULL`.

To find out what tables the default database contains (for example, when you are not sure about the name of a table), use this command:

```
mysql> SHOW TABLES;
```

Tables_in_menagerie
event
pet

The name of the column in the output produced by this statement is always `Tables_in_db_name`, where `db_name` is the name of the database. See [Section 13.7.5.38, “SHOW TABLES Syntax”](#), for more information.

If you want to find out about the structure of a table, the `DESCRIBE` statement is useful; it displays information about each of a table's columns:

```
mysql> DESCRIBE pet;
```

Field	Type	Null	Key	Default	Extra
name	<code>varchar(20)</code>	YES		NULL	
owner	<code>varchar(20)</code>	YES		NULL	
species	<code>varchar(20)</code>	YES		NULL	
sex	<code>char(1)</code>	YES		NULL	
birth	<code>date</code>	YES		NULL	
death	<code>date</code>	YES		NULL	

`Field` indicates the column name, `Type` is the data type for the column, `NULL` indicates whether the column can contain `NULL` values, `Key` indicates whether the column is indexed, and `Default` specifies the column's default value. `Extra` displays special information about columns: If a column was created with the `AUTO_INCREMENT` option, the value will be `auto_increment` rather than empty.

`DESC` is a short form of `DESCRIBE`. See [Section 13.8.1, “DESCRIBE Syntax”](#), for more information.

You can obtain the `CREATE TABLE` statement necessary to create an existing table using the `SHOW CREATE TABLE` statement. See [Section 13.7.5.12, “SHOW CREATE TABLE Syntax”](#).

If you have indexes on a table, `SHOW INDEX FROM tbl_name` produces information about them. See [Section 13.7.5.23, “SHOW INDEX Syntax”](#), for more about this statement.

3.5 Using `mysql` in Batch Mode

In the previous sections, you used `mysql` interactively to enter queries and view the results. You can also run `mysql` in batch mode. To do this, put the commands you want to run in a file, then tell `mysql` to read its input from the file:

```
shell> mysql < batch-file
```

If you are running `mysql` under Windows and have some special characters in the file that cause problems, you can do this:

```
C:\> mysql -e "source batch-file"
```

If you need to specify connection parameters on the command line, the command might look like this:

```
shell> mysql -h host -u user -p < batch-file
Enter password: *****
```

When you use `mysql` this way, you are creating a script file, then executing the script.

If you want the script to continue even if some of the statements in it produce errors, you should use the `--force` command-line option.

Why use a script? Here are a few reasons:

- If you run a query repeatedly (say, every day or every week), making it a script enables you to avoid retyping it each time you execute it.
- You can generate new queries from existing ones that are similar by copying and editing script files.
- Batch mode can also be useful while you're developing a query, particularly for multiple-line commands or multiple-statement sequences of commands. If you make a mistake, you don't have to retype everything. Just edit your script to correct the error, then tell `mysql` to execute it again.

- If you have a query that produces a lot of output, you can run the output through a pager rather than watching it scroll off the top of your screen:

```
shell> mysql < batch-file | more
```

- You can catch the output in a file for further processing:

```
shell> mysql < batch-file > mysql.out
```

- You can distribute your script to other people so that they can also run the commands.
- Some situations do not allow for interactive use, for example, when you run a query from a [cron](#) job. In this case, you must use batch mode.

The default output format is different (more concise) when you run `mysql` in batch mode than when you use it interactively. For example, the output of `SELECT DISTINCT species FROM pet` looks like this when `mysql` is run interactively:

```
+-----+  
| species |  
+-----+  
| bird   |  
| cat    |  
| dog    |  
| hamster|  
| snake  |  
+-----+
```

In batch mode, the output looks like this instead:

```
species  
bird  
cat  
dog  
hamster  
snake
```

If you want to get the interactive output format in batch mode, use `mysql -t`. To echo to the output the commands that are executed, use `mysql -vvv`.

You can also use scripts from the `mysql` prompt by using the `source` command or `\.` command:

```
mysql> source filename;  
mysql> \. filename
```

See [Section 4.5.1.5, “Executing SQL Statements from a Text File”](#), for more information.

3.6 Examples of Common Queries

Here are examples of how to solve some common problems with MySQL.

Some of the examples use the table `shop` to hold the price of each article (item number) for certain traders (dealers). Supposing that each trader has a single fixed price per article, then `(article, dealer)` is a primary key for the records.

Start the command-line tool `mysql` and select a database:

```
shell> mysql your-database-name
```

(In most MySQL installations, you can use the database named `test`).

You can create and populate the example table with these statements:

```
CREATE TABLE shop (
  article INT(4) UNSIGNED ZEROFILL DEFAULT '0000' NOT NULL,
  dealer CHAR(20) DEFAULT '' NOT NULL,
  price DOUBLE(16,2) DEFAULT '0.00' NOT NULL,
  PRIMARY KEY(article, dealer));
INSERT INTO shop VALUES
  (1,'A',3.45),(1,'B',3.99),(2,'A',10.99),(3,'B',1.45),
  (3,'C',1.69),(3,'D',1.25),(4,'D',19.95);
```

After issuing the statements, the table should have the following contents:

```
SELECT * FROM shop;
```

article	dealer	price
0001	A	3.45
0001	B	3.99
0002	A	10.99
0003	B	1.45
0003	C	1.69
0003	D	1.25
0004	D	19.95

3.6.1 The Maximum Value for a Column

“What is the highest item number?”

```
SELECT MAX(article) AS article FROM shop;
```

article
4

3.6.2 The Row Holding the Maximum of a Certain Column

Task: Find the number, dealer, and price of the most expensive article.

This is easily done with a subquery:

```
SELECT article, dealer, price
FROM shop
WHERE price=(SELECT MAX(price) FROM shop);
```

article	dealer	price
0004	D	19.95

Other solutions are to use a [LEFT JOIN](#) or to sort all rows descending by price and get only the first row using the MySQL-specific [LIMIT](#) clause:

```
SELECT s1.article, s1.dealer, s1.price
FROM shop s1
LEFT JOIN shop s2 ON s1.price < s2.price
WHERE s2.article IS NULL;

SELECT article, dealer, price
FROM shop
ORDER BY price DESC
LIMIT 1;
```

Note

If there were several most expensive articles, each with a price of 19.95, the [LIMIT](#) solution would show only one of them.

3.6.3 Maximum of Column per Group

Task: Find the highest price per article.

```
SELECT article, MAX(price) AS price
FROM shop
GROUP BY article;
```

article	price
0001	3.99
0002	10.99
0003	1.69
0004	19.95

3.6.4 The Rows Holding the Group-wise Maximum of a Certain Column

Task: For each article, find the dealer or dealers with the most expensive price.

This problem can be solved with a subquery like this one:

```
SELECT article, dealer, price
FROM shop s1
WHERE price=(SELECT MAX(s2.price)
              FROM shop s2
              WHERE s1.article = s2.article);
```

article	dealer	price
0001	B	3.99
0002	A	10.99
0003	C	1.69
0004	D	19.95

The preceding example uses a correlated subquery, which can be inefficient (see [Section 13.2.10.7, “Correlated Subqueries”](#)). Other possibilities for solving the problem are to use an uncorrelated subquery in the [FROM](#) clause or a [LEFT JOIN](#).

Uncorrelated subquery:

```
SELECT s1.article, dealer, s1.price
FROM shop s1
JOIN (
  SELECT article, MAX(price) AS price
  FROM shop
  GROUP BY article) AS s2
ON s1.article = s2.article AND s1.price = s2.price;
```

LEFT JOIN:

```
SELECT s1.article, s1.dealer, s1.price
FROM shop s1
LEFT JOIN shop s2 ON s1.article = s2.article AND s1.price < s2.price
WHERE s2.article IS NULL;
```

The `LEFT JOIN` works on the basis that when `s1.price` is at its maximum value, there is no `s2.price` with a greater value and the `s2` rows values will be `NULL`. See [Section 13.2.9.2, “JOIN Syntax”](#).

3.6.5 Using User-Defined Variables

You can employ MySQL user variables to remember results without having to store them in temporary variables in the client. (See [Section 9.4, “User-Defined Variables”](#).)

For example, to find the articles with the highest and lowest price you can do this:

```
mysql> SELECT @min_price:=MIN(price),@max_price:=MAX(price) FROM shop;
mysql> SELECT * FROM shop WHERE price=@min_price OR price=@max_price;
+-----+-----+-----+
| article | dealer | price |
+-----+-----+-----+
| 0003    | D      | 1.25   |
| 0004    | D      | 19.95  |
+-----+-----+-----+
```

Note

It is also possible to store the name of a database object such as a table or a column in a user variable and then to use this variable in an SQL statement; however, this requires the use of a prepared statement. See [Section 13.5, “SQL Syntax for Prepared Statements”](#), for more information.

3.6.6 Using Foreign Keys

In MySQL, `InnoDB` tables support checking of foreign key constraints. See [Chapter 14, *The InnoDB Storage Engine*](#), and [Section 1.8.2.4, “Foreign Key Differences”](#).

A foreign key constraint is not required merely to join two tables. For storage engines other than `InnoDB`, it is possible when defining a column to use a `REFERENCES tbl_name(col_name)` clause, which has no actual effect, and serves only as a memo or comment to you that the column which you are currently defining is intended to refer to a column in another table. It is extremely important to realize when using this syntax that:

- MySQL does not perform any sort of `CHECK` to make sure that `col_name` actually exists in `tbl_name` (or even that `tbl_name` itself exists).

- MySQL does not perform any sort of action on *tbl_name* such as deleting rows in response to actions taken on rows in the table which you are defining; in other words, this syntax induces no **ON DELETE** or **ON UPDATE** behavior whatsoever. (Although you can write an **ON DELETE** or **ON UPDATE** clause as part of the **REFERENCES** clause, it is also ignored.)
- This syntax creates a *column*; it does **not** create any sort of index or key.

You can use a column so created as a join column, as shown here:

```
CREATE TABLE person (
  id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,
  name CHAR(60) NOT NULL,
  PRIMARY KEY (id)
);

CREATE TABLE shirt (
  id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,
  style ENUM('t-shirt', 'polo', 'dress') NOT NULL,
  color ENUM('red', 'blue', 'orange', 'white', 'black') NOT NULL,
  owner SMALLINT UNSIGNED NOT NULL REFERENCES person(id),
  PRIMARY KEY (id)
);

INSERT INTO person VALUES (NULL, 'Antonio Paz');

SELECT @last := LAST_INSERT_ID();

INSERT INTO shirt VALUES
(NULL, 'polo', 'blue', @last),
(NULL, 'dress', 'white', @last),
(NULL, 't-shirt', 'blue', @last);

INSERT INTO person VALUES (NULL, 'Lilliana Angelovska');

SELECT @last := LAST_INSERT_ID();

INSERT INTO shirt VALUES
(NULL, 'dress', 'orange', @last),
(NULL, 'polo', 'red', @last),
(NULL, 'dress', 'blue', @last),
(NULL, 't-shirt', 'white', @last);

SELECT * FROM person;
+-----+
| id | name           |
+-----+
| 1  | Antonio Paz   |
| 2  | Lilliana Angelovska |
+-----+

SELECT * FROM shirt;
+-----+
| id | style  | color  | owner |
+-----+
| 1  | polo   | blue   | 1     |
| 2  | dress  | white  | 1     |
| 3  | t-shirt| blue   | 1     |
| 4  | dress  | orange | 2     |
| 5  | polo   | red    | 2     |
| 6  | dress  | blue   | 2     |
| 7  | t-shirt| white  | 2     |
+-----+

SELECT s.* FROM person p INNER JOIN shirt s
```

```
ON s.owner = p.id
WHERE p.name LIKE 'Lilliana%'
AND s.color <> 'white';
```

```
+-----+-----+-----+-----+
| id | style | color | owner |
+-----+-----+-----+-----+
| 4 | dress | orange | 2 |
| 5 | polo | red | 2 |
| 6 | dress | blue | 2 |
+-----+-----+-----+-----+
```

When used in this fashion, the [REFERENCES](#) clause is not displayed in the output of [SHOW CREATE TABLE](#) or [DESCRIBE](#):

```
SHOW CREATE TABLE shirt\G
***** 1. row *****
Table: shirt
Create Table: CREATE TABLE `shirt` (
  `id` smallint(5) unsigned NOT NULL auto_increment,
  `style` enum('t-shirt','polo','dress') NOT NULL,
  `color` enum('red','blue','orange','white','black') NOT NULL,
  `owner` smallint(5) unsigned NOT NULL,
  PRIMARY KEY (`id`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1
```

The use of [REFERENCES](#) in this way as a comment or “reminder” in a column definition works with [MyISAM](#) tables.

3.6.7 Searching on Two Keys

An [OR](#) using a single key is well optimized, as is the handling of [AND](#).

The one tricky case is that of searching on two different keys combined with [OR](#):

```
SELECT field1_index, field2_index FROM test_table
WHERE field1_index = '1' OR field2_index = '1'
```

This case is optimized. See [Section 8.2.1.4, “Index Merge Optimization”](#).

You can also solve the problem efficiently by using a [UNION](#) that combines the output of two separate [SELECT](#) statements. See [Section 13.2.9.4, “UNION Syntax”](#).

Each [SELECT](#) searches only one key and can be optimized:

```
SELECT field1_index, field2_index
  FROM test_table WHERE field1_index = '1'
UNION
SELECT field1_index, field2_index
  FROM test_table WHERE field2_index = '1';
```

3.6.8 Calculating Visits Per Day

The following example shows how you can use the bit group functions to calculate the number of days per month a user has visited a Web page.

```
CREATE TABLE t1 (year YEAR(4), month INT(2) UNSIGNED ZEROFILL,
                  day INT(2) UNSIGNED ZEROFILL);
INSERT INTO t1 VALUES(2000,1,1),(2000,1,20),(2000,1,30),(2000,2,2),
```

```
(2000,2,23),(2000,2,23);
```

The example table contains year-month-day values representing visits by users to the page. To determine how many different days in each month these visits occur, use this query:

```
SELECT year,month,BIT_COUNT(BIT_OR(1<<day)) AS days FROM t1
      GROUP BY year,month;
```

Which returns:

```
+-----+-----+-----+
| year | month | days |
+-----+-----+-----+
| 2000 |    01 |    3 |
| 2000 |    02 |    2 |
+-----+-----+-----+
```

The query calculates how many different days appear in the table for each year/month combination, with automatic removal of duplicate entries.

3.6.9 Using `AUTO_INCREMENT`

The `AUTO_INCREMENT` attribute can be used to generate a unique identity for new rows:

```
CREATE TABLE animals (
    id MEDIUMINT NOT NULL AUTO_INCREMENT,
    name CHAR(30) NOT NULL,
    PRIMARY KEY (id)
);

INSERT INTO animals (name) VALUES
    ('dog'),('cat'),('penguin'),
    ('lax'),('whale'),('ostrich');

SELECT * FROM animals;
```

Which returns:

```
+-----+-----+
| id | name  |
+-----+-----+
| 1  | dog   |
| 2  | cat   |
| 3  | penguin |
| 4  | lax   |
| 5  | whale |
| 6  | ostrich |
+-----+-----+
```

No value was specified for the `AUTO_INCREMENT` column, so MySQL assigned sequence numbers automatically. You can also explicitly assign 0 to the column to generate sequence numbers. If the column is declared `NOT NULL`, it is also possible to assign `NULL` to the column to generate sequence numbers.

You can retrieve the most recent `AUTO_INCREMENT` value with the `LAST_INSERT_ID()` SQL function or the `mysql_insert_id()` C API function. These functions are connection-specific, so their return values are not affected by another connection which is also performing inserts.

Use the smallest integer data type for the `AUTO_INCREMENT` column that is large enough to hold the maximum sequence value you will need. When the column reaches the upper limit of the data type, the

next attempt to generate a sequence number fails. Use the `UNSIGNED` attribute if possible to allow a greater range. For example, if you use `TINYINT`, the maximum permissible sequence number is 127. For `TINYINT UNSIGNED`, the maximum is 255. See [Section 11.2.1, “Integer Types \(Exact Value\) - `INTEGER`, `INT`, `SMALLINT`, `TINYINT`, `MEDIUMINT`, `BIGINT`”](#) for the ranges of all the integer types.

Note

For a multiple-row insert, `LAST_INSERT_ID()` and `mysql_insert_id()` actually return the `AUTO_INCREMENT` key from the *first* of the inserted rows. This enables multiple-row inserts to be reproduced correctly on other servers in a replication setup.

To start with an `AUTO_INCREMENT` value other than 1, set that value with `CREATE TABLE` or `ALTER TABLE`, like this:

```
mysql> ALTER TABLE tbl AUTO_INCREMENT = 100;
```

InnoDB Notes

For `InnoDB` tables, be careful if you modify the column containing the auto-increment value in the middle of a sequence of `INSERT` statements. For example, if you use an `UPDATE` statement to put a new, larger value in the auto-increment column, a subsequent `INSERT` could encounter a “Duplicate entry” error. The test whether an auto-increment value is already present occurs if you do a `DELETE` followed by more `INSERT` statements, or when you `COMMIT` the transaction, but not after an `UPDATE` statement.

MyISAM Notes

- For `MyISAM` tables, you can specify `AUTO_INCREMENT` on a secondary column in a multiple-column index. In this case, the generated value for the `AUTO_INCREMENT` column is calculated as `MAX(auto_increment_column) + 1 WHERE prefix=given-prefix`. This is useful when you want to put data into ordered groups.

```
CREATE TABLE animals (
  grp ENUM('fish','mammal','bird') NOT NULL,
  id MEDIUMINT NOT NULL AUTO_INCREMENT,
  name CHAR(30) NOT NULL,
  PRIMARY KEY (grp,id)
) ENGINE=MyISAM;

INSERT INTO animals (grp,name) VALUES
  ('mammal','dog'),('mammal','cat'),
  ('bird','penguin'),('fish','lax'),('mammal','whale'),
  ('bird','ostrich');

SELECT * FROM animals ORDER BY grp,id;
```

Which returns:

grp	id	name
fish	1	lax
mammal	1	dog
mammal	2	cat
mammal	3	whale
bird	1	penguin
bird	2	ostrich

In this case (when the `AUTO_INCREMENT` column is part of a multiple-column index), `AUTO_INCREMENT` values are reused if you delete the row with the biggest `AUTO_INCREMENT` value in any group. This happens even for `MyISAM` tables, for which `AUTO_INCREMENT` values normally are not reused.

- If the `AUTO_INCREMENT` column is part of multiple indexes, MySQL generates sequence values using the index that begins with the `AUTO_INCREMENT` column, if there is one. For example, if the `animals` table contained indexes `PRIMARY KEY (grp, id)` and `INDEX (id)`, MySQL would ignore the `PRIMARY KEY` for generating sequence values. As a result, the table would contain a single sequence, not a sequence per `grp` value.

Further Reading

More information about `AUTO_INCREMENT` is available here:

- How to assign the `AUTO_INCREMENT` attribute to a column: [Section 13.1.17, “CREATE TABLE Syntax”](#), and [Section 13.1.7, “ALTER TABLE Syntax”](#).
- How `AUTO_INCREMENT` behaves depending on the `NO_AUTO_VALUE_ON_ZERO` SQL mode: [Section 5.1.7, “Server SQL Modes”](#).
- How to use the `LAST_INSERT_ID()` function to find the row that contains the most recent `AUTO_INCREMENT` value: [Section 12.14, “Information Functions”](#).
- Setting the `AUTO_INCREMENT` value to be used: [Section 5.1.4, “Server System Variables”](#).
- `AUTO_INCREMENT` and replication: [Section 17.4.1.1, “Replication and AUTO_INCREMENT”](#).
- Server-system variables related to `AUTO_INCREMENT` (`auto_increment_increment` and `auto_increment_offset`) that can be used for replication: [Section 5.1.4, “Server System Variables”](#).

3.7 Using MySQL with Apache

There are programs that let you authenticate your users from a MySQL database and also let you write your log files into a MySQL table.

You can change the Apache logging format to be easily readable by MySQL by putting the following into the Apache configuration file:

```
LogFormat \
    "%h\" ,%{Y%m%d%H%M%S}t,%>s,\"%b\", \"%{Content-Type}o\", \
    \"%U\", \"%{Referer}i\", \"%{User-Agent}i\""
```

To load a log file in that format into MySQL, you can use a statement something like this:

```
LOAD DATA INFILE '/local/access_log' INTO TABLE tbl_name
FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"' ESCAPED BY '\\'
```

The named table should be created to have columns that correspond to those that the `LogFormat` line writes to the log file.

Chapter 4 MySQL Programs

Table of Contents

4.1 Overview of MySQL Programs	254
4.2 Using MySQL Programs	258
4.2.1 Invoking MySQL Programs	258
4.2.2 Connecting to the MySQL Server	259
4.2.3 Specifying Program Options	263
4.2.4 Using Options on the Command Line	264
4.2.5 Program Option Modifiers	265
4.2.6 Using Option Files	266
4.2.7 Command-Line Options that Affect Option-File Handling	270
4.2.8 Using Options to Set Program Variables	271
4.2.9 Option Defaults, Options Expecting Values, and the = Sign	272
4.2.10 Setting Environment Variables	276
4.3 MySQL Server and Server-Startup Programs	277
4.3.1 <code>mysqld</code> — The MySQL Server	277
4.3.2 <code>mysqld_safe</code> — MySQL Server Startup Script	277
4.3.3 <code>mysql.server</code> — MySQL Server Startup Script	282
4.3.4 <code>mysqld_multi</code> — Manage Multiple MySQL Servers	283
4.4 MySQL Installation-Related Programs	288
4.4.1 <code>comp_err</code> — Compile MySQL Error Message File	288
4.4.2 <code>mysqlbug</code> — Generate Bug Report	289
4.4.3 <code>mysql_install_db</code> — Initialize MySQL Data Directory	289
4.4.4 <code>mysql_plugin</code> — Configure MySQL Server Plugins	291
4.4.5 <code>mysql_secure_installation</code> — Improve MySQL Installation Security	293
4.4.6 <code>mysql_tzinfo_to_sql</code> — Load the Time Zone Tables	294
4.4.7 <code>mysql_upgrade</code> — Check and Upgrade MySQL Tables	295
4.5 MySQL Client Programs	299
4.5.1 <code>mysql</code> — The MySQL Command-Line Tool	299
4.5.2 <code>mysqladmin</code> — Client for Administering a MySQL Server	322
4.5.3 <code>mysqlcheck</code> — A Table Maintenance Program	330
4.5.4 <code>mysqldump</code> — A Database Backup Program	337
4.5.5 <code>mysqlimport</code> — A Data Import Program	356
4.5.6 <code>mysqlshow</code> — Display Database, Table, and Column Information	362
4.5.7 <code>mysqlslap</code> — Load Emulation Client	366
4.6 MySQL Administrative and Utility Programs	375
4.6.1 <code>innochecksum</code> — Offline InnoDB File Checksum Utility	375
4.6.2 <code>myisam_ftdump</code> — Display Full-Text Index information	375
4.6.3 <code>myisamchk</code> — MyISAM Table-Maintenance Utility	377
4.6.4 <code>myisamlog</code> — Display MyISAM Log File Contents	394
4.6.5 <code>myisampack</code> — Generate Compressed, Read-Only MyISAM Tables	395
4.6.6 <code>mysqlaccess</code> — Client for Checking Access Privileges	401
4.6.7 <code>mysqlbinlog</code> — Utility for Processing Binary Log Files	404
4.6.8 <code>mysqldumpslow</code> — Summarize Slow Query Log Files	420
4.6.9 <code>mysqlhotcopy</code> — A Database Backup Program	422
4.6.10 <code>mysql_convert_table_format</code> — Convert Tables to Use a Given Storage Engine	425
4.6.11 <code>mysql_find_rows</code> — Extract SQL Statements from Files	426
4.6.12 <code>mysql_fix_extensions</code> — Normalize Table File Name Extensions	427
4.6.13 <code>mysql_setpermission</code> — Interactively Set Permissions in Grant Tables	427
4.6.14 <code>mysql_waitpid</code> — Kill Process and Wait for Its Termination	428

4.6.15 <code>mysql_zap</code> — Kill Processes That Match a Pattern	428
4.7 MySQL Program Development Utilities	429
4.7.1 <code>mysql2mysql</code> — Convert mSQL Programs for Use with MySQL	429
4.7.2 <code>mysql_config</code> — Display Options for Compiling Clients	430
4.7.3 <code>my_print_defaults</code> — Display Options from Option Files	431
4.7.4 <code>resolve_stack_dump</code> — Resolve Numeric Stack Trace Dump to Symbols	432
4.8 Miscellaneous Programs	432
4.8.1 <code>pererror</code> — Explain Error Codes	432
4.8.2 <code>replace</code> — A String-Replacement Utility	433
4.8.3 <code>resolveip</code> — Resolve Host name to IP Address or Vice Versa	434

This chapter provides a brief overview of the MySQL command-line programs provided by Oracle Corporation. It also discusses the general syntax for specifying options when you run these programs. Most programs have options that are specific to their own operation, but the option syntax is similar for all of them. Finally, the chapter provides more detailed descriptions of individual programs, including which options they recognize.

4.1 Overview of MySQL Programs

There are many different programs in a MySQL installation. This section provides a brief overview of them. Later sections provide a more detailed description of each one, with the exception of MySQL Cluster programs. Each program's description indicates its invocation syntax and the options that it supports. [Chapter 18, MySQL Cluster NDB 7.2](#), describes programs specific to MySQL Cluster.

Most MySQL distributions include all of these programs, except for those programs that are platform-specific. (For example, the server startup scripts are not used on Windows.) The exception is that RPM distributions are more specialized. There is one RPM for the server, another for client programs, and so forth. If you appear to be missing one or more programs, see [Chapter 2, Installing and Upgrading MySQL](#), for information on types of distributions and what they contain. It may be that you have a distribution that does not include all programs and you need to install an additional package.

Each MySQL program takes many different options. Most programs provide a `--help` option that you can use to get a description of the program's different options. For example, try `mysql --help`.

You can override default option values for MySQL programs by specifying options on the command line or in an option file. See [Section 4.2, "Using MySQL Programs"](#), for general information on invoking programs and specifying program options.

The MySQL server, `mysqld`, is the main program that does most of the work in a MySQL installation. The server is accompanied by several related scripts that assist you in starting and stopping the server:

- `mysqld`

The SQL daemon (that is, the MySQL server). To use client programs, `mysqld` must be running, because clients gain access to databases by connecting to the server. See [Section 4.3.1, "mysqld — The MySQL Server"](#).

- `mysqld_safe`

A server startup script. `mysqld_safe` attempts to start `mysqld`. See [Section 4.3.2, "mysqld_safe — MySQL Server Startup Script"](#).

- `mysql.server`

A server startup script. This script is used on systems that use System V-style run directories containing scripts that start system services for particular run levels. It invokes `mysqld_safe` to start the MySQL server. See [Section 4.3.3, "mysql.server — MySQL Server Startup Script"](#).

- `mysqld_multi`

A server startup script that can start or stop multiple servers installed on the system. See [Section 4.3.4, “mysqld_multi — Manage Multiple MySQL Servers”](#).

Several programs perform setup operations during MySQL installation or upgrading:

- `comp_err`

This program is used during the MySQL build/installation process. It compiles error message files from the error source files. See [Section 4.4.1, “comp_err — Compile MySQL Error Message File”](#).

- `mysql_install_db`

This script creates the MySQL database and initializes the grant tables with default privileges. It is usually executed only once, when first installing MySQL on a system. See [Section 4.4.3, “mysql_install_db — Initialize MySQL Data Directory”](#), [Section 2.10.1, “Postinstallation Procedures for Unix-like Systems”](#), and [Section 4.4.3, “mysql_install_db — Initialize MySQL Data Directory”](#).

- `mysql_plugin`

This program configures MySQL server plugins. See [Section 4.4.4, “mysql_plugin — Configure MySQL Server Plugins”](#).

- `mysql_secure_installation`

This program enables you to improve the security of your MySQL installation. SQL. See [Section 4.4.5, “mysql_secure_installation — Improve MySQL Installation Security”](#).

- `mysql_tzinfo_to_sql`

This program loads the time zone tables in the `mysql` database using the contents of the host system `zoneinfo` database (the set of files describing time zones). SQL. See [Section 4.4.6, “mysql_tzinfo_to_sql — Load the Time Zone Tables”](#).

- `mysql_upgrade`

This program is used after a MySQL upgrade operation. It checks tables for incompatibilities and repairs them if necessary, and updates the grant tables with any changes that have been made in newer versions of MySQL. See [Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”](#).

MySQL client programs that connect to the MySQL server:

- `mysql`

The command-line tool for interactively entering SQL statements or executing them from a file in batch mode. See [Section 4.5.1, “mysql — The MySQL Command-Line Tool”](#).

- `mysqladmin`

A client that performs administrative operations, such as creating or dropping databases, reloading the grant tables, flushing tables to disk, and reopening log files. `mysqladmin` can also be used to retrieve version, process, and status information from the server. See [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

- `mysqlcheck`

A table-maintenance client that checks, repairs, analyzes, and optimizes tables. See [Section 4.5.3, “mysqlcheck — A Table Maintenance Program”](#).

- `mysqldump`

A client that dumps a MySQL database into a file as SQL, text, or XML. See [Section 4.5.4, “mysqldump — A Database Backup Program”](#).

- `mysqlimport`

A client that imports text files into their respective tables using `LOAD DATA INFILE`. See [Section 4.5.5, “mysqlimport — A Data Import Program”](#).

- `mysqlshow`

A client that displays information about databases, tables, columns, and indexes. See [Section 4.5.6, “mysqlshow — Display Database, Table, and Column Information”](#).

- `mysqlslap`

A client that is designed to emulate client load for a MySQL server and report the timing of each stage. It works as if multiple clients are accessing the server. See [Section 4.5.7, “mysqlslap — Load Emulation Client”](#).

MySQL administrative and utility programs:

- `innochecksum`

An offline `InnoDB` offline file checksum utility. See [Section 4.6.1, “innochecksum — Offline InnoDB File Checksum Utility”](#).

- `myisam_ftdump`

A utility that displays information about full-text indexes in `MyISAM` tables. See [Section 4.6.2, “myisam_ftdump — Display Full-Text Index information”](#).

- `myisamchk`

A utility to describe, check, optimize, and repair `MyISAM` tables. See [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#).

- `myisamlog`

A utility that processes the contents of a `MyISAM` log file. See [Section 4.6.4, “myisamlog — Display MyISAM Log File Contents”](#).

- `myisampack`

A utility that compresses `MyISAM` tables to produce smaller read-only tables. See [Section 4.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#).

- `mysqlaccess`

A script that checks the access privileges for a host name, user name, and database combination. See [Section 4.6.6, “mysqlaccess — Client for Checking Access Privileges”](#).

- `mysqlbinlog`

A utility for reading statements from a binary log. The log of executed statements contained in the binary log files can be used to help recover from a crash. See [Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”](#).

- `mysqldumpslow`

A utility to read and summarize the contents of a slow query log. See [Section 4.6.8, “mysqldumpslow — Summarize Slow Query Log Files”](#).

- `mysqlhotcopy`

A utility that quickly makes backups of `MyISAM` tables while the server is running. See [Section 4.6.9, “mysqlhotcopy — A Database Backup Program”](#).

- `mysql_convert_table_format`

A utility that converts tables in a database to use a given storage engine. See [Section 4.6.10, “mysql_convert_table_format — Convert Tables to Use a Given Storage Engine”](#).

- `mysql_find_rows`

A utility that reads files containing SQL statements (such as update logs) and extracts statements that match a given regular expression. See [Section 4.6.11, “mysql_find_rows — Extract SQL Statements from Files”](#).

- `mysql_fix_extensions`

A utility that converts the extensions for `MyISAM` table files to lowercase. This can be useful after transferring the files from a system with case-insensitive file names to a system with case-sensitive file names. See [Section 4.6.12, “mysql_fix_extensions — Normalize Table File Name Extensions”](#).

- `mysql_setpermission`

A utility for interactively setting permissions in the MySQL grant tables. See [Section 4.6.13, “mysql_setpermission — Interactively Set Permissions in Grant Tables”](#).

- `mysql_waitpid`

A utility that kills the process with a given process ID. See [Section 4.6.14, “mysql_waitpid — Kill Process and Wait for Its Termination”](#).

- `mysql_zap`

A utility that kills processes that match a pattern. See [Section 4.6.15, “mysql_zap — Kill Processes That Match a Pattern”](#).

MySQL program-development utilities:

- `msql2mysql`

A shell script that converts `mSQL` programs to MySQL. It doesn't handle every case, but it gives a good start when converting. See [Section 4.7.1, “msql2mysql — Convert mSQL Programs for Use with MySQL”](#).

- `mysql_config`

A shell script that produces the option values needed when compiling MySQL programs. See [Section 4.7.2, “mysql_config — Display Options for Compiling Clients”](#).

- `my_print_defaults`

A utility that shows which options are present in option groups of option files. See [Section 4.7.3, “my_print_defaults — Display Options from Option Files”](#).

- `resolve_stack_dump`

A utility program that resolves a numeric stack trace dump to symbols. See [Section 4.7.4, “`resolve_stack_dump` — Resolve Numeric Stack Trace Dump to Symbols](#)”.

Miscellaneous utilities:

- `perror`

A utility that displays the meaning of system or MySQL error codes. See [Section 4.8.1, “`perror` — Explain Error Codes](#)”.

- `replace`

A utility program that performs string replacement in the input text. See [Section 4.8.2, “`replace` — A String-Replacement Utility](#)”.

- `resolveip`

A utility program that resolves a host name to an IP address or vice versa. See [Section 4.8.3, “`resolveip` — Resolve Host name to IP Address or Vice Versa](#)”.

Oracle Corporation also provides the [MySQL Workbench](#) GUI tool, which is used to administer MySQL servers and databases, to create, execute, and evaluate queries, and to migrate schemas and data from other relational database management systems for use with MySQL. Additional GUI tools include [MySQL Notifier for Microsoft Windows](#) [MySQL for Excel](#).

MySQL client programs that communicate with the server using the MySQL client/server library use the following environment variables.

Environment Variable	Meaning
<code>MYSQL_UNIX_PORT</code>	The default Unix socket file; used for connections to <code>localhost</code>
<code>MYSQL_TCP_PORT</code>	The default port number; used for TCP/IP connections
<code>MYSQL_PWD</code>	The default password
<code>MYSQL_DEBUG</code>	Debug trace options when debugging
<code>TMPDIR</code>	The directory where temporary tables and files are created

For a full list of environment variables used by MySQL programs, see [Section 2.12, “Environment Variables](#)”.

Use of `MYSQL_PWD` is insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security](#)”.

4.2 Using MySQL Programs

4.2.1 Invoking MySQL Programs

To invoke a MySQL program from the command line (that is, from your shell or command prompt), enter the program name followed by any options or other arguments needed to instruct the program what you want it to do. The following commands show some sample program invocations. “`shell>`” represents the prompt for your command interpreter; it is not part of what you type. The particular prompt you see depends on your command interpreter. Typical prompts are `$` for `sh`, `ksh`, or `bash`, `%` for `cs`h or `tc`sh, and `C:\>` for the Windows [command.com](#) or `cmd.exe` command interpreters.

```
shell> mysql --user=root test
```

```
shell> mysqladmin extended-status variables
shell> mysqlshow --help
shell> mysqldump -u root personnel
```

Arguments that begin with a single or double dash (“-”, “--”) specify program options. Options typically indicate the type of connection a program should make to the server or affect its operational mode. Option syntax is described in [Section 4.2.3, “Specifying Program Options”](#).

Nonoption arguments (arguments with no leading dash) provide additional information to the program. For example, the `mysql` program interprets the first nonoption argument as a database name, so the command `mysql --user=root test` indicates that you want to use the `test` database.

Later sections that describe individual programs indicate which options a program supports and describe the meaning of any additional nonoption arguments.

Some options are common to a number of programs. The most frequently used of these are the `--host` (or `-h`), `--user` (or `-u`), and `--password` (or `-p`) options that specify connection parameters. They indicate the host where the MySQL server is running, and the user name and password of your MySQL account. All MySQL client programs understand these options; they enable you to specify which server to connect to and the account to use on that server. Other connection options are `--port` (or `-P`) to specify a TCP/IP port number and `--socket` (or `-S`) to specify a Unix socket file on Unix (or named pipe name on Windows). For more information on options that specify connection options, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

You may find it necessary to invoke MySQL programs using the path name to the `bin` directory in which they are installed. This is likely to be the case if you get a “program not found” error whenever you attempt to run a MySQL program from any directory other than the `bin` directory. To make it more convenient to use MySQL, you can add the path name of the `bin` directory to your `PATH` environment variable setting. That enables you to run a program by typing only its name, not its entire path name. For example, if `mysql` is installed in `/usr/local/mysql/bin`, you can run the program by invoking it as `mysql`, and it is not necessary to invoke it as `/usr/local/mysql/bin/mysql`.

Consult the documentation for your command interpreter for instructions on setting your `PATH` variable. The syntax for setting environment variables is interpreter-specific. (Some information is given in [Section 4.2.10, “Setting Environment Variables”](#).) After modifying your `PATH` setting, open a new console window on Windows or log in again on Unix so that the setting goes into effect.

4.2.2 Connecting to the MySQL Server

For a client program to be able to connect to the MySQL server, it must use the proper connection parameters, such as the name of the host where the server is running and the user name and password of your MySQL account. Each connection parameter has a default value, but you can override them as necessary using program options specified either on the command line or in an option file.

The examples here use the `mysql` client program, but the principles apply to other clients such as `mysqldump`, `mysqladmin`, or `mysqlshow`.

This command invokes `mysql` without specifying any connection parameters explicitly:

```
shell> mysql
```

Because there are no parameter options, the default values apply:

- The default host name is `localhost`. On Unix, this has a special meaning, as described later.
- The default user name is `ODBC` on Windows or your Unix login name on Unix.

- No password is sent if neither `-p` nor `--password` is given.
- For `mysql`, the first nonoption argument is taken as the name of the default database. If there is no such option, `mysql` does not select a default database.

To specify the host name and user name explicitly, as well as a password, supply appropriate options on the command line:

```
shell> mysql --host=localhost --user=myname --password=mypass mydb
shell> mysql -h localhost -u myname -pmypass mydb
```

For password options, the password value is optional:

- If you use a `-p` or `--password` option and specify the password value, there must be *no space* between `-p` or `--password=` and the password following it.
- If you use a `-p` or `--password` option but do not specify the password value, the client program prompts you to enter the password. The password is not displayed as you enter it. This is more secure than giving the password on the command line. Other users on your system may be able to see a password specified on the command line by executing a command such as `ps auxw`. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#).

As just mentioned, including the password value on the command line can be a security risk. To avoid this problem, specify the `--password` or `-p` option without any following password value:

```
shell> mysql --host=localhost --user=myname --password mydb
shell> mysql -h localhost -u myname -p mydb
```

When the password option has no password value, the client program prints a prompt and waits for you to enter the password. (In these examples, `mydb` is *not* interpreted as a password because it is separated from the preceding password option by a space.)

On some systems, the library routine that MySQL uses to prompt for a password automatically limits the password to eight characters. That is a problem with the system library, not with MySQL. Internally, MySQL does not have any limit for the length of the password. To work around the problem, change your MySQL password to a value that is eight or fewer characters long, or put your password in an option file.

On Unix, MySQL programs treat the host name `localhost` specially, in a way that is likely different from what you expect compared to other network-based programs. For connections to `localhost`, MySQL programs attempt to connect to the local server by using a Unix socket file. This occurs even if a `--port` or `-P` option is given to specify a port number. To ensure that the client makes a TCP/IP connection to the local server, use `--host` or `-h` to specify a host name value of `127.0.0.1`, or the IP address or name of the local server. You can also specify the connection protocol explicitly, even for `localhost`, by using the `--protocol=TCP` option. For example:

```
shell> mysql --host=127.0.0.1
shell> mysql --protocol=TCP
```

The `--protocol` option enables you to establish a particular type of connection even when the other options would normally default to some other protocol.

If the server is configured to accept IPv6 connections, client can connect over IPv6 using `--host>:::1`. See [Section 5.1.9, “IPv6 Support”](#).

On Windows, you can force a MySQL client to use a named-pipe connection by specifying the `--pipe` or `--protocol=PIPE` option, or by specifying `.` (period) as the host name. If named-pipe connections are

not enabled, an error occurs. Use the `--socket` option to specify the name of the pipe if you do not want to use the default pipe name.

Connections to remote servers always use TCP/IP. This command connects to the server running on `remote.example.com` using the default port number (3306):

```
shell> mysql --host=remote.example.com
```

To specify a port number explicitly, use the `--port` or `-P` option:

```
shell> mysql --host=remote.example.com --port=13306
```

You can specify a port number for connections to a local server, too. However, as indicated previously, connections to `localhost` on Unix will use a socket file by default. You will need to force a TCP/IP connection as already described or any option that specifies a port number will be ignored.

For this command, the program uses a socket file on Unix and the `--port` option is ignored:

```
shell> mysql --port=13306 --host=localhost
```

To cause the port number to be used, invoke the program in either of these ways:

```
shell> mysql --port=13306 --host=127.0.0.1
shell> mysql --port=13306 --protocol=TCP
```

The following list summarizes the options that can be used to control how client programs connect to the server:

- `--host=host_name`, `-h host_name`

The host where the server is running. The default value is `localhost`.

- `--password[=pass_val]`, `-p[pass_val]`

The password of the MySQL account. As described earlier, the password value is optional, but if given, there must be *no space* between `-p` or `--password=` and the password following it. The default is to send no password.

- `--pipe`, `-W`

On Windows, connect to the server using a named pipe. The server must be started with the `--enable-named-pipe` option to enable named-pipe connections.

- `--port=port_num`, `-P port_num`

The port number to use for the connection, for connections made using TCP/IP. The default port number is 3306.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

This option explicitly specifies a protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For example, connections on Unix to `localhost` are made using a Unix socket file by default:

```
shell> mysql --host=localhost
```

To force a TCP/IP connection to be used instead, specify a `--protocol` option:

```
shell> mysql --host=localhost --protocol=TCP
```

The following table shows the permissible `--protocol` option values and indicates the platforms on which each value may be used. The values are not case sensitive.

<code>--protocol</code> Value	Connection Protocol	Permissible Operating Systems
TCP	TCP/IP connection to local or remote server	All
SOCKET	Unix socket file connection to local server	Unix only
PIPE	Named-pipe connection to local or remote server	Windows only
MEMORY	Shared-memory connection to local server	Windows only

- `--shared-memory-base-name=name`

On Windows, the shared-memory name to use, for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case sensitive.

The server must be started with the `--shared-memory` option to enable shared-memory connections.

- `--socket=file_name, -S file_name`

On Unix, the name of the Unix socket file to use, for connections made using a named pipe to a local server. The default Unix socket file name is `/tmp/mysql.sock`.

On Windows, the name of the named pipe to use, for connections to a local server. The default Windows pipe name is `MySQL`. The pipe name is not case sensitive.

The server must be started with the `--enable-named-pipe` option to enable named-pipe connections.

- `--ssl*`

Options that begin with `--ssl` are used for establishing a secure connection to the server using SSL, if the server is configured with SSL support. For details, see [Section 6.3.9.4, “SSL Command Options”](#).

- `--user=user_name, -u user_name`

The user name of the MySQL account you want to use. The default user name is `ODBC` on Windows or your Unix login name on Unix.

It is possible to specify different default values to be used when you make a connection so that you need not enter them on the command line each time you invoke a client program. This can be done in a couple of ways:

- You can specify connection parameters in the `[client]` section of an option file. The relevant section of the file might look like this:

```
[client]
host=host_name
user=user_name
password=your_pass
```

[Section 4.2.6, “Using Option Files”](#), discusses option files further.

- You can specify some connection parameters using environment variables. The host can be specified for `mysql` using `MYSQL_HOST`. The MySQL user name can be specified using `USER` (this is for Windows only). The password can be specified using `MYSQL_PWD`, although this is insecure; see [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). For a list of variables, see [Section 2.12, “Environment Variables”](#).

4.2.3 Specifying Program Options

There are several ways to specify options for MySQL programs:

- List the options on the command line following the program name. This is common for options that apply to a specific invocation of the program.
- List the options in an option file that the program reads when it starts. This is common for options that you want the program to use each time it runs.
- List the options in environment variables (see [Section 4.2.10, “Setting Environment Variables”](#)). This method is useful for options that you want to apply each time the program runs. In practice, option files are used more commonly for this purpose, but [Section 5.3.3, “Running Multiple MySQL Instances on Unix”](#), discusses one situation in which environment variables can be very helpful. It describes a handy technique that uses such variables to specify the TCP/IP port number and Unix socket file for the server and for client programs.

Options are processed in order, so if an option is specified multiple times, the last occurrence takes precedence. The following command causes `mysql` to connect to the server running on `localhost`:

```
shell> mysql -h example.com -h localhost
```

If conflicting or related options are given, later options take precedence over earlier options. The following command runs `mysql` in “no column names” mode:

```
shell> mysql --column-names --skip-column-names
```

MySQL programs determine which options are given first by examining environment variables, then by reading option files, and then by checking the command line. This means that environment variables have the lowest precedence and command-line options the highest.

You can take advantage of the way that MySQL programs process options by specifying default option values for a program in an option file. That enables you to avoid typing them each time you run the program while enabling you to override the defaults if necessary by using command-line options.

An option can be specified by writing it in full or as any unambiguous prefix. For example, the `--compress` option can be given to `mysqldump` as `--compr`, but not as `--comp` because the latter is ambiguous:

```
shell> mysqldump --comp
mysqldump: ambiguous option '--comp' (compatible, compress)
```

Be aware that the use of option prefixes can cause problems in the event that new options are implemented for a program. A prefix that is unambiguous now might become ambiguous in the future.

Note

As of MySQL 5.5.33, unambiguous prefixes are deprecated. If an unambiguous prefix is given, a warning occurs to provide feedback. Option prefixes are no longer supported in MySQL 5.7; only full options are accepted.

4.2.4 Using Options on the Command Line

Program options specified on the command line follow these rules:

- Options are given after the command name.
- An option argument begins with one dash or two dashes, depending on whether it is a short form or long form of the option name. Many options have both short and long forms. For example, `-?` and `--help` are the short and long forms of the option that instructs a MySQL program to display its help message.
- Option names are case sensitive. `-v` and `-V` are both legal and have different meanings. (They are the corresponding short forms of the `--verbose` and `--version` options.)
- Some options take a value following the option name. For example, `-h localhost` or `--host=localhost` indicate the MySQL server host to a client program. The option value tells the program the name of the host where the MySQL server is running.
- For a long option that takes a value, separate the option name and the value by an “=” sign. For a short option that takes a value, the option value can immediately follow the option letter, or there can be a space between: `-hlocalhost` and `-h localhost` are equivalent. An exception to this rule is the option for specifying your MySQL password. This option can be given in long form as `--password=pass_val` or as `--password`. In the latter case (with no password value given), the program prompts you for the password. The password option also may be given in short form as `-ppass_val` or as `-p`. However, for the short form, if the password value is given, it must follow the option letter with *no intervening space*. The reason for this is that if a space follows the option letter, the program has no way to tell whether a following argument is supposed to be the password value or some other kind of argument. Consequently, the following two commands have two completely different meanings:

```
shell> mysql -ptest
shell> mysql -p test
```

The first command instructs `mysql` to use a password value of `test`, but specifies no default database. The second instructs `mysql` to prompt for the password value and to use `test` as the default database.

- Within option names, dash (“-”) and underscore (“_”) may be used interchangeably. For example, `--skip-grant-tables` and `--skip_grant_tables` are equivalent. (However, the leading dashes cannot be given as underscores.)
- For options that take a numeric value, the value can be given with a suffix of `K`, `M`, or `G` (either uppercase or lowercase) to indicate a multiplier of 1024 , 1024^2 or 1024^3 . For example, the following command tells `mysqladmin` to ping the server 1024 times, sleeping 10 seconds between each ping:

```
mysql> mysqladmin --count=1K --sleep=10 ping
```

Option values that contain spaces must be quoted when given on the command line. For example, the `--execute` (or `-e`) option can be used with `mysql` to pass SQL statements to the server. When this option is used, `mysql` executes the statements in the option value and exits. The statements must be enclosed by quotation marks. For example, you can use the following command to obtain a list of user accounts:

```
mysql> mysql -u root -p --execute="SELECT User, Host FROM mysql.user"
Enter password: *****
+-----+-----+
| User | Host |
+-----+-----+
|      | gigan |
+-----+-----+
```

```
| root | gigan |
|      | localhost |
| jon  | localhost |
| root | localhost |
+-----+-----+
shell>
```

Note that the long form (`--execute`) is followed by an equal sign (=).

If you wish to use quoted values within a statement, you will either need to escape the inner quotation marks, or use a different type of quotation marks within the statement from those used to quote the statement itself. The capabilities of your command processor dictate your choices for whether you can use single or double quotation marks and the syntax for escaping quote characters. For example, if your command processor supports quoting with single or double quotation marks, you can use double quotation marks around the statement, and single quotation marks for any quoted values within the statement.

Multiple SQL statements may be passed in the option value on the command line, separated by semicolons:

```
shell> mysql -u root -p -e "SELECT VERSION();SELECT NOW();"
Enter password: *****
+-----+
| VERSION() |
+-----+
| 5.1.5-alpha-log |
+-----+
+-----+
| NOW() |
+-----+
| 2006-01-05 21:19:04 |
+-----+
```

4.2.5 Program Option Modifiers

Some options are “boolean” and control behavior that can be turned on or off. For example, the `mysql` client supports a `--column-names` option that determines whether or not to display a row of column names at the beginning of query results. By default, this option is enabled. However, you may want to disable it in some instances, such as when sending the output of `mysql` into another program that expects to see only data and not an initial header line.

To disable column names, you can specify the option using any of these forms:

```
--disable-column-names
--skip-column-names
--column-names=0
```

The `--disable` and `--skip` prefixes and the `=0` suffix all have the same effect: They turn the option off.

The “enabled” form of the option may be specified in any of these ways:

```
--column-names
--enable-column-names
--column-names=1
```

As of MySQL 5.5.10, the values `ON`, `TRUE`, `OFF`, and `FALSE` are also recognized for boolean options (not case sensitive).

If an option is prefixed by `--loose`, a program does not exit with an error if it does not recognize the option, but instead issues only a warning:

```
shell> mysql --loose-no-such-option
mysql: WARNING: unknown option '--no-such-option'
```

The `--loose` prefix can be useful when you run programs from multiple installations of MySQL on the same machine and list options in an option file. An option that may not be recognized by all versions of a program can be given using the `--loose` prefix (or `loose` in an option file). Versions of the program that recognize the option process it normally, and versions that do not recognize it issue a warning and ignore it.

`mysqld` enables a limit to be placed on how large client programs can set dynamic system variables. To do this, use a `--maximum` prefix with the variable name. For example, `--maximum-query_cache_size=4M` prevents any client from making the query cache size larger than 4MB.

4.2.6 Using Option Files

Most MySQL programs can read startup options from option files (also sometimes called configuration files). Option files provide a convenient way to specify commonly used options so that they need not be entered on the command line each time you run a program. For the MySQL server, MySQL provides a number of [preconfigured option files](#).

To determine whether a program reads option files, invoke it with the `--help` option. (For `mysqld`, use `--verbose` and `--help`.) If the program reads option files, the help message indicates which files it looks for and which option groups it recognizes.

Note

Option files used with MySQL Cluster programs are covered in [Section 18.3](#), “[Configuration of MySQL Cluster NDB 7.2](#)”.

On Windows, MySQL programs read startup options from the following files, in the specified order (top items are used first).

File Name	Purpose
%PROGRAMDATA%\MySQL \MySQL Server 5.5\my.ini, %PROGRAMDATA %\MySQL\MySQL Server 5.5\my.cnf	Global options
%WINDIR%\my.ini, %WINDIR %\my.cnf	Global options
C:\my.ini, C:\my.cnf	Global options
INSTALLDIR\my.ini, INSTALLDIR\my.cnf	Global options
defaults-extra-file	The file specified with <code>--defaults-extra-file=path</code> , if any

`%PROGRAMDATA%` represents the file system directory that contains application data for all users on the host. This path defaults to `C:\ProgramData` on Microsoft Windows Vista and greater, and `C:\Documents and Settings\All Users\Application Data` on older versions of Microsoft Windows.

`%WINDIR%` represents the location of your Windows directory. This is commonly `C:\WINDOWS`. You can determine its exact location from the value of the `WINDIR` environment variable using the following command:

```
C:\> echo %WINDIR%
```

`INSTALLDIR` represents the MySQL installation directory. This is typically `C:\PROGRAMDIR\MySQL\MySQL 5.5 Server` where `PROGRAMDIR` represents the programs directory (usually `Program Files` on English-language versions of Windows), when MySQL 5.5 has been installed using the installation and configuration wizards. See [Section 2.3.3, “Installing MySQL on Microsoft Windows Using MySQL Installer”](#).

On Unix, Linux and Mac OS X, MySQL programs read startup options from the following files, in the specified order (top items are used first).

File Name	Purpose
<code>/etc/my.cnf</code>	Global options
<code>/etc/mysql/my.cnf</code>	Global options
<code>SYSCONFDIR/my.cnf</code>	Global options
<code>\$MYSQL_HOME/my.cnf</code>	Server-specific options
<code>defaults-extra-file</code>	The file specified with <code>--defaults-extra-file=path</code> , if any
<code>~/my.cnf</code>	User-specific options

`~` represents the current user's home directory (the value of `$HOME`).

`SYSCONFDIR` represents the directory specified with the `SYSCONFDIR` option to `CMake` when MySQL was built. By default, this is the `etc` directory located under the compiled-in installation directory.

`MYSQL_HOME` is an environment variable containing the path to the directory in which the server-specific `my.cnf` file resides. If `MYSQL_HOME` is not set and you start the server using the `mysqld_safe` program, `mysqld_safe` attempts to set `MYSQL_HOME` as follows:

- Let `BASEDIR` and `DATADIR` represent the path names of the MySQL base directory and data directory, respectively.
- If there is a `my.cnf` file in `DATADIR` but not in `BASEDIR`, `mysqld_safe` sets `MYSQL_HOME` to `DATADIR`.
- Otherwise, if `MYSQL_HOME` is not set and there is no `my.cnf` file in `DATADIR`, `mysqld_safe` sets `MYSQL_HOME` to `BASEDIR`.

In MySQL 5.5, use of `DATADIR` as the location for `my.cnf` is deprecated.

Typically, `DATADIR` is `/usr/local/mysql/data` for a binary installation or `/usr/local/var` for a source installation. Note that this is the data directory location that was specified at configuration time, not the one specified with the `--datadir` option when `mysqld` starts. Use of `--datadir` at runtime has no effect on where the server looks for option files, because it looks for them before processing any options.

MySQL looks for option files in the order just described and reads any that exist. If an option file that you want to use does not exist, create it with a plain text editor.

If multiple instances of a given option are found, the last instance takes precedence. There is one exception: For `mysqld`, the *first* instance of the `--user` option is used as a security precaution, to prevent a user specified in an option file from being overridden on the command line.

Note

On Unix platforms, MySQL ignores configuration files that are world-writable. This is intentional as a security measure.

Any long option that may be given on the command line when running a MySQL program can be given in an option file as well. To get the list of available options for a program, run it with the `--help` option.

The syntax for specifying options in an option file is similar to command-line syntax (see [Section 4.2.4, “Using Options on the Command Line”](#)). However, in an option file, you omit the leading two dashes from the option name and you specify only one option per line. For example, `--quick` and `--host=localhost` on the command line should be specified as `quick` and `host=localhost` on separate lines in an option file. To specify an option of the form `--loose-opt_name` in an option file, write it as `loose-opt_name`.

Empty lines in option files are ignored. Nonempty lines can take any of the following forms:

- `#comment, ;comment`

Comment lines start with “#” or “;”. A “#” comment can start in the middle of a line as well.

- `[group]`

`group` is the name of the program or group for which you want to set options. After a group line, any option-setting lines apply to the named group until the end of the option file or another group line is given. Option group names are not case sensitive.

- `opt_name`

This is equivalent to `--opt_name` on the command line.

- `opt_name=value`

This is equivalent to `--opt_name=value` on the command line. In an option file, you can have spaces around the “=” character, something that is not true on the command line. You can optionally enclose the value within single quotation marks or double quotation marks, which is useful if the value contains a “#” comment character.

Leading and trailing spaces are automatically deleted from option names and values.

You can use the escape sequences “\b”, “\t”, “\n”, “\r”, “\\”, and “\s” in option values to represent the backspace, tab, newline, carriage return, backslash, and space characters. The escaping rules in option files are:

- If a backslash is followed by a valid escape sequence character, the sequence is converted to the character represented by the sequence. For example, “\s” is converted to a space.
- If a backslash is not followed by a valid escape sequence character, it remains unchanged. For example, “\S” is retained as is.

The preceding rules mean that a literal backslash can be given as “\\”, or as “\” if it is not followed by a valid escape sequence character.

The rules for escape sequences in option files differ slightly from the rules for escape sequences in string literals in SQL statements. In the latter context, if “x” is not a valid escape sequence character, “\x” becomes “x” rather than “\x”. See [Section 9.1.1, “String Literals”](#).

The escaping rules for option file values are especially pertinent for Windows path names, which use “\” as a path name separator. A separator in a Windows path name must be written as “\\” if it is followed by an escape sequence character. It can be written as “\” or “\” if it is not. Alternatively, “/” may be used in Windows path names and will be treated as “\”. Suppose that you want to specify a base directory of `C:\Program Files\MySQL\MySQL Server 5.5` in an option file. This can be done several ways. Some examples:

```
basedir="C:\Program Files\MySQL\MySQL Server 5.5"
basedir="C:\\Program Files\\MySQL\\MySQL Server 5.5"
basedir="C:/Program Files/MySQL/MySQL Server 5.5"
basedir=C:\\Program\\sFiles\\MySQL\\MySQL\\sServer\\s5.5
```

If an option group name is the same as a program name, options in the group apply specifically to that program. For example, the `[mysqld]` and `[mysql]` groups apply to the `mysqld` server and the `mysql` client program, respectively.

The `[client]` option group is read by all client programs (but *not* by `mysqld`). This enables you to specify options that apply to all clients. For example, `[client]` is the perfect group to use to specify the password that you use to connect to the server. (But make sure that the option file is readable and writable only by yourself, so that other people cannot find out your password.) Be sure not to put an option in the `[client]` group unless it is recognized by *all* client programs that you use. Programs that do not understand the option quit after displaying an error message if you try to run them.

Here is a typical global option file:

```
[client]
port=3306
socket=/tmp/mysql.sock

[mysqld]
port=3306
socket=/tmp/mysql.sock
key_buffer_size=16M
max_allowed_packet=8M

[mysqldump]
quick
```

The preceding option file uses `var_name=value` syntax for the lines that set the `key_buffer_size` and `max_allowed_packet` variables.

Here is a typical user option file:

```
[client]
# The following password will be sent to all standard MySQL clients
password="my_password"

[mysql]
no-auto-rehash
connect_timeout=2

[mysqlhotcopy]
interactive_timeout
```

If you want to create option groups that should be read by `mysqld` servers from a specific MySQL release series only, you can do this by using groups with names of `[mysqld-5.1]`, `[mysqld-5.5]`, and so forth. The following group indicates that the `--new` option should be used only by MySQL servers with 5.5.x version numbers:

```
[mysqld-5.5]
new
```

It is possible to use `!include` directives in option files to include other option files and `!includedir` to search specific directories for option files. For example, to include the `/home/mydir/myopt.cnf` file, use the following directive:

```
!include /home/mydir/myopt.cnf
```

To search the `/home/mydir` directory and read option files found there, use this directive:

```
!includedir /home/mydir
```

There is no guarantee about the order in which the option files in the directory will be read.

Note

Currently, any files to be found and included using the `!includedir` directive on Unix operating systems *must* have file names ending in `.cnf`. On Windows, this directive checks for files with the `.ini` or `.cnf` extension.

Write the contents of an included option file like any other option file. That is, it should contain groups of options, each preceded by a `[group]` line that indicates the program to which the options apply.

While an included file is being processed, only those options in groups that the current program is looking for are used. Other groups are ignored. Suppose that a `my.cnf` file contains this line:

```
!include /home/mydir/myopt.cnf
```

And suppose that `/home/mydir/myopt.cnf` looks like this:

```
[mysqladmin]
force

[mysqld]
key_buffer_size=16M
```

If `my.cnf` is processed by `mysqld`, only the `[mysqld]` group in `/home/mydir/myopt.cnf` is used. If the file is processed by `mysqladmin`, only the `[mysqladmin]` group is used. If the file is processed by any other program, no options in `/home/mydir/myopt.cnf` are used.

The `!includedir` directive is processed similarly except that all option files in the named directory are read.

4.2.7 Command-Line Options that Affect Option-File Handling

Most MySQL programs that support option files handle the following options. They affect option-file handling, so they must be given on the command line and not in an option file. To work properly, each of these options must be given before other options, with these exceptions:

- `--print-defaults` may be used immediately after `--defaults-file` or `--defaults-extra-file`.
- On Windows, if the server is started with the `--defaults-file` and `--install` options, `--install` must be first. See [Section 2.3.7.7, “Starting MySQL as a Windows Service”](#).

When specifying file names, you should avoid the use of the “~” shell metacharacter because it might not be interpreted as you expect.

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, `file_name` must be the full

path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, `file_name` must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, the `mysql` client normally reads the `[client]` and `[mysql]` groups. If the `--defaults-group-suffix=_other` option is given, `mysql` also reads the `[client_other]` and `[mysql_other]` groups.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

- `--print-defaults`

Print the program name and all options that it gets from option files.

4.2.8 Using Options to Set Program Variables

Many MySQL programs have internal variables that can be set at runtime using the `SET` statement. See [Section 13.7.4, “SET Syntax”](#), and [Section 5.1.5, “Using System Variables”](#).

Most of these program variables also can be set at server startup by using the same syntax that applies to specifying program options. For example, `mysql` has a `max_allowed_packet` variable that controls the maximum size of its communication buffer. To set the `max_allowed_packet` variable for `mysql` to a value of 16MB, use either of the following commands:

```
shell> mysql --max_allowed_packet=16777216
shell> mysql --max_allowed_packet=16M
```

The first command specifies the value in bytes. The second specifies the value in megabytes. For variables that take a numeric value, the value can be given with a suffix of `K`, `M`, or `G` (either uppercase or lowercase) to indicate a multiplier of 1024 , 1024^2 or 1024^3 . (For example, when used to set `max_allowed_packet`, the suffixes indicate units of kilobytes, megabytes, or gigabytes.)

In an option file, variable settings are given without the leading dashes:

```
[mysql]
max_allowed_packet=16777216
```

Or:

```
[mysql]
max_allowed_packet=16M
```

If you like, underscores in a variable name can be specified as dashes. The following option groups are equivalent. Both set the size of the server's key buffer to 512MB:

```
[mysqld]
key_buffer_size=512M

[mysqld]
key-buffer-size=512M
```

A variable can be specified by writing it in full or as any unambiguous prefix. For example, the `max_allowed_packet` variable can be set for `mysql` as `--max_a`, but not as `--max` because the latter is ambiguous:

```
shell> mysql --max=1000000
mysql: ambiguous option '--max=1000000' (max_allowed_packet, max_join_size)
```

Be aware that the use of variable prefixes can cause problems in the event that new variables are implemented for a program. A prefix that is unambiguous now might become ambiguous in the future.

Suffixes for specifying a value multiplier can be used when setting a variable at server startup, but not to set the value with `SET` at runtime. On the other hand, with `SET` you can assign a variable's value using an expression, which is not true when you set a variable at server startup. For example, the first of the following lines is legal at server startup, but the second is not:

```
shell> mysql --max_allowed_packet=16M
shell> mysql --max_allowed_packet=16*1024*1024
```

Conversely, the second of the following lines is legal at runtime, but the first is not:

```
mysql> SET GLOBAL max_allowed_packet=16M;
mysql> SET GLOBAL max_allowed_packet=16*1024*1024;
```

Note

Before MySQL 4.0.2, the only syntax for setting program variables was `--set-variable=option=value` (or `set-variable=option=value` in option files). Underscores cannot be given as dashes, and the variable name must be specified in full. This syntax is deprecated and was removed in MySQL 5.5.3.

4.2.9 Option Defaults, Options Expecting Values, and the = Sign

By convention, long forms of options that assign a value are written with an equals (=) sign, like this:

```
shell> mysql --host=tonfisk --user=jon
```

For options that require a value (that is, not having a default value), the equal sign is not required, and so the following is also valid:

```
shell> mysql --host tonfisk --user jon
```

In both cases, the `mysql` client attempts to connect to a MySQL server running on the host named “tonfisk” using an account with the user name “jon”.

Due to this behavior, problems can occasionally arise when no value is provided for an option that expects one. Consider the following example, where a user connects to a MySQL server running on host `tonfisk` as user `jon`:

```

shell> mysql --host 85.224.35.45 --user jon
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 3
Server version: 5.5.40 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT CURRENT_USER();
+-----+
| CURRENT_USER() |
+-----+
| jon@%          |
+-----+
1 row in set (0.00 sec)

```

Omitting the required value for one of these option yields an error, such as the one shown here:

```

shell> mysql --host 85.224.35.45 --user
mysql: option '--user' requires an argument

```

In this case, `mysql` was unable to find a value following the `--user` option because nothing came after it on the command line. However, if you omit the value for an option that is *not* the last option to be used, you obtain a different error that you may not be expecting:

```

shell> mysql --host --user jon
ERROR 2005 (HY000): Unknown MySQL server host '--user' (1)

```

Because `mysql` assumes that any string following `--host` on the command line is a host name, `--host --user` is interpreted as `--host=--user`, and the client attempts to connect to a MySQL server running on a host named “--user”.

Options having default values always require an equal sign when assigning a value; failing to do so causes an error. For example, the MySQL server `--log-error` option has the default value `host_name.err`, where `host_name` is the name of the host on which MySQL is running. Assume that you are running MySQL on a computer whose host name is “tonfisk”, and consider the following invocation of `mysqld_safe`:

```

shell> mysqld_safe &
[1] 11699
shell> 080112 12:53:40 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080112 12:53:40 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
shell>

```

After shutting down the server, restart it as follows:

```

shell> mysqld_safe --log-error &
[1] 11699
shell> 080112 12:53:40 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080112 12:53:40 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
shell>

```

The result is the same, since `--log-error` is not followed by anything else on the command line, and it supplies its own default value. (The `&` character tells the operating system to run MySQL in the background; it is ignored by MySQL itself.) Now suppose that you wish to log errors to a file named `my-errors.err`. You might try starting the server with `--log-error my-errors`, but this does not have the intended effect, as shown here:

```

shell> mysqld_safe --log-error my-errors &

```

```
[1] 31357
shell> 080111 22:53:31 mysqld_safe Logging to '/usr/local/mysql/var/tonfisk.err'.
080111 22:53:32 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var
080111 22:53:34 mysqld_safe mysqld from pid file /usr/local/mysql/var/tonfisk.pid ended

[1]+  Done                  ./mysqld_safe --log-error my-errors
```

The server attempted to start using `/usr/local/mysql/var/tonfisk.err` as the error log, but then shut down. Examining the last few lines of this file shows the reason:

```
shell> tail /usr/local/mysql/var/tonfisk.err
080111 22:53:32 InnoDB: Started; log sequence number 0 46409
/usr/local/mysql/libexec/mysqld: Too many arguments (first extra is 'my-errors').
Use --verbose --help to get a list of available options
080111 22:53:32 [ERROR] Aborting

080111 22:53:32 InnoDB: Starting shutdown...
080111 22:53:34 InnoDB: Shutdown completed; log sequence number 0 46409
080111 22:53:34 [Note] /usr/local/mysql/libexec/mysqld: Shutdown complete

080111 22:53:34 mysqld_safe mysqld from pid file /usr/local/mysql/var/tonfisk.pid ended
```

Because the `--log-error` option supplies a default value, you must use an equal sign to assign a different value to it, as shown here:

```
shell> mysqld_safe --log-error=my-errors &
[1] 31437
shell> 080111 22:54:15 mysqld_safe Logging to '/usr/local/mysql/var/my-errors.err'.
080111 22:54:15 mysqld_safe Starting mysqld daemon with databases from /usr/local/mysql/var

shell>
```

Now the server has been started successfully, and is logging errors to the file `/usr/local/mysql/var/my-errors.err`.

Similar issues can arise when specifying option values in option files. For example, consider a `my.cnf` file that contains the following:

```
[mysql]

host
user
```

When the `mysql` client reads this file, these entries are parsed as `--host --user` or `--host=--user`, with the result shown here:

```
shell> mysql
ERROR 2005 (HY000): Unknown MySQL server host '--user' (1)
```

However, in option files, an equal sign is not assumed. Suppose the `my.cnf` file is as shown here:

```
[mysql]

user jon
```

Trying to start `mysql` in this case causes a different error:

```
shell> mysql
mysql: unknown option '--user jon'
```

A similar error would occur if you were to write `host tonfisk` in the option file rather than `host=tonfisk`. Instead, you must use the equal sign:

```
[mysql]
user=jon
```

Now the login attempt succeeds:

```
shell> mysql
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 5
Server version: 5.5.40 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT USER();
+-----+
| USER() |
+-----+
| jon@localhost |
+-----+
1 row in set (0.00 sec)
```

This is not the same behavior as with the command line, where the equals sign is not required:

```
shell> mysql --user jon --host tonfisk
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 6
Server version: 5.5.40 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT USER();
+-----+
| USER() |
+-----+
| jon@tonfisk |
+-----+
1 row in set (0.00 sec)
```

In MySQL 5.5, specifying an option requiring a value without a value in an option file causes the server to abort with an error. Suppose that `my.cnf` contains the following:

```
[mysqld]
log_error
relay_log
relay_log_index
```

This causes the server to fail on startup, as shown here:

```
shell> mysqld_safe &

090514 09:48:39 mysqld_safe Logging to '/home/jon/bin/mysql/var/tonfisk.err'.
090514 09:48:39 mysqld_safe Starting mysqld daemon with databases from /home/jon/bin/mysql/var
090514 09:48:39 mysqld_safe mysqld from pid file /home/jon/bin/mysql/var/tonfisk.pid ended
```

The `--log-error` option does not require an argument; however, the `--relay-log` option requires one, as shown in the error log (which in the absence of a specified value, defaults to `datadir/hostname.err`):

```
shell> tail -n 3 ../var/tonfisk.err

090514 09:48:39 mysqld_safe Starting mysqld daemon with databases from /home/jon/bin/mysql/var
090514 9:48:39 [ERROR] /home/jon/bin/mysql/libexec/mysqld: option '--relay-log' requires an argument
090514 9:48:39 [ERROR] Aborting
```

This is a change from previous behavior, where the server would have interpreted the last two lines in the example `my.cnf` file as `--relay-log=relay_log_index` and created a relay log file using “`relay_log_index`” as the basename. (Bug #25192)

4.2.10 Setting Environment Variables

Environment variables can be set at the command prompt to affect the current invocation of your command processor, or set permanently to affect future invocations. To set a variable permanently, you can set it in a startup file or by using the interface provided by your system for this purpose. Consult the documentation for your command interpreter for specific details. [Section 2.12, “Environment Variables”](#), lists all environment variables that affect MySQL program operation.

To specify a value for an environment variable, use the syntax appropriate for your command processor. For example, on Windows, you can set the `USER` variable to specify your MySQL account name. To do so, use this syntax:

```
SET USER=your_name
```

The syntax on Unix depends on your shell. Suppose that you want to specify the TCP/IP port number using the `MYSQL_TCP_PORT` variable. Typical syntax (such as for `sh`, `ksh`, `bash`, `zsh`, and so on) is as follows:

```
MYSQL_TCP_PORT=3306
export MYSQL_TCP_PORT
```

The first command sets the variable, and the `export` command exports the variable to the shell environment so that its value becomes accessible to MySQL and other processes.

For `csh` and `tcsh`, use `setenv` to make the shell variable available to the environment:

```
setenv MYSQL_TCP_PORT 3306
```

The commands to set environment variables can be executed at your command prompt to take effect immediately, but the settings persist only until you log out. To have the settings take effect each time you log in, use the interface provided by your system or place the appropriate command or commands in a startup file that your command interpreter reads each time it starts.

On Windows, you can set environment variables using the System Control Panel (under Advanced).

On Unix, typical shell startup files are `.bashrc` or `.bash_profile` for `bash`, or `.tcshrc` for `tcsh`.

Suppose that your MySQL programs are installed in `/usr/local/mysql/bin` and that you want to make it easy to invoke these programs. To do this, set the value of the `PATH` environment variable to include that directory. For example, if your shell is `bash`, add the following line to your `.bashrc` file:

```
PATH=${PATH}:/usr/local/mysql/bin
```

`bash` uses different startup files for login and nonlogin shells, so you might want to add the setting to `.bashrc` for login shells and to `.bash_profile` for nonlogin shells to make sure that `PATH` is set regardless.

If your shell is `tcsh`, add the following line to your `.tcshrc` file:

```
setenv PATH ${PATH}:/usr/local/mysql/bin
```

If the appropriate startup file does not exist in your home directory, create it with a text editor.

After modifying your `PATH` setting, open a new console window on Windows or log in again on Unix so that the setting goes into effect.

4.3 MySQL Server and Server-Startup Programs

This section describes `mysqld`, the MySQL server, and several programs that are used to start the server.

4.3.1 `mysqld` — The MySQL Server

`mysqld`, also known as MySQL Server, is the main program that does most of the work in a MySQL installation. MySQL Server manages access to the MySQL data directory that contains databases and tables. The data directory is also the default location for other information such as log files and status files.

When MySQL server starts, it listens for network connections from client programs and manages access to databases on behalf of those clients.

The `mysqld` program has many options that can be specified at startup. For a complete list of options, run this command:

```
shell> mysqld --verbose --help
```

MySQL Server also has a set of system variables that affect its operation as it runs. System variables can be set at server startup, and many of them can be changed at runtime to effect dynamic server reconfiguration. MySQL Server also has a set of status variables that provide information about its operation. You can monitor these status variables to access runtime performance characteristics.

For a full description of MySQL Server command options, system variables, and status variables, see [Section 5.1, “The MySQL Server”](#). For information about installing MySQL and setting up the initial configuration, see [Chapter 2, *Installing and Upgrading MySQL*](#).

4.3.2 `mysqld_safe` — MySQL Server Startup Script

`mysqld_safe` is the recommended way to start a `mysqld` server on Unix. `mysqld_safe` adds some safety features such as restarting the server when an error occurs and logging runtime information to an error log file. A description of error logging is given later in this section.

`mysqld_safe` tries to start an executable named `mysqld`. To override the default behavior and specify explicitly the name of the server you want to run, specify a `--mysqld` or `--mysqld-version` option to `mysqld_safe`. You can also use `--ledir` to indicate the directory where `mysqld_safe` should look for the server.

Many of the options to `mysqld_safe` are the same as the options to `mysqld`. See [Section 5.1.3, “Server Command Options”](#).

Options unknown to `mysqld_safe` are passed to `mysqld` if they are specified on the command line, but ignored if they are specified in the `[mysqld_safe]` group of an option file. See [Section 4.2.6, “Using Option Files”](#).

`mysql_safe` reads all options from the `[mysql]`, `[server]`, and `[mysql_safe]` sections in option files. For example, if you specify a `[mysql]` section like this, `mysql_safe` will find and use the `--log-error` option:

```
[mysql]
log-error=error.log
```

For backward compatibility, `mysql_safe` also reads `[safe_mysql]` sections, although you should rename such sections to `[mysql_safe]` in MySQL 5.5 installations.

`mysql_safe` supports the following options. It also reads option files and supports the options for processing them described at [Section 4.2.7, “Command-Line Options that Affect Option-File Handling”](#).

Table 4.1 `mysql_safe` Options

Format	Option File	Description	Introduced
<code>--basedir=path</code>	<code>basedir</code>	The path to the MySQL installation directory	
<code>--core-file-size=size</code>	<code>core-file-size</code>	The size of the core file that <code>mysqld</code> should be able to create	
<code>--datadir=path</code>	<code>datadir</code>	The path to the data directory	
<code>--defaults-extra-file=path</code>	<code>defaults-extra-file</code>	Read option file in addition to the usual option files	
<code>--defaults-file=file_name</code>	<code>defaults-file</code>	Read only the given option file	
<code>--help</code>		Display a help message and exit	
<code>--ledir=path</code>	<code>ledir</code>	Use this option to indicate the path name to the directory where the server is located	
<code>--log-error=file_name</code>	<code>log-error</code>	Write the error log to the given file	
<code>--malloc-lib=[lib-name]</code>	<code>malloc-lib</code>	Alternative malloc library to use for <code>mysqld</code>	
<code>--mysqld=prog_name</code>	<code>mysqld</code>	The name of the server program (in the <code>ledir</code> directory) that you want to start	
<code>--mysqld-version=suffix</code>	<code>mysqld-version</code>	This option is similar to the <code>--mysqld</code> option, but you specify only the suffix for the server program name	
<code>--nice=priority</code>	<code>nice</code>	Use the <code>nice</code> program to set the server's scheduling priority to the given value	
<code>--no-defaults</code>	<code>no-defaults</code>	Do not read any option files	
<code>--open-files-limit=count</code>	<code>open-files-limit</code>	The number of files that <code>mysqld</code> should be able to open	
<code>--pid-file=file_name</code>	<code>pid-file=file_name</code>	The path name of the process ID file	
<code>--plugin-dir=path</code>	<code>plugin-dir=path</code>	The directory where plugins are located	5.5.3
<code>--port=number</code>	<code>port</code>	The port number that the server should use when listening for TCP/IP connections	
<code>--skip-kill-mysqld</code>	<code>skip-kill-mysqld</code>	Do not try to kill stray <code>mysqld</code> processes	
<code>--skip-syslog</code>	<code>skip-syslog</code>	Do not write error messages to syslog; use error log file	

Format	Option File	Description	Introduced
<code>--socket=path</code>	<code>socket</code>	The Unix socket file that the server should use when listening for local connections	
<code>--syslog</code>	<code>syslog</code>	Write error messages to syslog	
<code>--syslog-tag=tag</code>	<code>syslog-tag</code>	Tag suffix for messages written to syslog	
<code>-- timezone=timezone</code>	<code>timezone</code>	Set the TZ time zone environment variable to the given option value	
<code>-- user={user_name user_id}</code>	<code>user</code>	Run the mysqld server as the user having the name user_name or the numeric user ID user_id	

- `--help`

Display a help message and exit.

- `--basedir=path`

The path to the MySQL installation directory.

- `--core-file-size=size`

The size of the core file that `mysqld` should be able to create. The option value is passed to `ulimit -c`.

- `--datadir=path`

The path to the data directory.

- `--defaults-extra-file=path`

The name of an option file to be read in addition to the usual option files. This must be the first option on the command line if it is used. If the file does not exist or is otherwise inaccessible, the server will exit with an error.

- `--defaults-file=file_name`

The name of an option file to be read instead of the usual option files. This must be the first option on the command line if it is used.

- `--ledir=path`

If `mysqld_safe` cannot find the server, use this option to indicate the path name to the directory where the server is located.

- `--log-error=file_name`

Write the error log to the given file. See [Section 5.2.2, “The Error Log”](#).

- `--malloc-lib=[lib_name]`

The name of the library to use for memory allocation instead of the system `malloc()` library. Any library can be used by specifying its path name, but there is a shortcut form to enable use of the `tcmalloc` library that is shipped with binary MySQL distributions for Linux in MySQL 5.5. It is possible that the shortcut form will not work under certain configurations, in which case you should specify a path name instead.

The `--malloc-lib` option works by modifying the `LD_PRELOAD` environment value to affect dynamic linking to enable the loader to find the memory-allocation library when `mysqld` runs:

- If the option is not given, or is given without a value (`--malloc-lib=`), `LD_PRELOAD` is not modified and no attempt is made to use `tcmalloc`.
- If the option is given as `--malloc-lib=tcmalloc`, `mysqld_safe` looks for a `tcmalloc` library in `/usr/lib` and then in the MySQL `pkglibdir` location (for example, `/usr/local/mysql/lib` or whatever is appropriate). If `tcmalloc` is found, its path name is added to the beginning of the `LD_PRELOAD` value for `mysqld`. If `tcmalloc` is not found, `mysqld_safe` aborts with an error.
- If the option is given as `--malloc-lib=/path/to/some/library`, that full path is added to the beginning of the `LD_PRELOAD` value. If the full path points to a nonexistent or unreadable file, `mysqld_safe` aborts with an error.
- For cases where `mysqld_safe` adds a path name to `LD_PRELOAD`, it adds the path to the beginning of any existing value the variable already has.

Linux users can use the `libtcmalloc_minimal.so` included in binary packages by adding these lines to the `my.cnf` file:

```
[mysqld_safe]
malloc-lib=tcmalloc
```

Those lines also suffice for users on any platform who have installed a `tcmalloc` package in `/usr/lib`. To use a specific `tcmalloc` library, specify its full path name. Example:

```
[mysqld_safe]
malloc-lib=/opt/lib/libtcmalloc_minimal.so
```

- `--mysqld=prog_name`

The name of the server program (in the `ledir` directory) that you want to start. This option is needed if you use the MySQL binary distribution but have the data directory outside of the binary distribution. If `mysqld_safe` cannot find the server, use the `--ledir` option to indicate the path name to the directory where the server is located.

- `--mysqld-version=suffix`

This option is similar to the `--mysqld` option, but you specify only the suffix for the server program name. The basename is assumed to be `mysqld`. For example, if you use `--mysqld-version=debug`, `mysqld_safe` starts the `mysqld-debug` program in the `ledir` directory. If the argument to `--mysqld-version` is empty, `mysqld_safe` uses `mysqld` in the `ledir` directory.

- `--nice=priority`

Use the `nice` program to set the server's scheduling priority to the given value.

- `--no-defaults`

Do not read any option files. This must be the first option on the command line if it is used.

- `--open-files-limit=count`

The number of files that `mysqld` should be able to open. The option value is passed to `ulimit -n`. Note that you need to start `mysqld_safe` as `root` for this to work properly!

- `--pid-file=file_name`

The path name of the process ID file.

- `--plugin-dir=path`

The path name of the plugin directory. This option was added in MySQL 5.5.3.

- `--port=port_num`

The port number that the server should use when listening for TCP/IP connections. The port number must be 1024 or higher unless the server is started by the `root` system user.

- `--skip-kill-mysqld`

Do not try to kill stray `mysqld` processes at startup. This option works only on Linux.

- `--socket=path`

The Unix socket file that the server should use when listening for local connections.

- `--syslog, --skip-syslog`

`--syslog` causes error messages to be sent to `syslog` on systems that support the `logger` program. `--skip-syslog` suppresses the use of `syslog`; messages are written to an error log file.

When `syslog` is used, the `daemon.err` syslog priority/facility is used for all log messages.

- `--syslog-tag=tag`

For logging to `syslog`, messages from `mysqld_safe` and `mysqld` are written with a tag of `mysqld_safe` and `mysqld`, respectively. To specify a suffix for the tag, use `--syslog-tag=tag`, which modifies the tags to be `mysqld_safe-tag` and `mysqld-tag`.

- `--timezone=timezone`

Set the `TZ` time zone environment variable to the given option value. Consult your operating system documentation for legal time zone specification formats.

- `--user={user_name|user_id}`

Run the `mysqld` server as the user having the name `user_name` or the numeric user ID `user_id`. (“User” in this context refers to a system login account, not a MySQL user listed in the grant tables.)

If you execute `mysqld_safe` with the `--defaults-file` or `--defaults-extra-file` option to name an option file, the option must be the first one given on the command line or the option file will not be used. For example, this command will not use the named option file:

```
mysql> mysqld_safe --port=port_num --defaults-file=file_name
```

Instead, use the following command:

```
mysql> mysqld_safe --defaults-file=file_name --port=port_num
```

The `mysqld_safe` script is written so that it normally can start a server that was installed from either a source or a binary distribution of MySQL, even though these types of distributions typically install the

server in slightly different locations. (See [Section 2.1.5, “Installation Layouts”](#).) `mysqld_safe` expects one of the following conditions to be true:

- The server and databases can be found relative to the working directory (the directory from which `mysqld_safe` is invoked). For binary distributions, `mysqld_safe` looks under its working directory for `bin` and `data` directories. For source distributions, it looks for `libexec` and `var` directories. This condition should be met if you execute `mysqld_safe` from your MySQL installation directory (for example, `/usr/local/mysql` for a binary distribution).
- If the server and databases cannot be found relative to the working directory, `mysqld_safe` attempts to locate them by absolute path names. Typical locations are `/usr/local/libexec` and `/usr/local/var`. The actual locations are determined from the values configured into the distribution at the time it was built. They should be correct if MySQL is installed in the location specified at configuration time.

Because `mysqld_safe` tries to find the server and databases relative to its own working directory, you can install a binary distribution of MySQL anywhere, as long as you run `mysqld_safe` from the MySQL installation directory:

```
shell> cd mysql_installation_directory
shell> bin/mysqld_safe &
```

If `mysqld_safe` fails, even when invoked from the MySQL installation directory, you can specify the `--ledir` and `--datadir` options to indicate the directories in which the server and databases are located on your system.

Beginning with MySQL 5.5.21, `mysqld_safe` tries to use the `sleep` and `date` system utilities to determine how many times it has attempted to start this second, and—if these are present and this is greater than 5 times—is forced to wait 1 full second before starting again. This is intended to prevent excessive CPU usage in the event of repeated failures. (Bug #11761530, Bug #54035)

When you use `mysqld_safe` to start `mysqld`, `mysqld_safe` arranges for error (and notice) messages from itself and from `mysqld` to go to the same destination.

There are several `mysqld_safe` options for controlling the destination of these messages:

- `--syslog`: Write error messages to `syslog` on systems that support the `logger` program.
- `--skip-syslog`: Do not write error messages to `syslog`. Messages are written to the default error log file (`host_name.err` in the data directory), or to a named file if the `--log-error` option is given.
- `--log-error=file_name`: Write error messages to the named error file.

If none of these options is given, the default is `--skip-syslog`.

If `--syslog` and `--log-error` are both given, a warning is issued and `--log-error` takes precedence.

When `mysqld_safe` writes a message, notices go to the logging destination (`syslog` or the error log file) and `stdout`. Errors go to the logging destination and `stderr`.

Normally, you should not edit the `mysqld_safe` script. Instead, configure `mysqld_safe` by using command-line options or options in the `[mysqld_safe]` section of a `my.cnf` option file. In rare cases, it might be necessary to edit `mysqld_safe` to get it to start the server properly. However, if you do this, your modified version of `mysqld_safe` might be overwritten if you upgrade MySQL in the future, so you should make a copy of your edited version that you can reinstall.

4.3.3 `mysql.server` — MySQL Server Startup Script

MySQL distributions on Unix include a script named `mysql.server`. It can be used on systems such as Linux and Solaris that use System V-style run directories to start and stop system services. It is also used by the Mac OS X Startup Item for MySQL.

`mysql.server` can be found in the `support-files` directory under your MySQL installation directory or in a MySQL source distribution.

If you use the Linux server RPM package (`MySQL-server-VERSION.rpm`), the `mysql.server` script will be installed in the `/etc/init.d` directory with the name `mysql`. You need not install it manually. See [Section 2.5.1, “Installing MySQL on Linux Using RPM Packages”](#), for more information on the Linux RPM packages.

Some vendors provide RPM packages that install a startup script under a different name such as `mysqld`.

If you install MySQL from a source distribution or using a binary distribution format that does not install `mysql.server` automatically, you can install it manually. Instructions are provided in [Section 2.10.1.2, “Starting and Stopping MySQL Automatically”](#).

`mysql.server` reads options from the `[mysql.server]` and `[mysqld]` sections of option files. For backward compatibility, it also reads `[mysql_server]` sections, although you should rename such sections to `[mysql.server]` when using MySQL 5.5.

`mysql.server` supports the following options.

- `--basedir=path`

The path to the MySQL installation directory.

- `--datadir=path`

The path to the MySQL data directory.

- `--pid-file=file_name`

The path name of the file in which the server should write its process ID.

- `--service-startup-timeout=file_name`

How long in seconds to wait for confirmation of server startup. If the server does not start within this time, `mysql.server` exits with an error. The default value is 900. A value of 0 means not to wait at all for startup. Negative values mean to wait forever (no timeout).

- `--use-mysqld_safe`

Use `mysqld_safe` to start the server. This is the default.

- `--user=user_name`

The login user name to use for running `mysqld`.

4.3.4 `mysqld_multi` — Manage Multiple MySQL Servers

`mysqld_multi` is designed to manage several `mysqld` processes that listen for connections on different Unix socket files and TCP/IP ports. It can start or stop servers, or report their current status.

`mysqld_multi` searches for groups named `[mysqldN]` in `my.cnf` (or in the file named by the `--defaults-file` option). `N` can be any positive integer. This number is referred to in the following

discussion as the option group number, or *GNR*. Group numbers distinguish option groups from one another and are used as arguments to *mysqld_multi* to specify which servers you want to start, stop, or obtain a status report for. Options listed in these groups are the same that you would use in the *[mysqld]* group used for starting *mysqld*. (See, for example, [Section 2.10.1.2, “Starting and Stopping MySQL Automatically”](#).) However, when using multiple servers, it is necessary that each one use its own value for options such as the Unix socket file and TCP/IP port number. For more information on which options must be unique per server in a multiple-server environment, see [Section 5.3, “Running Multiple MySQL Instances on One Machine”](#).

To invoke *mysqld_multi*, use the following syntax:

```
shell> mysqld_multi [options] {start|stop|report} [GNR[,GNR] ...]
```

start, *stop*, and *report* indicate which operation to perform. You can perform the designated operation for a single server or multiple servers, depending on the *GNR* list that follows the option name. If there is no list, *mysqld_multi* performs the operation for all servers in the option file.

Each *GNR* value represents an option group number or range of group numbers. The value should be the number at the end of the group name in the option file. For example, the *GNR* for a group named *[mysqld17]* is 17. To specify a range of numbers, separate the first and last numbers by a dash. The *GNR* value 10-13 represents groups *[mysqld10]* through *[mysqld13]*. Multiple groups or group ranges can be specified on the command line, separated by commas. There must be no whitespace characters (spaces or tabs) in the *GNR* list; anything after a whitespace character is ignored.

This command starts a single server using option group *[mysqld17]*:

```
shell> mysqld_multi start 17
```

This command stops several servers, using option groups *[mysqld8]* and *[mysqld10]* through *[mysqld13]*:

```
shell> mysqld_multi stop 8,10-13
```

For an example of how you might set up an option file, use this command:

```
shell> mysqld_multi --example
```

mysqld_multi searches for option files as follows:

- With *--no-defaults*, no option files are read.
- With *--defaults-file=file_name*, only the named file is read.
- Otherwise, option files in the standard list of locations are read, including any file named by the *--defaults-extra-file=file_name* option, if one is given. (If the option is given multiple times, the last value is used.)

Option files read are searched for *[mysqld_multi]* and *[mysqldN]* option groups. The *[mysqld_multi]* group can be used for options to *mysqld_multi* itself. *[mysqldN]* groups can be used for options passed to specific *mysqld* instances.

The *[mysqld]* or *[mysqld_safe]* groups can be used for common options read by all instances of *mysqld* or *mysqld_safe*. You can specify a *--defaults-file=file_name* option to use a different

configuration file for that instance, in which case the `[mysqld]` or `[mysqld_safe]` groups from that file will be used for that instance.

`mysqld_multi` supports the following options.

- `--help`

Display a help message and exit.

- `--config-file=file_name`

This option is deprecated. If given, it is treated the same way as `--defaults-extra-file`, described earlier. `--config-file` was removed in MySQL 5.5.3.

- `--example`

Display a sample option file.

- `--log=file_name`

Specify the name of the log file. If the file exists, log output is appended to it.

- `--mysqladmin=prog_name`

The `mysqladmin` binary to be used to stop servers.

- `--mysqld=prog_name`

The `mysqld` binary to be used. Note that you can specify `mysqld_safe` as the value for this option also. If you use `mysqld_safe` to start the server, you can include the `mysqld` or `ledir` options in the corresponding `[mysqldN]` option group. These options indicate the name of the server that `mysqld_safe` should start and the path name of the directory where the server is located. (See the descriptions for these options in [Section 4.3.2, “mysqld_safe — MySQL Server Startup Script”](#).)
Example:

```
[mysqld38]
mysqld = mysqld-debug
ledir  = /opt/local/mysql/libexec
```

- `--no-log`

Print log information to `stdout` rather than to the log file. By default, output goes to the log file.

- `--password=password`

The password of the MySQL account to use when invoking `mysqladmin`. Note that the password value is not optional for this option, unlike for other MySQL programs.

- `--silent`

Silent mode; disable warnings.

- `--tcp-ip`

Connect to each MySQL server through the TCP/IP port instead of the Unix socket file. (If a socket file is missing, the server might still be running, but accessible only through the TCP/IP port.) By default, connections are made using the Unix socket file. This option affects `stop` and `report` operations.

- `--user=user_name`

The user name of the MySQL account to use when invoking `mysqladmin`.

- `--verbose`

Be more verbose.

- `--version`

Display version information and exit.

Some notes about `mysqld_multi`:

- **Most important:** Before using `mysqld_multi` be sure that you understand the meanings of the options that are passed to the `mysqld` servers and *why* you would want to have separate `mysqld` processes. Beware of the dangers of using multiple `mysqld` servers with the same data directory. Use separate data directories, unless you *know* what you are doing. Starting multiple servers with the same data directory does *not* give you extra performance in a threaded system. See [Section 5.3, “Running Multiple MySQL Instances on One Machine”](#).

-

Important

Make sure that the data directory for each server is fully accessible to the Unix account that the specific `mysqld` process is started as. *Do not* use the Unix `root` account for this, unless you *know* what you are doing. See [Section 6.1.5, “How to Run MySQL as a Normal User”](#).

- Make sure that the MySQL account used for stopping the `mysqld` servers (with the `mysqladmin` program) has the same user name and password for each server. Also, make sure that the account has the `SHUTDOWN` privilege. If the servers that you want to manage have different user names or passwords for the administrative accounts, you might want to create an account on each server that has the same user name and password. For example, you might set up a common `multi_admin` account by executing the following commands for each server:

```
shell> mysql -u root -S /tmp/mysql.sock -p
Enter password:
mysql> GRANT SHUTDOWN ON *.*
-> TO 'multi_admin'@'localhost' IDENTIFIED BY 'multipass';
```

See [Section 6.2, “The MySQL Access Privilege System”](#). You have to do this for each `mysqld` server. Change the connection parameters appropriately when connecting to each one. Note that the host name part of the account name must permit you to connect as `multi_admin` from the host where you want to run `mysqld_multi`.

- The Unix socket file and the TCP/IP port number must be different for every `mysqld`. (Alternatively, if the host has multiple network addresses, you can use `--bind-address` to cause different servers to listen to different interfaces.)
- The `--pid-file` option is very important if you are using `mysqld_safe` to start `mysqld` (for example, `--mysqld=mysqld_safe`). Every `mysqld` should have its own process ID file. The advantage of using `mysqld_safe` instead of `mysqld` is that `mysqld_safe` monitors its `mysqld` process and restarts it if the process terminates due to a signal sent using `kill -9` or for other reasons, such as a segmentation fault. Please note that the `mysqld_safe` script might require that you start it from a certain place. This means that you might have to change location to a certain directory before running `mysqld_multi`. If you have problems starting, please see the `mysqld_safe` script. Check especially the lines:

```
-----
MY_PWD=`pwd`
# Check if we are starting this relative (for the binary release)
if test -d $MY_PWD/data/mysql -a \
  -f ./share/mysql/english/errmsg.sys -a \
  -x ./bin/mysqld
-----
```

The test performed by these lines should be successful, or you might encounter problems. See [Section 4.3.2, “mysqld_safe — MySQL Server Startup Script”](#).

- You might want to use the `--user` option for `mysqld`, but to do this you need to run the `mysqld_multi` script as the Unix superuser (`root`). Having the option in the option file doesn't matter; you just get a warning if you are not the superuser and the `mysqld` processes are started under your own Unix account.

The following example shows how you might set up an option file for use with `mysqld_multi`. The order in which the `mysqld` programs are started or stopped depends on the order in which they appear in the option file. Group numbers need not form an unbroken sequence. The first and fifth `[mysqldN]` groups were intentionally omitted from the example to illustrate that you can have “gaps” in the option file. This gives you more flexibility.

```
# This file should probably be in your home dir (~/.my.cnf)
# or /etc/my.cnf
# Version 2.1 by Jani Tolonen

[mysqld_multi]
mysqld      = /usr/local/bin/mysqld_safe
mysqladmin  = /usr/local/bin/mysqladmin
user        = multi_admin
password    = multipass

[mysqld2]
socket      = /tmp/mysql.sock2
port        = 3307
pid-file    = /usr/local/mysql/var2/hostname.pid2
datadir     = /usr/local/mysql/var2
language    = /usr/local/share/mysql/english
user        = john

[mysqld3]
socket      = /tmp/mysql.sock3
port        = 3308
pid-file    = /usr/local/mysql/var3/hostname.pid3
datadir     = /usr/local/mysql/var3
language    = /usr/local/share/mysql/swedish
user        = monty

[mysqld4]
socket      = /tmp/mysql.sock4
port        = 3309
pid-file    = /usr/local/mysql/var4/hostname.pid4
datadir     = /usr/local/mysql/var4
language    = /usr/local/share/mysql/estonia
user        = tonu

[mysqld6]
socket      = /tmp/mysql.sock6
port        = 3311
pid-file    = /usr/local/mysql/var6/hostname.pid6
datadir     = /usr/local/mysql/var6
language    = /usr/local/share/mysql/japanese
user        = jani
```

See [Section 4.2.6, “Using Option Files”](#).

4.4 MySQL Installation-Related Programs

The programs in this section are used when installing or upgrading MySQL.

4.4.1 `comp_err` — Compile MySQL Error Message File

`comp_err` creates the `errmsg.sys` file that is used by `mysqld` to determine the error messages to display for different error codes. `comp_err` normally is run automatically when MySQL is built. It compiles the `errmsg.sys` file from the plaintext file located at `sql/share/errmsg.txt` in MySQL source distributions.

`comp_err` also generates `mysqld_error.h`, `mysqld_ename.h`, and `sql_state.h` header files.

For more information about how error messages are defined, see the [MySQL Internals Manual](#).

Invoke `comp_err` like this:

```
shell> comp_err [options]
```

`comp_err` supports the following options.

- `--help, -?`

Display a help message and exit.

- `--charset=path, -C path`

The character set directory. The default is `../sql/share/charsets`.

- `--debug=debug_options, -# debug_options`

Write a debugging log. A typical `debug_options` string is `d:t:0,file_name`. The default is `d:t:0,/tmp/comp_err.trace`.

- `--debug-info, -T`

Print some debugging information when the program exits.

- `--header_file=file_name, -H file_name`

The name of the error header file. The default is `mysqld_error.h`.

- `--in_file=file_name, -F file_name`

The name of the input file. The default is `../sql/share/errmsg.txt`.

- `--name_file=file_name, -N file_name`

The name of the error name file. The default is `mysqld_ename.h`.

- `--out_dir=path, -D path`

The name of the output base directory. The default is `../sql/share/`.

- `--out_file=file_name, -O file_name`

The name of the output file. The default is `errmsg.sys`.

- `--statefile=file_name, -S file_name`

The name for the SQLSTATE header file. The default is `sql_state.h`.

- `--version, -V`

Display version information and exit.

4.4.2 mysqlbug — Generate Bug Report

This program is obsolete.

The normal way to report bugs is to visit <http://bugs.mysql.com/>, which is the address for our bugs database. This database is public and can be browsed and searched by anyone. If you log in to the system, you can enter new reports.

4.4.3 mysql_install_db — Initialize MySQL Data Directory

`mysql_install_db` initializes the MySQL data directory and creates the system tables that it contains, if they do not exist. `mysql_install_db` is a shell script and is available only on Unix platforms. (As of MySQL 5.6, `mysql_install_db` is a Perl script and can be used on any system with Perl installed.)

To invoke `mysql_install_db`, use the following syntax:

```
shell> mysql_install_db [options]
```

Because the MySQL server, `mysqld`, must access the data directory when it runs later, you should either run `mysql_install_db` from the same system account that will be used for running `mysqld` or run it as `root` and use the `--user` option to indicate the user name that `mysqld` will run as. It might be necessary to specify other options such as `--basedir` or `--datadir` if `mysql_install_db` does not use the correct locations for the installation directory or data directory. For example:

```
shell> scripts/mysql_install_db --user=mysql \
      --basedir=/opt/mysql/mysql \
      --datadir=/opt/mysql/mysql/data
```

Note

If you have set a custom `TMPDIR` environment variable when performing the installation, and the specified directory is not accessible, `mysql_install_db` may fail. If so, unset `TMPDIR` or set `TMPDIR` to point to the system temporary directory (usually `/tmp`).

`mysql_install_db` supports the following options, which can be specified on the command line or in the `[mysql_install_db]` group of an option file. (Options that are common to `mysqld` can also be specified in the `[mysqld]` group.) Other options are passed to `mysqld`. For information about option files, see [Section 4.2.6, “Using Option Files”](#).

Table 4.2 `mysql_install_db` Options

Format	Option File	Description
<code>--basedir=path</code>	<code>basedir</code>	The MySQL base directory

Format	Option File	Description
<code>--builddir=path</code>	<code>builddir</code>	The build directory (for out-of-source builds)
<code>--cross-bootstrap</code>	<code>cross-bootstrap</code>	For internal use
<code>--datadir=path</code>	<code>datadir</code>	The MySQL data directory
<code>--defaults-extra-file=file_name</code>		Read option file in addition to the usual option files
<code>--defaults-file=file_name</code>		Read only the given option file
<code>--force</code>	<code>force</code>	Run even if DNS does not work
<code>--help</code>	<code>help</code>	Display help message and exit
<code>--ldata=path</code>	<code>ldata</code>	Synonym for <code>--datadir</code>
<code>--no-defaults</code>		Do not read any option files
<code>--rpm</code>	<code>rpm</code>	For internal use
<code>--skip-name-resolve</code>	<code>skip-name-resolve</code>	Use IP addresses rather than host names in grant tables
<code>--srcdir=path</code>	<code>srcdir</code>	For internal use
<code>--user=user_name</code>	<code>user</code>	System login user under which to execute
<code>--verbose</code>	<code>verbose</code>	Verbose mode
<code>--windows</code>	<code>windows</code>	For internal use

- `--help`

Display a help message and exit.

- `--basedir=path`

The path to the MySQL installation directory.

- `--builddir=path`

For use with `--srcdir` and out-of-source builds. Set this to the location of the directory where the built files reside.

- `--cross-bootstrap`

For internal use. This option is used for building system tables on one host intended for another.

- `--datadir=path, --ldata=path`

The path to the MySQL data directory.

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. `file_name` is interpreted relative to the current directory if given as a relative path name rather than a full path name.

- `--force`

Cause `mysql_install_db` to run even if DNS does not work. Grant table entries normally created using host names will use IP addresses instead.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

- `--rpm`

For internal use. This option is used during the MySQL installation process for install operations performed using RPM packages.

- `--skip-name-resolve`

Use IP addresses rather than host names when creating grant table entries. This option can be useful if your DNS does not work.

- `--srcdir=path`

For internal use. This option specifies the directory under which `mysql_install_db` looks for support files such as the error message file and the file for populating the help tables.

- `--user=user_name`

The system (login) user name to use for running `mysqld`. Files and directories created by `mysqld` will be owned by this user. You must be `root` to use this option. By default, `mysqld` runs using your current login name and files and directories that it creates will be owned by you.

- `--verbose`

Verbose mode. Print more information about what the program does.

- `--windows`

For internal use. This option is used for creating Windows distributions.

4.4.4 `mysql_plugin` — Configure MySQL Server Plugins

The `mysql_plugin` utility enables MySQL administrators to manage which plugins a MySQL server loads. It provides an alternative to manually specifying the `--plugin-load` option at server startup or using the `INSTALL PLUGIN` and `UNINSTALL PLUGIN` statements at runtime. `mysql_plugin` is available as of MySQL 5.5.16.

Depending on whether `mysql_plugin` is invoked to enable or disable plugins, it inserts or deletes rows in the `mysql.plugin` table that serves as a plugin registry. (To perform this operation, `mysql_plugin` invokes the MySQL server in bootstrap mode. This means that the server must not already be running.) For normal server startups, the server loads and enables plugins listed in `mysql.plugin` automatically. For additional control over plugin activation, use `--plugin_name` options named for specific plugins, as described in [Section 5.1.8.1, “Installing and Uninstalling Plugins”](#).

Each invocation of `mysql_plugin` reads a configuration file to determine how to configure the plugins contained in a single plugin library object file. To invoke `mysql_plugin`, use this syntax:

```
mysql_plugin [options] plugin {ENABLE|DISABLE}
```

plugin is the name of the plugin to configure. `ENABLE` or `DISABLE` (not case sensitive) specify whether to enable or disable components of the plugin library named in the configuration file. The order of the *plugin* and `ENABLE` or `DISABLE` arguments does not matter.

For example, to configure components of a plugin library file named `myplugins.so` on Linux or `myplugins.dll` on Windows, specify a *plugin* value of `myplugins`. Suppose that this plugin library contains three plugins, `plugin1`, `plugin2`, and `plugin3`, all of which should be configured under `mysql_plugin` control. By convention, configuration files have a suffix of `.ini` and the same basename as the plugin library, so the default configuration file name for this plugin library is `myplugins.ini`. The configuration file contents look like this:

```
myplugins
plugin1
plugin2
plugin3
```

The first line in the `myplugins.ini` file is the name of the library object file, without any extension such as `.so` or `.dll`. The remaining lines are the names of the components to be enabled or disabled. Each value in the file should be on a separate line. Lines on which the first character is `#` are taken as comments and ignored.

To enable the plugins listed in the configuration file, invoke `mysql_plugin` this way:

```
shell> mysql_plugin myplugins ENABLE
```

To disable the plugins, use `DISABLE` rather than `ENABLE`.

An error occurs if `mysql_plugin` cannot find the configuration file or plugin library file, or if `mysql_plugin` cannot start the MySQL server.

`mysql_plugin` supports the following options, which can be specified on the command line or in the `[mysqld]` group of any option file. For options specified in a `[mysqld]` group, `mysql_plugin` recognizes the `--basedir`, `--datadir`, and `--plugin-dir` options and ignores others. For information about option files, see [Section 4.2.6, “Using Option Files”](#).

Table 4.3 `mysql_plugin` Options

Format	Option File	Description
<code>--basedir=path</code>	<code>basedir=path</code>	The server base directory
<code>--datadir=path</code>	<code>datadir=path</code>	The server data directory
<code>--help</code>		Display help message and exit
<code>--my-print-defaults=path</code>	<code>my-print-defaults=path</code>	The path to <code>my_print_defaults</code>
<code>--mysqld=path</code>	<code>mysqld=path</code>	The path to the server
<code>--no-defaults</code>	<code>no-defaults</code>	Do not read configuration file
<code>--plugin-dir=path</code>	<code>plugin-dir=path</code>	The directory where plugins are located
<code>--plugin-ini=file_name</code>	<code>plugin-ini=file_name</code>	The plugin configuration file
<code>--print-defaults</code>	<code>print-defaults</code>	Show configuration file defaults
<code>--verbose</code>		Verbose mode
<code>--version</code>		Display version information and exit

- `--help, -?`

Display a help message and exit.

- `--basedir=path, -b path`

The server base directory.

- `--datadir=path, -d path`

The server data directory.

- `--my-print-defaults=path, -b path`

The path to the `my_print_defaults` program.

- `--mysqld=path, -b path`

The path to the `mysqld` server.

- `--no-defaults, -p`

Do not read values from the configuration file. This option enables an administrator to skip reading defaults from the configuration file.

With `mysql_plugin`, this option need not be given first on the command line, unlike most other MySQL programs that support `--no-defaults`.

- `--plugin-dir=path, -p path`

The server plugin directory.

- `--plugin-ini=file_name, -i file_name`

The `mysql_plugin` configuration file. Relative path names are interpreted relative to the current directory. If this option is not given, the default is `plugin.ini` in the plugin directory, where `plugin` is the `plugin` argument on the command line.

- `--print-defaults, -P`

Display the default values from the configuration file. This option causes `mysql_plugin` to print the defaults for `--basedir`, `--datadir`, and `--plugin-dir` if they are found in the configuration file. If no value for a variable is found, nothing is shown.

With `mysql_plugin`, this option need not be given first on the command line, unlike most other MySQL programs that support `--print-defaults`.

- `--verbose, -v`

Verbose mode. Print more information about what the program does. This option can be used multiple times to increase the amount of information.

- `--version, -V`

Display version information and exit.

4.4.5 `mysql_secure_installation` — Improve MySQL Installation Security

This program enables you to improve the security of your MySQL installation in the following ways:

- You can set a password for `root` accounts.
- You can remove `root` accounts that are accessible from outside the local host.
- You can remove anonymous-user accounts.
- You can remove the `test` database (which by default can be accessed by all users, even anonymous users), and privileges that permit anyone to access databases with names that start with `test_`.

`mysql_secure_installation` helps you implement security recommendations similar to those described at [Section 2.10.2, “Securing the Initial MySQL Accounts”](#).

Invoke `mysql_secure_installation` without arguments:

```
shell> mysql_secure_installation
```

When executed, the script prompts you to determine which actions to perform.

4.4.6 `mysql_tzinfo_to_sql` — Load the Time Zone Tables

The `mysql_tzinfo_to_sql` program loads the time zone tables in the `mysql` database. It is used on systems that have a `zoneinfo` database (the set of files describing time zones). Examples of such systems are Linux, FreeBSD, Solaris, and Mac OS X. One likely location for these files is the `/usr/share/zoneinfo` directory (`/usr/share/lib/zoneinfo` on Solaris). If your system does not have a `zoneinfo` database, you can use the downloadable package described in [Section 10.6, “MySQL Server Time Zone Support”](#).

`mysql_tzinfo_to_sql` can be invoked several ways:

```
shell> mysql_tzinfo_to_sql tz_dir
shell> mysql_tzinfo_to_sql tz_file tz_name
shell> mysql_tzinfo_to_sql --leap tz_file
```

For the first invocation syntax, pass the `zoneinfo` directory path name to `mysql_tzinfo_to_sql` and send the output into the `mysql` program. For example:

```
shell> mysql_tzinfo_to_sql /usr/share/zoneinfo | mysql -u root mysql
```

`mysql_tzinfo_to_sql` reads your system's time zone files and generates SQL statements from them. `mysql` processes those statements to load the time zone tables.

The second syntax causes `mysql_tzinfo_to_sql` to load a single time zone file `tz_file` that corresponds to a time zone name `tz_name`:

```
shell> mysql_tzinfo_to_sql tz_file tz_name | mysql -u root mysql
```

If your time zone needs to account for leap seconds, invoke `mysql_tzinfo_to_sql` using the third syntax, which initializes the leap second information. `tz_file` is the name of your time zone file:

```
shell> mysql_tzinfo_to_sql --leap tz_file | mysql -u root mysql
```

After running `mysql_tzinfo_to_sql`, it is best to restart the server so that it does not continue to use any previously cached time zone data.

4.4.7 mysql_upgrade — Check and Upgrade MySQL Tables

`mysql_upgrade` examines all tables in all databases for incompatibilities with the current version of MySQL Server. `mysql_upgrade` also upgrades the system tables so that you can take advantage of new privileges or capabilities that might have been added.

`mysql_upgrade` should be executed each time you upgrade MySQL.

If `mysql_upgrade` finds that a table has a possible incompatibility, it performs a table check and, if problems are found, attempts a table repair. If the table cannot be repaired, see [Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”](#) for manual table repair strategies.

Note

On Windows Server 2008, Vista, and newer, you must run `mysql_upgrade` with administrator privileges. You can do this by running a Command Prompt as Administrator and running the command. Failure to do so may result in the upgrade failing to execute correctly.

Caution

You should always back up your current MySQL installation *before* performing an upgrade. See [Section 7.2, “Database Backup Methods”](#).

Some upgrade incompatibilities may require special handling before you upgrade your MySQL installation and run `mysql_upgrade`. See [Section 2.11.1, “Upgrading MySQL”](#), for instructions on determining whether any such incompatibilities apply to your installation and how to handle them.

To use `mysql_upgrade`, make sure that the server is running, and then invoke it like this:

```
shell> mysql_upgrade [options]
```

After running `mysql_upgrade`, stop the server and restart it so that any changes made to the system tables take effect.

`mysql_upgrade` executes the following commands to check and repair tables and to upgrade the system tables:

```
mysqlcheck --no-defaults --all-databases
--fix-db-names --fix-table-names
mysqlcheck --no-defaults --check-upgrade --all-databases
--auto-repair
mysql < fix_priv_tables
```

Notes about the preceding commands:

- `mysql_upgrade` also adds `--write-binlog` or `--skip-write-binlog` to the `mysqlcheck` commands, depending on whether the `--write-binlog` option was specified on the `mysql_upgrade` command.
- Because `mysql_upgrade` invokes `mysqlcheck` with the `--all-databases` option, it processes all tables in all databases, which might take a long time to complete. Each table is locked and therefore unavailable to other sessions while it is being processed. Check and repair operations can be time-consuming, particularly for large tables.

- For details about what checks the `--check-upgrade` option entails, see the description of the `FOR UPGRADE` option of the `CHECK TABLE` statement (see [Section 13.7.2.2, “CHECK TABLE Syntax”](#)).
- `fix_priv_tables` represents a script generated internally by `mysql_upgrade` that contains SQL statements to upgrade the tables in the `mysql` database.

All checked and repaired tables are marked with the current MySQL version number. This ensures that next time you run `mysql_upgrade` with the same version of the server, it can tell whether there is any need to check or repair the table again.

`mysql_upgrade` also saves the MySQL version number in a file named `mysql_upgrade_info` in the data directory. This is used to quickly check whether all tables have been checked for this release so that table-checking can be skipped. To ignore this file and perform the check regardless, use the `--force` option.

If you install MySQL from RPM packages on Linux, you must install the server and client RPMs. `mysql_upgrade` is included in the server RPM but requires the client RPM because the latter includes `mysqlcheck`. (See [Section 2.5.1, “Installing MySQL on Linux Using RPM Packages”](#).)

`mysql_upgrade` does not upgrade the contents of the help tables. For upgrade instructions, see [Section 5.1.10, “Server-Side Help”](#).

`mysql_upgrade` supports the following options, which can be specified on the command line or in the `[mysql_upgrade]` and `[client]` groups of an option file. Other options are passed to `mysqlcheck`. For example, it might be necessary to specify the `--password[=password]` option. For information about option files, see [Section 4.2.6, “Using Option Files”](#).

Table 4.4 `mysql_upgrade` Options

Format	Option File	Description	Introduced
<code>--basedir</code>	<code>basedir</code>	Not used; exists only for compatibility with some very old applications	
<code>--character-sets-dir=path</code>	<code>character-sets-dir</code>	Directory where character sets are.	
<code>--compress</code>	<code>compress</code>	Use compression in server/client protocol.	
<code>--datadir=path</code>	<code>datadir</code>	Not used; exists only for compatibility with some very old applications	
<code>--debug[=#]</code>	<code>debug</code>	If this is a non-debug version, catch error and exit.	
<code>--debug-check</code>	<code>debug-check</code>	--debug-check Check memory and open file usage at exit.	
<code>--default-auth=plugin</code>	<code>default-auth=plugin</code>	The authentication plugin to use	5.5.10
<code>--default-character-set=name</code>	<code>default-character-set</code>	Set the default character set.	
<code>--defaults-extra-file=file_name</code>		Read option file in addition to the usual option files	
<code>--defaults-file=file_name</code>		Read only the given option file	
<code>--defaults-group-suffix=str</code>		Option group suffix value	

Format	Option File	Description	Introduced
<code>--force</code>	<code>force</code>	Force execution even if mysql_upgrade has already been executed for the current version of MySQL.	
<code>--help</code>	<code>help</code>	Display a help message and exit	
<code>--host=name</code>	<code>host</code>	Connect to host.	
<code>--no-defaults</code>		Do not read any option files	
<code>--password[=name]</code>	<code>password</code>	Password to use when connecting to server. If password is not given it's solicited on the tty.	
<code>--plugin-dir=path</code>	<code>plugin-dir=path</code>	The directory where plugins are located	5.5.10
<code>--port=#</code>	<code>port</code>	Port number to use for connection or 0 for default to, in order of preference, my.cnf, \$MYSQL_TCP_PORT, /etc/services, built-in default (3306).	
<code>--print-defaults</code>		Print defaults	
<code>--protocol=name</code>	<code>protocol</code>	The connection protocol (TCP=default, socket, pipe, memory)	
<code>--socket=name</code>	<code>socket</code>	Socket file to use for connection.	
<code>--tmpdir=path</code>	<code>tmpdir</code>	Directory for temporary files	
<code>--user=name</code>	<code>user</code>	User for login if not current user.	
<code>--verbose</code>	<code>verbose</code>	Show more information about the process	
<code>--version-check</code>	<code>version-check</code>	Check for proper server version	5.5.32
<code>--write-binlog</code>	<code>write-binlog</code>	Enables binary logging of all commands including mysqlcheck.	

- `--help`

Display a short help message and exit.

- `--basedir=path`

The path to the MySQL installation directory. This option is accepted for backward compatibility but ignored. It is removed in MySQL 5.7.

- `--datadir=path`

The path to the data directory. This option is accepted for backward compatibility but ignored. It is removed in MySQL 5.7.

- `--debug=debug_options, -# debug_options`

Write a debugging log. A typical `debug_options` string is `d:t:0,file_name`. The default is `d:t:0,/tmp/mysql_upgrade.trace`.

- `--debug-check`

Print some debugging information when the program exits.

- `--debug-info, -T`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-auth=plugin`

The client-side authentication plugin to use. See [Section 6.3.6, “Pluggable Authentication”](#).

This option was added in MySQL 5.5.10.

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, `file_name` must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, `file_name` must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysql_upgrade` normally reads the `[client]` and `[mysql_upgrade]` groups. If the `--defaults-group-suffix=_other` option is given, `mysql_upgrade` also reads the `[client_other]` and `[mysql_upgrade_other]` groups.

- `--force`

Ignore the `mysql_upgrade_info` file and force execution of `mysqlcheck` even if `mysql_upgrade` has already been executed for the current version of MySQL.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

- `--plugin-dir=path`

The directory in which to look for plugins. It may be necessary to specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysql_upgrade` does not find it. See [Section 6.3.6, “Pluggable Authentication”](#).

This option was added in MySQL 5.5.10.

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--tmpdir=path, -t path`

The path name of the directory to use for creating temporary files.

- `--upgrade-system-tables, -s`

Upgrade only the system tables, do not upgrade data.

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server. The default user name is `root`.

- `--verbose`

Verbose mode. Print more information about what the program does.

- `--version-check, -k`

Check the version of the server to which `mysql_upgrade` is connecting to verify that it is the same as the version for which `mysql_upgrade` was built. If not, `mysql_upgrade` exits. This option is enabled by default; to disable the check, use `--skip-version-check`. This option was added in MySQL 5.5.32.

- `--write-binlog`

Cause binary logging to be enabled while `mysql_upgrade` runs. This is the default behavior; to disable binary logging during the upgrade, use the inverse of this option (that is, start the program with `--skip-write-binlog`).

4.5 MySQL Client Programs

This section describes client programs that connect to the MySQL server.

4.5.1 `mysql` — The MySQL Command-Line Tool

`mysql` is a simple SQL shell with input line editing capabilities. It supports interactive and noninteractive use. When used interactively, query results are presented in an ASCII-table format. When used noninteractively (for example, as a filter), the result is presented in tab-separated format. The output format can be changed using command options.

If you have problems due to insufficient memory for large result sets, use the `--quick` option. This forces `mysql` to retrieve results from the server a row at a time rather than retrieving the entire result set and buffering it in memory before displaying it. This is done by returning the result set using the `mysql_use_result()` C API function in the client/server library rather than `mysql_store_result()`.

Using `mysql` is very easy. Invoke it from the prompt of your command interpreter as follows:

```
shell> mysql db_name
```

Or:

```
shell> mysql --user=user_name --password=your_password db_name
```

Then type an SQL statement, end it with “;”, `\g`, or `\G` and press Enter.

Typing **Control+C** causes `mysql` to attempt to kill the current statement. If this cannot be done, or **Control+C** is typed again before the statement is killed, `mysql` exits.

You can execute SQL statements in a script file (batch file) like this:

```
shell> mysql db_name < script.sql > output.tab
```

On Unix, the `mysql` client logs statements executed interactively to a history file. See [Section 4.5.1.3](#), “`mysql` Logging”.

4.5.1.1 `mysql` Options

`mysql` supports the following options, which can be specified on the command line or in the `[mysql]` and `[client]` groups of an option file. For information about option files, see [Section 4.2.6, “Using Option Files”](#).

Table 4.5 `mysql` Options

Format	Option File	Description	Introduced	Removed
<code>--auto-rehash</code>	<code>auto-rehash</code>	Enable automatic rehashing		
<code>--auto-vertical-output</code>	<code>auto-vertical-output</code>	Enable automatic vertical result set display	5.5.3	
<code>--batch</code>	<code>batch</code>	Don't use history file		
<code>--character-sets-dir=path</code>	<code>character-sets-dir</code>	Set the default character set		
<code>--column-names</code>	<code>column-names</code>	Write column names in results		
<code>--column-type-info</code>	<code>column-type-info</code>	Display result set metadata		
<code>--comments</code>	<code>comments</code>	Whether to retain or strip comments in statements sent to the server		
<code>--compress</code>	<code>compress</code>	Compress all information sent between the client and the server		
<code>--connect_timeout=value</code>	<code>connect_timeout</code>	The number of seconds before connection timeout		
<code>--database=dbname</code>	<code>database</code>	The database to use		
<code>--debug[=debug_options]</code>	<code>debug</code>	Write a debugging log		
<code>--debug-check</code>	<code>debug-check</code>	Print debugging information when the program exits		
<code>--debug-info</code>	<code>debug-info</code>	Print debugging information, memory and CPU statistics when the program exits		
<code>--default-auth=plugin</code>	<code>default-auth=plugin</code>	The authentication plugin to use	5.5.7	
<code>--default-character-set=charset_name</code>	<code>default-character-set</code>	Use <code>charset_name</code> as the default character set		
<code>--defaults-extra-file=file_name</code>		Read option file in addition to the usual option files		
<code>--defaults-file=file_name</code>		Read only the given option file		
<code>--defaults-group-suffix=str</code>		Option group suffix value		
<code>--delimiter=str</code>	<code>delimiter</code>	Set the statement delimiter		
<code>--enable-cleartext-plugin</code>	<code>enable-cleartext-plugin</code>	Enable cleartext authentication plugin	5.5.27	
<code>--execute=statement</code>	<code>execute</code>	Execute the statement and quit		

Format	Option File	Description	Introduced	Removed
<code>--force</code>	<code>force</code>	Continue even if an SQL error occurs		
<code>--help</code>		Display help message and exit		
<code>--host=host_name</code>	<code>host</code>	Connect to the MySQL server on the given host		
<code>--html</code>	<code>html</code>	Produce HTML output		
<code>--ignore-spaces</code>	<code>ignore-spaces</code>	Ignore spaces after function names		
<code>--init-command=str</code>	<code>init-command</code>	SQL statement to execute after connecting		
<code>--line-numbers</code>	<code>line-numbers</code>	Write line numbers for errors		
<code>--local-infile[={0 1}]</code>	<code>local-infile</code>	Enable or disable for LOCAL capability for LOAD DATA INFILE		
<code>--max_allowed_packet=value</code>	<code>max_allowed_packet</code>	The maximum packet length to send to or receive from the server		
<code>--max_join_size=value</code>	<code>max_join_size</code>	The automatic limit for rows in a join when using <code>--safe-updates</code>		
<code>--named-commands</code>	<code>named-commands</code>	Enable named mysql commands		
<code>--net_buffer_length=value</code>	<code>net_buffer_length</code>	The buffer size for TCP/IP and socket communication		
<code>--no-auto-rehash</code>		Disable automatic rehashing		
<code>--no-beep</code>	<code>no-beep</code>	Do not beep when errors occur		
<code>--no-defaults</code>		Do not read any option files		
<code>--no-named-commands</code>	<code>no-named-commands</code>	Disable named mysql commands		5.5.3
<code>--no-pager</code>	<code>no-pager</code>	Deprecated form of <code>--skip-pager</code>		5.5.3
<code>--no-tee</code>	<code>no-tee</code>	Do not copy output to a file		5.5.3
<code>--one-database</code>	<code>one-database</code>	Ignore statements except those for the default database named on the command line		
<code>--pager[=command]</code>	<code>pager</code>	Use the given command for paging query output		
<code>--password[=password]</code>	<code>password</code>	The password to use when connecting to the server		
<code>--pipe</code>		On Windows, connect to server using a named pipe		
<code>--plugin-dir=path</code>	<code>plugin-dir=path</code>	The directory where plugins are located	5.5.7	
<code>--port=port_num</code>	<code>port</code>	The TCP/IP port number to use for the connection		
<code>--print-defaults</code>		Print defaults		
<code>--prompt=format_str</code>	<code>prompt</code>	Set the prompt to the specified format		
<code>--protocol=type</code>	<code>protocol</code>	The connection protocol to use		
<code>--quick</code>	<code>quick</code>	Do not cache each query result		

Format	Option File	Description	Introduced	Removed
<code>--raw</code>	<code>raw</code>	Write column values without escape conversion		
<code>--reconnect</code>	<code>reconnect</code>	If the connection to the server is lost, automatically try to reconnect		
<code>--safe-updates</code>	<code>safe-updates</code>	Allow only UPDATE and DELETE statements that specify key values		
<code>--secure-auth</code>	<code>secure-auth</code>	Do not send passwords to the server in old (pre-4.1.1) format		
<code>--select_limit=value</code>	<code>select_limit</code>	The automatic limit for SELECT statements when using <code>--safe-updates</code>		
<code>--show-warnings</code>	<code>show-warnings</code>	Show warnings after each statement if there are any		
<code>--sigint-ignore</code>	<code>sigint-ignore</code>	Ignore SIGINT signals (typically the result of typing Control+C)		
<code>--silent</code>	<code>silent</code>	Silent mode		
<code>--skip-auto-rehash</code>	<code>skip-auto-rehash</code>	Disable automatic rehashing		
<code>--skip-column-names</code>	<code>skip-column-names</code>	Do not write column names in results		
<code>--skip-line-numbers</code>	<code>skip-line-numbers</code>	Skip line numbers for errors		
<code>--skip-named-commands</code>	<code>skip-named-commands</code>	Disable named mysql commands		
<code>--skip-pager</code>	<code>skip-pager</code>	Disable paging		
<code>--skip-reconnect</code>	<code>skip-reconnect</code>	Disable reconnecting		
<code>--socket=path</code>	<code>socket</code>	For connections to localhost		
<code>--ssl[=TRUE FALSE]</code>		Enable an SSL connection to the server. This option is set to TRUE when any other SSL option is used, and so is normally not needed.		
<code>--ssl-ca=file_name</code>	<code>ssl-ca</code>	The path to a file that contains a list of trusted SSL CAs		
<code>--ssl-capath=dir_name</code>	<code>ssl-capath</code>	The path to a directory that contains trusted SSL CA certificates in PEM format		
<code>--ssl-cert=file_name</code>	<code>ssl-cert</code>	The name of the SSL certificate file to use for establishing a secure connection		
<code>--ssl-cipher=cipher_list</code>	<code>ssl-cipher</code>	A list of allowable ciphers to use for SSL encryption		
<code>--ssl-key=file_name</code>	<code>ssl-key</code>	The name of the SSL key file to use for establishing a secure connection		
<code>--ssl-verify-server-cert</code>	<code>ssl-verify-server-cert</code>	The server's Common Name value in its certificate is verified against the host name used when connecting to the server		
<code>--table</code>	<code>table</code>	Display output in tabular format		

Format	Option File	Description	Introduced	Removed
<code>--tee=file_name</code>	<code>tee</code>	Append a copy of output to the given file		
<code>--unbuffered</code>	<code>unbuffered</code>	Flush the buffer after each query		
<code>--user=user_name</code>	<code>user</code>	MySQL user name to use when connecting to server		
<code>--verbose</code>		Verbose mode		
<code>--version</code>		Display version information and exit		
<code>--vertical</code>	<code>vertical</code>	Print query output rows vertically (one line per column value)		
<code>--wait</code>	<code>wait</code>	If the connection cannot be established, wait and retry instead of aborting		
<code>--xml</code>	<code>xml</code>	Produce XML output		

- `--help, -?`

Display a help message and exit.

- `--auto-rehash`

Enable automatic rehashing. This option is on by default, which enables database, table, and column name completion. Use `--disable-auto-rehash` to disable rehashing. That causes `mysql` to start faster, but you must issue the `rehash` command or its `\#` shortcut if you want to use name completion.

To complete a name, enter the first part and press Tab. If the name is unambiguous, `mysql` completes it. Otherwise, you can press Tab again to see the possible names that begin with what you have typed so far. Completion does not occur if there is no default database.

Note

This feature requires a MySQL client that is compiled with the **readline** library. Typically, the **readline** library is not available on Windows.

- `--auto-vertical-output`

Cause result sets to be displayed vertically if they are too wide for the current window, and using normal tabular format otherwise. (This applies to statements terminated by `;` or `\G`.) This option was added in MySQL 5.5.3.

- `--batch, -B`

Print results using tab as the column separator, with each row on a new line. With this option, `mysql` does not use the history file.

Batch mode results in nontabular output format and escaping of special characters. Escaping may be disabled by using raw mode; see the description for the `--raw` option.

- `--bind-address=ip_address`

On a computer having multiple network interfaces, this option can be used to select which interface is employed when connecting to the MySQL server.

This option is supported only in the version of the `mysql` client that is supplied with MySQL Cluster. It is not available in standard MySQL Server 5.5 releases.

- `--character-sets-dir=path`

The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).

- `--column-names`

Write column names in results.

- `--column-type-info, -m`

Display result set metadata.

- `--comments, -c`

Whether to preserve comments in statements sent to the server. The default is `--skip-comments` (discard comments), enable with `--comments` (preserve comments).

- `--compress, -C`

Compress all information sent between the client and the server if both support compression.

- `--database=db_name, -D db_name`

The database to use. This is useful primarily in an option file.

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical *debug_options* string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysql.trace`.

- `--debug-check`

Print some debugging information when the program exits.

- `--debug-info, -T`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-auth=plugin`

The client-side authentication plugin to use. See [Section 6.3.6, “Pluggable Authentication”](#).

This option was added in MySQL 5.5.7.

- `--default-character-set=charset_name`

Use *charset_name* as the default character set for the client and connection.

A common issue that can occur when the operating system uses `utf8` or another multi-byte character set is that output from the `mysql` client is formatted incorrectly, due to the fact that the MySQL client uses the `latin1` character set by default. You can usually fix such issues by using this option to force the client to use the system character set instead.

See [Section 10.5, “Character Set Configuration”](#), for more information.

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, *file_name* must be the full

path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, *file_name* must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of *str*. For example, `mysql` normally reads the `[client]` and `[mysql]` groups. If the `--defaults-group-suffix=_other` option is given, `mysql` also reads the `[client_other]` and `[mysql_other]` groups.

- `--delimiter=str`

Set the statement delimiter. The default is the semicolon character (`;`).

- `--disable-named-commands`

Disable named commands. Use the `*` form only, or use named commands only at the beginning of a line ending with a semicolon (`;`). `mysql` starts with this option *enabled* by default. However, even with this option, long-format commands still work from the first line. See [Section 4.5.1.2, “mysql Commands”](#).

- `--enable-cleartext-plugin`

Enable the `mysql_clear_password` cleartext authentication plugin. (See [Section 6.3.7.5, “The Cleartext Client-Side Authentication Plugin”](#).) This option was added in MySQL 5.5.27.

- `--execute=statement, -e statement`

Execute the statement and quit. The default output format is like that produced with `--batch`. See [Section 4.2.4, “Using Options on the Command Line”](#), for some examples. With this option, `mysql` does not use the history file.

- `--force, -f`

Continue even if an SQL error occurs.

- `--host=host_name, -h host_name`

Connect to the MySQL server on the given host.

- `--html, -H`

Produce HTML output.

- `--ignore-spaces, -i`

Ignore spaces after function names. The effect of this is described in the discussion for the `IGNORE_SPACE` SQL mode (see [Section 5.1.7, “Server SQL Modes”](#)).

- `--init-command=str`

SQL statement to execute after connecting to the server. If auto-reconnect is enabled, the statement is executed again after reconnection occurs.

- `--line-numbers`

Write line numbers for errors. Disable this with `--skip-line-numbers`.

- `--local-infile[={0|1}]`

Enable or disable `LOCAL` capability for `LOAD DATA INFILE`. With no value, the option enables `LOCAL`. The option may be given as `--local-infile=0` or `--local-infile=1` to explicitly disable or enable `LOCAL`. Enabling `LOCAL` has no effect if the server does not also support it.

- `--named-commands, -G`

Enable named `mysql` commands. Long-format commands are permitted, not just short-format commands. For example, `quit` and `\q` both are recognized. Use `--skip-named-commands` to disable named commands. See [Section 4.5.1.2, “mysql Commands”](#).

- `--no-auto-rehash, -A`

This has the same effect as `--skip-auto-rehash`. See the description for `--auto-rehash`.

- `--no-beep, -b`

Do not beep when errors occur.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

- `--no-named-commands, -g`

Deprecated, use `--disable-named-commands` instead. `--no-named-commands` was removed in MySQL 5.5.3.

- `--no-pager`

Deprecated form of `--skip-pager`. See the `--pager` option. `--no-pager` was removed in MySQL 5.5.3.

- `--no-tee`

Deprecated form of `--skip-tee`. See the `--tee` option. `--no-tee` is removed in MySQL 5.5.3.

- `--one-database, -o`

Ignore statements except those that occur while the default database is the one named on the command line. This option is rudimentary and should be used with care. Statement filtering is based only on `USE` statements.

Initially, `mysql` executes statements in the input because specifying a database `db_name` on the command line is equivalent to inserting `USE db_name` at the beginning of the input. Then, for each `USE` statement encountered, `mysql` accepts or rejects following statements depending on whether the database named is the one on the command line. The content of the statements is immaterial.

Suppose that `mysql` is invoked to process this set of statements:

```
DELETE FROM db2.t2;
USE db2;
```

```
DROP TABLE db1.t1;
CREATE TABLE db1.t1 (i INT);
USE db1;
INSERT INTO t1 (i) VALUES(1);
CREATE TABLE db2.t1 (j INT);
```

If the command line is `mysql --force --one-database db1`, `mysql` handles the input as follows:

- The `DELETE` statement is executed because the default database is `db1`, even though the statement names a table in a different database.
- The `DROP TABLE` and `CREATE TABLE` statements are not executed because the default database is not `db1`, even though the statements name a table in `db1`.
- The `INSERT` and `CREATE TABLE` statements are executed because the default database is `db1`, even though the `CREATE TABLE` statement names a table in a different database.

- `--pager[=command]`

Use the given command for paging query output. If the command is omitted, the default pager is the value of your `PAGER` environment variable. Valid pagers are `less`, `more`, `cat [> filename]`, and so forth. This option works only on Unix and only in interactive mode. To disable paging, use `--skip-pager`. [Section 4.5.1.2, “mysql Commands”](#), discusses output paging further.

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysql` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe, -W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=path`

The directory in which to look for plugins. It may be necessary to specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysql` does not find it. See [Section 6.3.6, “Pluggable Authentication”](#).

This option was added in MySQL 5.5.7.

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--prompt=format_str`

Set the prompt to the specified format. The default is `mysql>`. The special sequences that the prompt can contain are described in [Section 4.5.1.2, “mysql Commands”](#).

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--quick, -q`

Do not cache each query result, print each row as it is received. This may slow down the server if the output is suspended. With this option, `mysql` does not use the history file.

- `--raw, -r`

For tabular output, the “boxing” around columns enables one column value to be distinguished from another. For nontabular output (such as is produced in batch mode or when the `--batch` or `--silent` option is given), special characters are escaped in the output so they can be identified easily. Newline, tab, `NUL`, and backslash are written as `\n`, `\t`, `\0`, and `\\`. The `--raw` option disables this character escaping.

The following example demonstrates tabular versus nontabular output and the use of raw mode to disable escaping:

```
% mysql
mysql> SELECT CHAR(92);
+-----+
| CHAR(92) |
+-----+
| \        |
+-----+

% mysql -s
mysql> SELECT CHAR(92);
CHAR(92)
\\

% mysql -s -r
mysql> SELECT CHAR(92);
CHAR(92)
\
```

- `--reconnect`

If the connection to the server is lost, automatically try to reconnect. A single reconnect attempt is made each time the connection is lost. To suppress reconnection behavior, use `--skip-reconnect`.

- `--safe-updates, --i-am-a-dummy, -U`

Permit only those `UPDATE` and `DELETE` statements that specify which rows to modify by using key values. If you have set this option in an option file, you can override it by using `--safe-updates` on the command line. See [Section 4.5.1.6, “mysql Tips”](#), for more information about this option.

- `--secure-auth`

Do not send passwords to the server in old (pre-4.1) format. This prevents connections except for servers that use the newer password format.

**Note**

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided.

- `--show-warnings`

Cause warnings to be shown after each statement if there are any. This option applies to interactive and batch mode.

- `--sigint-ignore`

Ignore `SIGINT` signals (typically the result of typing **Control+C**).

- `--silent, -s`

Silent mode. Produce less output. This option can be given multiple times to produce less and less output.

This option results in nontabular output format and escaping of special characters. Escaping may be disabled by using raw mode; see the description for the `--raw` option.

- `--skip-column-names, -N`

Do not write column names in results.

- `--skip-line-numbers, -L`

Do not write line numbers for errors. Useful when you want to compare result files that include error messages.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.3.9.4, “SSL Command Options”](#).

- `--table, -t`

Display output in table format. This is the default for interactive use, but can be used to produce table output in batch mode.

- `--tee=file_name`

Append a copy of output to the given file. This option works only in interactive mode. [Section 4.5.1.2, “mysql Commands”](#), discusses tee files further.

- `--unbuffered, -n`

Flush the buffer after each query.

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

- `--verbose, -v`

Verbose mode. Produce more output about what the program does. This option can be given multiple times to produce more and more output. (For example, `-v -v -v` produces table output format even in batch mode.)

- `--version, -V`

Display version information and exit.

- `--vertical, -E`

Print query output rows vertically (one line per column value). Without this option, you can specify vertical output for individual statements by terminating them with `\G`.

- `--wait, -w`

If the connection cannot be established, wait and retry instead of aborting.

- `--xml, -X`

Produce XML output.

```
<field name="column_name">NULL</field>
```

The output when `--xml` is used with `mysql` matches that of `mysqldump --xml`. See [Section 4.5.4, “mysqldump — A Database Backup Program”](#) for details.

The XML output also uses an XML namespace, as shown here:

```
shell> mysql --xml -uroot -e "SHOW VARIABLES LIKE 'version%'"
<?xml version="1.0"?>

<resultset statement="SHOW VARIABLES LIKE 'version%'" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<row>
<field name="Variable_name">version</field>
<field name="Value">5.0.40-debug</field>
</row>

<row>
<field name="Variable_name">version_comment</field>
<field name="Value">Source distribution</field>
</row>

<row>
<field name="Variable_name">version_compile_machine</field>
<field name="Value">i686</field>
</row>

<row>
<field name="Variable_name">version_compile_os</field>
<field name="Value">suse-linux-gnu</field>
</row>
</resultset>
```

(See Bug #25946.)

You can also set the following variables by using `--var_name=value`. The `--set-variable` format is deprecated and was removed in MySQL 5.5.3.

- `connect_timeout`

The number of seconds before connection timeout. (Default value is 0.)

- `max_allowed_packet`

The maximum size of the buffer for client/server communication. The default is 16MB, the maximum is 1GB.

- `max_join_size`

The automatic limit for rows in a join when using `--safe-updates`. (Default value is 1,000,000.)

- `net_buffer_length`

The buffer size for TCP/IP and socket communication. (Default value is 16KB.)

- `select_limit`

The automatic limit for `SELECT` statements when using `--safe-updates`. (Default value is 1,000.)

4.5.1.2 mysql Commands

`mysql` sends each SQL statement that you issue to the server to be executed. There is also a set of commands that `mysql` itself interprets. For a list of these commands, type `help` or `\h` at the `mysql>` prompt:

```
mysql> help

List of all MySQL commands:
Note that all text commands must be first on line and end with ';'
?          (?) Synonym for 'help'.
clear      (c) Clear command.
connect    (r) Reconnect to the server. Optional arguments are db and host.
delimiter (d) Set statement delimiter.
edit       (e) Edit command with $EDITOR.
ego        (G) Send command to mysql server, display result vertically.
exit       (q) Exit mysql. Same as quit.
go         (g) Send command to mysql server.
help       (h) Display this help.
nopager    (n) Disable pager, print to stdout.
notee      (t) Don't write into outfile.
pager      (P) Set PAGER [to_pager]. Print the query results via PAGER.
print      (p) Print current command.
prompt     (R) Change your mysql prompt.
quit       (q) Quit mysql.
rehash     (#) Rebuild completion hash.
source     (.) Execute an SQL script file. Takes a file name as an argument.
status     (s) Get status information from the server.
system     (!) Execute a system shell command.
tee        (T) Set outfile [to_outfile]. Append everything into given
           outfile.
use        (u) Use another database. Takes database name as argument.
charset    (C) Switch to another charset. Might be needed for processing
           binlog with multi-byte charsets.
warnings   (W) Show warnings after every statement.
nowarning  (w) Don't show warnings after every statement.

For server side help, type 'help contents'
```

Each command has both a long and short form. The long form is not case sensitive; the short form is. The long form can be followed by an optional semicolon terminator, but the short form should not.

The use of short-form commands within multi-line `/* ... */` comments is not supported.

- `help [arg], \h [arg], \? [arg], ? [arg]`

Display a help message listing the available `mysql` commands.

If you provide an argument to the `help` command, `mysql` uses it as a search string to access server-side help from the contents of the MySQL Reference Manual. For more information, see [Section 4.5.1.4, “mysql Server-Side Help”](#).

- `charset charset_name, \C charset_name`

Change the default character set and issue a `SET NAMES` statement. This enables the character set to remain synchronized on the client and server if `mysql` is run with auto-reconnect enabled (which is not recommended), because the specified character set is used for reconnects.

- `clear, \c`

Clear the current input. Use this if you change your mind about executing the statement that you are entering.

- `connect [db_name host_name]], \r [db_name host_name]]`

Reconnect to the server. The optional database name and host name arguments may be given to specify the default database or the host where the server is running. If omitted, the current values are used.

- `delimiter str, \d str`

Change the string that `mysql` interprets as the separator between SQL statements. The default is the semicolon character (“;”).

The delimiter string can be specified as an unquoted or quoted argument on the `delimiter` command line. Quoting can be done with either single quote (‘), double quote (”), or backtick (`) characters. To include a quote within a quoted string, either quote the string with a different quote character or escape the quote with a backslash (“\”) character. Backslash should be avoided outside of quoted strings because it is the escape character for MySQL. For an unquoted argument, the delimiter is read up to the first space or end of line. For a quoted argument, the delimiter is read up to the matching quote on the line.

`mysql` interprets instances of the delimiter string as a statement delimiter anywhere it occurs, except within quoted strings. Be careful about defining a delimiter that might occur within other words. For example, if you define the delimiter as `x`, you will be unable to use the word `INDEX` in statements. `mysql` interprets this as `INDE` followed by the delimiter `x`.

When the delimiter recognized by `mysql` is set to something other than the default of “;”, instances of that character are sent to the server without interpretation. However, the server itself still interprets “;” as a statement delimiter and processes statements accordingly. This behavior on the server side comes into play for multiple-statement execution (see [Section 23.8.17, “C API Support for Multiple Statement Execution”](#)), and for parsing the body of stored procedures and functions, triggers, and events (see [Section 20.1, “Defining Stored Programs”](#)).

- `edit, \e`

Edit the current input statement. `mysql` checks the values of the `EDITOR` and `VISUAL` environment variables to determine which editor to use. The default editor is `vi` if neither variable is set.

The `edit` command works only in Unix.

- `ego, \G`

Send the current statement to the server to be executed and display the result using vertical format.

- `exit, \q`

Exit `mysql`.

- `go, \g`

Send the current statement to the server to be executed.

- `nopager, \n`

Disable output paging. See the description for `pager`.

The `nopager` command works only in Unix.

- `notee, \t`

Disable output copying to the tee file. See the description for `tee`.

- `nowarning, \w`

Disable display of warnings after each statement.

- `pager [command], \P [command]`

Enable output paging. By using the `--pager` option when you invoke `mysql`, it is possible to browse or search query results in interactive mode with Unix programs such as `less`, `more`, or any other similar program. If you specify no value for the option, `mysql` checks the value of the `PAGER` environment variable and sets the pager to that. Pager functionality works only in interactive mode.

Output paging can be enabled interactively with the `pager` command and disabled with `nopager`. The command takes an optional argument; if given, the paging program is set to that. With no argument, the pager is set to the pager that was set on the command line, or `stdout` if no pager was specified.

Output paging works only in Unix because it uses the `popen()` function, which does not exist on Windows. For Windows, the `tee` option can be used instead to save query output, although it is not as convenient as `pager` for browsing output in some situations.

- `print, \p`

Print the current input statement without executing it.

- `prompt [str], \R [str]`

Reconfigure the `mysql` prompt to the given string. The special character sequences that can be used in the prompt are described later in this section.

If you specify the `prompt` command with no argument, `mysql` resets the prompt to the default of `mysql>`.

- `quit, \q`

Exit `mysql`.

- `rehash, \#`

Rebuild the completion hash that enables database, table, and column name completion while you are entering statements. (See the description for the `--auto-rehash` option.)

- `source file_name, \. file_name`

Read the named file and executes the statements contained therein. On Windows, you can specify path name separators as `/` or `\\`.

- `status, \s`

Provide status information about the connection and the server you are using. If you are running in `--safe-updates` mode, `status` also prints the values for the `mysql` variables that affect your queries.

- `system command, \! command`

Execute the given command using your default command interpreter.

The `system` command works only in Unix.

- `tee [file_name], \T [file_name]`

By using the `--tee` option when you invoke `mysql`, you can log statements and their output. All the data displayed on the screen is appended into a given file. This can be very useful for debugging purposes also. `mysql` flushes results to the file after each statement, just before it prints its next prompt. Tee functionality works only in interactive mode.

You can enable this feature interactively with the `tee` command. Without a parameter, the previous file is used. The `tee` file can be disabled with the `notee` command. Executing `tee` again re-enables logging.

- `use db_name, \u db_name`

Use `db_name` as the default database.

- `warnings, \W`

Enable display of warnings after each statement (if there are any).

Here are a few tips about the `pager` command:

- You can use it to write to a file and the results go only to the file:

```
mysql> pager cat > /tmp/log.txt
```

You can also pass any options for the program that you want to use as your pager:

```
mysql> pager less -n -i -S
```

- In the preceding example, note the `-S` option. You may find it very useful for browsing wide query results. Sometimes a very wide result set is difficult to read on the screen. The `-S` option to `less` can make the result set much more readable because you can scroll it horizontally using the left-arrow and right-arrow keys. You can also use `-S` interactively within `less` to switch the horizontal-browse mode on and off. For more information, read the `less` manual page:

```
shell> man less
```

- The `-F` and `-X` options may be used with `less` to cause it to exit if output fits on one screen, which is convenient when no scrolling is necessary:

```
mysql> pager less -n -i -S -F -X
```

- You can specify very complex pager commands for handling query output:

```
mysql> pager cat | tee /dr1/tmp/res.txt \  
      | tee /dr2/tmp/res2.txt | less -n -i -S
```

In this example, the command would send query results to two files in two different directories on two different file systems mounted on `/dr1` and `/dr2`, yet still display the results onscreen using `less`.

You can also combine the `tee` and `pager` functions. Have a `tee` file enabled and `pager` set to `less`, and you are able to browse the results using the `less` program and still have everything appended into a file the same time. The difference between the Unix `tee` used with the `pager` command and the `mysql` built-in `tee` command is that the built-in `tee` works even if you do not have the Unix `tee` available. The built-in `tee` also logs everything that is printed on the screen, whereas the Unix `tee` used with `pager` does not log quite that much. Additionally, `tee` file logging can be turned on and off interactively from within `mysql`. This is useful when you want to log some queries to a file, but not others.

The `prompt` command reconfigures the default `mysql>` prompt. The string for defining the prompt can contain the following special sequences.

Option	Description
<code>\c</code>	A counter that increments for each statement you issue
<code>\D</code>	The full current date
<code>\d</code>	The default database
<code>\h</code>	The server host
<code>\l</code>	The current delimiter
<code>\m</code>	Minutes of the current time
<code>\n</code>	A newline character
<code>\O</code>	The current month in three-letter format (Jan, Feb, ...)
<code>\o</code>	The current month in numeric format
<code>\P</code>	am/pm
<code>\p</code>	The current TCP/IP port or socket file
<code>\R</code>	The current time, in 24-hour military time (0–23)
<code>\r</code>	The current time, standard 12-hour time (1–12)
<code>\S</code>	Semicolon
<code>\s</code>	Seconds of the current time
<code>\t</code>	A tab character
<code>\U</code>	Your full <code>user_name@host_name</code> account name
<code>\u</code>	Your user name
<code>\v</code>	The server version
<code>\w</code>	The current day of the week in three-letter format (Mon, Tue, ...)
<code>\Y</code>	The current year, four digits

Option	Description
\y	The current year, two digits
_	A space
\	A space (a space follows the backslash)
\'	Single quote
\"	Double quote
\\	A literal “\” backslash character
\x	x, for any “x” not listed above

You can set the prompt in several ways:

- *Use an environment variable.* You can set the `MYSQL_PS1` environment variable to a prompt string. For example:

```
shell> export MYSQL_PS1="(\\u@\\h) [\\d]> "
```

- *Use a command-line option.* You can set the `--prompt` option on the command line to `mysql`. For example:

```
shell> mysql --prompt="(\\u@\\h) [\\d]> "
(user@host) [database]>
```

- *Use an option file.* You can set the `prompt` option in the `[mysql]` group of any MySQL option file, such as `/etc/my.cnf` or the `.my.cnf` file in your home directory. For example:

```
[mysql]
prompt=(\\u@\\h) [\\d]>\\_
```

In this example, note that the backslashes are doubled. If you set the prompt using the `prompt` option in an option file, it is advisable to double the backslashes when using the special prompt options. There is some overlap in the set of permissible prompt options and the set of special escape sequences that are recognized in option files. (The rules for escape sequences in option files are listed in [Section 4.2.6, “Using Option Files”](#).) The overlap may cause you problems if you use single backslashes. For example, `\\s` is interpreted as a space rather than as the current seconds value. The following example shows how to define a prompt within an option file to include the current time in `HH:MM:SS>` format:

```
[mysql]
prompt="\\r:\\m:\\s> "
```

- *Set the prompt interactively.* You can change your prompt interactively by using the `prompt` (or `\\R`) command. For example:

```
mysql> prompt (\\u@\\h) [\\d]>\\_
PROMPT set to '(\\u@\\h) [\\d]>\\_'
(user@host) [database]>
(user@host) [database]> prompt
Returning to default PROMPT of mysql>
mysql>
```

4.5.1.3 mysql Logging

On Unix, the `mysql` client logs statements executed interactively to a history file. By default, this file is named `.mysql_history` in your home directory. To specify a different file, set the value of the `MYSQL_HISTFILE` environment variable.

How Logging Occurs

Statement logging occurs as follows:

- Statements are logged only when executed interactively. Statements are noninteractive, for example, when read from a file or a pipe. It is also possible to suppress statement logging by using the `--batch` or `--execute` option.
- `mysql` logs each nonempty statement line individually.
- If a statement spans multiple lines (not including the terminating delimiter), `mysql` concatenates the lines to form the complete statement, maps newlines to spaces, and logs the result, plus a delimiter.

Consequently, an input statement that spans multiple lines can be logged twice. Consider this input:

```
mysql> SELECT
-> 'Today is'
-> ,
-> CONCAT()
-> ;
```

In this case, `mysql` logs the “SELECT”, “Today is”, “,”, “CONCAT()”, and “;” lines as it reads them. It also logs the complete statement, after mapping `SELECT\n'Today is'\n,\nCURDATE()` to `SELECT 'Today is' , CURDATE()`, plus a delimiter. Thus, these lines appear in logged output:

```
SELECT
'Today is'
,
CURDATE()
;
SELECT 'Today is' , CURDATE();
```

Controlling the History File

The `.mysql_history` file should be protected with a restrictive access mode because sensitive information might be written to it, such as the text of SQL statements that contain passwords. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#).

If you do not want to maintain a history file, first remove `.mysql_history` if it exists. Then use either of the following techniques to prevent it from being created again:

- Set the `MYSQL_HISTFILE` environment variable to `/dev/null`. To cause this setting to take effect each time you log in, put it in one of your shell's startup files.
- Create `.mysql_history` as a symbolic link to `/dev/null`; this need be done only once:

```
shell> ln -s /dev/null $HOME/.mysql_history
```

4.5.1.4 `mysql` Server-Side Help

```
mysql> help search_string
```

If you provide an argument to the `help` command, `mysql` uses it as a search string to access server-side help from the contents of the MySQL Reference Manual. The proper operation of this command requires

that the help tables in the `mysql` database be initialized with help topic information (see [Section 5.1.10](#), “Server-Side Help”).

If there is no match for the search string, the search fails:

```
mysql> help me

Nothing found
Please try to run 'help contents' for a list of all accessible topics
```

Use `help contents` to see a list of the help categories:

```
mysql> help contents
You asked for help about help category: "Contents"
For more information, type 'help <item>', where <item> is one of the
following categories:
  Account Management
  Administration
  Data Definition
  Data Manipulation
  Data Types
  Functions
  Functions and Modifiers for Use with GROUP BY
  Geographic Features
  Language Structure
  Plugins
  Storage Engines
  Stored Routines
  Table Maintenance
  Transactions
  Triggers
```

If the search string matches multiple items, `mysql` shows a list of matching topics:

```
mysql> help logs
Many help items for your request exist.
To make a more specific request, please type 'help <item>',
where <item> is one of the following topics:
  SHOW
  SHOW BINARY LOGS
  SHOW ENGINE
  SHOW LOGS
```

Use a topic as the search string to see the help entry for that topic:

```
mysql> help show binary logs
Name: 'SHOW BINARY LOGS'
Description:
Syntax:
SHOW BINARY LOGS
SHOW MASTER LOGS

Lists the binary log files on the server. This statement is used as
part of the procedure described in [purge-binary-logs], that shows how
to determine which logs can be purged.

mysql> SHOW BINARY LOGS;
+-----+-----+
| Log_name          | File_size |
+-----+-----+
| binlog.000015     | 724935    |
| binlog.000016     | 733481    |
```

The search string can contain the wildcard characters “%” and “_”. These have the same meaning as for pattern-matching operations performed with the [LIKE](#) operator. For example, `HELP rep%` returns a list of topics that begin with `rep`:

```
mysql> HELP rep%
Many help items for your request exist.
To make a more specific request, please type 'help <item>',
where <item> is one of the following
topics:
  REPAIR TABLE
  REPEAT FUNCTION
  REPEAT LOOP
  REPLACE
  REPLACE FUNCTION
```

4.5.1.5 Executing SQL Statements from a Text File

The `mysql` client typically is used interactively, like this:

```
shell> mysql db_name
```

However, it is also possible to put your SQL statements in a file and then tell `mysql` to read its input from that file. To do so, create a text file `text_file` that contains the statements you wish to execute. Then invoke `mysql` as shown here:

```
shell> mysql db_name < text_file
```

If you place a `USE db_name` statement as the first statement in the file, it is unnecessary to specify the database name on the command line:

```
shell> mysql < text_file
```

If you are already running `mysql`, you can execute an SQL script file using the `source` command or `\.` command:

```
mysql> source file_name
mysql> \. file_name
```

Sometimes you may want your script to display progress information to the user. For this you can insert statements like this:

```
SELECT '<info_to_display>' AS ' ';
```

The statement shown outputs `<info_to_display>`.

You can also invoke `mysql` with the `--verbose` option, which causes each statement to be displayed before the result that it produces.

`mysql` ignores Unicode byte order mark (BOM) characters at the beginning of input files. Previously, it read them and sent them to the server, resulting in a syntax error. Presence of a BOM does not cause `mysql` to change its default character set. To do that, invoke `mysql` with an option such as `--default-character-set=utf8`.

For more information about batch mode, see [Section 3.5, “Using `mysql` in Batch Mode”](#).

4.5.1.6 mysql Tips

This section describes some techniques that can help you use `mysql` more effectively.

Input-Line Editing

`mysql` supports input-line editing, which enables you to modify the current input line in place or recall previous input lines. For example, the **left-arrow** and **right-arrow** keys move horizontally within the current input line, and the **up-arrow** and **down-arrow** keys move up and down through the set of previously entered lines. **Backspace** deletes the character before the cursor and typing new characters enters them at the cursor position. To enter the line, press **Enter**.

On Windows, the editing key sequences are the same as supported for command editing in console windows. On Unix, the key sequences depend on the input library used to build `mysql` (for example, the `libedit` or `readline` library).

Documentation for the `libedit` and `readline` libraries is available online. To change the set of key sequences permitted by a given input library, define key bindings in the library startup file. This is a file in your home directory: `.editrc` for `libedit` and `.inputrc` for `readline`.

For example, in `libedit`, **Control+W** deletes everything before the current cursor position and **Control+U** deletes the entire line. In `readline`, **Control+W** deletes the word before the cursor and **Control+U** deletes everything before the current cursor position. If `mysql` was built using `libedit`, a user who prefers the `readline` behavior for these two keys can put the following lines in the `.editrc` file (creating the file if necessary):

```
bind "^W" ed-delete-prev-word
bind "^U" vi-kill-line-prev
```

To see the current set of key bindings, temporarily put a line that says only `bind` at the end of `.editrc`. `mysql` will show the bindings when it starts.

Displaying Query Results Vertically

Some query results are much more readable when displayed vertically, instead of in the usual horizontal table format. Queries can be displayed vertically by terminating the query with `\G` instead of a semicolon. For example, longer text values that include newlines often are much easier to read with vertical output:

```
mysql> SELECT * FROM mails WHERE LENGTH(txt) < 300 LIMIT 300,1\G
***** 1. row *****
  msg_nro: 3068
    date: 2000-03-01 23:29:50
time_zone: +0200
mail_from: Monty
   reply: monty@no.spam.com
  mail_to: "Thimble Smith" <tim@no.spam.com>
    sbj: UTF-8
   txt: >>>> "Thimble" == Thimble Smith writes:

Thimble> Hi. I think this is a good idea. Is anyone familiar
Thimble> with UTF-8 or Unicode? Otherwise, I'll put this on my
Thimble> TODO list and see what happens.

Yes, please do that.

Regards,
Monty
   file: inbox-jani-1
  hash: 190402944
1 row in set (0.09 sec)
```

Using the `--safe-updates` Option

For beginners, a useful startup option is `--safe-updates` (or `--i-am-a-dummy`, which has the same effect). It is helpful for cases when you might have issued a `DELETE FROM tbl_name` statement but forgotten the `WHERE` clause. Normally, such a statement deletes all rows from the table. With `--safe-updates`, you can delete rows only by specifying the key values that identify them. This helps prevent accidents.

When you use the `--safe-updates` option, `mysql` issues the following statement when it connects to the MySQL server:

```
SET sql_safe_updates=1, sql_select_limit=1000, sql_max_join_size=1000000;
```

See [Section 5.1.4, “Server System Variables”](#).

The `SET` statement has the following effects:

- You are not permitted to execute an `UPDATE` or `DELETE` statement unless you specify a key constraint in the `WHERE` clause or provide a `LIMIT` clause (or both). For example:

```
UPDATE tbl_name SET not_key_column=val WHERE key_column=val;
UPDATE tbl_name SET not_key_column=val LIMIT 1;
```

- The server limits all large `SELECT` results to 1,000 rows unless the statement includes a `LIMIT` clause.
- The server aborts multiple-table `SELECT` statements that probably need to examine more than 1,000,000 row combinations.

To specify limits different from 1,000 and 1,000,000, you can override the defaults by using the `--select_limit` and `--max_join_size` options:

```
shell> mysql --safe-updates --select_limit=500 --max_join_size=10000
```

Disabling `mysql` Auto-Reconnect

If the `mysql` client loses its connection to the server while sending a statement, it immediately and automatically tries to reconnect once to the server and send the statement again. However, even if `mysql` succeeds in reconnecting, your first connection has ended and all your previous session objects and settings are lost: temporary tables, the autocommit mode, and user-defined and session variables. Also, any current transaction rolls back. This behavior may be dangerous for you, as in the following example where the server was shut down and restarted between the first and second statements without you knowing it:

```
mysql> SET @a=1;
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO t VALUES(@a);
ERROR 2006: MySQL server has gone away
No connection. Trying to reconnect...
Connection id: 1
Current database: test

Query OK, 1 row affected (1.30 sec)

mysql> SELECT * FROM t;
+-----+
| a      |
```

```
+-----+
| NULL |
+-----+
1 row in set (0.05 sec)
```

The `@a` user variable has been lost with the connection, and after the reconnection it is undefined. If it is important to have `mysql` terminate with an error if the connection has been lost, you can start the `mysql` client with the `--skip-reconnect` option.

For more information about auto-reconnect and its effect on state information when a reconnection occurs, see [Section 23.8.16, “Controlling Automatic Reconnection Behavior”](#).

4.5.2 mysqladmin — Client for Administering a MySQL Server

`mysqladmin` is a client for performing administrative operations. You can use it to check the server's configuration and current status, to create and drop databases, and more.

Invoke `mysqladmin` like this:

```
shell> mysqladmin [options] command [command-arg] [command [command-arg]] ...
```

`mysqladmin` supports the following commands. Some of the commands take an argument following the command name.

- `create db_name`

Create a new database named `db_name`.

- `debug`

Tell the server to write debug information to the error log. Format and content of this information is subject to change.

This includes information about the Event Scheduler. See [Section 20.4.5, “Event Scheduler Status”](#).

- `drop db_name`

Delete the database named `db_name` and all its tables.

- `extended-status`

Display the server status variables and their values.

- `flush-hosts`

Flush all information in the host cache.

- `flush-logs`

Flush all logs.

- `flush-privileges`

Reload the grant tables (same as `reload`).

- `flush-status`

Clear status variables.

- `flush-tables`

Flush all tables.

- `flush-threads`

Flush the thread cache.

- `kill id,id,...`

Kill server threads. If multiple thread ID values are given, there must be no spaces in the list.

- `old-password new-password`

This is like the `password` command but stores the password using the old (pre-4.1) password-hashing format. (See [Section 6.1.2.4, “Password Hashing in MySQL”](#).)

- `password new-password`

Set a new password. This changes the password to `new-password` for the account that you use with `mysqladmin` for connecting to the server. Thus, the next time you invoke `mysqladmin` (or any other client program) using the same account, you will need to specify the new password.

If the `new-password` value contains spaces or other characters that are special to your command interpreter, you need to enclose it within quotation marks. On Windows, be sure to use double quotation marks rather than single quotation marks; single quotation marks are not stripped from the password, but rather are interpreted as part of the password. For example:

```
shell> mysqladmin password "my new password"
```

As of MySQL 5.5.3, the new password can be omitted following the `password` command. In this case, `mysqladmin` prompts for the password value, which enables you to avoid specifying the password on the command line. Omitting the password value should be done only if `password` is the final command on the `mysqladmin` command line. Otherwise, the next argument is taken as the password.

Caution

Do not use this command used if the server was started with the `--skip-grant-tables` option. No password change will be applied. This is true even if you precede the `password` command with `flush-privileges` on the same command line to re-enable the grant tables because the flush operation occurs after you connect. However, you can use `mysqladmin flush-privileges` to re-enable the grant table and then use a separate `mysqladmin password` command to change the password.

- `ping`

Check whether the server is available. The return status from `mysqladmin` is 0 if the server is running, 1 if it is not. This is 0 even in case of an error such as `Access denied`, because this means that the server is running but refused the connection, which is different from the server not running.

- `processlist`

Show a list of active server threads. This is like the output of the `SHOW PROCESSLIST` statement. If the `--verbose` option is given, the output is like that of `SHOW FULL PROCESSLIST`. (See [Section 13.7.5.30, “SHOW PROCESSLIST Syntax”](#).)

- `reload`

Reload the grant tables.

- `refresh`

Flush all tables and close and open log files.

- `shutdown`

Stop the server.

- `start-slave`

Start replication on a slave server.

- `status`

Display a short server status message.

- `stop-slave`

Stop replication on a slave server.

- `variables`

Display the server system variables and their values.

- `version`

Display version information from the server.

All commands can be shortened to any unique prefix. For example:

```
shell> mysqladmin proc stat
+-----+-----+-----+-----+-----+-----+-----+-----+
| Id | User | Host | db | Command | Time | State | Info |
+-----+-----+-----+-----+-----+-----+-----+
| 51 | monty | localhost | | Query | 0 | | show processlist |
+-----+-----+-----+-----+-----+-----+
Uptime: 1473624 Threads: 1 Questions: 39487
Slow queries: 0 Opens: 541 Flush tables: 1
Open tables: 19 Queries per second avg: 0.0268
```

The `mysqladmin status` command result displays the following values:

- `Uptime`

The number of seconds the MySQL server has been running.

- `Threads`

The number of active threads (clients).

- `Questions`

The number of questions (queries) from clients since the server was started.

- `Slow queries`

The number of queries that have taken more than `long_query_time` seconds. See [Section 5.2.5, “The Slow Query Log”](#).

- `Opens`

The number of tables the server has opened.

- `Flush tables`

The number of `flush-*`, `refresh`, and `reload` commands the server has executed.

- `Open tables`

The number of tables that currently are open.

- `Memory in use`

The amount of memory allocated directly by `mysqld`. This value is displayed only when MySQL has been compiled with `safemalloc`, which is available only before MySQL 5.5.6.

- `Maximum memory used`

The maximum amount of memory allocated directly by `mysqld`. This value is displayed only when MySQL has been compiled with `safemalloc`, which is available only before MySQL 5.5.6.

If you execute `mysqladmin shutdown` when connecting to a local server using a Unix socket file, `mysqladmin` waits until the server's process ID file has been removed, to ensure that the server has stopped properly.

`mysqladmin` supports the following options, which can be specified on the command line or in the `[mysqladmin]` and `[client]` groups of an option file. For information about option files, see [Section 4.2.6, “Using Option Files”](#).

Table 4.6 `mysqladmin` Options

Format	Option File	Description	Introduced
<code>--compress</code>	<code>compress</code>	Compress all information sent between the client and the server	
<code>--connect_timeout=seconds</code>	<code>connect_timeout</code>	The number of seconds before connection timeout	
<code>--count=#</code>	<code>count</code>	The number of iterations to make for repeated command execution	
<code>--debug[=debug_options]</code>	<code>debug</code>	Write a debugging log	
<code>--debug-check</code>	<code>debug-check</code>	Print debugging information when the program exits	
<code>--debug-info</code>	<code>debug-info</code>	Print debugging information, memory and CPU statistics when the program exits	
<code>--default-auth=plugin</code>	<code>default-auth=plugin</code>	The authentication plugin to use	5.5.9
<code>--default-character-set=charset_name</code>	<code>default-character-set</code>	Use <code>charset_name</code> as the default character set	
<code>--defaults-extra-file=file_name</code>		Read option file in addition to the usual option files	
<code>--defaults-file=file_name</code>		Read only the given option file	

Format	Option File	Description	Introduced
--defaults-group-suffix=str		Option group suffix value	
--enable-cleartext-plugin	enable-cleartext-plugin	Enable cleartext authentication plugin	5.5.27
--force	force	Continue even if an SQL error occurs	
--help		Display help message and exit	
--host=host_name	host	Connect to the MySQL server on the given host	
--no-beep	no-beep	Do not beep when errors occur	
--no-defaults		Do not read any option files	
--password[=password]	password	The password to use when connecting to the server	
--pipe		On Windows, connect to server using a named pipe	
--plugin-dir=path	plugin-dir=path	The directory where plugins are located	5.5.9
--port=port_num	port	The TCP/IP port number to use for the connection	
--print-defaults		Print defaults	
--protocol=type	protocol	The connection protocol to use	
--relative	relative	Show the difference between the current and previous values when used with the --sleep option	
--shutdown_timeout=seconds	shutdown_timeout	The maximum number of seconds to wait for server shutdown	
--silent	silent	Silent mode	
--sleep=delay	sleep	Execute commands repeatedly, sleeping for delay seconds in between	
--socket=path	socket	For connections to localhost	
--ssl-ca=file_name	ssl-ca	The path to a file that contains a list of trusted SSL CAs	
--ssl-capath=dir_name	ssl-capath	The path to a directory that contains trusted SSL CA certificates in PEM format	
--ssl-cert=file_name	ssl-cert	The name of the SSL certificate file to use for establishing a secure connection	
--ssl-cipher=cipher_list	ssl-cipher	A list of allowable ciphers to use for SSL encryption	
--ssl-key=file_name	ssl-key	The name of the SSL key file to use for establishing a secure connection	
--ssl-verify-server-cert	ssl-verify-server-cert	The server's Common Name value in its certificate is verified against the host name used when connecting to the server	
--user=user_name,	user	MySQL user name to use when connecting to server	
--verbose		Verbose mode	
--version		Display version information and exit	

Format	Option File	Description	Introduced
<code>--vertical</code>	<code>vertical</code>	Print query output rows vertically (one line per column value)	
<code>--wait</code>	<code>wait</code>	If the connection cannot be established, wait and retry instead of aborting	

- `--help, -?`

Display a help message and exit.

- `--bind-address=ip_address`

On a computer having multiple network interfaces, this option can be used to select which interface is employed when connecting to the MySQL server.

This option is supported only in the version of `mysqladmin` that is supplied with MySQL Cluster. It is not available in standard MySQL Server 5.5 releases.

- `--character-sets-dir=path`

The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).

- `--compress, -C`

Compress all information sent between the client and the server if both support compression.

- `--count=N, -c N`

The number of iterations to make for repeated command execution if the `--sleep` option is given.

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysqladmin.trace`.

- `--debug-check`

Print some debugging information when the program exits.

- `--debug-info`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-auth=plugin`

The client-side authentication plugin to use. See [Section 6.3.6, “Pluggable Authentication”](#).

This option was added in MySQL 5.5.9.

- `--default-character-set=charset_name`

Use `charset_name` as the default character set. See [Section 10.5, “Character Set Configuration”](#).

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, `file_name` must be the full

path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, `file_name` must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqladmin` normally reads the `[client]` and `[mysqladmin]` groups. If the `--defaults-group-suffix=_other` option is given, `mysqladmin` also reads the `[client_other]` and `[mysqladmin_other]` groups.

- `--enable-cleartext-plugin`

Enable the `mysql_clear_password` cleartext authentication plugin. (See [Section 6.3.7.5, “The Cleartext Client-Side Authentication Plugin”](#).) This option was added in MySQL 5.5.27.

- `--force, -f`

Do not ask for confirmation for the `drop db_name` command. With multiple commands, continue even if an error occurs.

- `--host=host_name, -h host_name`

Connect to the MySQL server on the given host.

- `--no-beep, -b`

Suppress the warning beep that is emitted by default for errors such as a failure to connect to the server.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysqladmin` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe, -W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=path`

The directory in which to look for plugins. It may be necessary to specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqladmin` does not find it. See [Section 6.3.6, “Pluggable Authentication”](#).

This option was added in MySQL 5.5.9.

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--relative, -r`

Show the difference between the current and previous values when used with the `--sleep` option. This option works only with the `extended-status` command.

- `--silent, -s`

Exit silently if a connection to the server cannot be established.

- `--sleep=delay, -i delay`

Execute commands repeatedly, sleeping for `delay` seconds in between. The `--count` option determines the number of iterations. If `--count` is not given, `mysqladmin` executes commands indefinitely until interrupted.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.3.9.4, “SSL Command Options”](#).

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

- `--verbose, -v`

Verbose mode. Print more information about what the program does.

- `--version, -V`

Display version information and exit.

- `--vertical, -E`

Print output vertically. This is similar to `--relative`, but prints output vertically.

- `--wait[=count], -w[count]`

If the connection cannot be established, wait and retry instead of aborting. If a `count` value is given, it indicates the number of times to retry. The default is one time.

You can also set the following variables by using `--var_name=value`. The `--set-variable` format is deprecated and was removed in MySQL 5.5.3. syntax:

- `connect_timeout`

The maximum number of seconds before connection timeout. The default value is 43200 (12 hours).

- `shutdown_timeout`

The maximum number of seconds to wait for server shutdown. The default value is 3600 (1 hour).

4.5.3 mysqlcheck — A Table Maintenance Program

The `mysqlcheck` client performs table maintenance: It checks, repairs, optimizes, or analyzes tables.

Each table is locked and therefore unavailable to other sessions while it is being processed, although for check operations, the table is locked with a `READ` lock only (see [Section 13.3.5, “LOCK TABLES and UNLOCK TABLES Syntax”](#), for more information about `READ` and `WRITE` locks). Table maintenance operations can be time-consuming, particularly for large tables. If you use the `--databases` or `--all-databases` option to process all tables in one or more databases, an invocation of `mysqlcheck` might take a long time. (This is also true for `mysql_upgrade` because that program invokes `mysqlcheck` to check all tables and repair them if necessary.)

`mysqlcheck` is similar in function to `myisamchk`, but works differently. The main operational difference is that `mysqlcheck` must be used when the `mysqld` server is running, whereas `myisamchk` should be used when it is not. The benefit of using `mysqlcheck` is that you do not have to stop the server to perform table maintenance.

`mysqlcheck` uses the SQL statements `CHECK TABLE`, `REPAIR TABLE`, `ANALYZE TABLE`, and `OPTIMIZE TABLE` in a convenient way for the user. It determines which statements to use for the operation you want to perform, and then sends the statements to the server to be executed. For details about which storage engines each statement works with, see the descriptions for those statements in [Section 13.7.2, “Table Maintenance Statements”](#).

The `MyISAM` storage engine supports all four maintenance operations, so `mysqlcheck` can be used to perform any of them on `MyISAM` tables. Other storage engines do not necessarily support all operations. In such cases, an error message is displayed. For example, if `test.t` is a `MEMORY` table, an attempt to check it produces this result:

```
shell> mysqlcheck test t
test.t
note      : The storage engine for the table doesn't support check
```

If `mysqlcheck` is unable to repair a table, see [Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”](#) for manual table repair strategies. This will be the case, for example, for `InnoDB` tables, which can be checked with `CHECK TABLE`, but not repaired with `REPAIR TABLE`.

Caution

It is best to make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors.

There are three general ways to invoke `mysqlcheck`:

```

shell> mysqlcheck [options] db_name [tbl_name ...]
shell> mysqlcheck [options] --databases db_name ...
shell> mysqlcheck [options] --all-databases

```

If you do not name any tables following `db_name` or if you use the `--databases` or `--all-databases` option, entire databases are checked.

`mysqlcheck` has a special feature compared to other client programs. The default behavior of checking tables (`--check`) can be changed by renaming the binary. If you want to have a tool that repairs tables by default, you should just make a copy of `mysqlcheck` named `mysqlrepair`, or make a symbolic link to `mysqlcheck` named `mysqlrepair`. If you invoke `mysqlrepair`, it repairs tables.

The names shown in the following table can be used to change `mysqlcheck` default behavior.

Command	Meaning
<code>mysqlrepair</code>	The default option is <code>--repair</code>
<code>mysqanalyze</code>	The default option is <code>--analyze</code>
<code>mysqoptimize</code>	The default option is <code>--optimize</code>

`mysqlcheck` supports the following options, which can be specified on the command line or in the `[mysqlcheck]` and `[client]` groups of an option file. For information about option files, see Section 4.2.6, “Using Option Files”.

Table 4.7 `mysqlcheck` Options

Format	Option File	Description	Introduced
<code>--all-databases</code>	<code>all-databases</code>	Check all tables in all databases	
<code>--all-in-1</code>	<code>all-in-1</code>	Execute a single statement for each database that names all the tables from that database	
<code>--analyze</code>	<code>analyze</code>	Analyze the tables	
<code>--auto-repair</code>	<code>auto-repair</code>	If a checked table is corrupted, automatically fix it	
<code>--character-sets-dir=path</code>	<code>character-sets-dir</code>	The directory where character sets are installed	
<code>--check</code>	<code>check</code>	Check the tables for errors	
<code>--check-only-changed</code>	<code>check-only-changed</code>	Check only tables that have changed since the last check	
<code>--check-upgrade</code>	<code>check-upgrade</code>	Invoke CHECK TABLE with the FOR UPGRADE option	
<code>--compress</code>	<code>compress</code>	Compress all information sent between the client and the server	
<code>--databases</code>	<code>databases</code>	Process all tables in the named databases	
<code>--debug[=debug_options]</code>	<code>debug</code>	Write a debugging log	
<code>--debug-check</code>	<code>debug-check</code>	Print debugging information when the program exits	
<code>--debug-info</code>	<code>debug-info</code>	Print debugging information, memory and CPU statistics when the program exits	
<code>--default-auth=plugin</code>	<code>default-auth=plugin</code>	The authentication plugin to use	5.5.10

Format	Option File	Description	Introduced
<code>--default-character-set=charset_name</code>	<code>default-character-set</code>	Use <code>charset_name</code> as the default character set	
<code>--defaults-extra-file=file_name</code>		Read option file in addition to the usual option files	
<code>--defaults-file=file_name</code>		Read only the given option file	
<code>--defaults-group-suffix=str</code>		Option group suffix value	
<code>--extended</code>	<code>extended</code>	Check and repair tables	
<code>--fast</code>	<code>fast</code>	Check only tables that have not been closed properly	
<code>--fix-db-names</code>	<code>fix-db-names</code>	Convert database names to 5.1 format	
<code>--fix-table-names</code>	<code>fix-table-names</code>	Convert table names to 5.1 format	
<code>--force</code>	<code>force</code>	Continue even if an SQL error occurs	
<code>--help</code>		Display help message and exit	
<code>--host=host_name</code>	<code>host</code>	Connect to the MySQL server on the given host	
<code>--medium-check</code>	<code>medium-check</code>	Do a check that is faster than an <code>--extended</code> operation	
<code>--no-defaults</code>		Do not read any option files	
<code>--optimize</code>	<code>optimize</code>	Optimize the tables	
<code>--password[=password]</code>	<code>password</code>	The password to use when connecting to the server	
<code>--pipe</code>		On Windows, connect to server using a named pipe	
<code>--plugin-dir=path</code>	<code>plugin-dir=path</code>	The directory where plugins are located	5.5.10
<code>--port=port_num</code>	<code>port</code>	The TCP/IP port number to use for the connection	
<code>--print-defaults</code>		Print defaults	
<code>--protocol=type</code>	<code>protocol</code>	The connection protocol to use	
<code>--quick</code>	<code>quick</code>	The fastest method of checking	
<code>--repair</code>	<code>repair</code>	Perform a repair that can fix almost anything except unique keys that are not unique	
<code>--silent</code>	<code>silent</code>	Silent mode	
<code>--socket=path</code>	<code>socket</code>	For connections to localhost	
<code>--ssl-ca=file_name</code>	<code>ssl-ca</code>	The path to a file that contains a list of trusted SSL CAs	
<code>--ssl-capath=dir_name</code>	<code>ssl-capath</code>	The path to a directory that contains trusted SSL CA certificates in PEM format	
<code>--ssl-cert=file_name</code>	<code>ssl-cert</code>	The name of the SSL certificate file to use for establishing a secure connection	
<code>--ssl-cipher=cipher_list</code>	<code>ssl-cipher</code>	A list of allowable ciphers to use for SSL encryption	

Format	Option File	Description	Introduced
<code>--ssl-key=file_name</code>	<code>ssl-key</code>	The name of the SSL key file to use for establishing a secure connection	
<code>--ssl-verify-server-cert</code>	<code>ssl-verify-server-cert</code>	The server's Common Name value in its certificate is verified against the host name used when connecting to the server	
<code>--tables</code>	<code>tables</code>	Overrides the <code>--databases</code> or <code>-B</code> option	
<code>--use-frm</code>	<code>use-frm</code>	For repair operations on MyISAM tables	
<code>--user=user_name,</code>	<code>user</code>	MySQL user name to use when connecting to server	
<code>--verbose</code>		Verbose mode	
<code>--version</code>		Display version information and exit	
<code>--write-binlog</code>	<code>write-binlog</code>	Log ANALYZE, OPTIMIZE, REPAIR statements to binary log. <code>--skip-write-binlog</code> adds <code>NO_WRITE_TO_BINLOG</code> to these statements.	

- `--help, -?`

Display a help message and exit.

- `--all-databases, -A`

Check all tables in all databases. This is the same as using the `--databases` option and naming all the databases on the command line, except that the `INFORMATION_SCHEMA` and `performance_schema` databases are not dumped. They can be dumped by explicitly naming them with the `--databases` option.

- `--all-in-1, -l`

Instead of issuing a statement for each table, execute a single statement for each database that names all the tables from that database to be processed.

- `--analyze, -a`

Analyze the tables.

- `--auto-repair`

If a checked table is corrupted, automatically fix it. Any necessary repairs are done after all tables have been checked.

- `--bind-address=ip_address`

On a computer having multiple network interfaces, this option can be used to select which interface is employed when connecting to the MySQL server.

This option is supported only in the version of `mysqlcheck` that is supplied with MySQL Cluster. It is not available in standard MySQL Server 5.5 releases.

- `--character-sets-dir=path`

The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).

- `--check, -c`

Check the tables for errors. This is the default operation.

- `--check-only-changed, -C`

Check only tables that have changed since the last check or that have not been closed properly.

- `--check-upgrade, -g`

Invoke `CHECK TABLE` with the `FOR UPGRADE` option to check tables for incompatibilities with the current version of the server. This option automatically enables the `--fix-db-names` and `--fix-table-names` options.

- `--compress`

Compress all information sent between the client and the server if both support compression.

- `--databases, -B`

Process all tables in the named databases. Normally, `mysqlcheck` treats the first name argument on the command line as a database name and following names as table names. With this option, it treats all name arguments as database names.

This option may be used to dump the `INFORMATION_SCHEMA` and `performance_schema` databases, which normally are not dumped even with the `--all-databases` option. (Also use the `--skip-lock-tables` option.)

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o`.

- `--debug-check`

Print some debugging information when the program exits.

- `--debug-info`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-character-set=charset_name`

Use `charset_name` as the default character set. See [Section 10.5, “Character Set Configuration”](#).

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, `file_name` must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, `file_name` must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of *str*. For example, `mysqlcheck` normally reads the `[client]` and `[mysqlcheck]` groups. If the `--defaults-group-suffix=_other` option is given, `mysqlcheck` also reads the `[client_other]` and `[mysqlcheck_other]` groups.

- `--extended, -e`

If you are using this option to check tables, it ensures that they are 100% consistent but takes a long time.

If you are using this option to repair tables, it runs an extended repair that may not only take a long time to execute, but may produce a lot of garbage rows also!

- `--default-auth=plugin`

The client-side authentication plugin to use. See [Section 6.3.6, “Pluggable Authentication”](#).

This option was added in MySQL 5.5.10.

- `--fast, -F`

Check only tables that have not been closed properly.

- `--fix-db-names`

Convert database names to 5.1 format. Only database names that contain special characters are affected.

- `--fix-table-names`

Convert table names to 5.1 format. Only table names that contain special characters are affected. This option also applies to views.

- `--force, -f`

Continue even if an SQL error occurs.

- `--host=host_name, -h host_name`

Connect to the MySQL server on the given host.

- `--medium-check, -m`

Do a check that is faster than an `--extended` operation. This finds only 99.99% of all errors, which should be good enough in most cases.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

- `--optimize, -o`

Optimize the tables.

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysqlcheck` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe, -W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=path`

The directory in which to look for plugins. It may be necessary to specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlcheck` does not find it. See [Section 6.3.6, “Pluggable Authentication”](#).

This option was added in MySQL 5.5.10.

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--quick, -q`

If you are using this option to check tables, it prevents the check from scanning the rows to check for incorrect links. This is the fastest check method.

If you are using this option to repair tables, it tries to repair only the index tree. This is the fastest repair method.

- `--repair, -r`

Perform a repair that can fix almost anything except unique keys that are not unique.

- `--silent, -s`

Silent mode. Print only error messages.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.3.9.4, “SSL Command Options”](#).

- `--tables`

Override the `--databases` or `-B` option. All name arguments following the option are regarded as table names.

- `--use-frm`

For repair operations on [MyISAM](#) tables, get the table structure from the `.frm` file so that the table can be repaired even if the `.MYI` header is corrupted.

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

- `--verbose, -v`

Verbose mode. Print information about the various stages of program operation.

- `--version, -V`

Display version information and exit.

- `--write-binlog`

This option is enabled by default, so that [ANALYZE TABLE](#), [OPTIMIZE TABLE](#), and [REPAIR TABLE](#) statements generated by `mysqlcheck` are written to the binary log. Use `--skip-write-binlog` to cause [NO_WRITE_TO_BINLOG](#) to be added to the statements so that they are not logged. Use the `--skip-write-binlog` when these statements should not be sent to replication slaves or run when using the binary logs for recovery from backup.

4.5.4 `mysqldump` — A Database Backup Program

The `mysqldump` client is a utility that performs [logical backups](#), producing a set of SQL statements that can be run to reproduce the original schema objects, table data, or both. It dumps one or more MySQL database for backup or transfer to another SQL server. The `mysqldump` command can also generate output in CSV, other delimited text, or XML format.

`mysqldump` requires at least the [SELECT](#) privilege for dumped tables, [SHOW VIEW](#) for dumped views, [TRIGGER](#) for dumped triggers, and [LOCK TABLES](#) if the `--single-transaction` option is not used. Certain options might require other privileges as noted in the option descriptions.

To reload a dump file, you must have the same privileges needed to create each of the dumped objects by issuing [CREATE](#) statements manually.

`mysqldump` output can include [ALTER DATABASE](#) statements that change the database collation. These may be used when dumping stored programs to preserve their character encodings. To reload a dump file containing such statements, the [ALTER](#) privilege for the affected database is required.

If you are performing a backup on the server and your tables all are [MyISAM](#) tables, you can also use [mysqlhotcopy](#) for this purpose.

Performance and Scalability Considerations

`mysqldump` advantages include the convenience and flexibility of viewing or even editing the output before restoring. You can clone databases for development and DBA work, or produce slight variations of an

existing database for testing. It is not intended as a fast or scalable solution for backing up substantial amounts of data. With large data sizes, even if the backup step takes a reasonable time, restoring the data can be very slow because replaying the SQL statements involves disk I/O for insertion, index creation, and so on.

For large-scale backup and restore, a [physical](#) backup is more appropriate, to copy the data files in their original format that can be restored quickly:

- If your tables are primarily [InnoDB](#) tables, or if you have a mix of [InnoDB](#) and [MyISAM](#) tables, consider using the [mysqlbackup](#) command of the MySQL Enterprise Backup product. (Available as part of the Enterprise subscription.) It provides the best performance for [InnoDB](#) backups with minimal disruption; it can also back up tables from [MyISAM](#) and other storage engines; and it provides a number of convenient options to accommodate different backup scenarios. See [Section 25.2, “MySQL Enterprise Backup”](#).
- If your tables are primarily [MyISAM](#) tables, consider using the [mysqlhotcopy](#) instead, for better performance than [mysqldump](#) of backup and restore operations. See [Section 4.6.9, “mysqlhotcopy — A Database Backup Program”](#).

[mysqldump](#) can retrieve and dump table contents row by row, or it can retrieve the entire content from a table and buffer it in memory before dumping it. Buffering in memory can be a problem if you are dumping large tables. To dump tables row by row, use the [--quick](#) option (or [--opt](#), which enables [--quick](#)). The [--opt](#) option (and hence [--quick](#)) is enabled by default, so to enable memory buffering, use [--skip-quick](#).

If you are using a recent version of [mysqldump](#) to generate a dump to be reloaded into a very old MySQL server, use the [--skip-opt](#) option instead of the [--opt](#) or [--extended-insert](#) option.

For additional information about [mysqldump](#), see [Section 7.4, “Using mysqldump for Backups”](#).

Syntax

There are in general three ways to use [mysqldump](#)—in order to dump a set of one or more tables, a set of one or more complete databases, or an entire MySQL server—as shown here:

```
shell> mysqldump [options] db_name [tbl_name ...]
shell> mysqldump [options] --databases db_name ...
shell> mysqldump [options] --all-databases
```

To dump entire databases, do not name any tables following [db_name](#), or use the [--databases](#) or [--all-databases](#) option.

[mysqldump](#) does not dump the [INFORMATION_SCHEMA](#) or [performance_schema](#) database by default. To dump either of these, name it explicitly on the command line and also use the [--skip-lock-tables](#) option. You can also name them with the [--databases](#) option. Before MySQL 5.5 [mysqldump](#) silently ignores [INFORMATION_SCHEMA](#) even if you name it explicitly on the command line.

[mysqldump](#) does not dump the [performance_schema](#) database.

Before MySQL 5.5.25, [mysqldump](#) does not dump the [general_log](#) or [slow_query_log](#) tables for dumps of the [mysql](#) database. As of 5.5.25, the dump includes statements to recreate those tables so that they are not missing after reloading the dump file. Log table contents are not dumped.

[mysqldump](#) also does not dump the MySQL Cluster [ndbinfo](#) information database.

To see a list of the options your version of [mysqldump](#) supports, execute [mysqldump --help](#).

Some [mysqldump](#) options are shorthand for groups of other options:

- Use of `--opt` is the same as specifying `--add-drop-table`, `--add-locks`, `--create-options`, `--disable-keys`, `--extended-insert`, `--lock-tables`, `--quick`, and `--set-charset`. All of the options that `--opt` stands for also are on by default because `--opt` is on by default.
- Use of `--compact` is the same as specifying `--skip-add-drop-table`, `--skip-add-locks`, `--skip-comments`, `--skip-disable-keys`, and `--skip-set-charset` options.

To reverse the effect of a group option, uses its `--skip-xxx` form (`--skip-opt` or `--skip-compact`). It is also possible to select only part of the effect of a group option by following it with options that enable or disable specific features. Here are some examples:

- To select the effect of `--opt` except for some features, use the `--skip` option for each feature. To disable extended inserts and memory buffering, use `--opt --skip-extended-insert --skip-quick`. (Actually, `--skip-extended-insert --skip-quick` is sufficient because `--opt` is on by default.)
- To reverse `--opt` for all features except index disabling and table locking, use `--skip-opt --disable-keys --lock-tables`.

When you selectively enable or disable the effect of a group option, order is important because options are processed first to last. For example, `--disable-keys --lock-tables --skip-opt` would not have the intended effect; it is the same as `--skip-opt` by itself.

`mysqldump` can retrieve and dump table contents row by row, or it can retrieve the entire content from a table and buffer it in memory before dumping it. Buffering in memory can be a problem if you are dumping large tables. To dump tables row by row, use the `--quick` option (or `--opt`, which enables `--quick`). The `--opt` option (and hence `--quick`) is enabled by default, so to enable memory buffering, use `--skip-quick`.

If you are using a recent version of `mysqldump` to generate a dump to be reloaded into a very old MySQL server, you should not use the `--opt` or `--extended-insert` option. Use `--skip-opt` instead.

For additional information about `mysqldump`, see [Section 7.4, “Using `mysqldump` for Backups”](#).

`mysqldump` supports the following options, which can be specified on the command line or in the `[mysqldump]` and `[client]` groups of an option file. For information about option files, see [Section 4.2.6, “Using Option Files”](#).

Table 4.8 `mysqldump` Options

Format	Option File	Description	Introduced	Removed
<code>--add-drop-database</code>	<code>add-drop-database</code>	Add a DROP DATABASE statement before each CREATE DATABASE statement		
<code>--add-drop-table</code>	<code>add-drop-table</code>	Add a DROP TABLE statement before each CREATE TABLE statement		
<code>--add-locks</code>	<code>add-locks</code>	Surround each table dump with LOCK TABLES and UNLOCK TABLES statements		
<code>--all-databases</code>	<code>all-databases</code>	Dump all tables in all databases		
<code>--allow-keywords</code>	<code>allow-keywords</code>	Allow creation of column names that are keywords		
<code>--apply-slave-statements</code>	<code>apply-slave-statements</code>	Include STOP SLAVE prior to CHANGE MASTER statement and START SLAVE at end of output	5.5.3	
<code>--bind-address=ip_address</code>	<code>bind-address</code>	Use the specified network interface to connect to the MySQL Server	5.5.8	

Format	Option File	Description	Introduced	Removed
--comments	comments	Add comments to the dump file		
--compact	compact	Produce more compact output		
--compatible=name compatible=[name,...]	compatible	Produce output that is more compatible with other database systems or with older MySQL servers		
--complete-insert	complete-insert	Use complete INSERT statements that include column names		
--create-options	create-options	Include all MySQL-specific table options in CREATE TABLE statements		
--databases	databases	Dump several databases		
--debug debug[=debug_options]	debug	Write a debugging log		
--debug-check	debug-check	Print debugging information when the program exits		
--debug-info	debug-info	Print debugging information, memory and CPU statistics when the program exits		
--default-auth=plugin	default-auth=plugin	The authentication plugin to use	5.5.9	
--default-character-set=charset_name	default-character-set	Use charset_name as the default character set		
--defaults-extra-file=file_name		Read option file in addition to the usual option files		
--defaults-file=file_name		Read only the given option file		
--defaults-group-suffix=str		Option group suffix value		
--delayed-insert	delayed-insert	Write INSERT DELAYED statements rather than INSERT statements		
--delete-master-logs	delete-master-logs	On a master replication server, delete the binary logs after performing the dump operation		
--disable-keys	disable-keys	For each table, surround the INSERT statements with statements to disable and enable keys		
--dump-date	dump-date	Include dump date as "Dump completed on" comment if --comments is given		
--dump-slave[=value]	dump-slave	Include CHANGE MASTER statement that lists binary log coordinates of slave's master	5.5.3	
--events	events	Dump events from the dumped databases		
--extended-insert	extended-insert	Use multiple-row INSERT syntax that include several VALUES lists		

Format	Option File	Description	Introduced	Removed
--fields-enclosed-by=string	fields-enclosed-by	This option is used with the --tab option and has the same meaning as the corresponding clause for LOAD DATA INFILE		
--fields-escaped-by	fields-escaped-by	This option is used with the --tab option and has the same meaning as the corresponding clause for LOAD DATA INFILE		
--fields-optionally-enclosed-by=string	fields-optionally-enclosed-by	This option is used with the --tab option and has the same meaning as the corresponding clause for LOAD DATA INFILE		
--fields-terminated-by=string	fields-terminated-by	This option is used with the --tab option and has the same meaning as the corresponding clause for LOAD DATA INFILE		
--first-slave	first-slave	Deprecated; use --lock-all-tables instead		5.5.3
--flush-logs	flush-logs	Flush the MySQL server log files before starting the dump		
--flush-privileges	flush-privileges	Emit a FLUSH PRIVILEGES statement after dumping the mysql database		
--help		Display help message and exit		
--hex-blob	hex-blob	Dump binary columns using hexadecimal notation (for example, 'abc' becomes 0x616263)		
--host	host	Host to connect to (IP address or hostname)		
--ignore-table=db_name.tbl_name	ignore-table	Do not dump the given table		
--include-master-host-port	include-master-host-port	Include MASTER_HOST/MASTER_PORT options in CHANGE MASTER statement produced with --dump-slave	5.5.3	
--insert-ignore	insert-ignore	Write INSERT IGNORE statements rather than INSERT statements		
--lines-terminated-by=string	lines-terminated-by	This option is used with the --tab option and has the same meaning as the corresponding clause for LOAD DATA INFILE		
--lock-all-tables	lock-all-tables	Lock all tables across all databases		
--lock-tables	lock-tables	Lock all tables before dumping them		
--log-error=file_name	log-error	Append warnings and errors to the named file		
--master-data[=value]	master-data	Write the binary log file name and position to the output		
--max_allowed_packet=value	max_allowed_packet	The maximum packet length to send to or receive from the server		
--net_buffer_length=value	net_buffer_length	The buffer size for TCP/IP and socket communication		

Format	Option File	Description	Introduced	Removed
<code>--no-autocommit</code>	<code>no-autocommit</code>	Enclose the INSERT statements for each dumped table within SET autocommit = 0 and COMMIT statements		
<code>--no-create-db</code>	<code>no-create-db</code>	This option suppresses the CREATE DATABASE statements		
<code>--no-create-info</code>	<code>no-create-info</code>	Do not write CREATE TABLE statements that re-create each dumped table		
<code>--no-data</code>	<code>no-data</code>	Do not dump table contents		
<code>--no-defaults</code>		Do not read any option files		
<code>--no-set-names</code>	<code>no-set-names</code>	Same as --skip-set-charset		
<code>--no-tablespaces</code>	<code>no-tablespaces</code>	Do not write any CREATE LOGFILE GROUP or CREATE TABLESPACE statements in output		
<code>--opt</code>	<code>opt</code>	Shorthand for --add-drop-table --add-locks --create-options --disable-keys --extended-insert --lock-tables --quick --set-charset.		
<code>--order-by-primary</code>	<code>order-by-primary</code>	Dump each table's rows sorted by its primary key, or by its first unique index		
<code>--password[=password]</code>	<code>password</code>	The password to use when connecting to the server		
<code>--pipe</code>		On Windows, connect to server using a named pipe		
<code>--plugin-dir=path</code>	<code>plugin-dir=path</code>	The directory where plugins are located	5.5.9	
<code>--port=port_num</code>	<code>port</code>	The TCP/IP port number to use for the connection		
<code>--print-defaults</code>		Print defaults		
<code>--protocol=type</code>	<code>protocol</code>	The connection protocol to use		
<code>--quick</code>	<code>quick</code>	Retrieve rows for a table from the server a row at a time		
<code>--quote-names</code>	<code>quote-names</code>	Quote identifiers within backtick characters		
<code>--replace</code>	<code>replace</code>	Write REPLACE statements rather than INSERT statements		
<code>--result-file=file</code>	<code>result-file</code>	Direct output to a given file		
<code>--routines</code>	<code>routines</code>	Dump stored routines (procedures and functions) from the dumped databases		
<code>--set-charset</code>	<code>set-charset</code>	Add SET NAMES default_character_set to output		
<code>--single-transaction</code>	<code>single-transaction</code>	This option issues a BEGIN SQL statement before dumping data from the server		
<code>--skip-add-drop-table</code>	<code>skip-add-drop-table</code>	Do not add a DROP TABLE statement before each CREATE TABLE statement		
<code>--skip-add-locks</code>	<code>skip-add-locks</code>	Do not add locks		
<code>--skip-comments</code>	<code>skip-comments</code>	Do not add comments to the dump file		

Format	Option File	Description	Introduced	Removed
<code>--skip-compact</code>	<code>skip-compact</code>	Do not produce more compact output		
<code>--skip-disable-keys</code>	<code>skip-disable-keys</code>	Do not disable keys		
<code>--skip-extended-insert</code>	<code>skip-extended-insert</code>	Turn off extended-insert		
<code>--skip-opt</code>	<code>skip-opt</code>	Turn off the options set by <code>--opt</code>		
<code>--skip-quick</code>	<code>skip-quick</code>	Do not retrieve rows for a table from the server a row at a time		
<code>--skip-quote-names</code>	<code>skip-quote-names</code>	Do not quote identifiers		
<code>--skip-set-charset</code>	<code>skip-set-charset</code>	Suppress the SET NAMES statement		
<code>--skip-triggers</code>	<code>skip-triggers</code>	Do not dump triggers		
<code>--skip-tz-utc</code>	<code>skip-tz-utc</code>	Turn off tz-utc		
<code>--socket=path</code>	<code>socket</code>	For connections to localhost		
<code>--ssl-ca=file_name</code>	<code>ssl-ca</code>	The path to a file that contains a list of trusted SSL CAs		
<code>--ssl-capath=dir_name</code>	<code>ssl-capath</code>	The path to a directory that contains trusted SSL CA certificates in PEM format		
<code>--ssl-cert=file_name</code>	<code>ssl-cert</code>	The name of the SSL certificate file to use for establishing a secure connection		
<code>--ssl-cipher=cipher_list</code>	<code>ssl-cipher</code>	A list of allowable ciphers to use for SSL encryption		
<code>--ssl-key=file_name</code>	<code>ssl-key</code>	The name of the SSL key file to use for establishing a secure connection		
<code>--ssl-verify-server-cert</code>	<code>ssl-verify-server-cert</code>	The server's Common Name value in its certificate is verified against the host name used when connecting to the server		
<code>--tab=path</code>	<code>tab</code>	Produce tab-separated data files		
<code>--tables</code>	<code>tables</code>	Override the <code>--databases</code> or <code>-B</code> option		
<code>--triggers</code>	<code>triggers</code>	Dump triggers for each dumped table		
<code>--tz-utc</code>	<code>tz-utc</code>	Add SET TIME_ZONE='+00:00' to the dump file		
<code>--user=user_name</code>	<code>user</code>	MySQL user name to use when connecting to server		
<code>--verbose</code>		Verbose mode		
<code>--version</code>		Display version information and exit		
<code>--where='where_condition'</code>	<code>where</code>	Dump only rows selected by the given WHERE condition		
<code>--xml</code>	<code>xml</code>	Produce XML output		

- `--help, -?`

Display a help message and exit.

- `--add-drop-database`

Add a `DROP DATABASE` statement before each `CREATE DATABASE` statement. This option is typically used in conjunction with the `--all-databases` or `--databases` option because no `CREATE DATABASE` statements are written unless one of those options is specified.

- `--add-drop-table`

Add a `DROP TABLE` statement before each `CREATE TABLE` statement.

- `--add-drop-trigger`

Add a `DROP TRIGGER` statement before each `CREATE TRIGGER` statement.

**Note**

This option is supported only by `mysqldump` as supplied with MySQL Cluster. It is not available when using MySQL Server 5.5.

- `--add-locks`

Surround each table dump with `LOCK TABLES` and `UNLOCK TABLES` statements. This results in faster inserts when the dump file is reloaded. See [Section 8.2.2.1, “Speed of INSERT Statements”](#).

- `--all-databases, -A`

Dump all tables in all databases. This is the same as using the `--databases` option and naming all the databases on the command line.

- `--all-tablespaces, -Y`

Adds to a table dump all SQL statements needed to create any tablespaces used by an `NDBCLUSTER` table. This information is not otherwise included in the output from `mysqldump`. This option is currently relevant only to MySQL Cluster tables.

- `--allow-keywords`

Permit creation of column names that are keywords. This works by prefixing each column name with the table name.

- `--apply-slave-statements`

For a slave dump produced with the `--dump-slave` option, add a `STOP SLAVE` statement before the `CHANGE MASTER TO` statement and a `START SLAVE` statement at the end of the output. This option was added in MySQL 5.5.3.

- `--bind-address=ip_address`

On a computer having multiple network interfaces, this option can be used to select which interface is employed when connecting to the MySQL server.

This option is supported only in the version of `mysqldump` that is supplied with MySQL Cluster. It is not available in standard MySQL Server 5.5 releases.

- `--character-sets-dir=path`

The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).

- `--comments, -i`

Write additional information in the dump file such as program version, server version, and host. This option is enabled by default. To suppress this additional information, use `--skip-comments`.

- `--compact`

Produce more compact output. This option enables the `--skip-add-drop-table`, `--skip-add-locks`, `--skip-comments`, `--skip-disable-keys`, and `--skip-set-charset` options.

- `--compatible=name`

Produce output that is more compatible with other database systems or with older MySQL servers. The value of `name` can be `ansi`, `mysql323`, `mysql40`, `postgresql`, `oracle`, `mssql`, `db2`, `maxdb`, `no_key_options`, `no_table_options`, or `no_field_options`. To use several values, separate them by commas. These values have the same meaning as the corresponding options for setting the server SQL mode. See [Section 5.1.7, “Server SQL Modes”](#).

This option does not guarantee compatibility with other servers. It only enables those SQL mode values that are currently available for making dump output more compatible. For example, `--compatible=oracle` does not map data types to Oracle types or use Oracle comment syntax.

This option requires a server version of 4.1.0 or higher. With older servers, it does nothing.

- `--complete-insert, -c`

Use complete `INSERT` statements that include column names.

- `--compress, -C`

Compress all information sent between the client and the server if both support compression.

- `--create-options`

Include all MySQL-specific table options in the `CREATE TABLE` statements.

- `--databases, -B`

Dump several databases. Normally, `mysqldump` treats the first name argument on the command line as a database name and following names as table names. With this option, it treats all name arguments as database names. `CREATE DATABASE` and `USE` statements are included in the output before each new database.

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default value is `d:t:o,/tmp/mysqldump.trace`.

- `--debug-check`

Print some debugging information when the program exits.

- `--debug-info`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-auth=plugin`

The client-side authentication plugin to use. See [Section 6.3.6, “Pluggable Authentication”](#).

This option was added in MySQL 5.5.9.

- `--default-character-set=charset_name`

Use `charset_name` as the default character set. See [Section 10.5, “Character Set Configuration”](#). If no character set is specified, `mysqldump` uses `utf8`, and earlier versions use `latin1`.

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, `file_name` must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, `file_name` must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqldump` normally reads the `[client]` and `[mysqldump]` groups. If the `--defaults-group-suffix=_other` option is given, `mysqldump` also reads the `[client_other]` and `[mysqldump_other]` groups.

- `--delayed-insert`

Write `INSERT DELAYED` statements rather than `INSERT` statements.

- `--delete-master-logs`

On a master replication server, delete the binary logs by sending a `PURGE BINARY LOGS` statement to the server after performing the dump operation. This option automatically enables `--master-data`.

- `--disable-keys, -K`

For each table, surround the `INSERT` statements with `/*!40000 ALTER TABLE tbl_name DISABLE KEYS */;` and `/*!40000 ALTER TABLE tbl_name ENABLE KEYS */;` statements. This makes loading the dump file faster because the indexes are created after all rows are inserted. This option is effective only for nonunique indexes of `MyISAM` tables. It has no effect for other tables.

- `--dump-date`

If the `--comments` option is given, `mysqldump` produces a comment at the end of the dump of the following form:

```
-- Dump completed on DATE
```

However, the date causes dump files taken at different times to appear to be different, even if the data are otherwise identical. `--dump-date` and `--skip-dump-date` control whether the date is added to the comment. The default is `--dump-date` (include the date in the comment). `--skip-dump-date` suppresses date printing.

- `--dump-slave[=value]`

This option is similar to `--master-data` except that it is used to dump a replication slave server to produce a dump file that can be used to set up another server as a slave that has the same master as the dumped server. It causes the dump output to include a `CHANGE MASTER TO` statement that indicates the binary log coordinates (file name and position) of the dumped slave's master. These are the master server coordinates from which the slave should start replicating.

`--dump-slave` causes the coordinates from the master to be used rather than those of the dumped server, as is done by the `--master-data` option. In addition, specifying this option causes the `--master-data` option to be overridden, if used, and effectively ignored.

The option value is handled the same way as for `--master-data` (setting no value or 1 causes a `CHANGE MASTER TO` statement to be written to the dump, setting 2 causes the statement to be written but encased in SQL comments) and has the same effect as `--master-data` in terms of enabling or disabling other options and in how locking is handled.

This option causes `mysqldump` to stop the slave SQL thread before the dump and restart it again after.

In conjunction with `--dump-slave`, the `--apply-slave-statements` and `--include-master-host-port` options can also be used.

This option was added in MySQL 5.5.3.

- `--events, -E`

Include Event Scheduler events for the dumped databases in the output.

- `--extended-insert, -e`

Use multiple-row `INSERT` syntax that include several `VALUES` lists. This results in a smaller dump file and speeds up inserts when the file is reloaded.

- `--fields-terminated-by=...`, `--fields-enclosed-by=...`, `--fields-optionally-enclosed-by=...`, `--fields-escaped-by=...`

These options are used with the `--tab` option and have the same meaning as the corresponding `FIELDS` clauses for `LOAD DATA INFILE`. See [Section 13.2.6, “LOAD DATA INFILE Syntax”](#).

- `--first-slave`

Deprecated. Use `--lock-all-tables` instead. `--first-slave` was removed in MySQL 5.5.3.

- `--flush-logs, -F`

Flush the MySQL server log files before starting the dump. This option requires the `RELOAD` privilege. If you use this option in combination with the `--all-databases` option, the logs are flushed *for each database dumped*. The exception is when using `--lock-all-tables`, `--master-data`, or (as of MySQL 5.5.21) `--single-transaction`: In this case, the logs are flushed only once, corresponding to the moment that all tables are locked. If you want your dump and the log flush to happen at exactly the same moment, you should use `--flush-logs` together with `--lock-all-tables`, `--master-data`, or `--single-transaction`.

- `--flush-privileges`

Add a `FLUSH PRIVILEGES` statement to the dump output after dumping the `mysql` database. This option should be used any time the dump contains the `mysql` database and any other database that depends on the data in the `mysql` database for proper restoration.

- `--force, -f`

Continue even if an SQL error occurs during a table dump.

One use for this option is to cause `mysqldump` to continue executing even when it encounters a view that has become invalid because the definition refers to a table that has been dropped. Without `--force`, `mysqldump` exits with an error message. With `--force`, `mysqldump` prints the error message, but it also writes an SQL comment containing the view definition to the dump output and continues executing.

- `--host=host_name, -h host_name`

Dump data from the MySQL server on the given host. The default host is `localhost`.

- `--hex-blob`

Dump binary columns using hexadecimal notation (for example, `'abc'` becomes `0x616263`). The affected data types are `BINARY`, `VARBINARY`, the `BLOB` types, and `BIT`.

- `--include-master-host-port`

For the `CHANGE MASTER TO` statement in a slave dump produced with the `--dump-slave` option, add `MASTER_HOST` and `MASTER_PORT` options for the host name and TCP/IP port number of the slave's master. This option was added in MySQL 5.5.3.

- `--ignore-table=db_name.tbl_name`

Do not dump the given table, which must be specified using both the database and table names. To ignore multiple tables, use this option multiple times. This option also can be used to ignore views.

- `--insert-ignore`

Write `INSERT IGNORE` statements rather than `INSERT` statements.

- `--lines-terminated-by=...`

This option is used with the `--tab` option and has the same meaning as the corresponding `LINES` clause for `LOAD DATA INFILE`. See [Section 13.2.6, “LOAD DATA INFILE Syntax”](#).

- `--lock-all-tables, -x`

Lock all tables across all databases. This is achieved by acquiring a global read lock for the duration of the whole dump. This option automatically turns off `--single-transaction` and `--lock-tables`.

- `--lock-tables, -l`

For each dumped database, lock all tables to be dumped before dumping them. The tables are locked with `READ LOCAL` to permit concurrent inserts in the case of `MyISAM` tables. For transactional tables such as `InnoDB`, `--single-transaction` is a much better option than `--lock-tables` because it does not need to lock the tables at all.

Because `--lock-tables` locks tables for each database separately, this option does not guarantee that the tables in the dump file are logically consistent between databases. Tables in different databases may be dumped in completely different states.

- `--log-error=file_name`

Log warnings and errors by appending them to the named file. The default is to do no logging.

- `--master-data[=value]`

Use this option to dump a master replication server to produce a dump file that can be used to set up another server as a slave of the master. It causes the dump output to include a `CHANGE MASTER TO` statement that indicates the binary log coordinates (file name and position) of the dumped server. These are the master server coordinates from which the slave should start replicating after you load the dump file into the slave.

If the option value is 2, the `CHANGE MASTER TO` statement is written as an SQL comment, and thus is informative only; it has no effect when the dump file is reloaded. If the option value is 1, the statement is not written as a comment and takes effect when the dump file is reloaded. If no option value is specified, the default value is 1.

This option requires the `RELOAD` privilege and the binary log must be enabled.

The `--master-data` option automatically turns off `--lock-tables`. It also turns on `--lock-all-tables`, unless `--single-transaction` also is specified, in which case, a global read lock is acquired only for a short time at the beginning of the dump (see the description for `--single-transaction`). In all cases, any action on logs happens at the exact moment of the dump.

It is also possible to set up a slave by dumping an existing slave of the master. In MySQL 5.5.3 and later, you can create such a dump using the `--dump-slave` option, which overrides `--master-data` and causes it to be ignored if both options are used.

In MySQL 5.2.2 and earlier, use the following procedure on the existing slave:

1. Stop the slave's SQL thread and get its current status:

```
mysql> STOP SLAVE SQL_THREAD;
mysql> SHOW SLAVE STATUS;
```

2. From the output of the `SHOW SLAVE STATUS` statement, the binary log coordinates of the master server from which the new slave should start replicating are the values of the `Relay_Master_Log_File` and `Exec_Master_Log_Pos` fields. Denote those values as *file_name* and *file_pos*.
3. Dump the slave server:

```
shell> mysqldump --master-data=2 --all-databases > dumpfile
```

Using `--master-data=2` works only if binary logging has been enabled on the slave. Otherwise, `mysqldump` fails with the error `Binlogging on server not active`. In this case you must handle any locking issues in another manner, using one or more of `--add-locks`, `--lock-tables`, `--lock-all-tables`, or `--single-transaction`, as required by your application and environment.

4. Restart the slave:

```
mysql> START SLAVE;
```

5. On the new slave, load the dump file:

```
shell> mysql < dumpfile
```

6. On the new slave, set the replication coordinates to those of the master server obtained earlier:

```
mysql> CHANGE MASTER TO
-> MASTER_LOG_FILE = 'file_name', MASTER_LOG_POS = file_pos;
```

The `CHANGE MASTER TO` statement might also need other parameters, such as `MASTER_HOST` to point the slave to the correct master server host. Add any such parameters as necessary.

- `--no-autocommit`

Enclose the `INSERT` statements for each dumped table within `SET autocommit = 0` and `COMMIT` statements.

- `--no-create-db, -n`

This option suppresses the `CREATE DATABASE` statements that are otherwise included in the output if the `--databases` or `--all-databases` option is given.

- `--no-create-info, -t`

Do not write `CREATE TABLE` statements that re-create each dumped table.

Note

This option does *not* not exclude statements creating log file groups or tablespaces from `mysqldump` output; however, you can use the `--no-tablespaces` option for this purpose.

- `--no-data, -d`

Do not write any table row information (that is, do not dump table contents). This is useful if you want to dump only the `CREATE TABLE` statement for the table (for example, to create an empty copy of the table by loading the dump file).

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

- `--no-set-names, -N`

This has the same effect as `--skip-set-charset`.

- `--no-tablespaces, -y`

This option suppresses all `CREATE LOGFILE GROUP` and `CREATE TABLESPACE` statements in the output of `mysqldump`.

- `--opt`

This option is shorthand. It is the same as specifying `--add-drop-table --add-locks --create-options --disable-keys --extended-insert --lock-tables --quick --set-charset`. It should give you a fast dump operation and produce a dump file that can be reloaded into a MySQL server quickly.

The `--opt` option is enabled by default. Use `--skip-opt` to disable it. See the discussion at the beginning of this section for information about selectively enabling or disabling a subset of the options affected by `--opt`.

- `--order-by-primary`

Dump each table's rows sorted by its primary key, or by its first unique index, if such an index exists. This is useful when dumping a [MyISAM](#) table to be loaded into an [InnoDB](#) table, but will make the dump operation take considerably longer.

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, [mysqldump](#) prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe, -W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=path`

The directory in which to look for plugins. It may be necessary to specify this option if the `--default-auth` option is used to specify an authentication plugin but [mysqldump](#) does not find it. See [Section 6.3.6, “Pluggable Authentication”](#).

This option was added in MySQL 5.5.9.

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--quick, -q`

This option is useful for dumping large tables. It forces [mysqldump](#) to retrieve rows for a table from the server a row at a time rather than retrieving the entire row set and buffering it in memory before writing it out.

- `--quote-names, -Q`

Quote identifiers (such as database, table, and column names) within “`” characters. If the [ANSI_QUOTES](#) SQL mode is enabled, identifiers are quoted within “” characters. This option is enabled

by default. It can be disabled with `--skip-quote-names`, but this option should be given after any option such as `--compatible` that may enable `--quote-names`.

- `--replace`

Write `REPLACE` statements rather than `INSERT` statements.

- `--result-file=file_name, -r file_name`

Direct output to a given file. This option should be used on Windows to prevent newline “`\n`” characters from being converted to “`\r\n`” carriage return/newline sequences. The result file is created and its previous contents overwritten, even if an error occurs while generating the dump.

- `--routines, -R`

Include stored routines (procedures and functions) for the dumped databases in the output. Use of this option requires the `SELECT` privilege for the `mysql.proc` table. The output generated by using `--routines` contains `CREATE PROCEDURE` and `CREATE FUNCTION` statements to re-create the routines. However, these statements do not include attributes such as the routine creation and modification timestamps. This means that when the routines are reloaded, they will be created with the timestamps equal to the reload time.

If you require routines to be re-created with their original timestamp attributes, do not use `--routines`. Instead, dump and reload the contents of the `mysql.proc` table directly, using a MySQL account that has appropriate privileges for the `mysql` database.

Prior to MySQL 5.5.21, this option had no effect when used together with the `--xml` option. (Bug #11760384, Bug #52792)

- `--set-charset`

Add `SET NAMES default_character_set` to the output. This option is enabled by default. To suppress the `SET NAMES` statement, use `--skip-set-charset`.

- `--single-transaction`

This option sets the transaction isolation mode to `REPEATABLE READ` and sends a `START TRANSACTION` SQL statement to the server before dumping data. It is useful only with transactional tables such as `InnoDB`, because then it dumps the consistent state of the database at the time when `START TRANSACTION` was issued without blocking any applications.

When using this option, you should keep in mind that only `InnoDB` tables are dumped in a consistent state. For example, any `MyISAM` or `MEMORY` tables dumped while using this option may still change state.

While a `--single-transaction` dump is in process, to ensure a valid dump file (correct table contents and binary log coordinates), no other connection should use the following statements: `ALTER TABLE`, `CREATE TABLE`, `DROP TABLE`, `RENAME TABLE`, `TRUNCATE TABLE`. A consistent read is not isolated from those statements, so use of them on a table to be dumped can cause the `SELECT` that is performed by `mysqldump` to retrieve the table contents to obtain incorrect contents or fail.

The `--single-transaction` option and the `--lock-tables` option are mutually exclusive because `LOCK TABLES` causes any pending transactions to be committed implicitly.

This option is not supported for MySQL Cluster tables; the results cannot be guaranteed to be consistent due to the fact that the `NDBCLUSTER` storage engine supports only the `READ_COMMITTED` transaction isolation level. You should always use `NDB` backup and restore instead.

To dump large tables, combine the `--single-transaction` option with the `--quick` option.

- `--skip-comments`

See the description for the `--comments` option.

- `--skip-opt`

See the description for the `--opt` option.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.3.9.4, “SSL Command Options”](#).

- `--tab=path, -T path`

Produce tab-separated text-format data files. For each dumped table, `mysqldump` creates a `tbl_name.sql` file that contains the `CREATE TABLE` statement that creates the table, and the server writes a `tbl_name.txt` file that contains its data. The option value is the directory in which to write the files.

Note

This option should be used only when `mysqldump` is run on the same machine as the `mysqld` server. You must have the `FILE` privilege, and the server must have permission to write files in the directory that you specify.

By default, the `.txt` data files are formatted using tab characters between column values and a newline at the end of each line. The format can be specified explicitly using the `--fields-xxx` and `--lines-terminated-by` options.

Column values are converted to the character set specified by the `--default-character-set` option.

- `--tables`

Override the `--databases` or `-B` option. `mysqldump` regards all name arguments following the option as table names.

- `--triggers`

Include triggers for each dumped table in the output. This option is enabled by default; disable it with `--skip-triggers`.

- `--tz-utc`

This option enables `TIMESTAMP` columns to be dumped and reloaded between servers in different time zones. `mysqldump` sets its connection time zone to UTC and adds `SET TIME_ZONE='+00:00'` to the dump file. Without this option, `TIMESTAMP` columns are dumped and reloaded in the time zones local to the source and destination servers, which can cause the values to change if the servers are in different

time zones. `--tz-utc` also protects against changes due to daylight saving time. `--tz-utc` is enabled by default. To disable it, use `--skip-tz-utc`.

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

- `--verbose, -v`

Verbose mode. Print more information about what the program does.

- `--version, -V`

Display version information and exit.

- `--where='where_condition', -w 'where_condition'`

Dump only rows selected by the given `WHERE` condition. Quotes around the condition are mandatory if it contains spaces or other characters that are special to your command interpreter.

Examples:

```
--where="user='jimf'"
-w"userid>1"
-w"userid<1"
```

- `--xml, -X`

Write dump output as well-formed XML.

NULL, 'NULL', and Empty Values: For a column named `column_name`, the `NULL` value, an empty string, and the string value `'NULL'` are distinguished from one another in the output generated by this option as follows.

Value:	XML Representation:
<code>NULL</code> (<i>unknown value</i>)	<code><field name="column_name" xsi:nil="true" /></code>
<code>' '</code> (<i>empty string</i>)	<code><field name="column_name"></field></code>
<code>'NULL'</code> (<i>string value</i>)	<code><field name="column_name">NULL</field></code>

The output from the `mysql` client when run using the `--xml` option also follows the preceding rules. (See [Section 4.5.1.1, “mysql Options”](#).)

XML output from `mysqldump` includes the XML namespace, as shown here:

```
shell> mysqldump --xml -u root world City
<?xml version="1.0"?>
<mysqldump xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<database name="world">
<table_structure name="City">
<field Field="ID" Type="int(11)" Null="NO" Key="PRI" Extra="auto_increment" />
<field Field="Name" Type="char(35)" Null="NO" Key="" Default="" Extra="" />
<field Field="CountryCode" Type="char(3)" Null="NO" Key="" Default="" Extra="" />
<field Field="District" Type="char(20)" Null="NO" Key="" Default="" Extra="" />
<field Field="Population" Type="int(11)" Null="NO" Key="" Default="0" Extra="" />
<key Table="City" Non_unique="0" Key_name="PRIMARY" Seq_in_index="1" Column_name="ID"
```

```

Collation="A" Cardinality="4079" Null="" Index_type="BTREE" Comment="" />
<options Name="City" Engine="MyISAM" Version="10" Row_format="Fixed" Rows="4079"

<field name="ID">1</field>
<field name="Name">Kabul</field>
<field name="CountryCode">AFG</field>
<field name="District">Kabol</field>
<field name="Population">1780000</field>
</row>
...
<row>
<field name="ID">4079</field>
<field name="Name">Rafah</field>
<field name="CountryCode">PSE</field>
<field name="District">Rafah</field>
<field name="Population">92020</field>
</row>
</table_data>
</database>
</mysqldump>

```

Prior to MySQL 5.5.21, this option prevented the `--routines` option from working correctly—that is, no stored routines, triggers, or events could be dumped in XML format. (Bug #11760384, Bug #52792)

You can also set the following variables by using `--var_name=value` syntax:

- `max_allowed_packet`

The maximum size of the buffer for client/server communication. The default is 24MB, the maximum is 1GB.

- `net_buffer_length`

The initial size of the buffer for client/server communication. When creating multiple-row `INSERT` statements (as with the `--extended-insert` or `--opt` option), `mysqldump` creates rows up to `net_buffer_length` length. If you increase this variable, you should also ensure that the `net_buffer_length` variable in the MySQL server is at least this large.

Some options, such as `--opt`, automatically enable `--lock-tables`. If you want to override this, use `--skip-lock-tables` at the end of the option list.

A common use of `mysqldump` is for making a backup of an entire database:

```
shell> mysqldump db_name > backup-file.sql
```

You can load the dump file back into the server like this:

```
shell> mysql db_name < backup-file.sql
```

Or like this:

```
shell> mysql -e "source /path-to-backup/backup-file.sql" db_name
```

`mysqldump` is also very useful for populating databases by copying data from one MySQL server to another:

```
shell> mysqldump --opt db_name | mysql --host=remote_host -C db_name
```

It is possible to dump several databases with one command:

```
shell> mysqldump --databases db_name1 [db_name2 ...] > my_databases.sql
```

To dump all databases, use the `--all-databases` option:

```
shell> mysqldump --all-databases > all_databases.sql
```

For InnoDB tables, `mysqldump` provides a way of making an online backup:

```
shell> mysqldump --all-databases --single-transaction > all_databases.sql
```

This backup acquires a global read lock on all tables (using `FLUSH TABLES WITH READ LOCK`) at the beginning of the dump. As soon as this lock has been acquired, the binary log coordinates are read and the lock is released. If long updating statements are running when the `FLUSH` statement is issued, the MySQL server may get stalled until those statements finish. After that, the dump becomes lock free and does not disturb reads and writes on the tables. If the update statements that the MySQL server receives are short (in terms of execution time), the initial lock period should not be noticeable, even with many updates.

For point-in-time recovery (also known as “roll-forward,” when you need to restore an old backup and replay the changes that happened since that backup), it is often useful to rotate the binary log (see [Section 5.2.4, “The Binary Log”](#)) or at least know the binary log coordinates to which the dump corresponds:

```
shell> mysqldump --all-databases --master-data=2 > all_databases.sql
```

Or:

```
shell> mysqldump --all-databases --flush-logs --master-data=2  
> all_databases.sql
```

The `--master-data` and `--single-transaction` options can be used simultaneously, which provides a convenient way to make an online backup suitable for use prior to point-in-time recovery if tables are stored using the InnoDB storage engine.

For more information on making backups, see [Section 7.2, “Database Backup Methods”](#), and [Section 7.3, “Example Backup and Recovery Strategy”](#).

If you encounter problems backing up views, please read the section that covers restrictions on views which describes a workaround for backing up views when this fails due to insufficient privileges. See [Section D.5, “Restrictions on Views”](#).

4.5.5 `mysqlimport` — A Data Import Program

The `mysqlimport` client provides a command-line interface to the `LOAD DATA INFILE` SQL statement. Most options to `mysqlimport` correspond directly to clauses of `LOAD DATA INFILE` syntax. See [Section 13.2.6, “LOAD DATA INFILE Syntax”](#).

Invoke `mysqlimport` like this:

```
shell> mysqlimport [options] db_name textfile1 [textfile2 ...]
```

For each text file named on the command line, `mysqlimport` strips any extension from the file name and uses the result to determine the name of the table into which to import the file's contents. For example, files named `patient.txt`, `patient.text`, and `patient` all would be imported into a table named `patient`.

`mysqlimport` supports the following options, which can be specified on the command line or in the `[mysqlimport]` and `[client]` groups of an option file. For information about option files, see Section 4.2.6, “Using Option Files”.

Table 4.9 `mysqlimport` Options

Format	Option File	Description	Introduced
<code>--columns=column_list</code>	<code>columns</code>	This option takes a comma-separated list of column names as its value	
<code>--compress</code>	<code>compress</code>	Compress all information sent between the client and the server	
<code>--debug[=debug_options]</code>	<code>debug</code>	Write a debugging log	
<code>--debug-check</code>	<code>debug-check</code>	Print debugging information when the program exits	
<code>--debug-info</code>	<code>debug-info</code>	Print debugging information, memory and CPU statistics when the program exits	
<code>--default-auth=plugin</code>	<code>default-auth=plugin</code>	The authentication plugin to use	5.5.10
<code>--default-character-set=charset_name</code>	<code>default-character-set</code>	Use <code>charset_name</code> as the default character set	
<code>--defaults-extra-file=file_name</code>		Read option file in addition to the usual option files	
<code>--defaults-file=file_name</code>		Read only the given option file	
<code>--defaults-group-suffix=str</code>		Option group suffix value	
<code>--delete</code>	<code>delete</code>	Empty the table before importing the text file	
<code>--fields-enclosed-by=string</code>	<code>fields-enclosed-by</code>	This option has the same meaning as the corresponding clause for LOAD DATA INFILE	
<code>--fields-escaped-by</code>	<code>fields-escaped-by</code>	This option has the same meaning as the corresponding clause for LOAD DATA INFILE	
<code>--fields-optionally-enclosed-by=string</code>	<code>fields-optionally-enclosed-by</code>	This option has the same meaning as the corresponding clause for LOAD DATA INFILE	
<code>--fields-terminated-by=string</code>	<code>fields-terminated-by</code>	-- This option has the same meaning as the corresponding clause for LOAD DATA INFILE	
<code>--force</code>	<code>force</code>	Continue even if an SQL error occurs	
<code>--help</code>		Display help message and exit	
<code>--host=host_name</code>	<code>host</code>	Connect to the MySQL server on the given host	
<code>--ignore</code>	<code>ignore</code>	See the description for the <code>--replace</code> option	

Format	Option File	Description	Introduced
<code>--ignore-lines=#</code>	<code>ignore-lines</code>	Ignore the first N lines of the data file	
<code>--lines-terminated-by=string</code>	<code>lines-terminated-by</code>	This option has the same meaning as the corresponding clause for LOAD DATA INFILE	
<code>--local</code>	<code>local</code>	Read input files locally from the client host	
<code>--lock-tables</code>	<code>lock-tables</code>	Lock all tables for writing before processing any text files	
<code>--low-priority</code>	<code>low-priority</code>	Use LOW_PRIORITY when loading the table.	
<code>--no-defaults</code>		Do not read any option files	
<code>--password[=password]</code>	<code>password</code>	The password to use when connecting to the server	
<code>--pipe</code>		On Windows, connect to server using a named pipe	
<code>--plugin-dir=path</code>	<code>plugin-dir=path</code>	The directory where plugins are located	5.5.10
<code>--port=port_num</code>	<code>port</code>	The TCP/IP port number to use for the connection	
<code>--print-defaults</code>		Print defaults	
<code>--protocol=type</code>	<code>protocol</code>	The connection protocol to use	
<code>--replace</code>	<code>replace</code>	The <code>--replace</code> and <code>--ignore</code> options control handling of input rows that duplicate existing rows on unique key values	
<code>--silent</code>	<code>silent</code>	Produce output only when errors occur	
<code>--socket=path</code>	<code>socket</code>	For connections to localhost	
<code>--ssl-ca=file_name</code>	<code>ssl-ca</code>	The path to a file that contains a list of trusted SSL CAs	
<code>--ssl-capath=dir_name</code>	<code>ssl-capath</code>	The path to a directory that contains trusted SSL CA certificates in PEM format	
<code>--ssl-cert=file_name</code>	<code>ssl-cert</code>	The name of the SSL certificate file to use for establishing a secure connection	
<code>--ssl-cipher=cipher_list</code>	<code>ssl-cipher</code>	A list of allowable ciphers to use for SSL encryption	
<code>--ssl-key=file_name</code>	<code>ssl-key</code>	The name of the SSL key file to use for establishing a secure connection	
<code>--ssl-verify-server-cert</code>	<code>ssl-verify-server-cert</code>	The server's Common Name value in its certificate is verified against the host name used when connecting to the server	
<code>--use-threads=#</code>	<code>use-threads</code>	The number of threads for parallel file-loading	
<code>--user=user_name,</code>	<code>user</code>	MySQL user name to use when connecting to server	
<code>--verbose</code>		Verbose mode	
<code>--version</code>		Display version information and exit	

- `--help, -?`

Display a help message and exit.

- `--bind-address=ip_address`

On a computer having multiple network interfaces, this option can be used to select which interface is employed when connecting to the MySQL server.

This option is supported only in the version of `mysqlimport` that is supplied with MySQL Cluster. It is not available in standard MySQL Server 5.5 releases.

- `--character-sets-dir=path`

The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).

- `--columns=column_list, -c column_list`

This option takes a comma-separated list of column names as its value. The order of the column names indicates how to match data file columns with table columns.

- `--compress, -C`

Compress all information sent between the client and the server if both support compression.

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o`.

- `--debug-check`

Print some debugging information when the program exits.

- `--debug-info`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-character-set=charset_name`

Use `charset_name` as the default character set. See [Section 10.5, “Character Set Configuration”](#).

- `--default-auth=plugin`

The client-side authentication plugin to use. See [Section 6.3.6, “Pluggable Authentication”](#).

This option was added in MySQL 5.5.10.

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, `file_name` must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, `file_name` must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqlimport` normally reads the `[client]` and `[mysqlimport]` groups. If the `--`

`defaults-group-suffix=_other` option is given, `mysqlimport` also reads the `[client_other]` and `[mysqlimport_other]` groups.

- `--delete, -D`

Empty the table before importing the text file.

- `--fields-terminated-by=...`, `--fields-enclosed-by=...`, `--fields-optionally-enclosed-by=...`, `--fields-escaped-by=...`

These options have the same meaning as the corresponding clauses for `LOAD DATA INFILE`. See [Section 13.2.6, “LOAD DATA INFILE Syntax”](#).

- `--force, -f`

Ignore errors. For example, if a table for a text file does not exist, continue processing any remaining files. Without `--force`, `mysqlimport` exits if a table does not exist.

- `--host=host_name, -h host_name`

Import data to the MySQL server on the given host. The default host is `localhost`.

- `--ignore, -i`

See the description for the `--replace` option.

- `--ignore-lines=N`

Ignore the first `N` lines of the data file.

- `--lines-terminated-by=...`

This option has the same meaning as the corresponding clause for `LOAD DATA INFILE`. For example, to import Windows files that have lines terminated with carriage return/linefeed pairs, use `--lines-terminated-by="\r\n"`. (You might have to double the backslashes, depending on the escaping conventions of your command interpreter.) See [Section 13.2.6, “LOAD DATA INFILE Syntax”](#).

- `--local, -L`

Read input files locally from the client host.

- `--lock-tables, -l`

Lock *all* tables for writing before processing any text files. This ensures that all tables are synchronized on the server.

- `--low-priority`

Use `LOW_PRIORITY` when loading the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysqlimport` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe, -W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=path`

The directory in which to look for plugins. It may be necessary to specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlimport` does not find it. See [Section 6.3.6, “Pluggable Authentication”](#).

This option was added in MySQL 5.5.10.

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--replace, -r`

The `--replace` and `--ignore` options control handling of input rows that duplicate existing rows on unique key values. If you specify `--replace`, new rows replace existing rows that have the same unique key value. If you specify `--ignore`, input rows that duplicate an existing row on a unique key value are skipped. If you do not specify either option, an error occurs when a duplicate key value is found, and the rest of the text file is ignored.

- `--silent, -s`

Silent mode. Produce output only when errors occur.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.3.9.4, “SSL Command Options”](#).

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

- `--use-threads=N`

Load files in parallel using *N* threads.

- `--verbose, -v`

Verbose mode. Print more information about what the program does.

- `--version, -V`

Display version information and exit.

Here is a sample session that demonstrates use of `mysqlimport`:

```
shell> mysql -e 'CREATE TABLE impptest(id INT, n VARCHAR(30))' test
shell> ed
a
100      Max Sydow
101      Count Dracula
.
w impptest.txt
32
q
shell> od -c impptest.txt
0000000  1  0  0  \t  M  a  x           S  y  d  o  w  \n  1  0
0000020  1  \t  C  o  u  n  t           D  r  a  c  u  l  a  \n
0000040
shell> mysqlimport --local test impptest.txt
test.impptest: Records: 2 Deleted: 0 Skipped: 0 Warnings: 0
shell> mysql -e 'SELECT * FROM impptest' test
+-----+-----+
| id  | n                |
+-----+-----+
| 100 | Max Sydow        |
| 101 | Count Dracula    |
+-----+-----+
```

4.5.6 mysqlshow — Display Database, Table, and Column Information

The `mysqlshow` client can be used to quickly see which databases exist, their tables, or a table's columns or indexes.

`mysqlshow` provides a command-line interface to several SQL `SHOW` statements. See [Section 13.7.5, “SHOW Syntax”](#). The same information can be obtained by using those statements directly. For example, you can issue them from the `mysql` client program.

Invoke `mysqlshow` like this:

```
shell> mysqlshow [options] [db_name [tbl_name [col_name]]]
```

- If no database is given, a list of database names is shown.
- If no table is given, all matching tables in the database are shown.
- If no column is given, all matching columns and column types in the table are shown.

The output displays only the names of those databases, tables, or columns for which you have some privileges.

If the last argument contains shell or SQL wildcard characters (“*”, “?”, “%”, or “_”), only those names that are matched by the wildcard are shown. If a database name contains any underscores, those should be escaped with a backslash (some Unix shells require two) to get a list of the proper tables or columns. “*” and “?” characters are converted into SQL “%” and “_” wildcard characters. This might cause some confusion when you try to display the columns for a table with a “_” in the name, because in this case, `mysqlshow` shows you only the table names that match the pattern. This is easily fixed by adding an extra “%” last on the command line as a separate argument.

`mysqlshow` supports the following options, which can be specified on the command line or in the `[mysqlshow]` and `[client]` groups of an option file. For information about option files, see Section 4.2.6, “Using Option Files”.

Table 4.10 `mysqlshow` Options

Format	Option File	Description	Introduced
<code>--bind-address=ip_address</code>	<code>bind-address</code>	Use the specified network interface to connect to the MySQL Server	5.5.8
<code>--compress</code>	<code>compress</code>	Compress all information sent between the client and the server	
<code>--count</code>	<code>count</code>	Show the number of rows per table	
<code>--debug[=debug_options]</code>	<code>debug</code>	Write a debugging log	
<code>--debug-check</code>	<code>debug-check</code>	Print debugging information when the program exits	
<code>--debug-info</code>	<code>debug-info</code>	Print debugging information, memory and CPU statistics when the program exits	
<code>--default-auth=plugin</code>	<code>default-auth=plugin</code>	The authentication plugin to use	5.5.10
<code>--default-character-set=charset_name</code>	<code>default-character-set</code>	Use <code>charset_name</code> as the default character set	
<code>--defaults-extra-file=file_name</code>		Read option file in addition to the usual option files	
<code>--defaults-file=file_name</code>		Read only the given option file	
<code>--defaults-group-suffix=str</code>		Option group suffix value	
<code>--help</code>		Display help message and exit	
<code>--host=host_name</code>	<code>host</code>	Connect to the MySQL server on the given host	
<code>--keys</code>	<code>keys</code>	Show table indexes	
<code>--no-defaults</code>		Do not read any option files	
<code>--password[=password]</code>	<code>password</code>	The password to use when connecting to the server	
<code>--pipe</code>		On Windows, connect to server using a named pipe	
<code>--plugin-dir=path</code>	<code>plugin-dir=path</code>	The directory where plugins are located	5.5.10
<code>--port=port_num</code>	<code>port</code>	The TCP/IP port number to use for the connection	
<code>--print-defaults</code>		Print defaults	

Format	Option File	Description	Introduced
<code>--protocol=type</code>	<code>protocol</code>	The connection protocol to use	
<code>--show-table-type</code>		Show a column indicating the table type	
<code>--socket=path</code>	<code>socket</code>	For connections to localhost	
<code>--ssl-ca=file_name</code>	<code>ssl-ca</code>	The path to a file that contains a list of trusted SSL CAs	
<code>--ssl-capath=dir_name</code>	<code>ssl-capath</code>	The path to a directory that contains trusted SSL CA certificates in PEM format	
<code>--ssl-cert=file_name</code>	<code>ssl-cert</code>	The name of the SSL certificate file to use for establishing a secure connection	
<code>--ssl-cipher=cipher_list</code>	<code>ssl-cipher</code>	A list of allowable ciphers to use for SSL encryption	
<code>--ssl-key=file_name</code>	<code>ssl-key</code>	The name of the SSL key file to use for establishing a secure connection	
<code>--ssl-verify-server-cert</code>	<code>ssl-verify-server-cert</code>	The server's Common Name value in its certificate is verified against the host name used when connecting to the server	
<code>--status</code>	<code>status</code>	Display extra information about each table	
<code>--user=user_name,</code>	<code>user</code>	MySQL user name to use when connecting to server	
<code>--verbose</code>		Verbose mode	
<code>--version</code>		Display version information and exit	

- `--help, -?`

Display a help message and exit.

- `--bind-address=ip_address`

On a computer having multiple network interfaces, this option can be used to select which interface is employed when connecting to the MySQL server.

This option is supported only in the version of `mysqlshow` that is supplied with MySQL Cluster. It is not available in standard MySQL Server 5.5 releases.

- `--character-sets-dir=path`

The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).

- `--compress, -C`

Compress all information sent between the client and the server if both support compression.

- `--count`

Show the number of rows per table. This can be slow for non-`MyISAM` tables.

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o`.

- `--debug-check`

Print some debugging information when the program exits.

- `--debug-info`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-character-set=charset_name`

Use *charset_name* as the default character set. See [Section 10.5, “Character Set Configuration”](#).

- `--default-auth=plugin`

The client-side authentication plugin to use. See [Section 6.3.6, “Pluggable Authentication”](#).

This option was added in MySQL 5.5.10.

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, *file_name* must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, *file_name* must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of *str*. For example, `mysqlshow` normally reads the `[client]` and `[mysqlshow]` groups. If the `--defaults-group-suffix=_other` option is given, `mysqlshow` also reads the `[client_other]` and `[mysqlshow_other]` groups.

- `--host=host_name, -h host_name`

Connect to the MySQL server on the given host.

- `--keys, -k`

Show table indexes.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the *password* value following the `--password` or `-p` option on the command line, `mysqlshow` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe, -W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=path`

The directory in which to look for plugins. It may be necessary to specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlshow` does not find it. See [Section 6.3.6, “Pluggable Authentication”](#).

This option was added in MySQL 5.5.10.

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--show-table-type, -t`

Show a column indicating the table type, as in `SHOW FULL TABLES`. The type is `BASE TABLE` or `VIEW`.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.3.9.4, “SSL Command Options”](#).

- `--status, -i`

Display extra information about each table.

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

- `--verbose, -v`

Verbose mode. Print more information about what the program does. This option can be used multiple times to increase the amount of information.

- `--version, -V`

Display version information and exit.

4.5.7 mysqlslap — Load Emulation Client

`mysqlslap` is a diagnostic program designed to emulate client load for a MySQL server and to report the timing of each stage. It works as if multiple clients are accessing the server.

Invoke `mysqlslap` like this:

```
shell> mysqlslap [options]
```

Some options such as `--create` or `--query` enable you to specify a string containing an SQL statement or a file containing statements. If you specify a file, by default it must contain one statement per line. (That is, the implicit statement delimiter is the newline character.) Use the `--delimiter` option to specify a different delimiter, which enables you to specify statements that span multiple lines or place multiple statements on a single line. You cannot include comments in a file; `mysqlslap` does not understand them.

`mysqlslap` runs in three stages:

1. Create schema, table, and optionally any stored programs or data to use for the test. This stage uses a single client connection.
2. Run the load test. This stage can use many client connections.
3. Clean up (disconnect, drop table if specified). This stage uses a single client connection.

Examples:

Supply your own create and query SQL statements, with 50 clients querying and 200 selects for each (enter the command on a single line):

```
mysqlslap --delimiter=";"
--create="CREATE TABLE a (b int);INSERT INTO a VALUES (23)"
--query="SELECT * FROM a" --concurrency=50 --iterations=200
```

Let `mysqlslap` build the query SQL statement with a table of two `INT` columns and three `VARCHAR` columns. Use five clients querying 20 times each. Do not create the table or insert the data (that is, use the previous test's schema and data):

```
mysqlslap --concurrency=5 --iterations=20
--number-int-cols=2 --number-char-cols=3
--auto-generate-sql
```

Tell the program to load the create, insert, and query SQL statements from the specified files, where the `create.sql` file has multiple table creation statements delimited by `;` and multiple insert statements delimited by `;`. The `--query` file will have multiple queries delimited by `;`. Run all the load statements, then run all the queries in the query file with five clients (five times each):

```
mysqlslap --concurrency=5
--iterations=5 --query=query.sql --create=create.sql
--delimiter=";"
```

`mysqlslap` supports the following options, which can be specified on the command line or in the `[mysqlslap]` and `[client]` groups of an option file. For information about option files, see [Section 4.2.6, “Using Option Files”](#).

Table 4.11 `mysqlslap` Options

Format	Option File	Description	Introduced
<code>--auto-generate-sql</code>	<code>auto-generate-sql</code>	Generate SQL statements automatically when they are not supplied in files or using command options	

Format	Option File	Description	Introduced
<code>--auto-generate-sql-add-autoincrement</code>	<code>auto-generate-sql-add-autoincrement</code>	Add AUTO_INCREMENT column to automatically generated tables	
<code>--auto-generate-sql-execute-number=#</code>	<code>auto-generate-sql-execute-number</code>	Specify how many queries to generate automatically	
<code>--auto-generate-sql-guid-primary</code>	<code>auto-generate-sql-guid-primary</code>	Add a GUID-based primary key to automatically generated tables	
<code>--auto-generate-sql-load-type=type</code>	<code>auto-generate-sql-load-type</code>	Specify how many queries to generate automatically	
<code>--auto-generate-sql-secondary-indexes=#</code>	<code>auto-generate-sql-secondary-indexes</code>	Specify how many secondary indexes to add to automatically generated tables	
<code>--auto-generate-sql-unique-query-number=#</code>	<code>auto-generate-sql-unique-query-number</code>	How many different queries to generate for automatic tests.	
<code>--auto-generate-sql-unique-write-number=#</code>	<code>auto-generate-sql-unique-write-number</code>	How many different queries to generate for <code>--auto-generate-sql-write-number</code>	
<code>--auto-generate-sql-write-number=#</code>	<code>auto-generate-sql-write-number</code>	How many row inserts to perform on each thread	
<code>--commit=#</code>	<code>commit</code>	How many statements to execute before committing.	
<code>--compress</code>	<code>compress</code>	Compress all information sent between the client and the server	
<code>--concurrency=#</code>	<code>concurrency</code>	The number of clients to simulate when issuing the SELECT statement	
<code>--create=value</code>	<code>create</code>	The file or string containing the statement to use for creating the table	
<code>--create-schema=value</code>	<code>create-schema</code>	The schema in which to run the tests	
<code>--csv=[file]</code>	<code>csv</code>	Generate output in comma-separated values format	
<code>--debug[=debug_options]</code>	<code>debug</code>	Write a debugging log	
<code>--debug-check</code>	<code>debug-check</code>	Print debugging information when the program exits	
<code>--debug-info</code>	<code>debug-info</code>	Print debugging information, memory and CPU statistics when the program exits	
<code>--default-auth=plugin</code>	<code>default-auth=plugin</code>	The authentication plugin to use	5.5.10
<code>--defaults-extra-file=file_name</code>		Read option file in addition to the usual option files	
<code>--defaults-file=file_name</code>		Read only the given option file	

Format	Option File	Description	Introduced
--defaults-group-suffix=str		Option group suffix value	
--delimiter=str	delimiter	The delimiter to use in SQL statements	
--detach=#	detach	Detach (close and reopen) each connection after each N statements	
--enable-cleartext-plugin	enable-cleartext-plugin	Enable cleartext authentication plugin	5.5.27
--engine=engine_name	engine	The storage engine to use for creating the table	
--help		Display help message and exit	
--host=host_name	host	Connect to the MySQL server on the given host	
--iterations=#	iterations	The number of times to run the tests	
--no-defaults		Do not read any option files	
--no-drop	no-drop	Do not drop any schema created during the test run	5.5.12
--number-char-cols=#	number-char-cols	The number of VARCHAR columns to use if --auto-generate-sql is specified	
--number-int-cols=#	number-int-cols	The number of INT columns to use if --auto-generate-sql is specified	
--number-of-queries=#	number-of-queries	Limit each client to approximately this number of queries	
--only-print	only-print	Do not connect to databases. mysqlslap only prints what it would have done	
--password[=password]	password	The password to use when connecting to the server	
--pipe		On Windows, connect to server using a named pipe	
--plugin-dir=path	plugin-dir=path	The directory where plugins are located	5.5.10
--port=port_num	port	The TCP/IP port number to use for the connection	
--post-query=value	post-query	The file or string containing the statement to execute after the tests have completed	
--post-system=str	post-system	The string to execute using system() after the tests have completed	
--pre-query=value	pre-query	The file or string containing the statement to execute before running the tests	
--pre-system=str	pre-system	The string to execute using system() before running the tests	
--print-defaults		Print defaults	
--protocol=type	protocol	The connection protocol to use	
--query=value	query	The file or string containing the SELECT statement to use for retrieving data	
--silent	silent	Silent mode	
--socket=path	socket	For connections to localhost	

Format	Option File	Description	Introduced
<code>--ssl-ca=file_name</code>	<code>ssl-ca</code>	The path to a file that contains a list of trusted SSL CAs	
<code>--ssl-capath=dir_name</code>	<code>ssl-capath</code>	The path to a directory that contains trusted SSL CA certificates in PEM format	
<code>--ssl-cert=file_name</code>	<code>ssl-cert</code>	The name of the SSL certificate file to use for establishing a secure connection	
<code>--ssl-cipher=cipher_list</code>	<code>ssl-cipher</code>	A list of allowable ciphers to use for SSL encryption	
<code>--ssl-key=file_name</code>	<code>ssl-key</code>	The name of the SSL key file to use for establishing a secure connection	
<code>--ssl-verify-server-cert</code>	<code>ssl-verify-server-cert</code>	The server's Common Name value in its certificate is verified against the host name used when connecting to the server	
<code>--user=user_name,</code>	<code>user</code>	MySQL user name to use when connecting to server	
<code>--verbose</code>		Verbose mode	
<code>--version</code>		Display version information and exit	

- `--help, -?`

Display a help message and exit.

- `--auto-generate-sql, -a`

Generate SQL statements automatically when they are not supplied in files or using command options.

- `--auto-generate-sql-add-autoincrement`

Add an `AUTO_INCREMENT` column to automatically generated tables.

- `--auto-generate-sql-execute-number=N`

Specify how many queries to generate automatically.

- `--auto-generate-sql-guid-primary`

Add a GUID-based primary key to automatically generated tables.

- `--auto-generate-sql-load-type=type`

Specify the test load type. The permissible values are `read` (scan tables), `write` (insert into tables), `key` (read primary keys), `update` (update primary keys), or `mixed` (half inserts, half scanning selects). The default is `mixed`.

- `--auto-generate-sql-secondary-indexes=N`

Specify how many secondary indexes to add to automatically generated tables. By default, none are added.

- `--auto-generate-sql-unique-query-number=N`

How many different queries to generate for automatic tests. For example, if you run a [key](#) test that performs 1000 selects, you can use this option with a value of 1000 to run 1000 unique queries, or with a value of 50 to perform 50 different selects. The default is 10.

- `--auto-generate-sql-unique-write-number=N`

How many different queries to generate for `--auto-generate-sql-write-number`. The default is 10.

- `--auto-generate-sql-write-number=N`

How many row inserts to perform on each thread. The default is 100.

- `--commit=N`

How many statements to execute before committing. The default is 0 (no commits are done).

- `--compress, -C`

Compress all information sent between the client and the server if both support compression.

- `--concurrency=N, -c N`

The number of clients to simulate when issuing the [SELECT](#) statement.

- `--create=value`

The file or string containing the statement to use for creating the table.

- `--create-schema=value`

The schema in which to run the tests.

**Note**

If the `--auto-generate-sql` option is also given, `mysqlslap` drops the schema at the end of the test run. To avoid this, use the `--no-drop` option as well.

- `--csv[=file_name]`

Generate output in comma-separated values format. The output goes to the named file, or to the standard output if no file is given.

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysqlslap.trace`.

- `--debug-check`

Print some debugging information when the program exits.

- `--debug-info, -T`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-auth=plugin`

The client-side authentication plugin to use. See [Section 6.3.6, “Pluggable Authentication”](#).

This option was added in MySQL 5.5.10.

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, `file_name` must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, `file_name` must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqlslap` normally reads the `[client]` and `[mysqlslap]` groups. If the `--defaults-group-suffix=_other` option is given, `mysqlslap` also reads the `[client_other]` and `[mysqlslap_other]` groups.

- `--delimiter=str, -F str`

The delimiter to use in SQL statements supplied in files or using command options.

- `--detach=N`

Detach (close and reopen) each connection after each `N` statements. The default is 0 (connections are not detached).

- `--enable-cleartext-plugin`

Enable the `mysql_clear_password` cleartext authentication plugin. (See [Section 6.3.7.5, “The Cleartext Client-Side Authentication Plugin”](#).) This option was added in MySQL 5.5.27.

- `--engine=engine_name, -e engine_name`

The storage engine to use for creating tables.

- `--host=host_name, -h host_name`

Connect to the MySQL server on the given host.

- `--iterations=N, -i N`

The number of times to run the tests.

- `--no-drop`

Prevent `mysqlslap` from dropping any schema it creates during the test run. This option was added in MySQL 5.5.12.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

- `--number-char-cols=N, -x N`

The number of `VARCHAR` columns to use if `--auto-generate-sql` is specified.

- `--number-int-cols=N, -y N`

The number of `INT` columns to use if `--auto-generate-sql` is specified.

- `--number-of-queries=N`

Limit each client to approximately this many queries. Query counting takes into account the statement delimiter. For example, if you invoke `mysqlslap` as follows, the `;` delimiter is recognized so that each instance of the query string counts as two queries. As a result, 5 rows (not 10) are inserted.

```
shell> mysqlslap --delimiter=";" --number-of-queries=10
      --query="use test;insert into t values(null)"
```

- `--only-print`

Do not connect to databases. `mysqlslap` only prints what it would have done.

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysqlslap` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--pipe, -W`

On Windows, connect to the server using a named pipe. This option applies only if the server supports named-pipe connections.

- `--plugin-dir=path`

The directory in which to look for plugins. It may be necessary to specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlslap` does not find it. See [Section 6.3.6, “Pluggable Authentication”](#).

This option was added in MySQL 5.5.10.

- `--port=port_num, -P port_num`

The TCP/IP port number to use for the connection.

- `--post-query=value`

The file or string containing the statement to execute after the tests have completed. This execution is not counted for timing purposes.

- `--post-system=str`

The string to execute using `system()` after the tests have completed. This execution is not counted for timing purposes.

- `--pre-query=value`

The file or string containing the statement to execute before running the tests. This execution is not counted for timing purposes.

- `--pre-system=str`

The string to execute using `system()` before running the tests. This execution is not counted for timing purposes.

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--query=value, -q value`

The file or string containing the `SELECT` statement to use for retrieving data.

- `--shared-memory-base-name=name`

On Windows, the shared-memory name to use, for connections made using shared memory to a local server. This option applies only if the server supports shared-memory connections.

- `--silent, -s`

Silent mode. No output.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--ssl*`

Options that begin with `--ssl` specify whether to connect to the server using SSL and indicate where to find SSL keys and certificates. See [Section 6.3.9.4, “SSL Command Options”](#).

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

- `--verbose, -v`

Verbose mode. Print more information about what the program does. This option can be used multiple times to increase the amount of information.

- `--version, -V`

Display version information and exit.

4.6 MySQL Administrative and Utility Programs

This section describes administrative programs and programs that perform miscellaneous utility operations.

4.6.1 `innochecksum` — Offline InnoDB File Checksum Utility

`innochecksum` prints checksums for `InnoDB` files. This tool reads an `InnoDB` tablespace file, calculates the checksum for each page, compares the calculated checksum to the stored checksum, and reports mismatches, which indicate damaged pages. It was originally developed to speed up verifying the integrity of tablespace files after power outages but can also be used after file copies. Because checksum mismatches will cause `InnoDB` to deliberately shut down a running server, it can be preferable to use this tool rather than waiting for a server in production usage to encounter the damaged pages. `innochecksum` supports files up to 2GB in size.

`innochecksum` cannot be used on tablespace files that the server already has open. For such files, you should use `CHECK TABLE` to check tables within the tablespace.

If checksum mismatches are found, you would normally restore the tablespace from backup or start the server and attempt to use `mysqldump` to make a backup of the tables within the tablespace.

Invoke `innochecksum` like this:

```
shell> innochecksum [options] file_name
```

`innochecksum` supports the following options. For options that refer to page numbers, the numbers are zero-based.

- `-c`
Print a count of the number of pages in the file.
- `-d`
Debug mode; prints checksums for each page.
- `-e num`
End at this page number.
- `-p num`
Check only this page number.
- `-s num`
Start at this page number.
- `-v`
Verbose mode; print a progress indicator every five seconds.

4.6.2 `myisam_ftdump` — Display Full-Text Index information

`myisam_ftdump` displays information about `FULLTEXT` indexes in `MyISAM` tables. It reads the `MyISAM` index file directly, so it must be run on the server host where the table is located. Before using `myisam_ftdump`, be sure to issue a `FLUSH TABLES` statement first if the server is running.

`myisam_ftdump` scans and dumps the entire index, which is not particularly fast. On the other hand, the distribution of words changes infrequently, so it need not be run often.

Invoke `myisam_ftdump` like this:

```
shell> myisam_ftdump [options] tbl_name index_num
```

The `tbl_name` argument should be the name of a `MyISAM` table. You can also specify a table by naming its index file (the file with the `.MYI` suffix). If you do not invoke `myisam_ftdump` in the directory where the table files are located, the table or index file name must be preceded by the path name to the table's database directory. Index numbers begin with 0.

Example: Suppose that the `test` database contains a table named `mytexttable` that has the following definition:

```
CREATE TABLE mytexttable
(
  id    INT NOT NULL,
  txt   TEXT NOT NULL,
  PRIMARY KEY (id),
  FULLTEXT (txt)
) ENGINE=MyISAM;
```

The index on `id` is index 0 and the `FULLTEXT` index on `txt` is index 1. If your working directory is the `test` database directory, invoke `myisam_ftdump` as follows:

```
shell> myisam_ftdump mytexttable 1
```

If the path name to the `test` database directory is `/usr/local/mysql/data/test`, you can also specify the table name argument using that path name. This is useful if you do not invoke `myisam_ftdump` in the database directory:

```
shell> myisam_ftdump /usr/local/mysql/data/test/mytexttable 1
```

You can use `myisam_ftdump` to generate a list of index entries in order of frequency of occurrence like this:

```
shell> myisam_ftdump -c mytexttable 1 | sort -r
```

`myisam_ftdump` supports the following options:

- `--help, -h -?`
Display a help message and exit.
- `--count, -c`
Calculate per-word statistics (counts and global weights).
- `--dump, -d`
Dump the index, including data offsets and word weights.
- `--length, -l`
Report the length distribution.
- `--stats, -s`

Report global index statistics. This is the default operation if no other operation is specified.

- `--verbose, -v`

Verbose mode. Print more output about what the program does.

4.6.3 myisamchk — MyISAM Table-Maintenance Utility

The `myisamchk` utility gets information about your database tables or checks, repairs, or optimizes them. `myisamchk` works with MyISAM tables (tables that have `.MYD` and `.MYI` files for storing data and indexes).

You can also use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair MyISAM tables. See [Section 13.7.2.2, “CHECK TABLE Syntax”](#), and [Section 13.7.2.5, “REPAIR TABLE Syntax”](#).

The use of `myisamchk` with partitioned tables is not supported.

Caution

It is best to make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors.

Invoke `myisamchk` like this:

```
shell> myisamchk [options] tbl_name ...
```

The `options` specify what you want `myisamchk` to do. They are described in the following sections. You can also get a list of options by invoking `myisamchk --help`.

With no options, `myisamchk` simply checks your table as the default operation. To get more information or to tell `myisamchk` to take corrective action, specify options as described in the following discussion.

`tbl_name` is the database table you want to check or repair. If you run `myisamchk` somewhere other than in the database directory, you must specify the path to the database directory, because `myisamchk` has no idea where the database is located. In fact, `myisamchk` does not actually care whether the files you are working on are located in a database directory. You can copy the files that correspond to a database table into some other location and perform recovery operations on them there.

You can name several tables on the `myisamchk` command line if you wish. You can also specify a table by naming its index file (the file with the `.MYI` suffix). This enables you to specify all tables in a directory by using the pattern `*.MYI`. For example, if you are in a database directory, you can check all the MyISAM tables in that directory like this:

```
shell> myisamchk *.MYI
```

If you are not in the database directory, you can check all the tables there by specifying the path to the directory:

```
shell> myisamchk /path/to/database_dir/*.MYI
```

You can even check all tables in all databases by specifying a wildcard with the path to the MySQL data directory:

```
shell> myisamchk /path/to/datadir/*/*.MYI
```

The recommended way to quickly check all [MyISAM](#) tables is:

```
shell> myisamchk --silent --fast /path/to/datadir/*/*.MYI
```

If you want to check all [MyISAM](#) tables and repair any that are corrupted, you can use the following command:

```
shell> myisamchk --silent --force --fast --update-state \
  --key_buffer_size=64M --myisam_sort_buffer_size=64M \
  --read_buffer_size=1M --write_buffer_size=1M \
  /path/to/datadir/*/*.MYI
```

This command assumes that you have more than 64MB free. For more information about memory allocation with [myisamchk](#), see [Section 4.6.3.6, “myisamchk Memory Usage”](#).

For additional information about using [myisamchk](#), see [Section 7.6, “MyISAM Table Maintenance and Crash Recovery”](#).

Important

You must ensure that no other program is using the tables while you are running [myisamchk](#). The most effective means of doing so is to shut down the MySQL server while running [myisamchk](#), or to lock all tables that [myisamchk](#) is being used on.

Otherwise, when you run [myisamchk](#), it may display the following error message:

```
warning: clients are using or haven't closed the table properly
```

This means that you are trying to check a table that has been updated by another program (such as the [mysqld](#) server) that hasn't yet closed the file or that has died without closing the file properly, which can sometimes lead to the corruption of one or more [MyISAM](#) tables.

If [mysqld](#) is running, you must force it to flush any table modifications that are still buffered in memory by using [FLUSH TABLES](#). You should then ensure that no one is using the tables while you are running [myisamchk](#).

However, the easiest way to avoid this problem is to use [CHECK TABLE](#) instead of [myisamchk](#) to check tables. See [Section 13.7.2.2, “CHECK TABLE Syntax”](#).

[myisamchk](#) supports the following options, which can be specified on the command line or in the [\[myisamchk\]](#) group of an option file. For information about option files, see [Section 4.2.6, “Using Option Files”](#).

Table 4.12 [myisamchk](#) Options

Format	Option File	Description	Introduced	Deprecated
--analyze	analyze	Analyze the distribution of key values		
--backup	backup	Make a backup of the .MYD file as file_name-time.BAK		
--block-search=offset	block-search	Find the record that a block at the given offset belongs to		
--check	check	Check the table for errors		

Format	Option File	Description	Introduced	Deprecated
<code>--check-only-changed</code>	<code>check-only-changed</code>	Check only tables that have changed since the last check		
<code>--correct-checksum</code>	<code>correct-checksum</code>	Correct the checksum information for the table		
<code>--data-file-length=len</code>	<code>data-file-length</code>	Maximum length of the data file (when re-creating data file when it is full)		
<code>--debug[=debug_options]</code>	<code>debug</code>	Write a debugging log		
<code>decode_bits=#</code>	<code>decode_bits</code>	<code>Decode_bits</code>		
<code>--defaults-extra-file=file_name</code>		Read option file in addition to the usual option files		
<code>--defaults-file=file_name</code>		Read only the given option file		
<code>--defaults-group-suffix=str</code>		Option group suffix value		
<code>--description</code>	<code>description</code>	Print some descriptive information about the table		
<code>--extend-check</code>	<code>extend-check</code>	Do very thorough table check or repair that tries to recover every possible row from the data file		
<code>--fast</code>	<code>fast</code>	Check only tables that haven't been closed properly		
<code>--force</code>	<code>force</code>	Do a repair operation automatically if myisamchk finds any errors in the table		
<code>--force</code>	<code>force-recover</code>	Overwrite old temporary files. For use with the <code>-r</code> or <code>-o</code> option		
<code>ft_max_word_len=#</code>	<code>ft_max_word_len</code>	Maximum word length for FULLTEXT indexes		
<code>ft_min_word_len=#</code>	<code>ft_min_word_len</code>	Minimum word length for FULLTEXT indexes		
<code>ft_stopword_file=filename</code>	<code>ft_stopword_file</code>	Use stopwords from this file instead of built-in list		
<code>--HELP</code>		Display help message and exit		
<code>--help</code>		Display help message and exit		
<code>--information</code>	<code>information</code>	Print informational statistics about the table that is checked		
<code>key_buffer_size=#</code>	<code>key_buffer_size</code>	The size of the buffer used for index blocks for MyISAM tables		
<code>--keys-used=val</code>	<code>keys-used</code>	A bit-value that indicates which indexes to update		
<code>--max-record-length=len</code>	<code>max-record-length</code>	Skip rows larger than the given length if myisamchk cannot allocate memory to hold them		
<code>--medium-check</code>	<code>medium-check</code>	Do a check that is faster than an <code>--extend-check</code> operation		

Format	Option File	Description	Introduced	Deprecated
myisam_block_size=#	myisam_block_size=#	Block size to be used for MyISAM index pages		
myisam_sort_buffer_size=#	myisam_sort_buffer_size=#	The buffer that is allocated when sorting the index when doing a REPAIR or when creating indexes with CREATE INDEX or ALTER TABLE	5.5.29	
--no-defaults		Do not read any option files		
--parallel-recover	parallel-recover	Uses the same technique as -r and -n, but creates all the keys in parallel, using different threads (beta)		
--print-defaults		Print defaults		
--quick	quick	Achieve a faster repair by not modifying the data file.		
read_buffer_size=#	read_buffer_size=#	Each thread that does a sequential scan allocates a buffer of this size for each table it scans		
--read-only	read-only	Don't mark the table as checked		
--recover	recover	Do a repair that can fix almost any problem except unique keys that aren't unique		
--safe-recover	safe-recover	Do a repair using an old recovery method that reads through all rows in order and updates all index trees based on the rows found		
--set-auto-increment[=value]	set-auto-increment	Force AUTO_INCREMENT numbering for new records to start at the given value		
--set-collation=name	set-collation	Specify the collation to use for sorting table indexes		
--silent	silent	Silent mode		
sort_buffer_size=#	sort_buffer_size=#	The buffer that is allocated when sorting the index when doing a REPAIR or when creating indexes with CREATE INDEX or ALTER TABLE		5.5.29
--sort-index	sort-index	Sort the index tree blocks in high-low order		
sort_key_blocks=#	sort_key_blocks=#	sort_key_blocks		
--sort-records=#	sort-records	Sort records according to a particular index		
--sort-recover	sort-recover	Force myisamchk to use sorting to resolve the keys even if the temporary files would be very large		
stats_method=value	stats_method	Specifies how MyISAM index statistics collection code should treat NULLs		
--tmpdir=path	tmpdir	Path of the directory to be used for storing temporary files		
--unpack	unpack	Unpack a table that was packed with myisampack		

Format	Option File	Description	Introduced	Deprecated
<code>--update-state</code>	<code>update-state</code>	Store information in the .MYI file to indicate when the table was checked and whether the table crashed		
<code>--verbose</code>		Verbose mode		
<code>--version</code>		Display version information and exit		
<code>write_buffer_size=</code>	<code>write_buffer_size</code>	Write buffer size		

4.6.3.1 myisamchk General Options

The options described in this section can be used for any type of table maintenance operation performed by `myisamchk`. The sections following this one describe options that pertain only to specific operations, such as table checking or repairing.

- `--help, -?`

Display a help message and exit. Options are grouped by type of operation.

- `--HELP, -H`

Display a help message and exit. Options are presented in a single list.

- `--debug=debug_options, -# debug_options`

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/myisamchk.trace`.

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, `file_name` must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, `file_name` must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `myisamchk` normally reads the `[myisamchk]` group. If the `--defaults-group-suffix=_other` option is given, `myisamchk` also reads the `[myisamchk_other]` group.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--silent, -s`

Silent mode. Write output only when errors occur. You can use `-s` twice (`-ss`) to make `myisamchk` very silent.

- `--verbose, -v`

Verbose mode. Print more information about what the program does. This can be used with `-d` and `-e`. Use `-v` multiple times (`-vv`, `-vvv`) for even more output.

- `--version, -V`

Display version information and exit.

- `--wait, -w`

Instead of terminating with an error if the table is locked, wait until the table is unlocked before continuing. If you are running `mysqld` with external locking disabled, the table can be locked only by another `myisamchk` command.

You can also set the following variables by using `--var_name=value` syntax:

Variable	Default Value
<code>decode_bits</code>	9
<code>ft_max_word_len</code>	version-dependent
<code>ft_min_word_len</code>	4
<code>ft_stopword_file</code>	built-in list
<code>key_buffer_size</code>	523264
<code>myisam_block_size</code>	1024
<code>myisam_sort_key_blocks</code>	16
<code>read_buffer_size</code>	262136
<code>sort_buffer_size</code>	2097144
<code>sort_key_blocks</code>	16
<code>stats_method</code>	nulls_unequal
<code>write_buffer_size</code>	262136

The possible `myisamchk` variables and their default values can be examined with `myisamchk --help`:

`sort_buffer_size` is used when the keys are repaired by sorting keys, which is the normal case when you use `--recover`. As of MySQL 5.5.29, `myisam_sort_buffer_size` is available as an alternative name to `sort_buffer_size`. `myisam_sort_buffer_size` is preferable to `sort_buffer_size` because its name corresponds to the `myisam_sort_buffer_size` server system variable that has a similar meaning. `sort_buffer_size` should be considered deprecated.

`key_buffer_size` is used when you are checking the table with `--extend-check` or when the keys are repaired by inserting keys row by row into the table (like when doing normal inserts). Repairing through the key buffer is used in the following cases:

- You use `--safe-recover`.
- The temporary files needed to sort the keys would be more than twice as big as when creating the key file directly. This is often the case when you have large key values for `CHAR`, `VARCHAR`, or `TEXT` columns, because the sort operation needs to store the complete key values as it proceeds. If you have

lots of temporary space and you can force `myisamchk` to repair by sorting, you can use the `--sort-recover` option.

Repairing through the key buffer takes much less disk space than using sorting, but is also much slower.

If you want a faster repair, set the `key_buffer_size` and `myisam_sort_buffer_size` variables to about 25% of your available memory. You can set both variables to large values, because only one of them is used at a time.

`myisam_block_size` is the size used for index blocks.

`stats_method` influences how `NULL` values are treated for index statistics collection when the `--analyze` option is given. It acts like the `myisam_stats_method` system variable. For more information, see the description of `myisam_stats_method` in [Section 5.1.4, “Server System Variables”](#), and [Section 8.3.7, “InnoDB and MyISAM Index Statistics Collection”](#).

`ft_min_word_len` and `ft_max_word_len` indicate the minimum and maximum word length for `FULLTEXT` indexes. `ft_stopword_file` names the stopwords file. These need to be set under the following circumstances.

If you use `myisamchk` to perform an operation that modifies table indexes (such as repair or analyze), the `FULLTEXT` indexes are rebuilt using the default full-text parameter values for minimum and maximum word length and the stopwords file unless you specify otherwise. This can result in queries failing.

The problem occurs because these parameters are known only by the server. They are not stored in `MyISAM` index files. To avoid the problem if you have modified the minimum or maximum word length or the stopwords file in the server, specify the same `ft_min_word_len`, `ft_max_word_len`, and `ft_stopword_file` values to `myisamchk` that you use for `mysqld`. For example, if you have set the minimum word length to 3, you can repair a table with `myisamchk` like this:

```
shell> myisamchk --recover --ft_min_word_len=3 tbl_name.MYI
```

To ensure that `myisamchk` and the server use the same values for full-text parameters, you can place each one in both the `[mysqld]` and `[myisamchk]` sections of an option file:

```
[mysqld]
ft_min_word_len=3

[myisamchk]
ft_min_word_len=3
```

An alternative to using `myisamchk` is to use the `REPAIR TABLE`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, or `ALTER TABLE`. These statements are performed by the server, which knows the proper full-text parameter values to use.

4.6.3.2 `myisamchk` Check Options

`myisamchk` supports the following options for table checking operations:

- `--check, -c`
Check the table for errors. This is the default operation if you specify no option that selects an operation type explicitly.
- `--check-only-changed, -C`
Check only tables that have changed since the last check.
- `--extend-check, -e`

Check the table very thoroughly. This is quite slow if the table has many indexes. This option should only be used in extreme cases. Normally, `myisamchk` or `myisamchk --medium-check` should be able to determine whether there are any errors in the table.

If you are using `--extend-check` and have plenty of memory, setting the `key_buffer_size` variable to a large value helps the repair operation run faster.

See also the description of this option under table repair options.

For a description of the output format, see [Section 4.6.3.5, “Obtaining Table Information with myisamchk”](#).

- `--fast, -F`

Check only tables that haven't been closed properly.

- `--force, -f`

Do a repair operation automatically if `myisamchk` finds any errors in the table. The repair type is the same as that specified with the `--recover` or `-r` option.

- `--information, -i`

Print informational statistics about the table that is checked.

- `--medium-check, -m`

Do a check that is faster than an `--extend-check` operation. This finds only 99.99% of all errors, which should be good enough in most cases.

- `--read-only, -T`

Do not mark the table as checked. This is useful if you use `myisamchk` to check a table that is in use by some other application that does not use locking, such as `mysqld` when run with external locking disabled.

- `--update-state, -U`

Store information in the `.MYI` file to indicate when the table was checked and whether the table crashed. This should be used to get full benefit of the `--check-only-changed` option, but you shouldn't use this option if the `mysqld` server is using the table and you are running it with external locking disabled.

4.6.3.3 myisamchk Repair Options

`myisamchk` supports the following options for table repair operations (operations performed when an option such as `--recover` or `--safe-recover` is given):

- `--backup, -B`

Make a backup of the `.MYD` file as `file_name-time.BAK`

- `--character-sets-dir=path`

The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).

- `--correct-checksum`

Correct the checksum information for the table.

- `--data-file-length=len, -D len`

The maximum length of the data file (when re-creating data file when it is “full”).

- `--extend-check, -e`

Do a repair that tries to recover every possible row from the data file. Normally, this also finds a lot of garbage rows. Do not use this option unless you are desperate.

See also the description of this option under table checking options.

For a description of the output format, see [Section 4.6.3.5, “Obtaining Table Information with myisamchk”](#).

- `--force, -f`

Overwrite old intermediate files (files with names like `tbl_name.TMD`) instead of aborting.

- `--keys-used=val, -k val`

For `myisamchk`, the option value is a bit-value that indicates which indexes to update. Each binary bit of the option value corresponds to a table index, where the first index is bit 0. An option value of 0 disables updates to all indexes, which can be used to get faster inserts. Deactivated indexes can be reactivated by using `myisamchk -r`.

- `--no-symlinks, -l`

Do not follow symbolic links. Normally `myisamchk` repairs the table that a symlink points to. This option does not exist as of MySQL 4.0 because versions from 4.0 on do not remove symlinks during repair operations.

- `--max-record-length=len`

Skip rows larger than the given length if `myisamchk` cannot allocate memory to hold them.

- `--parallel-recover, -p`

Use the same technique as `-r` and `-n`, but create all the keys in parallel, using different threads. *This is beta-quality code. Use at your own risk!*

- `--quick, -q`

Achieve a faster repair by modifying only the index file, not the data file. You can specify this option twice to force `myisamchk` to modify the original data file in case of duplicate keys.

- `--recover, -r`

Do a repair that can fix almost any problem except unique keys that are not unique (which is an extremely unlikely error with `MyISAM` tables). If you want to recover a table, this is the option to try first. You should try `--safe-recover` only if `myisamchk` reports that the table cannot be recovered using `--recover`. (In the unlikely case that `--recover` fails, the data file remains intact.)

If you have lots of memory, you should increase the value of `myisam_sort_buffer_size`.

- `--safe-recover, -o`

Do a repair using an old recovery method that reads through all rows in order and updates all index trees based on the rows found. This is an order of magnitude slower than `--recover`, but can handle

a couple of very unlikely cases that `--recover` cannot. This recovery method also uses much less disk space than `--recover`. Normally, you should repair first using `--recover`, and then with `--safe-recover` only if `--recover` fails.

If you have lots of memory, you should increase the value of `key_buffer_size`.

- `--set-character-set=name`

Change the character set used by the table indexes. This option was replaced by `--set-collation` in MySQL 5.0.3.

- `--set-collation=name`

Specify the collation to use for sorting table indexes. The character set name is implied by the first part of the collation name.

- `--sort-recover, -n`

Force `myisamchk` to use sorting to resolve the keys even if the temporary files would be very large.

- `--tmpdir=path, -t path`

The path of the directory to be used for storing temporary files. If this is not set, `myisamchk` uses the value of the `TMPDIR` environment variable. `--tmpdir` can be set to a list of directory paths that are used successively in round-robin fashion for creating temporary files. The separator character between directory names is the colon (":") on Unix and the semicolon (";") on Windows.

- `--unpack, -u`

Unpack a table that was packed with `myisampack`.

4.6.3.4 Other `myisamchk` Options

`myisamchk` supports the following options for actions other than table checks and repairs:

- `--analyze, -a`

Analyze the distribution of key values. This improves join performance by enabling the join optimizer to better choose the order in which to join the tables and which indexes it should use. To obtain information about the key distribution, use a `myisamchk --description --verbose tbl_name` command or the `SHOW INDEX FROM tbl_name` statement.

- `--block-search=offset, -b offset`

Find the record that a block at the given offset belongs to.

- `--description, -d`

Print some descriptive information about the table. Specifying the `--verbose` option once or twice produces additional information. See [Section 4.6.3.5, “Obtaining Table Information with `myisamchk`”](#).

- `--set-auto-increment[=value], -A[value]`

Force `AUTO_INCREMENT` numbering for new records to start at the given value (or higher, if there are existing records with `AUTO_INCREMENT` values this large). If `value` is not specified, `AUTO_INCREMENT` numbers for new records begin with the largest value currently in the table, plus one.

- `--sort-index, -S`

Sort the index tree blocks in high-low order. This optimizes seeks and makes table scans that use indexes faster.

- `--sort-records=N, -R N`

Sort records according to a particular index. This makes your data much more localized and may speed up range-based `SELECT` and `ORDER BY` operations that use this index. (The first time you use this option to sort a table, it may be very slow.) To determine a table's index numbers, use `SHOW INDEX`, which displays a table's indexes in the same order that `myisamchk` sees them. Indexes are numbered beginning with 1.

If keys are not packed (`PACK_KEYS=0`), they have the same length, so when `myisamchk` sorts and moves records, it just overwrites record offsets in the index. If keys are packed (`PACK_KEYS=1`), `myisamchk` must unpack key blocks first, then re-create indexes and pack the key blocks again. (In this case, re-creating indexes is faster than updating offsets for each index.)

4.6.3.5 Obtaining Table Information with `myisamchk`

To obtain a description of a `MyISAM` table or statistics about it, use the commands shown here. The output from these commands is explained later in this section.

- `myisamchk -d tbl_name`

Runs `myisamchk` in “describe mode” to produce a description of your table. If you start the MySQL server with external locking disabled, `myisamchk` may report an error for a table that is updated while it runs. However, because `myisamchk` does not change the table in describe mode, there is no risk of destroying data.

- `myisamchk -dv tbl_name`

Adding `-v` runs `myisamchk` in verbose mode so that it produces more information about the table. Adding `-v` a second time produces even more information.

- `myisamchk -eis tbl_name`

Shows only the most important information from a table. This operation is slow because it must read the entire table.

- `myisamchk -eiv tbl_name`

This is like `-eis`, but tells you what is being done.

The `tbl_name` argument can be either the name of a `MyISAM` table or the name of its index file, as described in [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#). Multiple `tbl_name` arguments can be given.

Suppose that a table named `person` has the following structure. (The `MAX_ROWS` table option is included so that in the example output from `myisamchk` shown later, some values are smaller and fit the output format more easily.)

```
CREATE TABLE person
(
  id          INT NOT NULL AUTO_INCREMENT,
  last_name   VARCHAR(20) NOT NULL,
  first_name  VARCHAR(20) NOT NULL,
  birth       DATE,
  death       DATE,
  PRIMARY KEY (id),
```

```
INDEX (last_name, first_name),
INDEX (birth)
) MAX_ROWS = 1000000;
```

Suppose also that the table has these data and index file sizes:

```
-rw-rw---- 1 mysql mysql 9347072 Aug 19 11:47 person.MYD
-rw-rw---- 1 mysql mysql 6066176 Aug 19 11:47 person.MYI
```

Example of `myisamchk -dvv` output:

```
MyISAM file:          person
Record format:        Packed
Character set:        latin1_swedish_ci (8)
File-version:         1

Datafile parts:      306688 Deleted data:      0
Datafile pointer (bytes): 4 Keyfile pointer (bytes): 3
Datafile length:     9347072 Keyfile length:    6066176
Max datafile length: 4294967294 Max keyfile length: 17179868159
Recordlength:        54

table description:
Key Start Len Index  Type          Rec/key      Root  Blocksize
1  2      4  unique  long          1          99328    1024
2  6      20  multip. varchar prefix  512       3563520   1024
   27      20  varchar          512
3  48      3  multip. uint24 NULL  306688     6065152   1024

Field Start Length Nullpos Nullbit Type
1  1      1
2  2      4          no zeros
3  6      21         varchar
4  27     21         varchar
5  48      3          1          1  no zeros
6  51      3          1          2  no zeros
```

Explanations for the types of information `myisamchk` produces are given here. “Keyfile” refers to the index file. “Record” and “row” are synonymous, as are “field” and “column.”

The initial part of the table description contains these values:

- `MyISAM file`

Name of the `MyISAM` (index) file.

- `Record format`

The format used to store table rows. The preceding examples use `Fixed length`. Other possible values are `Compressed` and `Packed`. (`Packed` corresponds to what `SHOW TABLE STATUS` reports as `Dynamic`.)

- `Chararacter set`

The table default character set.

- `File-version`

Version of `MyISAM` format. Currently always 1.

- `Creation time`

When the data file was created.

- `Recover time`

When the index/data file was last reconstructed.

- `Status`

Table status flags. Possible values are `crashed`, `open`, `changed`, `analyzed`, `optimized keys`, and `sorted index pages`.

- `Auto increment key, Last value`

The key number associated the table's `AUTO_INCREMENT` column, and the most recently generated value for this column. These fields do not appear if there is no such column.

- `Data records`

The number of rows in the table.

- `Deleted blocks`

How many deleted blocks still have reserved space. You can optimize your table to minimize this space. See [Section 7.6.4, “MyISAM Table Optimization”](#).

- `Datafile parts`

For dynamic-row format, this indicates how many data blocks there are. For an optimized table without fragmented rows, this is the same as `Data records`.

- `Deleted data`

How many bytes of unreclaimed deleted data there are. You can optimize your table to minimize this space. See [Section 7.6.4, “MyISAM Table Optimization”](#).

- `Datafile pointer`

The size of the data file pointer, in bytes. It is usually 2, 3, 4, or 5 bytes. Most tables manage with 2 bytes, but this cannot be controlled from MySQL yet. For fixed tables, this is a row address. For dynamic tables, this is a byte address.

- `Keyfile pointer`

The size of the index file pointer, in bytes. It is usually 1, 2, or 3 bytes. Most tables manage with 2 bytes, but this is calculated automatically by MySQL. It is always a block address.

- `Max datafile length`

How long the table data file can become, in bytes.

- `Max keyfile length`

How long the table index file can become, in bytes.

- `Recordlength`

How much space each row takes, in bytes.

The `table description` part of the output includes a list of all keys in the table. For each key, `myisamchk` displays some low-level information:

- `Key`

This key's number. This value is shown only for the first column of the key. If this value is missing, the line corresponds to the second or later column of a multiple-column key. For the table shown in the example, there are two `table description` lines for the second index. This indicates that it is a multiple-part index with two parts.

- `Start`

Where in the row this portion of the index starts.

- `Len`

How long this portion of the index is. For packed numbers, this should always be the full length of the column. For strings, it may be shorter than the full length of the indexed column, because you can index a prefix of a string column. The total length of a multiple-part key is the sum of the `Len` values for all key parts.

- `Index`

Whether a key value can exist multiple times in the index. Possible values are `unique` or `multip.` (multiple).

- `Type`

What data type this portion of the index has. This is a `MyISAM` data type with the possible values `packed`, `stripped`, or `empty`.

- `Root`

Address of the root index block.

- `Blocksize`

The size of each index block. By default this is 1024, but the value may be changed at compile time when MySQL is built from source.

- `Rec/key`

This is a statistical value used by the optimizer. It tells how many rows there are per value for this index. A unique index always has a value of 1. This may be updated after a table is loaded (or greatly changed) with `myisamchk -a`. If this is not updated at all, a default value of 30 is given.

The last part of the output provides information about each column:

- `Field`

The column number.

- `Start`

The byte position of the column within table rows.

- `Length`

The length of the column in bytes.

- `Nullpos, Nullbit`

For columns that can be `NULL`, `MyISAM` stores `NULL` values as a flag in a byte. Depending on how many nullable columns there are, there can be one or more bytes used for this purpose. The `Nullpos` and `Nullbit` values, if nonempty, indicate which byte and bit contains that flag indicating whether the column is `NULL`.

The position and number of bytes used to store `NULL` flags is shown in the line for field 1. This is why there are six `Field` lines for the `person` table even though it has only five columns.

- `Type`

The data type. The value may contain any of the following descriptors:

- `constant`

All rows have the same value.

- `no endspace`

Do not store endspace.

- `no endspace, not_always`

Do not store endspace and do not do endspace compression for all values.

- `no endspace, no empty`

Do not store endspace. Do not store empty values.

- `table-lookup`

The column was converted to an `ENUM`.

- `zerofill(N)`

The most significant `N` bytes in the value are always 0 and are not stored.

- `no zeros`

Do not store zeros.

- `always zero`

Zero values are stored using one bit.

- `Huff tree`

The number of the Huffman tree associated with the column.

- `Bits`

The number of bits used in the Huffman tree.

The `Huff tree` and `Bits` fields are displayed if the table has been compressed with `myisampack`. See [Section 4.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#), for an example of this information.

Example of `myisamchk -eiv` output:

```

Checking MyISAM file: person

Voluntary context switches 0, Involuntary context switches 0
Maximum memory usage: 1046926 bytes (1023k)

```

`myisamchk -eiv` output includes the following information:

- **Data records**

The number of rows in the table.

- **Deleted blocks**

How many deleted blocks still have reserved space. You can optimize your table to minimize this space. See [Section 7.6.4, “MyISAM Table Optimization”](#).

- **Key**

The key number.

- **Keyblocks used**

What percentage of the keyblocks are used. When a table has just been reorganized with `myisamchk`, the values are very high (very near theoretical maximum).

- **Packed**

MySQL tries to pack key values that have a common suffix. This can only be used for indexes on `CHAR` and `VARCHAR` columns. For long indexed strings that have similar leftmost parts, this can significantly reduce the space used. In the preceding example, the second key is 40 bytes long and a 97% reduction in space is achieved.

- **Max levels**

How deep the B-tree for this key is. Large tables with long key values get high values.

- `Records`

How many rows are in the table.

- `M.recordlength`

The average row length. This is the exact row length for tables with fixed-length rows, because all rows have the same length.

- `Packed`

MySQL strips spaces from the end of strings. The `Packed` value indicates the percentage of savings achieved by doing this.

- `Recordspace used`

What percentage of the data file is used.

- `Empty space`

What percentage of the data file is unused.

- `Blocks/Record`

Average number of blocks per row (that is, how many links a fragmented row is composed of). This is always 1.0 for fixed-format tables. This value should stay as close to 1.0 as possible. If it gets too large, you can reorganize the table. See [Section 7.6.4, “MyISAM Table Optimization”](#).

- `Recordblocks`

How many blocks (links) are used. For fixed-format tables, this is the same as the number of rows.

- `Deleteblocks`

How many blocks (links) are deleted.

- `Recorddata`

How many bytes in the data file are used.

- `Deleted data`

How many bytes in the data file are deleted (unused).

- `Lost space`

If a row is updated to a shorter length, some space is lost. This is the sum of all such losses, in bytes.

- `Linkdata`

When the dynamic table format is used, row fragments are linked with pointers (4 to 7 bytes each). `Linkdata` is the sum of the amount of storage used by all such pointers.

4.6.3.6 myisamchk Memory Usage

Memory allocation is important when you run `myisamchk`. `myisamchk` uses no more memory than its memory-related variables are set to. If you are going to use `myisamchk` on very large tables, you should first decide how much memory you want it to use. The default is to use only about 3MB to perform repairs. By using larger values, you can get `myisamchk` to operate faster. For example, if you have more than

512MB RAM available, you could use options such as these (in addition to any other options you might specify):

```
shell> myisamchk --myisam_sort_buffer_size=256M \
             --key_buffer_size=512M \
             --read_buffer_size=64M \
             --write_buffer_size=64M ...
```

Using `--myisam_sort_buffer_size=16M` is probably enough for most cases.

Be aware that `myisamchk` uses temporary files in `TMPDIR`. If `TMPDIR` points to a memory file system, out of memory errors can easily occur. If this happens, run `myisamchk` with the `--tmpdir=path` option to specify a directory located on a file system that has more space.

When performing repair operations, `myisamchk` also needs a lot of disk space:

- Twice the size of the data file (the original file and a copy). This space is not needed if you do a repair with `--quick`; in this case, only the index file is re-created. *This space must be available on the same file system as the original data file*, as the copy is created in the same directory as the original.
- Space for the new index file that replaces the old one. The old index file is truncated at the start of the repair operation, so you usually ignore this space. This space must be available on the same file system as the original data file.
- When using `--recover` or `--sort-recover` (but not when using `--safe-recover`), you need space on disk for sorting. This space is allocated in the temporary directory (specified by `TMPDIR` or `--tmpdir=path`). The following formula yields the amount of space required:

$$(\text{largest_key} + \text{row_pointer_length}) * \text{number_of_rows} * 2$$

You can check the length of the keys and the `row_pointer_length` with `myisamchk -dv tbl_name` (see [Section 4.6.3.5, “Obtaining Table Information with myisamchk”](#)). The `row_pointer_length` and `number_of_rows` values are the `Datafile pointer` and `Data records` values in the table description. To determine the `largest_key` value, check the `Key` lines in the table description. The `Len` column indicates the number of bytes for each key part. For a multiple-column index, the key size is the sum of the `Len` values for all key parts.

If you have a problem with disk space during repair, you can try `--safe-recover` instead of `--recover`.

4.6.4 myisamlog — Display MyISAM Log File Contents

`myisamlog` processes the contents of a `MyISAM` log file. To create such a file, start the server with a `--log-isam=log_file` option.

Invoke `myisamlog` like this:

```
shell> myisamlog [options] [file_name [tbl_name] ...]
```

The default operation is update (`-u`). If a recovery is done (`-r`), all writes and possibly updates and deletes are done and errors are only counted. The default log file name is `myisam.log` if no `log_file` argument is given. If tables are named on the command line, only those tables are updated.

`myisamlog` supports the following options:

- `-, -I`

Display a help message and exit.

- `-c N`
Execute only *N* commands.
- `-f N`
Specify the maximum number of open files.
- `-i`
Display extra information before exiting.
- `-o offset`
Specify the starting offset.
- `-p N`
Remove *N* components from path.
- `-r`
Perform a recovery operation.
- `-R record_pos_file record_pos`
Specify record position file and record position.
- `-u`
Perform an update operation.
- `-v`
Verbose mode. Print more output about what the program does. This option can be given multiple times to produce more and more output.
- `-w write_file`
Specify the write file.
- `-V`
Display version information.

4.6.5 myisampack — Generate Compressed, Read-Only MyISAM Tables

The `myisampack` utility compresses `MyISAM` tables. `myisampack` works by compressing each column in the table separately. Usually, `myisampack` packs the data file 40% to 70%.

When the table is used later, the server reads into memory the information needed to decompress columns. This results in much better performance when accessing individual rows, because you only have to uncompress exactly one row.

MySQL uses `mmap()` when possible to perform memory mapping on compressed tables. If `mmap()` does not work, MySQL falls back to normal read/write file operations.

Please note the following:

- If the `mysqld` server was invoked with external locking disabled, it is not a good idea to invoke `myisampack` if the table might be updated by the server during the packing process. It is safest to compress tables with the server stopped.
- After packing a table, it becomes read only. This is generally intended (such as when accessing packed tables on a CD).
- `myisampack` does not support partitioned tables.

Invoke `myisampack` like this:

```
shell> myisampack [options] file_name ...
```

Each file name argument should be the name of an index (`.MYI`) file. If you are not in the database directory, you should specify the path name to the file. It is permissible to omit the `.MYI` extension.

After you compress a table with `myisampack`, you should use `myisamchk -rq` to rebuild its indexes. [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#).

`myisampack` supports the following options. It also reads option files and supports the options for processing them described at [Section 4.2.7, “Command-Line Options that Affect Option-File Handling”](#).

- `--help, -?`

Display a help message and exit.

- `--backup, -b`

Make a backup of each table's data file using the name `tbl_name.OLD`.

- `--character-sets-dir=path`

The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o`.

- `--force, -f`

Produce a packed table even if it becomes larger than the original or if the intermediate file from an earlier invocation of `myisampack` exists. (`myisampack` creates an intermediate file named `tbl_name.TMD` in the database directory while it compresses the table. If you kill `myisampack`, the `.TMD` file might not be deleted.) Normally, `myisampack` exits with an error if it finds that `tbl_name.TMD` exists. With `--force`, `myisampack` packs the table anyway.

- `--join=big_tbl_name, -j big_tbl_name`

Join all tables named on the command line into a single packed table `big_tbl_name`. All tables that are to be combined *must* have identical structure (same column names and types, same indexes, and so forth).

`big_tbl_name` must not exist prior to the join operation. All source tables named on the command line to be merged into `big_tbl_name` must exist. The source tables are read for the join operation but not modified. The join operation does not create a `.frm` file for `big_tbl_name`, so after the join operation finishes, copy the `.frm` file from one of the source tables and name it `big_tbl_name.frm`.

- `--silent, -s`

Silent mode. Write output only when errors occur.

- `--test, -t`

Do not actually pack the table, just test packing it.

- `--tmpdir=path, -T path`

Use the named directory as the location where `myisampack` creates temporary files.

- `--verbose, -v`

Verbose mode. Write information about the progress of the packing operation and its result.

- `--version, -V`

Display version information and exit.

- `--wait, -w`

Wait and retry if the table is in use. If the `mysqld` server was invoked with external locking disabled, it is not a good idea to invoke `myisampack` if the table might be updated by the server during the packing process.

The following sequence of commands illustrates a typical table compression session:

```
shell> ls -l station.*
-rw-rw-r-- 1 monty my 994128 Apr 17 19:00 station.MYD
-rw-rw-r-- 1 monty my 53248 Apr 17 19:00 station.MYI
-rw-rw-r-- 1 monty my 5767 Apr 17 19:00 station.frm

shell> myisamchk -dvv station

`myisampack` displays the following kinds of information:

- `normal`

The number of columns for which no extra packing is used.

- `empty-space`

The number of columns containing values that are only spaces. These occupy one bit.

- `empty-zero`

The number of columns containing values that are only binary zeros. These occupy one bit.

- `empty-fill`

The number of integer columns that do not occupy the full byte range of their type. These are changed to a smaller type. For example, a `BIGINT` column (eight bytes) can be stored as a `TINYINT` column (one byte) if all its values are in the range from `-128` to `127`.

- `pre-space`

The number of decimal columns that are stored with leading spaces. In this case, each value contains a count for the number of leading spaces.

- `end-space`

The number of columns that have a lot of trailing spaces. In this case, each value contains a count for the number of trailing spaces.

- `table-lookup`

The column had only a small number of different values, which were converted to an `ENUM` before Huffman compression.

- `zero`

The number of columns for which all values are zero.

- `Original trees`

The initial number of Huffman trees.

- `After join`

The number of distinct Huffman trees left after joining trees to save some header space.

After a table has been compressed, the `Field` lines displayed by `myisamchk -dvv` include additional information about each column:

- `Type`

The data type. The value may contain any of the following descriptors:

- `constant`

All rows have the same value.

- `no endspace`

Do not store endspace.

- `no endspace, not_always`

Do not store endspace and do not do endspace compression for all values.

- `no endspace, no empty`

Do not store endspace. Do not store empty values.

- `table-lookup`

The column was converted to an `ENUM`.

- `zerofill(N)`

The most significant `N` bytes in the value are always 0 and are not stored.

- `no zeros`

Do not store zeros.

- `always zero`

Zero values are stored using one bit.

- `Huff tree`

The number of the Huffman tree associated with the column.

- `Bits`

The number of bits used in the Huffman tree.

After you run `myisampack`, you must run `myisamchk` to re-create any indexes. At this time, you can also sort the index blocks and create statistics needed for the MySQL optimizer to work more efficiently:

```
shell> myisamchk -rq --sort-index --analyze tbl_name.MYI
```

After you have installed the packed table into the MySQL database directory, you should execute `mysqladmin flush-tables` to force `mysqld` to start using the new table.

To unpack a packed table, use the `--unpack` option to `myisamchk`.

4.6.6 mysqlaccess — Client for Checking Access Privileges

`mysqlaccess` is a diagnostic tool that Yves Carlier has provided for the MySQL distribution. It checks the access privileges for a host name, user name, and database combination. Note that `mysqlaccess` checks access using only the `user`, `db`, and `host` tables. It does not check table, column, or routine privileges specified in the `tables_priv`, `columns_priv`, or `procs_priv` tables.

Invoke `mysqlaccess` like this:

```
shell> mysqlaccess [host_name [user_name [db_name]]] [options]
```

mysqlaccess supports the following options.

Table 4.13 mysqlaccess Options

Format	Option File	Description
<code>--brief</code>	<code>brief</code>	Generate reports in single-line tabular format
<code>--commit</code>	<code>commit</code>	Copy the new access privileges from the temporary tables to the original grant tables
<code>--copy</code>	<code>copy</code>	Reload the temporary grant tables from original ones
<code>--db=db_name</code>	<code>db</code>	Specify the database name
<code>--debug=#</code>	<code>debug</code>	Specify the debug level
<code>--help</code>		Display help message and exit
<code>--host=host_name</code>	<code>host</code>	Connect to the MySQL server on the given host
<code>--howto</code>	<code>howto</code>	Display some examples that show how to use mysqlaccess
<code>--old_server</code>	<code>old_server</code>	Assume that the server is an old MySQL server (prior to MySQL 3.21)
<code>--password[=password]</code>	<code>password</code>	The password to use when connecting to the server
<code>--plan</code>	<code>plan</code>	Display suggestions and ideas for future releases
<code>--preview</code>	<code>preview</code>	Show the privilege differences after making changes to the temporary grant tables
<code>--relnotes</code>	<code>relnotes</code>	Display the release notes
<code>--rhost=host_name</code>	<code>rhost</code>	Connect to the MySQL server on the given host
<code>--rollback</code>	<code>rollback</code>	Undo the most recent changes to the temporary grant tables.
<code>--spassword[=password]</code>	<code>spassword</code>	The password to use when connecting to the server as the superuser
<code>--superuser=user_name</code>	<code>superuser</code>	Specify the user name for connecting as the superuser
<code>--table</code>	<code>table</code>	Generate reports in table format
<code>--user=user_name,</code>	<code>user</code>	MySQL user name to use when connecting to server
<code>--version</code>		Display version information and exit

- `--help, -?`

Display a help message and exit.

- `--brief, -b`

Generate reports in single-line tabular format.

- `--commit`

Copy the new access privileges from the temporary tables to the original grant tables. The grant tables must be flushed for the new privileges to take effect. (For example, execute a `mysqladmin reload` command.)

- `--copy`
Reload the temporary grant tables from original ones.
- `--db=db_name, -d db_name`
Specify the database name.
- `--debug=N`
Specify the debug level. *N* can be an integer from 0 to 3.
- `--host=host_name, -h host_name`
The host name to use in the access privileges.
- `--howto`
Display some examples that show how to use `mysqlaccess`.
- `--old_server`
Assume that the server is an old MySQL server (before MySQL 3.21) that does not yet know how to handle full `WHERE` clauses.
- `--password[=password], -p[password]`
The password to use when connecting to the server. If you omit the *password* value following the `--password` or `-p` option on the command line, `mysqlaccess` prompts for one.
Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#).
- `--plan`
Display suggestions and ideas for future releases.
- `--preview`
Show the privilege differences after making changes to the temporary grant tables.
- `--relnotes`
Display the release notes.
- `--rhost=host_name, -H host_name`
Connect to the MySQL server on the given host.
- `--rollback`
Undo the most recent changes to the temporary grant tables.
- `--spassword[=password], -P[password]`
The password to use when connecting to the server as the superuser. If you omit the *password* value following the `--spassword` or `-P` option on the command line, `mysqlaccess` prompts for one.
Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#).

- `--superuser=user_name, -U user_name`

Specify the user name for connecting as the superuser.

- `--table, -t`

Generate reports in table format.

- `--user=user_name, -u user_name`

The user name to use in the access privileges.

- `--version, -v`

Display version information and exit.

If your MySQL distribution is installed in some nonstandard location, you must change the location where `mysqlaccess` expects to find the `mysql` client. Edit the `mysqlaccess` script at approximately line 18. Search for a line that looks like this:

```
$MYSQL      = '/usr/local/bin/mysql';    # path to mysql executable
```

Change the path to reflect the location where `mysql` actually is stored on your system. If you do not do this, a `Broken pipe` error will occur when you run `mysqlaccess`.

4.6.7 mysqlbinlog — Utility for Processing Binary Log Files

The server's binary log consists of files containing “events” that describe modifications to database contents. The server writes these files in binary format. To display their contents in text format, use the `mysqlbinlog` utility. You can also use `mysqlbinlog` to display the contents of relay log files written by a slave server in a replication setup because relay logs have the same format as binary logs. The binary log and relay log are discussed further in [Section 5.2.4, “The Binary Log”](#), and [Section 17.2.2, “Replication Relay and Status Logs”](#).

Invoke `mysqlbinlog` like this:

```
shell> mysqlbinlog [options] log_file ...
```

For example, to display the contents of the binary log file named `binlog.000003`, use this command:

```
shell> mysqlbinlog binlog.000003
```

The output includes events contained in `binlog.000003`. For statement-based logging, event information includes the SQL statement, the ID of the server on which it was executed, the timestamp when the statement was executed, how much time it took, and so forth. For row-based logging, the event indicates a row change rather than an SQL statement. See [Section 17.1.2, “Replication Formats”](#), for information about logging modes.

Events are preceded by header comments that provide additional information. For example:

```
# at 141
#100309  9:28:36 server id 123  end_log_pos 245
  Query thread_id=3350  exec_time=11  error_code=0
```

In the first line, the number following `at` indicates the file offset, or starting position, of the event in the binary log file.

The second line starts with a date and time indicating when the statement started on the server where the event originated. For replication, this timestamp is propagated to slave servers. `server_id` is the `server_id` value of the server where the event originated. `end_log_pos` indicates where the next event starts (that is, it is the end position of the current event + 1). `thread_id` indicates which thread executed the event. `exec_time` is the time spent executing the event, on a master server. On a slave, it is the difference of the end execution time on the slave minus the beginning execution time on the master. The difference serves as an indicator of how much replication lags behind the master. `error_code` indicates the result from executing the event. Zero means that no error occurred.

Note

When using event groups, the file offsets of all events are grouped together and the comments of all events are grouped together. For example:

```
# at 587
# at 630
# at 5662
#140627 13:16:52 server id 1  end_log_pos 630      Table_map: `test`.`t1` mapped to number
#140627 13:16:52 server id 1  end_log_pos 5662      Write_rows: table id 41
#140627 13:16:52 server id 1  end_log_pos 10694     Write_rows: table id 41 flags: STMT_E
```

The three file offsets do not represent blank events.

The output from `mysqlbinlog` can be re-executed (for example, by using it as input to `mysql`) to redo the statements in the log. This is useful for recovery operations after a server crash. For other usage examples, see the discussion later in this section and in [Section 7.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#).

Normally, you use `mysqlbinlog` to read binary log files directly and apply them to the local MySQL server. It is also possible to read binary logs from a remote server by using the `--read-from-remote-server` option. To read remote binary logs, the connection parameter options can be given to indicate how to connect to the server. These options are `--host`, `--password`, `--port`, `--protocol`, `--socket`, and `--user`; they are ignored except when you also use the `--read-from-remote-server` option.

`mysqlbinlog` supports the following options, which can be specified on the command line or in the `[mysqlbinlog]` and `[client]` groups of an option file. For information about option files, see [Section 4.2.6, “Using Option Files”](#).

Table 4.14 `mysqlbinlog` Options

Format	Option File	Description	Introduced	Removed
<code>--base64-output=value</code>	<code>base64-output</code>	Print binary log entries using base-64 encoding		
<code>--character-sets-dir=path</code>	<code>character-sets-dir</code>	The directory where character sets are installed		
<code>--database=db_name</code>	<code>database</code>	List entries for just this database		
<code>--debug[=debug_options]</code>	<code>debug</code>	Write a debugging log		
<code>--debug-check</code>	<code>debug-check</code>	Print debugging information when the program exits		
<code>--debug-info</code>	<code>debug-info</code>	Print debugging information, memory and CPU statistics when the program exits		

Format	Option File	Description	Introduced	Removed
<code>--default-auth=plugin</code>	<code>default-auth=plugin</code>	The authentication plugin to use	5.5.10	
<code>--defaults-extra-file=file_name</code>		Read option file in addition to the usual option files		
<code>--defaults-file=file_name</code>		Read only the given option file		
<code>--defaults-group-suffix=str</code>		Option group suffix value		
<code>--disable-log-bin</code>	<code>disable-log-bin</code>	Disable binary logging		
<code>--force-if-open</code>	<code>force-if-open</code>	Read binary log files even if open or not closed properly		
<code>--force-read</code>	<code>force-read</code>	If mysqlbinlog reads a binary log event that it does not recognize, it prints a warning		
<code>--help</code>		Display help message and exit		
<code>--hexdump</code>	<code>hexdump</code>	Display a hex dump of the log in comments		
<code>--host=host_name</code>	<code>host</code>	Connect to the MySQL server on the given host		
<code>--local-load=path</code>	<code>local-load</code>	Prepare local temporary files for LOAD DATA INFILE in the specified directory		
<code>--no-defaults</code>		Do not read any option files		
<code>--offset=#</code>	<code>offset</code>	Skip the first N entries in the log		
<code>--password[=password]</code>	<code>password</code>	The password to use when connecting to the server		
<code>--plugin-dir=path</code>	<code>plugin-dir=path</code>	The directory where plugins are located	5.5.10	
<code>--port=port_num</code>	<code>port</code>	The TCP/IP port number to use for the connection		
<code>--position=#</code>	<code>position</code>	Deprecated. Use <code>--start-position</code>		5.5.3
<code>--print-defaults</code>		Print defaults		
<code>--protocol=type</code>	<code>protocol</code>	The connection protocol to use		
<code>--read-from-remote-server</code>	<code>read-from-remote-server</code>	Read binary log from MySQL server rather than local log file		
<code>--result-file=name</code>	<code>result-file</code>	Direct output to the given file		
<code>--server-id=id</code>	<code>server-id</code>	Extract only those events created by the server having the given server ID		
<code>--server-id-bits=#</code>	<code>server-id-bits</code>	Tell mysqlbinlog how to interpret server IDs in binary log when log was written by a mysqld having its server-id-bits set to less than the maximum; supported only by MySQL Cluster version of mysqlbinlog		
<code>--set-charset=charset_name</code>	<code>set-charset_name</code>	Add a SET NAMES charset_name statement to the output		

Format	Option File	Description	Introduced	Removed
<code>--short-form</code>	<code>short-form</code>	Display only the statements contained in the log		
<code>--socket=path</code>	<code>socket</code>	For connections to localhost		
<code>--start-datetime=datetime</code>	<code>start-datetime</code>	Read binary log from first event with timestamp equal to or later than datetime argument		
<code>--start-position=#</code>	<code>start-position</code>	Read binary log from first event with position equal to or greater than argument		
<code>--stop-datetime=datetime</code>	<code>stop-datetime</code>	Stop reading binary log at first event with timestamp equal to or greater than datetime argument		
<code>--stop-position=#</code>	<code>stop-position</code>	Stop reading binary log at first event with position equal to or greater than argument		
<code>--to-last-log</code>	<code>to-last-log</code>	Do not stop at the end of requested binary log from a MySQL server, but rather continue printing to end of last binary log		
<code>--user=user_name</code>	<code>user</code>	MySQL user name to use when connecting to server		
<code>--verbose</code>		Reconstruct row events as SQL statements		
<code>--version</code>		Display version information and exit		

- `--help, -?`

Display a help message and exit.

- `--base64-output[=value]`

This option determines when events should be displayed encoded as base-64 strings using `BINLOG` statements. The option has these permissible values (not case sensitive):

- `AUTO` ("automatic") or `UNSPEC` ("unspecified") displays `BINLOG` statements automatically when necessary (that is, for format description events and row events). If no `--base64-output` option is given, the effect is the same as `--base64-output=AUTO`.

Note

Automatic `BINLOG` display is the only safe behavior if you intend to use the output of `mysqlbinlog` to re-execute binary log file contents. The other option values are intended only for debugging or testing purposes because they may produce output that does not include all events in executable form.

- `ALWAYS` displays `BINLOG` statements whenever possible. If the `--base64-output` option is given without a value, the effect is the same as `--base64-output=ALWAYS`.

Note

Changes to replication in MySQL 5.6 make output generated by this option unusable, so `ALWAYS` is deprecated as of MySQL 5.5.8 and will be an invalid value in MySQL 5.6

- **NEVER** causes **BINLOG** statements not to be displayed. **mysqlbinlog** exits with an error if a row event is found that must be displayed using **BINLOG**.
- **DECODE-ROWS** specifies to **mysqlbinlog** that you intend for row events to be decoded and displayed as commented SQL statements by also specifying the **--verbose** option. Like **NEVER**, **DECODE-ROWS** suppresses display of **BINLOG** statements, but unlike **NEVER**, it does not exit with an error if a row event is found.

For examples that show the effect of **--base64-output** and **--verbose** on row event output, see [Section 4.6.7.2, “mysqlbinlog Row Event Display”](#).

- **--bind-address=ip_address**

On a computer having multiple network interfaces, this option can be used to select which interface is employed when connecting to the MySQL server.

This option is supported beginning with MySQL 5.5.8.

- **--character-sets-dir=path**

The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).

- **--database=db_name, -d db_name**

This option causes **mysqlbinlog** to output entries from the binary log (local log only) that occur while **db_name** is been selected as the default database by **USE**.

The **--database** option for **mysqlbinlog** is similar to the **--binlog-do-db** option for **mysqld**, but can be used to specify only one database. If **--database** is given multiple times, only the last instance is used.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of **--binlog-do-db** depend on whether statement-based or row-based logging is in use.

Statement-based logging. The **--database** option works as follows:

- While **db_name** is the default database, statements are output whether they modify tables in **db_name** or a different database.
- Unless **db_name** is selected as the default database, statements are not output, even if they modify tables in **db_name**.
- There is an exception for **CREATE DATABASE**, **ALTER DATABASE**, and **DROP DATABASE**. The database being *created*, *altered*, or *dropped* is considered to be the default database when determining whether to output the statement.

Suppose that the binary log was created by executing these statements using statement-based-logging:

```
INSERT INTO test.t1 (i) VALUES(100);
INSERT INTO db2.t2 (j) VALUES(200);
USE test;
INSERT INTO test.t1 (i) VALUES(101);
INSERT INTO t1 (i) VALUES(102);
INSERT INTO db2.t2 (j) VALUES(201);
USE db2;
INSERT INTO test.t1 (i) VALUES(103);
```

```
INSERT INTO db2.t2 (j) VALUES(202);
INSERT INTO t2 (j) VALUES(203);
```

`mysqlbinlog --database=test` does not output the first two `INSERT` statements because there is no default database. It outputs the three `INSERT` statements following `USE test`, but not the three `INSERT` statements following `USE db2`.

`mysqlbinlog --database=db2` does not output the first two `INSERT` statements because there is no default database. It does not output the three `INSERT` statements following `USE test`, but does output the three `INSERT` statements following `USE db2`.

Row-based logging. `mysqlbinlog` outputs only entries that change tables belonging to `db_name`. The default database has no effect on this. Suppose that the binary log just described was created using row-based logging rather than statement-based logging. `mysqlbinlog --database=test` outputs only those entries that modify `t1` in the test database, regardless of whether `USE` was issued or what the default database is.

If a server is running with `binlog_format` set to `MIXED` and you want it to be possible to use `mysqlbinlog` with the `--database` option, you must ensure that tables that are modified are in the database selected by `USE`. (In particular, no cross-database updates should be used.)

Note

Prior to MySQL Cluster NDB 7.2.2, this option did not work correctly with MySQL Cluster tables unless, unless the binary log was generated using `--log-bin-use-v1-row-events=0`. (Bug #13067813)

- `--debug[=debug_options], -# [debug_options]`

Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysqlbinlog.trace`.

- `--debug-check`

Print some debugging information when the program exits.

- `--debug-info`

Print debugging information and memory and CPU usage statistics when the program exits.

- `--default-auth=plugin`

The client-side authentication plugin to use. See [Section 6.3.6, “Pluggable Authentication”](#).

This option was added in MySQL 5.5.10.

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, `file_name` must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, `file_name` must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqlbinlog` normally reads the `[client]` and `[mysqlbinlog]` groups. If the `--defaults-group-suffix=_other` option is given, `mysqlbinlog` also reads the `[client_other]` and `[mysqlbinlog_other]` groups.

- `--disable-log-bin, -D`

Disable binary logging. This is useful for avoiding an endless loop if you use the `--to-last-log` option and are sending the output to the same MySQL server. This option also is useful when restoring after a crash to avoid duplication of the statements you have logged.

This option requires that you have the `SUPER` privilege. It causes `mysqlbinlog` to include a `SET sql_log_bin = 0` statement in its output to disable binary logging of the remaining output. The `SET` statement is ineffective unless you have the `SUPER` privilege.

- `--force-if-open, -F`

Read binary log files even if they are open or were not closed properly.

- `--force-read, -f`

With this option, if `mysqlbinlog` reads a binary log event that it does not recognize, it prints a warning, ignores the event, and continues. Without this option, `mysqlbinlog` stops if it reads such an event.

- `--hexdump, -H`

Display a hex dump of the log in comments, as described in [Section 4.6.7.1, “mysqlbinlog Hex Dump Format”](#). The hex output can be helpful for replication debugging.

- `--host=host_name, -h host_name`

Get the binary log from the MySQL server on the given host.

- `--local-load=path, -l path`

Prepare local temporary files for `LOAD DATA INFILE` in the specified directory.

Important

These temporary files are not automatically removed by `mysqlbinlog` or any other MySQL program.

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

- `--offset=N, -o N`

Skip the first `N` entries in the log.

- `--password[=password], -p[password]`

The password to use when connecting to the server. If you use the short option form (`-p`), you *cannot* have a space between the option and the password. If you omit the `password` value following the `--password` or `-p` option on the command line, `mysqlbinlog` prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--plugin-dir=path`

The directory in which to look for plugins. It may be necessary to specify this option if the `--default-auth` option is used to specify an authentication plugin but `mysqlbinlog` does not find it. See [Section 6.3.6, “Pluggable Authentication”](#).

This option was added in MySQL 5.5.10.

- `--port=port_num, -P port_num`

The TCP/IP port number to use for connecting to a remote server.

- `--position=N`

Deprecated. Use `--start-position` instead. `--position` was removed in MySQL 5.5.3.

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--protocol={TCP|SOCKET|PIPE|MEMORY}`

The connection protocol to use for connecting to the server. It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want. For details on the permissible values, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

- `--read-from-remote-server, -R`

Read the binary log from a MySQL server rather than reading a local log file. Any connection parameter options are ignored unless this option is given as well. These options are `--host`, `--password`, `--port`, `--protocol`, `--socket`, and `--user`.

This option requires that the remote server be running. It works only for binary log files on the remote server, not relay log files.

- `--result-file=name, -r name`

Direct output to the given file.

- `--server-id=id`

Display only those events created by the server having the given server ID.

- `--server-id-bits=N`

Use only the first *N* bits of the `server_id` to identify the server. If the binary log was written by a `mysqld` with `server-id-bits` set to less than 32 and user data stored in the most significant bit, running `mysqlbinlog` with `--server-id-bits` set to 32 enables this data to be seen.

This option is supported only by the versions of `mysqlbinlog` supplied with the MySQL Cluster distribution, or built from the MySQL Cluster sources.

- `--set-charset=charset_name`

Add a `SET NAMES charset_name` statement to the output to specify the character set to be used for processing log files.

- `--short-form, -s`

Display only the statements contained in the log, without any extra information or row-based events. This is for testing only, and should not be used in production systems.

- `--socket=path, -S path`

For connections to `localhost`, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

- `--start-datetime=datetime`

Start reading the binary log at the first event having a timestamp equal to or later than the `datetime` argument. The `datetime` value is relative to the local time zone on the machine where you run `mysqlbinlog`. The value should be in a format accepted for the `DATETIME` or `TIMESTAMP` data types. For example:

```
shell> mysqlbinlog --start-datetime="2005-12-25 11:25:56" binlog.000003
```

This option is useful for point-in-time recovery. See [Section 7.3, “Example Backup and Recovery Strategy”](#).

- `--start-position=N, -j N`

Start reading the binary log at the first event having a position equal to or greater than `N`. This option applies to the first log file named on the command line.

This option is useful for point-in-time recovery. See [Section 7.3, “Example Backup and Recovery Strategy”](#).

- `--stop-datetime=datetime`

Stop reading the binary log at the first event having a timestamp equal to or later than the `datetime` argument. This option is useful for point-in-time recovery. See the description of the `--start-datetime` option for information about the `datetime` value.

This option is useful for point-in-time recovery. See [Section 7.3, “Example Backup and Recovery Strategy”](#).

- `--stop-position=N`

Stop reading the binary log at the first event having a position equal to or greater than `N`. This option applies to the last log file named on the command line.

This option is useful for point-in-time recovery. See [Section 7.3, “Example Backup and Recovery Strategy”](#).

- `--to-last-log, -t`

Do not stop at the end of the requested binary log from a MySQL server, but rather continue printing until the end of the last binary log. If you send the output to the same MySQL server, this may lead to an endless loop. This option requires `--read-from-remote-server`.

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to a remote server.

- `--verbose, -v`

Reconstruct row events and display them as commented SQL statements. If this option is given twice, the output includes comments to indicate column data types and some metadata.

For examples that show the effect of `--base64-output` and `--verbose` on row event output, see [Section 4.6.7.2, “mysqlbinlog Row Event Display”](#).

- `--version, -V`

Display version information and exit.

In MySQL 5.5, the version number shown for `mysqlbinlog` is always 3.3.

You can also set the following variable by using `--var_name=value` syntax:

- `open_files_limit`

Specify the number of open file descriptors to reserve.

You can pipe the output of `mysqlbinlog` into the `mysql` client to execute the events contained in the binary log. This technique is used to recover from a crash when you have an old backup (see [Section 7.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#)). For example:

```
shell> mysqlbinlog binlog.000001 | mysql -u root -p
```

Or:

```
shell> mysqlbinlog binlog.[0-9]* | mysql -u root -p
```

You can also redirect the output of `mysqlbinlog` to a text file instead, if you need to modify the statement log first (for example, to remove statements that you do not want to execute for some reason). After editing the file, execute the statements that it contains by using it as input to the `mysql` program:

```
shell> mysqlbinlog binlog.000001 > tmpfile
shell> ... edit tmpfile ...
shell> mysql -u root -p < tmpfile
```

When `mysqlbinlog` is invoked with the `--start-position` option, it displays only those events with an offset in the binary log greater than or equal to a given position (the given position must match the start of one event). It also has options to stop and start when it sees an event with a given date and time. This enables you to perform point-in-time recovery using the `--stop-datetime` option (to be able to say, for example, “roll forward my databases to how they were today at 10:30 a.m.”).

If you have more than one binary log to execute on the MySQL server, the safe method is to process them all using a single connection to the server. Here is an example that demonstrates what may be *unsafe*:

```
shell> mysqlbinlog binlog.000001 | mysql -u root -p # DANGER!!
shell> mysqlbinlog binlog.000002 | mysql -u root -p # DANGER!!
```

Processing binary logs this way using multiple connections to the server causes problems if the first log file contains a `CREATE TEMPORARY TABLE` statement and the second log contains a statement that uses the temporary table. When the first `mysql` process terminates, the server drops the temporary table. When the second `mysql` process attempts to use the table, the server reports “unknown table.”

To avoid problems like this, use a *single mysql* process to execute the contents of all binary logs that you want to process. Here is one way to do so:

```
shell> mysqlbinlog binlog.000001 binlog.000002 | mysql -u root -p
```

Another approach is to write all the logs to a single file and then process the file:

```
shell> mysqlbinlog binlog.000001 > /tmp/statements.sql
shell> mysqlbinlog binlog.000002 >> /tmp/statements.sql
shell> mysql -u root -p -e "source /tmp/statements.sql"
```

`mysqlbinlog` can produce output that reproduces a `LOAD DATA INFILE` operation without the original data file. `mysqlbinlog` copies the data to a temporary file and writes a `LOAD DATA LOCAL INFILE` statement that refers to the file. The default location of the directory where these files are written is system-specific. To specify a directory explicitly, use the `--local-load` option.

Because `mysqlbinlog` converts `LOAD DATA INFILE` statements to `LOAD DATA LOCAL INFILE` statements (that is, it adds `LOCAL`), both the client and the server that you use to process the statements must be configured with the `LOCAL` capability enabled. See [Section 6.1.6, “Security Issues with LOAD DATA LOCAL”](#).

Warning

The temporary files created for `LOAD DATA LOCAL` statements are *not* automatically deleted because they are needed until you actually execute those statements. You should delete the temporary files yourself after you no longer need the statement log. The files can be found in the temporary file directory and have names like `original_file_name-#-#`.

4.6.7.1 mysqlbinlog Hex Dump Format

The `--hexdump` option causes `mysqlbinlog` to produce a hex dump of the binary log contents:

```
shell> mysqlbinlog --hexdump master-bin.000001
```

The hex output consists of comment lines beginning with `#`, so the output might look like this for the preceding command:

```
/*!40019 SET @@session.max_insert_delayed_threads=0*/;
/*!50003 SET @OLD_COMPLETION_TYPE=@@COMPLETION_TYPE,COMPLETION_TYPE=0*/;
# at 4
#051024 17:24:13 server id 1  end_log_pos 98
# Position Timestamp Type Master ID Size Master Pos Flags
# 00000004 9d fc 5c 43 0f 01 00 00 00 5e 00 00 00 62 00 00 00 00 00
# 00000017 04 00 35 2e 30 2e 31 35 2d 64 65 62 75 67 2d 6c |..5.0.15.debug.1|
# 00000027 6f 67 00 00 00 00 00 00 00 00 00 00 00 00 00 00 |og.....|
# 00000037 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 |.....|
# 00000047 00 00 00 00 9d fc 5c 43 13 38 0d 00 08 00 12 00 |.....C.8.....|
# 00000057 04 04 04 04 12 00 00 4b 00 04 1a |.....K...|
# Start: binlog v 4, server v 5.0.15-debug-log created 051024 17:24:13
# at startup
ROLLBACK;
```

Hex dump output currently contains the elements in the following list. This format is subject to change. (For more information about binary log format, see [MySQL Internals: The Binary Log](#).)

- **Position:** The byte position within the log file.

- **Timestamp:** The event timestamp. In the example shown, '9d fc 5c 43' is the representation of '051024 17:24:13' in hexadecimal.
- **Type:** The event type code. In the example shown, '0f' indicates a `FORMAT_DESCRIPTION_EVENT`. The following table lists the possible type codes.

Type	Name	Meaning
00	UNKNOWN_EVENT	This event should never be present in the log.
01	START_EVENT_V3	This indicates the start of a log file written by MySQL 4 or earlier.
02	QUERY_EVENT	The most common type of events. These contain statements executed on the master.
03	STOP_EVENT	Indicates that master has stopped.
04	ROTATE_EVENT	Written when the master switches to a new log file.
05	INTVAR_EVENT	Used for <code>AUTO_INCREMENT</code> values or when the <code>LAST_INSERT_ID()</code> function is used in the statement.
06	LOAD_EVENT	Used for <code>LOAD DATA INFILE</code> in MySQL 3.23.
07	SLAVE_EVENT	Reserved for future use.
08	CREATE_FILE_EVENT	Used for <code>LOAD DATA INFILE</code> statements. This indicates the start of execution of such a statement. A temporary file is created on the slave. Used in MySQL 4 only.
09	APPEND_BLOCK_EVENT	Contains data for use in a <code>LOAD DATA INFILE</code> statement. The data is stored in the temporary file on the slave.
0a	EXEC_LOAD_EVENT	Used for <code>LOAD DATA INFILE</code> statements. The contents of the temporary file is stored in the table on the slave. Used in MySQL 4 only.
0b	DELETE_FILE_EVENT	Rollback of a <code>LOAD DATA INFILE</code> statement. The temporary file should be deleted on the slave.
0c	NEW_LOAD_EVENT	Used for <code>LOAD DATA INFILE</code> in MySQL 4 and earlier.
0d	RAND_EVENT	Used to send information about random values if the <code>RAND()</code> function is used in the statement.
0e	USER_VAR_EVENT	Used to replicate user variables.
0f	FORMAT_DESCRIPTION_EVENT	This indicates the start of a log file written by MySQL 5 or later.
10	XID_EVENT	Event indicating commit of an XA transaction.
11	BEGIN_LOAD_QUERY_EVENT	Used for <code>LOAD DATA INFILE</code> statements in MySQL 5 and later.
12	EXECUTE_LOAD_QUERY_EVENT	Used for <code>LOAD DATA INFILE</code> statements in MySQL 5 and later.
13	TABLE_MAP_EVENT	Information about a table definition. Used in MySQL 5.1.5 and later.
14	PRE_GA_WRITE_ROWS_EVENT	Row data for a single table that should be created. Used in MySQL 5.1.5 to 5.1.17.
15	PRE_GA_UPDATE_ROWS_EVENT	Row data for a single table that needs to be updated. Used in MySQL 5.1.5 to 5.1.17.

Type	Name	Meaning
16	PRE_GA_DELETE_ROWS_EVENT	Row data for a single table that should be deleted. Used in MySQL 5.1.5 to 5.1.17.
17	WRITE_ROWS_EVENT	Row data for a single table that should be created. Used in MySQL 5.1.18 and later.
18	UPDATE_ROWS_EVENT	Row data for a single table that needs to be updated. Used in MySQL 5.1.18 and later.
19	DELETE_ROWS_EVENT	Row data for a single table that should be deleted. Used in MySQL 5.1.18 and later.
1a	INCIDENT_EVENT	Something out of the ordinary happened. Added in MySQL 5.1.18.

- **Master ID:** The server ID of the master that created the event.
- **Size:** The size in bytes of the event.
- **Master Pos:** The position of the next event in the original master log file.
- **Flags:** 16 flags. Currently, the following flags are used. The others are reserved for future use.

Flag	Name	Meaning
01	LOG_EVENT_BINLOG_IN_USE_F	Log file correctly closed. (Used only in <code>FORMAT_DESCRIPTION_EVENT</code> .) If this flag is set (if the flags are, for example, '01 00') in a <code>FORMAT_DESCRIPTION_EVENT</code> , the log file has not been properly closed. Most probably this is because of a master crash (for example, due to power failure).
02		Reserved for future use.
04	LOG_EVENT_THREAD_SPECIFIC_F	Set if the event is dependent on the connection it was executed in (for example, '04 00'), for example, if the event uses temporary tables.
08	LOG_EVENT_SUPPRESS_USE_F	Set in some circumstances when the event is not dependent on the default database.

4.6.7.2 mysqlbinlog Row Event Display

The following examples illustrate how `mysqlbinlog` displays row events that specify data modifications. These correspond to events with the `WRITE_ROWS_EVENT`, `UPDATE_ROWS_EVENT`, and `DELETE_ROWS_EVENT` type codes. The `--base64-output=DECODE-ROWS` and `--verbose` options may be used to affect row event output.

Suppose that the server is using row-based binary logging and that you execute the following sequence of statements:

```
CREATE TABLE t
(
  id   INT NOT NULL,
  name VARCHAR(20) NOT NULL,
  date DATE NULL
) ENGINE = InnoDB;

START TRANSACTION;
```

```
INSERT INTO t VALUES(1, 'apple', NULL);
UPDATE t SET name = 'pear', date = '2009-01-01' WHERE id = 1;
DELETE FROM t WHERE id = 1;
COMMIT;
```

By default, `mysqlbinlog` displays row events encoded as base-64 strings using `BINLOG` statements. Omitting extraneous lines, the output for the row events produced by the preceding statement sequence looks like this:

```
shell> mysqlbinlog log_file
...
# at 218
#080828 15:03:08 server id 1  end_log_pos 258    Write_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAAALAAAAAaAAAAABEAAAAAAAAABHRLc3QAAXQAawMPCgIUAAQ=
fAS3SBcBAAAAKAAAAAIBAAAQABEAAAAAAAAEAA//8AQAAAVhcHBsZQ==
'/*!*/;
...
# at 302
#080828 15:03:08 server id 1  end_log_pos 356    Update_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAAALAAAC4BAAAAABEAAAAAAAAABHRLc3QAAXQAawMPCgIUAAQ=
fAS3SBgBAAAAANGAAQABEAAAAAAAAEAA///AEAAAFYXBwbGx4AQAAARwZWYyIbIP
'/*!*/;
...
# at 400
#080828 15:03:08 server id 1  end_log_pos 442    Delete_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAAALAAAAJABAAAAABEAAAAAAAAABHRLc3QAAXQAawMPCgIUAAQ=
fAS3SBkBAAAAKgAAALoBAAAQABEAAAAAAAAEAA//4AQAAARwZWYyIbIP
'/*!*/;
```

To see the row events as comments in the form of “pseudo-SQL” statements, run `mysqlbinlog` with the `--verbose` or `-v` option. The output will contain lines beginning with `###`:

```
shell> mysqlbinlog -v log_file
...
# at 218
#080828 15:03:08 server id 1  end_log_pos 258    Write_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAAALAAAAAaAAAAABEAAAAAAAAABHRLc3QAAXQAawMPCgIUAAQ=
fAS3SBcBAAAAKAAAAAIBAAAQABEAAAAAAAAEAA//8AQAAAVhcHBsZQ==
'/*!*/;
### INSERT INTO test.t
### SET
###   @1=1
###   @2='apple'
###   @3=NULL
...
# at 302
#080828 15:03:08 server id 1  end_log_pos 356    Update_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAAALAAAC4BAAAAABEAAAAAAAAABHRLc3QAAXQAawMPCgIUAAQ=
fAS3SBgBAAAAANGAAQABEAAAAAAAAEAA///AEAAAFYXBwbGx4AQAAARwZWYyIbIP
'/*!*/;
### UPDATE test.t
### WHERE
###   @1=1
###   @2='apple'
```

```

### @3=NULL
### SET
### @1=1
### @2='pear'
### @3='2009:01:01'
...
# at 400
#080828 15:03:08 server id 1 end_log_pos 442 Delete_rows: table id 17 flags: STMT_END_F

BINLOG '
fAS3SBMBAAAAALAAAAJABAAAAABEAAAAAAAAABHRlc3QAAXQAawMPCgIUAAQ=
fAS3SBkBAAAAKgAAALoBAAQABEAAAAAAAAEAA//4AQAAARwZWfYIbIP
'/*!*/;
### DELETE FROM test.t
### WHERE
### @1=1
### @2='pear'
### @3='2009:01:01'

```

Specify `--verbose` or `-v` twice to also display data types and some metadata for each column. The output will contain an additional comment following each column change:

```

shell> mysqlbinlog -vv log_file
...
# at 218
#080828 15:03:08 server id 1 end_log_pos 258 Write_rows: table id 17 flags: STMT_END_F

```

You can tell `mysqlbinlog` to suppress the `BINLOG` statements for row events by using the `--base64-output=DECODE-ROWS` option. This is similar to `--base64-output=NEVER` but does not exit with an error if a row event is found. The combination of `--base64-output=DECODE-ROWS` and `--verbose` provides a convenient way to see row events only as SQL statements:

```
shell> mysqlbinlog -v --base64-output=DECODE-ROWS log_file
...
# at 218
#080828 15:03:08 server id 1  end_log_pos 258    Write_rows: table id 17 flags: STMT_END_F
### INSERT INTO test.t
### SET
###   @1=1
###   @2='apple'
###   @3=NULL
...
# at 302
#080828 15:03:08 server id 1  end_log_pos 356    Update_rows: table id 17 flags: STMT_END_F
### UPDATE test.t
### WHERE
###   @1=1
###   @2='apple'

```

Note

You should not suppress `BINLOG` statements if you intend to re-execute `mysqlbinlog` output.

The SQL statements produced by `--verbose` for row events are much more readable than the corresponding `BINLOG` statements. However, they do not correspond exactly to the original SQL statements that generated the events. The following limitations apply:

- The original column names are lost and replaced by `@N`, where `N` is a column number.
- Character set information is not available in the binary log, which affects string column display:
 - There is no distinction made between corresponding binary and nonbinary string types (`BINARY` and `CHAR`, `VARBINARY` and `VARCHAR`, `BLOB` and `TEXT`). The output uses a data type of `STRING` for fixed-length strings and `VARSTRING` for variable-length strings.
 - For multi-byte character sets, the maximum number of bytes per character is not present in the binary log, so the length for string types is displayed in bytes rather than in characters. For example, `STRING(4)` will be used as the data type for values from either of these column types:

```
CHAR(4) CHARACTER SET latin1
CHAR(2) CHARACTER SET ucs2
```

- Due to the storage format for events of type `UPDATE_ROWS_EVENT`, `UPDATE` statements are displayed with the `WHERE` clause preceding the `SET` clause.

Proper interpretation of row events requires the information from the format description event at the beginning of the binary log. Because `mysqlbinlog` does not know in advance whether the rest of the log contains row events, by default it displays the format description event using a `BINLOG` statement in the initial part of the output.

If the binary log is known not to contain any events requiring a `BINLOG` statement (that is, no row events), the `--base64-output=NEVER` option can be used to prevent this header from being written.

4.6.8 `mysqldumpslow` — Summarize Slow Query Log Files

The MySQL slow query log contains information about queries that take a long time to execute (see [Section 5.2.5, “The Slow Query Log”](#)). `mysqldumpslow` parses MySQL slow query log files and prints a summary of their contents.

Normally, `mysqldumpslow` groups queries that are similar except for the particular values of number and string data values. It “abstracts” these values to `N` and `'S'` when displaying summary output. The `-a` and `-n` options can be used to modify value abstracting behavior.

Invoke `mysqldumpslow` like this:

```
shell> mysqldumpslow [options] [log_file ...]
```

`mysqldumpslow` supports the following options.

Table 4.15 `mysqldumpslow` Options

Format	Option File	Description
<code>-a</code>		Do not abstract all numbers to <code>N</code> and strings to <code>S</code>
<code>-n num</code>		Abstract numbers with at least the specified digits
<code>--debug</code>	<code>debug</code>	Write debugging information
<code>-g pattern</code>		Only consider statements that match the pattern
<code>--help</code>		Display help message and exit
<code>-h name</code>		Host name of the server in the log file name
<code>-i name</code>		Name of the server instance
<code>-l</code>		Do not subtract lock time from total time
<code>-r</code>		Reverse the sort order
<code>-s value</code>		How to sort output
<code>-t num</code>		Display only first <code>num</code> queries
<code>--verbose</code>	<code>verbose</code>	Verbose mode

- `--help`

Display a help message and exit.

- `-a`

Do not abstract all numbers to `N` and strings to `'S'`.

- `--debug`, `-d`

Run in debug mode.

- `-g pattern`

Consider only queries that match the (`grep`-style) pattern.

- `-h host_name`

Host name of MySQL server for `*-slow.log` file name. The value can contain a wildcard. The default is `*` (match all).

- `-i name`

Name of server instance (if using `mysql.server` startup script).

- `-l`

Do not subtract lock time from total time.

- `-n N`

Abstract numbers with at least `N` digits within names.

- `-r`

Reverse the sort order.

- `-s sort_type`

How to sort the output. The value of `sort_type` should be chosen from the following list:

- `t, at`: Sort by query time or average query time
- `l, al`: Sort by lock time or average lock time
- `r, ar`: Sort by rows sent or average rows sent
- `c`: Sort by count

By default, `mysqldumpslow` sorts by average query time (equivalent to `-s at`).

- `-t N`

Display only the first `N` queries in the output.

- `--verbose, -v`

Verbose mode. Print more information about what the program does.

Example of usage:

```
shell> mysqldumpslow

Reading mysql slow query log from /usr/local/mysql/data/mysqld51-apple-slow.log
Count: 1  Time=4.32s (4s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
insert into t2 select * from t1

Count: 3  Time=2.53s (7s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
```

```
insert into t2 select * from t1 limit N
Count: 3  Time=2.13s (6s)  Lock=0.00s (0s)  Rows=0.0 (0), root[root]@localhost
insert into t1 select * from t1
```

4.6.9 mysqlhotcopy — A Database Backup Program

`mysqlhotcopy` is a Perl script that was originally written and contributed by Tim Bunce. It uses `FLUSH TABLES`, `LOCK TABLES`, and `cp` or `scp` to make a database backup. It is a fast way to make a backup of the database or single tables, but it can be run only on the same machine where the database directories are located. `mysqlhotcopy` works only for backing up `MyISAM` and `ARCHIVE` tables. It runs on Unix.

To use `mysqlhotcopy`, you must have read access to the files for the tables that you are backing up, the `SELECT` privilege for those tables, the `RELOAD` privilege (to be able to execute `FLUSH TABLES`), and the `LOCK TABLES` privilege (to be able to lock the tables).

```
shell> mysqlhotcopy db_name [/path/to/new_directory]
```

```
shell> mysqlhotcopy db_name_1 ... db_name_n /path/to/new_directory
```

Back up tables in the given database that match a regular expression:

```
shell> mysqlhotcopy db_name./regex/
```

The regular expression for the table name can be negated by prefixing it with a tilde (“~”):

```
shell> mysqlhotcopy db_name./~regex/
```

`mysqlhotcopy` supports the following options, which can be specified on the command line or in the `[mysqlhotcopy]` and `[client]` groups of an option file. For information about option files, see [Section 4.2.6, “Using Option Files”](#).

Table 4.16 `mysqlhotcopy` Options

Format	Option File	Description	Introduced
<code>--addtodest</code>	<code>addtodest</code>	Do not rename target directory (if it exists); merely add files to it	
<code>--allowold</code>	<code>allowold</code>	Do not abort if a target exists; rename it by adding an <code>_old</code> suffix	
<code>--checkpoint=db_name.tbl_name</code>	<code>checkpoint</code>	Insert checkpoint entries	
<code>--chroot=path</code>	<code>chroot</code>	Base directory of the chroot jail in which <code>mysqld</code> operates	
<code>--debug</code>	<code>debug</code>	Write a debugging log	
<code>--dryrun</code>	<code>dryrun</code>	Report actions without performing them	
<code>--flushlog</code>	<code>flushlog</code>	Flush logs after all tables are locked	
<code>--help</code>		Display help message and exit	
<code>--host=host_name</code>	<code>host</code>	Connect to the MySQL server on the given host	
<code>--keepold</code>	<code>keepold</code>	Do not delete previous (renamed) target when done	

Format	Option File	Description	Introduced
<code>--method</code>	<code>method</code>	The method for copying files	
<code>--noindices</code>	<code>noindices</code>	Do not include full index files in the backup	
<code>--old_server</code>	<code>old_server</code>	Connect to server that does not support FLUSH TABLES <code>tbl_list</code> WITH READ LOCK	5.5.3
<code>--password[=password]</code>	<code>password</code>	The password to use when connecting to the server	
<code>--port=port_num</code>	<code>port</code>	The TCP/IP port number to use for the connection	
<code>--quiet</code>	<code>quiet</code>	Be silent except for errors	
<code>--regex</code>	<code>regex</code>	Copy all databases with names that match the given regular expression	
<code>--resetmaster</code>	<code>resetmaster</code>	Reset the binary log after locking all the tables	
<code>--resetslave</code>	<code>resetslave</code>	Reset the master.info file after locking all the tables	
<code>--socket=path</code>	<code>socket</code>	For connections to localhost	
<code>--tmpdir=path</code>	<code>tmpdir</code>	The temporary directory	
<code>--user=user_name,</code>	<code>user</code>	MySQL user name to use when connecting to server	

- `--help, -?`

Display a help message and exit.

- `--addtodest`

Do not rename target directory (if it exists); merely add files to it.

- `--allowold`

Do not abort if a target exists; rename it by adding an `_old` suffix.

- `--checkpoint=db_name.tbl_name`

Insert checkpoint entries into the specified database `db_name` and table `tbl_name`.

- `--chroot=path`

Base directory of the `chroot` jail in which `mysqld` operates. The `path` value should match that of the `--chroot` option given to `mysqld`.

- `--debug`

Enable debug output.

- `--dryrun, -n`

Report actions without performing them.

- `--flushlog`

Flush logs after all tables are locked.

- `--host=host_name, -h host_name`

The host name of the local host to use for making a TCP/IP connection to the local server. By default, the connection is made to `localhost` using a Unix socket file.

- `--keepold`

Do not delete previous (renamed) target when done.

- `--method=command`

The method for copying files (`cp` or `scp`). The default is `cp`.

- `--noindices`

Do not include full index files for `MyISAM` tables in the backup. This makes the backup smaller and faster. The indexes for reloaded tables can be reconstructed later with `myisamchk -rq`.

- `--password=password, -ppassword`

The password to use when connecting to the server. The password value is not optional for this option, unlike for other MySQL programs.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--port=port_num, -P port_num`

The TCP/IP port number to use when connecting to the local server.

- `--old_server`

As of MySQL 5.5.3, `mysqlhotcopy` uses `FLUSH TABLES tbl_list WITH READ LOCK` to flush and lock tables. Use the `--old_server` option if the server is older than 5.5.3, which is when that statement was introduced. This option was added in MySQL 5.5.3.

- `--quiet, -q`

Be silent except for errors.

- `--record_log_pos=db_name.tbl_name`

Record master and slave status in the specified database `db_name` and table `tbl_name`.

- `--regexp=expr`

Copy all databases with names that match the given regular expression.

- `--resetmaster`

Reset the binary log after locking all the tables.

- `--resetslave`

Reset the `master.info` file after locking all the tables.

- `--socket=path, -S path`

The Unix socket file to use for connections to `localhost`.

- `--suffix=str`

The suffix to use for names of copied databases.

- `--tmpdir=path`

The temporary directory. The default is `/tmp`.

- `--user=user_name, -u user_name`

The MySQL user name to use when connecting to the server.

Use `perldoc` for additional `mysqlhotcopy` documentation, including information about the structure of the tables needed for the `--checkpoint` and `--record_log_pos` options:

```
shell> perldoc mysqlhotcopy
```

4.6.10 `mysql_convert_table_format` — Convert Tables to Use a Given Storage Engine

`mysql_convert_table_format` converts the tables in a database to use a particular storage engine (MyISAM by default). `mysql_convert_table_format` is written in Perl and requires that the `DBI` and `DBD:mysql` Perl modules be installed (see [Section 2.13, “Perl Installation Notes”](#)).

Invoke `mysql_convert_table_format` like this:

```
shell> mysql_convert_table_format [options]db_name
```

The `db_name` argument indicates the database containing the tables to be converted.

`mysql_convert_table_format` supports the options described in the following list.

- `--help`

Display a help message and exit.

- `--force`

Continue even if errors occur.

- `--host=host_name`

Connect to the MySQL server on the given host.

- `--password=password`

The password to use when connecting to the server. Note that the password value is not optional for this option, unlike for other MySQL programs.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--port=port_num`

The TCP/IP port number to use for the connection.

- `--socket=path`

For connections to `localhost`, the Unix socket file to use.

- `--type=engine_name`

Specify the storage engine that the tables should be converted to use. The default is `MyISAM` if this option is not given.

- `--user=user_name`

The MySQL user name to use when connecting to the server.

- `--verbose`

Verbose mode. Print more information about what the program does.

- `--version`

Display version information and exit.

4.6.11 `mysql_find_rows` — Extract SQL Statements from Files

`mysql_find_rows` reads files containing SQL statements and extracts statements that match a given regular expression or that contain `USE db_name` or `SET` statements. The utility expects statements to be terminated with semicolon (`;`) characters.

Invoke `mysql_find_rows` like this:

```
shell> mysql_find_rows [options] [file_name ...]
```

Each `file_name` argument should be the name of file containing SQL statements. If no file names are given, `mysql_find_rows` reads the standard input.

Examples:

```
mysql_find_rows --regexp=problem_table --rows=20 < update.log
mysql_find_rows --regexp=problem_table update-log.1 update-log.2
```

`mysql_find_rows` supports the following options:

- `--help, --Information`

Display a help message and exit.

- `--regexp=pattern`

Display queries that match the pattern.

- `--rows=N`

Quit after displaying `N` queries.

- `--skip-use-db`

Do not include `USE db_name` statements in the output.

- `--start_row=N`

Start output from this row.

4.6.12 `mysql_fix_extensions` — Normalize Table File Name Extensions

`mysql_fix_extensions` converts the extensions for `MyISAM` (or `ISAM`) table files to their canonical forms. It looks for files with extensions matching any lettercase variant of `.frm`, `.myd`, `.myi`, `.isd`, and `.ism` and renames them to have extensions of `.frm`, `.MYD`, `.MYI`, `.ISD`, and `.ISM`, respectively. This can be useful after transferring the files from a system with case-insensitive file names (such as Windows) to a system with case-sensitive file names.

Invoke `mysql_fix_extensions` like this, where `data_dir` is the path name to the MySQL data directory.

```
shell> mysql_fix_extensions data_dir
```

4.6.13 `mysql_setpermission` — Interactively Set Permissions in Grant Tables

`mysql_setpermission` is a Perl script that was originally written and contributed by Luuk de Boer. It interactively sets permissions in the MySQL grant tables. `mysql_setpermission` is written in Perl and requires that the `DBI` and `DBD:mysql` Perl modules be installed (see [Section 2.13, “Perl Installation Notes”](#)).

Invoke `mysql_setpermission` like this:

```
shell> mysql_setpermission [options]
```

`options` should be either `--help` to display the help message, or options that indicate how to connect to the MySQL server. The account used when you connect determines which permissions you have when attempting to modify existing permissions in the grant tables.

`mysql_setpermissions` also reads options from the `[client]` and `[perl]` groups in the `.my.cnf` file in your home directory, if the file exists.

`mysql_setpermission` supports the following options:

- `--help`

Display a help message and exit.

- `--host=host_name`

Connect to the MySQL server on the given host.

- `--password=password`

The password to use when connecting to the server. Note that the password value is not optional for this option, unlike for other MySQL programs.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

- `--port=port_num`

The TCP/IP port number to use for the connection.

- `--socket=path`

For connections to `localhost`, the Unix socket file to use.

- `--user=user_name`

The MySQL user name to use when connecting to the server.

4.6.14 `mysql_waitpid` — Kill Process and Wait for Its Termination

`mysql_waitpid` signals a process to terminate and waits for the process to exit. It uses the `kill()` system call and Unix signals, so it runs on Unix and Unix-like systems.

Invoke `mysql_waitpid` like this:

```
shell> mysql_waitpid [options] pid wait_time
```

`mysql_waitpid` sends signal 0 to the process identified by `pid` and waits up to `wait_time` seconds for the process to terminate. `pid` and `wait_time` must be positive integers.

If process termination occurs within the wait time or the process does not exist, `mysql_waitpid` returns 0. Otherwise, it returns 1.

If the `kill()` system call cannot handle signal 0, `mysql_waitpid()` uses signal 1 instead.

`mysql_waitpid` supports the following options:

- `--help, -?, -I`

Display a help message and exit.

- `--verbose, -v`

Verbose mode. Display a warning if signal 0 could not be used and signal 1 is used instead.

- `--version, -V`

Display version information and exit.

4.6.15 `mysql_zap` — Kill Processes That Match a Pattern

`mysql_zap` kills processes that match a pattern. It uses the `ps` command and Unix signals, so it runs on Unix and Unix-like systems.

Invoke `mysql_zap` like this:

```
shell> mysql_zap [-signal] [-?If] pattern
```

A process matches if its output line from the `ps` command contains the pattern. By default, `mysql_zap` asks for confirmation for each process. Respond `y` to kill the process, or `q` to exit `mysql_zap`. For any other response, `mysql_zap` does not attempt to kill the process.

If the `-signal` option is given, it specifies the name or number of the signal to send to each process. Otherwise, `mysql_zap` tries first with `TERM` (signal 15) and then with `KILL` (signal 9).

`mysql_zap` supports the following additional options:

- `--help, -?, -I`

Display a help message and exit.

- `-f`

Force mode. `mysql_zap` attempts to kill each process without confirmation.

- `-t`

Test mode. Display information about each process but do not kill it.

4.7 MySQL Program Development Utilities

This section describes some utilities that you may find useful when developing MySQL programs.

In shell scripts, you can use the `my_print_defaults` program to parse option files and see what options would be used by a given program. The following example shows the output that `my_print_defaults` might produce when asked to show the options found in the `[client]` and `[mysql]` groups:

```
shell> my_print_defaults client mysql
--port=3306
--socket=/tmp/mysql.sock
--no-auto-rehash
```

Note for developers: Option file handling is implemented in the C client library simply by processing all options in the appropriate group or groups before any command-line arguments. This works well for programs that use the last instance of an option that is specified multiple times. If you have a C or C++ program that handles multiply specified options this way but that doesn't read option files, you need add only two lines to give it that capability. Check the source code of any of the standard MySQL clients to see how to do this.

Several other language interfaces to MySQL are based on the C client library, and some of them provide a way to access option file contents. These include Perl and Python. For details, see the documentation for your preferred interface.

4.7.1 `mysql2mysql` — Convert mSQL Programs for Use with MySQL

Initially, the MySQL C API was developed to be very similar to that for the mSQL database system. Because of this, mSQL programs often can be converted relatively easily for use with MySQL by changing the names of the C API functions.

The `mysql2mysql` utility performs the conversion of mSQL C API function calls to their MySQL equivalents. `mysql2mysql` converts the input file in place, so make a copy of the original before converting it. For example, use `mysql2mysql` like this:

```
shell> cp client-prog.c client-prog.c.orig
shell> mysql2mysql client-prog.c
client-prog.c converted
```

Then examine `client-prog.c` and make any post-conversion revisions that may be necessary.

`mysql2mysql` uses the `replace` utility to make the function name substitutions. See [Section 4.8.2, “replace — A String-Replacement Utility”](#).

4.7.2 mysql_config — Display Options for Compiling Clients

`mysql_config` provides you with useful information for compiling your MySQL client and connecting it to MySQL. It is a shell script, so it is available only on Unix and Unix-like systems.

`mysql_config` supports the following options.

- `--cflags`

Compiler flags to find include files and critical compiler flags and defines used when compiling the `libmysqlclient` library. The options returned are tied to the specific compiler that was used when the library was created and might clash with the settings for your own compiler. Use `--include` for more portable options that contain only include paths.

- `--include`

Compiler options to find MySQL include files.

- `--libmysqld-libs, --embedded`

Libraries and options required to link with the MySQL embedded server.

- `--libs`

Libraries and options required to link with the MySQL client library.

- `--libs_r`

Libraries and options required to link with the thread-safe MySQL client library. In MySQL 5.5, all client libraries are thread-safe, so this option need not be used. The `--libs` option can be used in all cases.

- `--plugindir`

The default plugin directory path name, defined when configuring MySQL.

- `--port`

The default TCP/IP port number, defined when configuring MySQL.

- `--socket`

The default Unix socket file, defined when configuring MySQL.

- `--version`

Version number for the MySQL distribution.

If you invoke `mysql_config` with no options, it displays a list of all options that it supports, and their values:

```
shell> mysql_config
Usage: /usr/local/mysql/bin/mysql_config [options]
Options:
--cflags          [-I/usr/local/mysql/include/mysql -mcpu=pentiumpro]
--include         [-I/usr/local/mysql/include/mysql]
--libs           [-L/usr/local/mysql/lib/mysql -lmysqlclient
                  -lpthread -lm -lrt -lssl -lcrypto -ldl]
--libs_r         [-L/usr/local/mysql/lib/mysql -lmysqlclient_r]
```

```
-lpthread -lm -lrt -lssl -lcrypto -ldl]
--socket      [/tmp/mysql.sock]
--port        [3306]
--version      [5.5.31]
--libmysqld-libs [-L/usr/local/mysql/lib/mysql -lmysqld
               -lpthread -lm -lrt -lssl -lcrypto -ldl -lcrypt]
```

You can use `mysql_config` within a command line using backticks to include the output that it produces for a particular option. For example, to compile and link a MySQL client program, use `mysql_config` as follows:

```
shell> gcc -c `mysql_config --cflags` progname.c
shell> gcc -o progname progname.o `mysql_config --libs`
```

4.7.3 my_print_defaults — Display Options from Option Files

`my_print_defaults` displays the options that are present in option groups of option files. The output indicates what options will be used by programs that read the specified option groups. For example, the `mysqlcheck` program reads the `[mysqlcheck]` and `[client]` option groups. To see what options are present in those groups in the standard option files, invoke `my_print_defaults` like this:

```
shell> my_print_defaults mysqlcheck client
--user=myusername
--password=secret
--host=localhost
```

The output consists of options, one per line, in the form that they would be specified on the command line.

`my_print_defaults` supports the following options.

- `--help, -?`
Display a help message and exit.
- `--config-file=file_name, --defaults-file=file_name, -c file_name`
Read only the given option file.
- `--debug=debug_options, -# debug_options`
Write a debugging log. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:o,/tmp/my_print_defaults.trace`.
- `--defaults-extra-file=file_name, --extra-file=file_name, -e file_name`
Read this option file after the global option file but (on Unix) before the user option file.
- `--defaults-group-suffix=suffix, -g suffix`
In addition to the groups named on the command line, read groups that have the given suffix.
- `--no-defaults, -n`
Return an empty string.
- `--verbose, -v`
Verbose mode. Print more information about what the program does.

- `--version, -V`

Display version information and exit.

4.7.4 `resolve_stack_dump` — Resolve Numeric Stack Trace Dump to Symbols

`resolve_stack_dump` resolves a numeric stack dump to symbols.

Invoke `resolve_stack_dump` like this:

```
shell> resolve_stack_dump [options] symbols_file [numeric_dump_file]
```

The symbols file should include the output from the `nm --numeric-sort mysqld` command. The numeric dump file should contain a numeric stack track from `mysqld`. If no numeric dump file is named on the command line, the stack trace is read from the standard input.

`resolve_stack_dump` supports the following options.

- `--help, -h`

Display a help message and exit.

- `--numeric-dump-file=file_name, -n file_name`

Read the stack trace from the given file.

- `--symbols-file=file_name, -s file_name`

Use the given symbols file.

- `--version, -V`

Display version information and exit.

For more information, see [Section 24.4.1.5, “Using a Stack Trace”](#).

4.8 Miscellaneous Programs

4.8.1 `perror` — Explain Error Codes

For most system errors, MySQL displays, in addition to an internal text message, the system error code in one of the following styles:

```
message ... (errno: #)
message ... (Errcode: #)
```

You can find out what the error code means by examining the documentation for your system or by using the `perror` utility.

`perror` prints a description for a system error code or for a storage engine (table handler) error code.

Invoke `perror` like this:

```
shell> perror [options] errorcode ...
```

Example:

```
shell> perror 13 64
OS error code 13: Permission denied
OS error code 64: Machine is not on the network
```

To obtain the error message for a MySQL Cluster error code, invoke `perror` with the `--ndb` option:

```
shell> perror --ndb errorcode
```

Note that the meaning of system error messages may be dependent on your operating system. A given error code may mean different things on different operating systems.

`perror` supports the following options.

- `--help, --info, -I, -?`
Display a help message and exit.
- `--ndb`
Print the error message for a MySQL Cluster error code.
- `--silent, -s`
Silent mode. Print only the error message.
- `--verbose, -v`
Verbose mode. Print error code and message. This is the default behavior.
- `--version, -V`
Display version information and exit.

4.8.2 `replace` — A String-Replacement Utility

The `replace` utility program changes strings in place in files or on the standard input.

Invoke `replace` in one of the following ways:

```
shell> replace from to [from to] ... -- file_name [file_name] ...
shell> replace from to [from to] ... < file_name
```

`from` represents a string to look for and `to` represents its replacement. There can be one or more pairs of strings.

Use the `--` option to indicate where the string-replacement list ends and the file names begin. In this case, any file named on the command line is modified in place, so you may want to make a copy of the original before converting it. `replace` prints a message indicating which of the input files it actually modifies.

If the `--` option is not given, `replace` reads the standard input and writes to the standard output.

`replace` uses a finite state machine to match longer strings first. It can be used to swap strings. For example, the following command swaps `a` and `b` in the given files, `file1` and `file2`:

```
shell> replace a b b a -- file1 file2 ...
```

The `replace` program is used by `mysql2mysql`. See [Section 4.7.1, “mysql2mysql — Convert mSQL Programs for Use with MySQL”](#).

`replace` supports the following options.

- `-, -I`
Display a help message and exit.
- `-#debug_options`
Enable debugging.
- `-s`
Silent mode. Print less information what the program does.
- `-v`
Verbose mode. Print more information about what the program does.
- `-V`
Display version information and exit.

4.8.3 `resolveip` — Resolve Host name to IP Address or Vice Versa

The `resolveip` utility resolves host names to IP addresses and vice versa.

Invoke `resolveip` like this:

```
shell> resolveip [options] {host_name|ip-addr} ...
```

`resolveip` supports the following options.

- `--help, --info, -, -I`
Display a help message and exit.
- `--silent, -s`
Silent mode. Produce less output.
- `--version, -V`
Display version information and exit.

Chapter 5 MySQL Server Administration

5.1 The MySQL Server	435
5.1.1 Server Option and Variable Reference	436
5.1.2 Server Configuration Defaults	465
5.1.3 Server Command Options	466
5.1.4 Server System Variables	501
5.1.5 Using System Variables	609
5.1.6 Server Status Variables	621
5.1.7 Server SQL Modes	648
5.1.8 Server Plugins	656
5.1.9 IPv6 Support	660
5.1.10 Server-Side Help	665
5.1.11 Server Response to Signals	665
5.1.12 The Shutdown Process	666
5.2 MySQL Server Logs	667
5.2.1 Selecting General Query and Slow Query Log Output Destinations	668
5.2.2 The Error Log	670
5.2.3 The General Query Log	672
5.2.4 The Binary Log	673
5.2.5 The Slow Query Log	686
5.2.6 Server Log Maintenance	687
5.3 Running Multiple MySQL Instances on One Machine	688
5.3.1 Setting Up Multiple Data Directories	690
5.3.2 Running Multiple MySQL Instances on Windows	691
5.3.3 Running Multiple MySQL Instances on Unix	694
5.3.4 Using Client Programs in a Multiple-Server Environment	695
5.4 Tracing <code>mysqld</code> Using DTrace	696
5.4.1 <code>mysqld</code> DTrace Probe Reference	697

MySQL Server (`mysqld`) is the main program that does most of the work in a MySQL installation. This chapter provides an overview of MySQL Server and covers general server administration:

- Server configuration.
- The server log files.
- Management of multiple servers on a single machine.

For additional information on administrative topics, see also:

- [Chapter 6, Security](#)
- [Chapter 7, Backup and Recovery](#)
- [Chapter 17, Replication](#)

5.1 The MySQL Server

`mysqld` is the MySQL server. The following discussion covers these MySQL server configuration topics:

- Startup options that the server supports. You can specify these options on the command line, through configuration files, or both.

- Server system variables. These variables reflect the current state and values of the startup options, some of which can be modified while the server is running.
- Server status variables. These variables contain counters and statistics about runtime operation.
- How to set the server SQL mode. This setting modifies certain aspects of SQL syntax and semantics, for example for compatibility with code from other database systems, or to control the error handling for particular situations.
- The server shutdown process. There are performance and reliability considerations depending on the type of table (transactional or nontransactional) and whether you use replication.

**Note**

Not all storage engines are supported by all MySQL server binaries and configurations. To find out how to determine which storage engines your MySQL server installation supports, see [Section 13.7.5.17](#), “[SHOW ENGINES Syntax](#)”.

5.1.1 Server Option and Variable Reference

The following table provides a list of all the command line options, server and status variables applicable within `mysqld`.

The table lists command-line options (Cmd-line), options valid in configuration files (Option file), server system variables (System Var), and status variables (Status var) in one unified list, with notification of where each option/variable is valid. If a server option set on the command line or in an option file differs from the name of the corresponding server system or status variable, the variable name is noted immediately below the corresponding option. For status variables, the scope of the variable is shown (Scope) as either global, session, or both. Please see the corresponding sections for details on setting and using the options and variables. Where appropriate, a direct link to further information on the item as available.

For a version of this table that is specific to MySQL Cluster, see [Section 18.3.4.1](#), “[MySQL Cluster `mysqld` Option and Variable Reference](#)”.

Table 5.1 Option/Variable Summary

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
abort-slave-event-count	Yes	Yes				
Aborted_clients				Yes	Global	No

^aThis option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

^bThis option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

5.1.2 Server Configuration Defaults

The MySQL server has many operating parameters, which you can change at server startup using command-line options or configuration files (option files). It is also possible to change many parameters at runtime. For general instructions on setting parameters at startup or runtime, see [Section 5.1.3, “Server Command Options”](#), and [Section 5.1.4, “Server System Variables”](#).

MySQL provides a number of preconfigured option files that can be used as a basis for tuning the MySQL server. Look for files named `my-small.cnf`, `my-medium.cnf`, `my-large.cnf`, and `my-huge.cnf`, which are sample option files for small, medium, large, and very large systems. On Windows, the extension is `.ini` rather than `.cnf`.

**Note**

On Windows, the `.ini` or `.cnf` option file extension might not be displayed.

For a binary distribution, look for the sample files in or under your installation directory. If you have a source distribution, look in the `support-files` directory. To use a sample file as a base configuration file, rename a copy of it and place the copy in the appropriate location. Regarding names and appropriate location, see the general information provided in [Section 4.2.6, “Using Option Files”](#). That section also describes option file format and syntax.

5.1.3 Server Command Options

When you start the `mysqld` server, you can specify program options using any of the methods described in [Section 4.2.3, “Specifying Program Options”](#). The most common methods are to provide options in an option file or on the command line. However, in most cases it is desirable to make sure that the server uses the same options each time it runs. The best way to ensure this is to list them in an option file. See [Section 4.2.6, “Using Option Files”](#).

`mysqld` reads options from the `[mysqld]` and `[server]` groups. `mysqld_safe` reads options from the `[mysqld]`, `[server]`, `[mysqld_safe]`, and `[safe_mysqld]` groups. `mysql.server` reads options from the `[mysqld]` and `[mysql.server]` groups.

An embedded MySQL server usually reads options from the `[server]`, `[embedded]`, and `[xxxxx_SERVER]` groups, where `xxxxx` is the name of the application into which the server is embedded.

`mysqld` accepts many command options. For a brief summary, execute `mysqld --help`. To see the full list, use `mysqld --verbose --help`.

The following list shows some of the most common server options. Additional options are described in other sections:

- Options that affect security: See [Section 6.1.4, “Security-Related `mysqld` Options and Variables”](#).
- SSL-related options: See [Section 6.3.9.4, “SSL Command Options”](#).
- Binary log control options: See [Section 5.2.4, “The Binary Log”](#).
- Replication-related options: See [Section 17.1.3, “Replication and Binary Logging Options and Variables”](#).
- Options for loading plugins such as pluggable storage engines: See [Section 5.1.8.1, “Installing and Uninstalling Plugins”](#).
- Options specific to particular storage engines: See [Section 14.15, “InnoDB Startup Options and System Variables”](#), [Section 15.3.1, “MyISAM Startup Options”](#), and [Section 18.3.4.2, “MySQL Server Options for MySQL Cluster”](#).

You can also set the values of server system variables by using variable names as options, as described at the end of this section.

Some options control the size of buffers or caches. For a given buffer, the server might need to allocate internal data structures. These structures typically are allocated from the total memory allocated to the buffer, and the amount of space required might be platform dependent. This means that when you assign a value to an option that controls a buffer size, the amount of space actually available might differ from the value assigned. In some cases, the amount might be less than the value assigned. It is also possible that the server will adjust a value upward. For example, if you assign a value of 0 to an option for which the minimal value is 1024, the server will set the value to 1024.

Values for buffer sizes, lengths, and stack sizes are given in bytes unless otherwise specified.

Some options take file name values. Unless otherwise specified, the default file location is the data directory if the value is a relative path name. To specify the location explicitly, use an absolute path name. Suppose that the data directory is `/var/mysql/data`. If a file-valued option is given as a relative path name, it will be located under `/var/mysql/data`. If the value is an absolute path name, its location is as given by the path name.

- `--help, -?`

Command-Line Format	<code>-?</code>
	<code>--help</code>
Option-File Format	<code>help</code>

Display a short help message and exit. Use both the `--verbose` and `--help` options to see the full message.

- `--allow-suspicious-udfs`

Command-Line Format	<code>--allow-suspicious-udfs</code>	
Option-File Format	<code>allow-suspicious-udfs</code>	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>FALSE</code>

This option controls whether user-defined functions that have only an `xxx` symbol for the main function can be loaded. By default, the option is off and only UDFs that have at least one auxiliary symbol can be loaded; this prevents attempts at loading functions from shared object files other than those containing legitimate UDFs. See [Section 24.3.2.6, “User-Defined Function Security Precautions”](#).

- `--ansi`

Command-Line Format	<code>--ansi</code>
	<code>-a</code>
Option-File Format	<code>ansi</code>

Use standard (ANSI) SQL syntax instead of MySQL syntax. For more precise control over the server SQL mode, use the `--sql-mode` option instead. See [Section 1.8, “MySQL Standards Compliance”](#), and [Section 5.1.7, “Server SQL Modes”](#).

- `--basedir=path, -b path`

Command-Line Format	<code>--basedir=path</code>
	<code>-b</code>
Option-File Format	<code>basedir</code>
System Variable Name	<code>basedir</code>
Variable Scope	Global
Dynamic Variable	No
	Permitted Values

	Type	<code>directory name</code>
--	-------------	-----------------------------

The path to the MySQL installation directory. All paths are usually resolved relative to this directory.

- `--big-tables`

Command-Line Format	<code>--big-tables</code>	
Option-File Format	<code>big-tables</code>	
System Variable Name	<code>big_tables</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>OFF</code>

Enable large result sets by saving all temporary sets in files. This option prevents most “table full” errors, but also slows down queries for which in-memory tables would suffice. Since MySQL 3.23.2, the server is able to handle large result sets automatically by using memory for small temporary tables and switching to disk tables where necessary.

- `--bind-address=addr`

Command-Line Format	<code>--bind-address=addr</code>	
Option-File Format	<code>bind-address</code>	
System Variable Name	<code>bind_address</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>string</code>
	Default	<code>0.0.0.0</code>

The MySQL server listens on a single network socket for TCP/IP connections. This socket is bound to a single address, but it is possible for an address to map onto multiple network interfaces. The default address is `0.0.0.0`. To specify an address explicitly, use the `--bind-address=addr` option at server startup, where `addr` is an IPv4 or IPv6 address or a host name. (IPv6 addresses are not supported before MySQL 5.5.3.) If `addr` is a host name, the server resolves the name to an IP address and binds to that address.

The server treats different types of addresses as follows:

- If the address is `0.0.0.0`, the server accepts TCP/IP connections on all server host IPv4 interfaces.
- If the address is `::`, the server accepts TCP/IP connections on all server host IPv4 and IPv6 interfaces. Use this address to permit both IPv4 and IPv6 connections on all server interfaces.
- If the address is an IPv4-mapped address, the server accepts TCP/IP connections for that address, in either IPv4 or IPv6 format. For example, if the server is bound to `::ffff:127.0.0.1`, clients can connect using `--host=127.0.0.1` or `--host>::ffff:127.0.0.1`.

- If the address is a “regular” IPv4 or IPv6 address (such as `127.0.0.1` or `::1`), the server accepts TCP/IP connections only for that IPv4 or IPv6 address.

If you intend to bind the server to a specific address, be sure that the `mysql.user` grant table contains an account with administrative privileges that you can use to connect to that address. Otherwise, you will not be able to shut down the server. For example, if you bind the server to `::`, you can connect to it using all existing accounts. But if you bind the server to `::1`, it accepts connections only on that address. In that case, first make sure that the `'root'@'::1'` account is present in the `mysql.user` table so you can still connect to the server to shut it down.

- `--binlog-format={ROW|STATEMENT|MIXED}`

Command-Line Format	<code>--binlog-format=format</code>	
Option-File Format	<code>binlog-format</code>	
System Variable Name	<code>binlog_format</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>enumeration</code>
	Default	<code>STATEMENT</code>
	Valid Values	<code>ROW</code>
		<code>STATEMENT</code>
		<code>MIXED</code>

Specify whether to use row-based, statement-based, or mixed replication. Statement-based is the default in MySQL 5.5. This is also true for MySQL Cluster NDB 7.2.1 and later. See [Section 17.1.2, “Replication Formats”](#).

Under some conditions, changing this variable at runtime is not possible, or causes replication to fail. See [Section 5.2.4.2, “Setting The Binary Log Format”](#), for more information.

Prior to MySQL 5.5, setting the binary logging format without enabling binary logging prevented the MySQL server from starting. In MySQL 5.5, the server starts in such cases, the `binlog_format` global system variable is set, and a warning is logged instead of an error. (Bug #42928)

- `--bootstrap`

Command-Line Format	<code>--bootstrap</code>
Option-File Format	<code>bootstrap</code>

This option is used by the `mysql_install_db` script to create the MySQL privilege tables without having to start a full MySQL server.

- `--character-sets-dir=path`

Command-Line Format	<code>--character-sets-dir=path</code>
Option-File Format	<code>character-sets-dir</code>
System Variable Name	<code>character_sets_dir</code>
Variable Scope	Global

Dynamic Variable	No	
	Permitted Values	
	Type	directory name

The directory where character sets are installed. See [Section 10.5, “Character Set Configuration”](#).

- `--character-set-client-handshake`

Command-Line Format	<code>--character-set-client-handshake</code>	
Option-File Format	<code>character-set-client-handshake</code>	
	Permitted Values	
	Type	boolean
	Default	TRUE

Do not ignore character set information sent by the client. To ignore client information and use the default server character set, use `--skip-character-set-client-handshake`; this makes MySQL behave like MySQL 4.0.

- `--character-set-filesystem=charset_name`

Command-Line Format	<code>--character-set-filesystem=name</code>	
Option-File Format	<code>character-set-filesystem</code>	
System Variable Name	<code>character_set_filesystem</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	string
	Default	binary

The file system character set. This option sets the `character_set_filesystem` system variable.

- `--character-set-server=charset_name, -C charset_name`

Command-Line Format	<code>--character-set-server</code>	
Option-File Format	<code>character-set-server</code>	
System Variable Name	<code>character_set_server</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	string
	Default	latin1

Use `charset_name` as the default server character set. See [Section 10.5, “Character Set Configuration”](#). If you use this option to specify a nondefault character set, you should also use `--collation-server` to specify the collation.

- `--chroot=path, -r path`

Command-Line Format	<code>--chroot=name</code>	
	<code>-r name</code>	
Option-File Format	<code>chroot</code>	
	Permitted Values	
	Type	directory name

Put the `mysqld` server in a closed environment during startup by using the `chroot()` system call. This is a recommended security measure. Note that use of this option somewhat limits `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE`.

- `--collation-server=collation_name`

Command-Line Format	<code>--collation-server</code>	
Option-File Format	<code>collation-server</code>	
System Variable Name	<code>collation_server</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	string
	Default	<code>latin1_swedish_ci</code>

Use `collation_name` as the default server collation. See [Section 10.5, “Character Set Configuration”](#).

- `--console`

Command-Line Format	<code>--console</code>
Option-File Format	<code>console</code>
Platform Specific	Windows

(Windows only.) Write error log messages to `stderr` and `stdout`. `mysqld` does not close the console window if this option is used.

As of MySQL 5.5.3, if both `--log-error` and `--console` are specified, `--log-error` takes precedence. The server writes to the log file, but not to the console. Before 5.5.3, whichever option is given last takes precedence.

- `--core-file`

Command-Line Format	<code>--core-file</code>	
Option-File Format	<code>core-file</code>	
	Permitted Values	
	Type	boolean
	Default	<code>OFF</code>

Write a core file if `mysqld` dies. The name and location of the core file is system dependent. On Linux, a core file named `core.pid` is written to the current working directory of the process, which for `mysqld` is the data directory. `pid` represents the process ID of the server process. On Mac OS X, a core file named

`core.pid` is written to the `/cores` directory. On Solaris, use the `coreadm` command to specify where to write the core file and how to name it.

For some systems, to get a core file you must also specify the `--core-file-size` option to `mysqld_safe`. See [Section 4.3.2, “mysqld_safe — MySQL Server Startup Script”](#). On some systems, such as Solaris, you do not get a core file if you are also using the `--user` option. There might be additional restrictions or limitations. For example, it might be necessary to execute `ulimit -c unlimited` before starting the server. Consult your system documentation.

- `--datadir=path, -h path`

Command-Line Format	<code>--datadir=path</code>	
	<code>-h</code>	
Option-File Format	<code>datadir</code>	
System Variable Name	<code>datadir</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>directory name</code>

The path to the data directory.

- `--debug[=debug_options], -# [debug_options]`

Command-Line Format	<code>--debug[=debug_options]</code>	
Option-File Format	<code>debug</code>	
System Variable Name	<code>debug</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type (Unix)	<code>string</code>
	Default	<code>d:t:i:o,/tmp/mysqld.trace</code>
	Permitted Values	
	Type (Windows)	<code>string</code>
	Default	<code>d:t:i:O,\mysqld.trace</code>

If MySQL is configured with `-DWITH_DEBUG=1`, you can use this option to get a trace file of what `mysqld` is doing. A typical `debug_options` string is `d:t:o,file_name`. The default is `d:t:i:o,/tmp/mysqld.trace` on Unix and `d:t:i:O,\mysqld.trace` on Windows.

Using `-DWITH_DEBUG=1` to configure MySQL with debugging support enables you to use the `--debug="d,parser_debug"` option when you start the server. This causes the Bison parser that is used to process SQL statements to dump a parser trace to the server's standard error output. Typically, this output is written to the error log.

This option may be given multiple times. Values that begin with `+` or `-` are added to or subtracted from the previous value. For example, `--debug=T --debug=+P` sets the value to `P:T`.

For more information, see [Section 24.4.3, “The DBUG Package”](#).

- `--debug-sync-timeout[=N]`

Command-Line Format	<code>--debug-sync-timeout[=#]</code>	
Option-File Format	<code>debug-sync-timeout</code>	
	Permitted Values	
	Type	<code>numeric</code>

Controls whether the Debug Sync facility for testing and debugging is enabled. Use of Debug Sync requires that MySQL be configured with the `-DENABLE_DEBUG_SYNC=1` option (see [Section 2.9.4, “MySQL Source-Configuration Options”](#)). If Debug Sync is not compiled in, this option is not available. The option value is a timeout in seconds. The default value is 0, which disables Debug Sync. To enable it, specify a value greater than 0; this value also becomes the default timeout for individual synchronization points. If the option is given without a value, the timeout is set to 300 seconds.

For a description of the Debug Sync facility and how to use synchronization points, see [MySQL Internals: Test Synchronization](#).

- `--default-character-set=charset_name`

Deprecated	5.0.0	
Command-Line Format	<code>--default-character-set=name</code>	
	<code>-C name</code>	
Option-File Format	<code>default-character-set</code>	
	Permitted Values	
	Type	<code>string</code>

Use `charset_name` as the default character set. This option is deprecated in favor of `--character-set-server`. See [Section 10.5, “Character Set Configuration”](#). `--default-character-set` was removed in MySQL 5.5.3.

- `--default-collation=collation_name`

Deprecated	4.1.3	
Command-Line Format	<code>--default-collation=name</code>	
Option-File Format	<code>default-collation</code>	
	Permitted Values	
	Type	<code>string</code>

Use `collation_name` as the default collation. This option is deprecated in favor of `--collation-server`. See [Section 10.5, “Character Set Configuration”](#). `--default-collation` was removed in MySQL 5.5.3.

- `--default-storage-engine=type`

Command-Line Format	<code>--default-storage-engine=name</code>
----------------------------	--------------------------------------------

Option-File Format	<code>default-storage-engine</code>	
System Variable Name	<code>default_storage_engine</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values (<= 5.5.4)	
	Type	<code>enumeration</code>
	Default	<code>MyISAM</code>
	Permitted Values (>= 5.5.5)	
	Type	<code>enumeration</code>
	Default	<code>InnoDB</code>

Set the default storage engine (table type) for tables. See [Chapter 15, Alternative Storage Engines](#).

If you disable the default storage engine at server startup, you must set the default engine to a different engine or the server will not start.

- `--default-time-zone=timezone`

Command-Line Format	<code>--default-time-zone=name</code>	
Option-File Format	<code>default-time-zone</code>	
	Permitted Values	
	Type	<code>string</code>

Set the default server time zone. This option sets the global `time_zone` system variable. If this option is not given, the default time zone is the same as the system time zone (given by the value of the `system_time_zone` system variable).

- `--defaults-extra-file=file_name`

Read this option file after the global option file but (on Unix) before the user option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, `file_name` must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- `--defaults-file=file_name`

Use only the given option file. If the file does not exist or is otherwise inaccessible, an error occurs. Before MySQL 5.5.8, `file_name` must be the full path name to the file. As of MySQL 5.5.8, the name is interpreted relative to the current directory if given as a relative path name.

- `--defaults-group-suffix=str`

Read not only the usual option groups, but also groups with the usual names and a suffix of `str`. For example, `mysqld` normally reads the `[mysqld]` group. If the `--defaults-group-suffix=_other` option is given, `mysqld` also reads the `[mysqld_other]` group.

- `--delay-key-write[={OFF|ON|ALL}]`

Command-Line Format	<code>--delay-key-write[=name]</code>
Option-File Format	<code>delay-key-write</code>

System Variable Name	<code>delay_key_write</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>enumeration</code>
	Default	<code>ON</code>
	Valid Values	<code>ON</code>
		<code>OFF</code>
		<code>ALL</code>

Specify how to use delayed key writes. Delayed key writing causes key buffers not to be flushed between writes for `MyISAM` tables. `OFF` disables delayed key writes. `ON` enables delayed key writes for those tables that were created with the `DELAY_KEY_WRITE` option. `ALL` delays key writes for all `MyISAM` tables. See [Section 8.11.2, “Tuning Server Parameters”](#), and [Section 15.3.1, “MyISAM Startup Options”](#).

**Note**

If you set this variable to `ALL`, you should not use `MyISAM` tables from within another program (such as another MySQL server or `myisamchk`) when the tables are in use. Doing so leads to index corruption.

- `--des-key-file=file_name`

Command-Line Format	<code>--des-key-file=file_name</code>
Option-File Format	<code>des-key-file</code>

Read the default DES keys from this file. These keys are used by the `DES_ENCRYPT()` and `DES_DECRYPT()` functions.

- `--enable-locking`

This option is deprecated and was removed in MySQL 5.5.3. Use `--external-locking` instead.

- `--enable-named-pipe`

Command-Line Format	<code>--enable-named-pipe</code>
Option-File Format	<code>enable-named-pipe</code>
Platform Specific	Windows

Enable support for named pipes. This option applies only on Windows.

- `--enable-pstack`

Deprecated	5.1.54	
Removed	5.5.7	
Command-Line Format	<code>--enable-pstack</code>	
Option-File Format	<code>enable-pstack</code>	
	Permitted Values	
	Type	<code>boolean</code>

	Default	<code>FALSE</code>
--	----------------	--------------------

This option is nonfunctional before MySQL 5.5.7 and removed in 5.5.7.

- `--engine-condition-pushdown={ON|OFF}`

Deprecated	5.5.3, by optimizer_switch	
Command-Line Format	<code>--engine-condition-pushdown</code>	
Option-File Format	<code>engine-condition-pushdown</code>	
System Variable Name	engine_condition_pushdown	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>ON</code>

Sets the [engine_condition_pushdown](#) system variable. For more information, see [Section 8.2.1.5, “Engine Condition Pushdown Optimization”](#).

- `--event-scheduler[=value]`

Command-Line Format	<code>--event-scheduler[=value]</code>	
Option-File Format	<code>event-scheduler</code>	
System Variable Name	event_scheduler	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>enumeration</code>
	Default	<code>OFF</code>
	Valid Values	<code>ON</code>
		<code>OFF</code>
		<code>DISABLED</code>

Enable or disable, and start or stop, the event scheduler.

For detailed information, see [The --event-scheduler Option \[2618\]](#).

- `--exit-info[=flags], -T [flags]`

Command-Line Format	<code>--exit-info[=flags]</code>	
	<code>-T [flags]</code>	
Option-File Format	<code>exit-info</code>	
	Permitted Values	
	Type	<code>numeric</code>

This is a bit mask of different flags that you can use for debugging the `mysqld` server. Do not use this option unless you know *exactly* what it does!

- `--external-locking`

Command-Line Format	<code>--external-locking</code>	
Option-File Format	<code>external-locking</code>	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>FALSE</code>

Enable external locking (system locking), which is disabled by default as of MySQL 4.0. Note that if you use this option on a system on which `lockd` does not fully work (such as Linux), it is easy for `mysqld` to deadlock.

To disable external locking explicitly, use `--skip-external-locking`.

External locking affects only `MyISAM` table access. For more information, including conditions under which it can and cannot be used, see [Section 8.10.5, “External Locking”](#).

- `--flush`

Command-Line Format	<code>--flush</code>	
Option-File Format	<code>flush</code>	
System Variable Name	<code>flush</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>OFF</code>

Flush (synchronize) all changes to disk after each SQL statement. Normally, MySQL does a write of all changes to disk only after each SQL statement and lets the operating system handle the synchronizing to disk. See [Section B.5.4.2, “What to Do If MySQL Keeps Crashing”](#).

- `--gdb`

Command-Line Format	<code>--gdb</code>	
Option-File Format	<code>gdb</code>	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>FALSE</code>

Install an interrupt handler for `SIGINT` (needed to stop `mysqld` with `^C` to set breakpoints) and disable stack tracing and core file handling. See [Section 24.4, “Debugging and Porting MySQL”](#).

- `--general-log[={0|1}]`

Command-Line Format	<code>--general-log</code>	
Option-File Format	<code>general-log</code>	
System Variable Name	<code>general_log</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>OFF</code>

Specify the initial general query log state. With no argument or an argument of 1, the `--general-log` option enables the log. If omitted or given with an argument of 0, the option disables the log.

- `--init-file=file_name`

Command-Line Format	<code>--init-file=file_name</code>	
Option-File Format	<code>init-file</code>	
System Variable Name	<code>init_file</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>file name</code>

Read SQL statements from this file at startup. Each statement must be on a single line and should not include comments.

- `--innodb-xxx`

Set an option for the `InnoDB` storage engine. The `InnoDB` options are listed in [Section 14.15, “InnoDB Startup Options and System Variables”](#).

- `--install [service_name]`

Command-Line Format	<code>--install [service_name]</code>
----------------------------	---------------------------------------

(Windows only) Install the server as a Windows service that starts automatically during Windows startup. The default service name is `MySQL` if no `service_name` value is given. For more information, see [Section 2.3.7.7, “Starting MySQL as a Windows Service”](#).

Note

If the server is started with the `--defaults-file` and `--install` options, `--install` must be first.

- `--install-manual [service_name]`

Command-Line Format	<code>--install-manual [service_name]</code>
----------------------------	----------------------------------------------

(Windows only) Install the server as a Windows service that must be started manually. It does not start automatically during Windows startup. The default service name is `MySQL` if no `service_name` value is given. For more information, see [Section 2.3.7.7, “Starting MySQL as a Windows Service”](#).

**Note**

If the server is started with the `--defaults-file` and `--install-manual` options, `--install-manual` must be first.

- `--language=lang_name, -L lang_name`

Deprecated	5.5.0, by <code>lc-messages-dir</code>	
Command-Line Format	<code>--language=name</code>	
	<code>-L</code>	
Option-File Format	<code>language</code>	
System Variable Name	<code>language</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>directory name</code>
	Default	<code>/usr/local/mysql/share/mysql/english/</code>

The language to use for error messages. `lang_name` can be given as the language name or as the full path name to the directory where the language files are installed. See [Section 10.2, “Setting the Error Message Language”](#).

As of MySQL 5.5, `--lc-messages-dir` and `--lc-messages` should be used rather than `--language`, which is deprecated and handled as an alias for `--lc-messages-dir`.

- `--large-pages`

Command-Line Format	<code>--large-pages</code>	
Option-File Format	<code>large-pages</code>	
System Variable Name	<code>large_pages</code>	
Variable Scope	Global	
Dynamic Variable	No	
Platform Specific	Linux	
	Permitted Values	
	Type (Linux)	<code>boolean</code>
	Default	<code>FALSE</code>

Some hardware/operating system architectures support memory pages greater than the default (usually 4KB). The actual implementation of this support depends on the underlying hardware and operating system. Applications that perform a lot of memory accesses may obtain performance improvements by using large pages due to reduced Translation Lookaside Buffer (TLB) misses.

MySQL 5.5 supports the Linux implementation of large page support (which is called HugeTLB in Linux). See [Section 8.11.4.2, “Enabling Large Page Support”](#). For Solaris support of large pages, see the description of the `--super-large-pages` option.

`--large-pages` is disabled by default.

- `--lc-messages=locale_name`

Command-Line Format	<code>--lc-messages=name</code>	
Option-File Format	<code>lc-messages</code>	
System Variable Name	<code>lc_messages</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>string</code>

The locale to use for error messages. The server converts the argument to a language name and combines it with the value of the `--lc-messages-dir` to produce the location for the error message file. See [Section 10.2, “Setting the Error Message Language”](#).

- `--lc-messages-dir=path`

Command-Line Format	<code>--lc-messages-dir=path</code>	
Option-File Format	<code>lc-messages-dir</code>	
System Variable Name	<code>lc_messages_dir</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>directory name</code>

The directory where error messages are located. The value is used together with the value of `--lc-messages` to produce the location for the error message file. See [Section 10.2, “Setting the Error Message Language”](#).

- `--local-service`

Command-Line Format	<code>--local-service</code>
----------------------------	------------------------------

(Windows only) A `--local-service` option following the service name causes the server to run using the `LocalService` Windows account that has limited system privileges. This account is available only for Windows XP or newer. If both `--defaults-file` and `--local-service` are given following the service name, they can be in any order. See [Section 2.3.7.7, “Starting MySQL as a Windows Service”](#).

- `--log[=file_name], -l [file_name]`

Deprecated	5.1.29, by general-log
Command-Line Format	<code>--log[=name]</code>
	<code>-l</code>

Option-File Format	log	
System Variable Name	log	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	string
	Default	OFF

This option enables logging to the general query log, which contains entries that record client connections and SQL statements received from clients. The log output destination can be selected with the `--log-output` option. If you omit the file name, MySQL uses `host_name.log` as the file name. See [Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”](#), and [Section 5.2.3, “The General Query Log”](#).

The `--log` option is deprecated and is removed (along with the `log` system variable) in MySQL 5.6. Instead, use the `--general_log` option to enable the general query log and the `--general_log_file=file_name` option to set the general query log file name.

- `--log-error[=file_name]`

Command-Line Format	--log-error[=name]	
Option-File Format	log-error	
System Variable Name	log_error	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	file name

Log errors and startup messages to this file. See [Section 5.2.2, “The Error Log”](#). If you omit the file name, MySQL uses `host_name.err`. If the file name has no extension, the server adds an extension of `.err`.

- `--log-isam[=file_name]`

Command-Line Format	<code>--log-isam[=name]</code>		
Option-File Format	<code>log-isam</code>		
	Permitted Values		
	Type	<code>file name</code>	

Log all `MyISAM` changes to this file (used only when debugging `MyISAM`).

- `--log-long-format`

Deprecated	4.1.0
Command-Line Format	<code>--log-long-format</code>
	<code>-0</code>
Option-File Format	<code>log-long-format</code>

Log extra information to the binary log and slow query log, if they have been activated. For example, the user name and timestamp are logged for all queries. This option is deprecated, as it now represents the default logging behavior. (See the description for `--log-short-format`.) The `--log-queries-not-using-indexes` option is available for the purpose of logging queries that do not use indexes to the slow query log. `--log-long-format` was removed in MySQL 5.5.3.

- `--log-output=value,...`

Command-Line Format	<code>--log-output=name</code>	
Option-File Format	<code>log-output</code>	
System Variable Name	<code>log_output</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>set</code>
	Default	<code>FILE</code>
	Valid Values	<code>TABLE</code>
		<code>FILE</code>
		<code>NONE</code>

This option determines the destination for general query log and slow query log output. The option value can be given as one or more of the words `TABLE`, `FILE`, or `NONE`. `TABLE` select logging to the `general_log` and `slow_log` tables in the `mysql` database as a destination. `FILE` selects logging to log files as a destination. `NONE` disables logging. If `NONE` is present in the option value, it takes precedence over any other words that are present. `TABLE` and `FILE` can both be given to select to both log output destinations.

This option selects log output destinations, but does not enable log output. To do that, use the `--general_log` and `--slow_query_log` options. For `FILE` logging, the `--general_log_file` and `--slow_query_log_file` options determine the log file location. For more information, see [Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”](#).

- `--log-queries-not-using-indexes`

Command-Line Format	<code>--log-queries-not-using-indexes</code>	
Option-File Format	<code>log-queries-not-using-indexes</code>	
System Variable Name	<code>log_queries_not_using_indexes</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>OFF</code>

If you are using this option with the slow query log enabled, queries that are expected to retrieve all rows are logged. See [Section 5.2.5, “The Slow Query Log”](#). This option does not necessarily mean that no index is used. For example, a query that uses a full index scan uses an index but would be logged because the index would not limit the number of rows.

- `--log-short-format`

Command-Line Format	<code>--log-short-format</code>	
Option-File Format	<code>log-short-format</code>	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>FALSE</code>

Log less information to the binary log and slow query log, if they have been activated.

- `--log-slow-admin-statements`

Command-Line Format	<code>--log-slow-admin-statements</code>	
Option-File Format	<code>log-slow-admin-statements</code>	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>OFF</code>

Include slow administrative statements in the statements written to the slow query log. Administrative statements include `ALTER TABLE`, `ANALYZE TABLE`, `CHECK TABLE`, `CREATE INDEX`, `DROP INDEX`, `OPTIMIZE TABLE`, and `REPAIR TABLE`.

- `--log-slow-queries[=file_name]`

Deprecated	5.1.29, by slow-query-log	
Command-Line Format	<code>--log-slow-queries[=name]</code>	
Option-File Format	<code>log-slow-queries</code>	
System Variable Name	log_slow_queries	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>

This option enables logging to the slow query log, which contains entries for all queries that have taken more than `long_query_time` seconds to execute. See the descriptions of the `--log-long-format` and `--log-short-format` options for details. The log output destination can be selected with the `--log-output` option. If you omit the file name, MySQL uses `host_name-slow.log` as the file name. See [Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”](#), and [Section 5.2.5, “The Slow Query Log”](#).

The `--log-slow-queries` option is deprecated and is removed (along with the `log_slow_queries` system variable) in MySQL 5.6. Instead, use the `--slow_query_log` option to enable the slow query log and the `--slow_query_log_file=file_name` option to set the slow query log file name.

- `--log-tc=file_name`

Command-Line Format	<code>--log-tc=name</code>	
Option-File Format	<code>log-tc</code>	483

	Permitted Values	
	Type	file name
	Default	tc.log

The name of the memory-mapped transaction coordinator log file (for XA transactions that affect multiple storage engines when the binary log is disabled). The default name is `tc.log`. The file is created under the data directory if not given as a full path name. Currently, this option is unused.

- `--log-tc-size=size`

Command-Line Format	<code>--log-tc-size=#</code>	
Option-File Format	<code>log-tc-size</code>	
	Permitted Values	
	Platform Bit Size	32
	Type	numeric
	Default	24576
	Max Value	4294967295
	Permitted Values	
	Platform Bit Size	64
	Type	numeric
	Default	24576
	Max Value	18446744073709547520

The size in bytes of the memory-mapped transaction coordinator log. The default size is 24KB.

- `--log-warnings[=level], -W [level]`

Command-Line Format	<code>--log-warnings[=#]</code>	
	<code>-W [#]</code>	
Option-File Format	<code>log-warnings[=#]</code>	
System Variable Name	<code>log_warnings</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Platform Bit Size	32
	Type	numeric
	Default	1
	Range	0 .. 4294967295
	Permitted Values	

Platform Bit Size	64
Type	numeric
Default	1
Range	0 .. 18446744073709547520

Print out warnings such as `Aborted connection...` to the error log. This option is enabled (1) by default. To disable it, use `--log-warnings=0`. Specifying the option without a `level` value increments the current value by 1. Enabling this option by setting it greater than 0 is recommended, for example, if you use replication (you get more information about what is happening, such as messages about network failures and reconnections). If the value is greater than 1, aborted connections are written to the error log, and access-denied errors for new connection attempts are written. See [Section B.5.2.11, “Communication Errors and Aborted Connections”](#).

If a slave server was started with `--log-warnings` enabled, the slave prints messages to the error log to provide information about its status, such as the binary log and relay log coordinates where it starts its job, when it is switching to another relay log, when it reconnects after a disconnect, and so forth. The server logs messages about statements that are unsafe for statement-based logging if `--log-warnings` is greater than 0.

- `--low-priority-updates`

Command-Line Format	<code>--low-priority-updates</code>	
Option-File Format	<code>low-priority-updates</code>	
System Variable Name	<code>low_priority_updates</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	boolean
	Default	FALSE

Give table-modifying operations (`INSERT`, `REPLACE`, `DELETE`, `UPDATE`) lower priority than selects. This can also be done using `{INSERT | REPLACE | DELETE | UPDATE} LOW_PRIORITY ...` to lower the priority of only one query, or by `SET LOW_PRIORITY_UPDATES=1` to change the priority in one thread. This affects only storage engines that use only table-level locking (`MyISAM`, `MEMORY`, `MERGE`). See [Section 8.10.2, “Table Locking Issues”](#).

- `--min-examined-row-limit=number`

Command-Line Format	<code>--min-examined-row-limit=#</code>	
Option-File Format	<code>min-examined-row-limit</code>	
System Variable Name	<code>min_examined_row_limit</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Platform Bit Size	32
	Type	numeric

	Default	0
	Range	0 .. 4294967295
	Permitted Values	
	Platform Bit Size	64
	Type	numeric
	Default	0
	Range	0 .. 18446744073709547520

When this option is set, queries which examine fewer than *number* rows are not written to the slow query log. The default is 0.

- `--memlock`

Command-Line Format	<code>--memlock</code>	
Option-File Format	<code>memlock</code>	
System Variable Name	<code>locked_in_memory</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	boolean
	Default	FALSE

Lock the `mysqld` process in memory. This option might help if you have a problem where the operating system is causing `mysqld` to swap to disk.

`--memlock` works on systems that support the `mlockall()` system call; this includes Solaris, most Linux distributions that use a 2.4 or newer kernel, and perhaps other Unix systems. On Linux systems, you can tell whether or not `mlockall()` (and thus this option) is supported by checking to see whether or not it is defined in the system `mman.h` file, like this:

```
shell> grep mlockall /usr/include/sys/mman.h
```

If `mlockall()` is supported, you should see in the output of the previous command something like the following:

```
extern int mlockall (int __flags) __THROW;
```

Important

Use of this option may require you to run the server as `root`, which, for reasons of security, is normally not a good idea. See [Section 6.1.5, “How to Run MySQL as a Normal User”](#).

On Linux and perhaps other systems, you can avoid the need to run the server as `root` by changing the `limits.conf` file. See the notes regarding the `memlock` limit in [Section 8.11.4.2, “Enabling Large Page Support”](#).

You must not try to use this option on a system that does not support the `mlockall()` system call; if you do so, `mysqld` will very likely crash as soon as you try to start it.

- `--myisam-block-size=N`

Command-Line Format	<code>--myisam-block-size=#</code>
Option-File Format	<code>myisam-block-size</code>
	Permitted Values
	Type numeric
	Default 1024
	Range 1024 .. 16384

The block size to be used for `MyISAM` index pages.

- `--myisam-recover[=option[,option]...]`

This option is renamed as of MySQL 5.5.3 to `--myisam-recover-options`. See the description of that option for more information.

- `--myisam-recover-options[=option[,option]...]`

Introduced	5.5.3	
Command-Line Format	<code>--myisam-recover-options[=name]</code>	
Option-File Format	<code>myisam-recover-options</code>	
	Permitted Values	
	Type	enumeration
	Default	OFF
	Valid Values	OFF
		DEFAULT
		BACKUP
		FORCE
		QUICK

Set the `MyISAM` storage engine recovery mode. The option value is any combination of the values of `OFF`, `DEFAULT`, `BACKUP`, `FORCE`, or `QUICK`. If you specify multiple values, separate them by commas. Specifying the option with no argument is the same as specifying `DEFAULT`, and specifying with an explicit value of `" "` disables recovery (same as a value of `OFF`). If recovery is enabled, each time `mysqld` opens a `MyISAM` table, it checks whether the table is marked as crashed or was not closed properly. (The last option works only if you are running with external locking disabled.) If this is the case, `mysqld` runs a check on the table. If the table was corrupted, `mysqld` attempts to repair it.

The following options affect how the repair works.

Option	Description
OFF	No recovery.
DEFAULT	Recovery without backup, forcing, or quick checking.

Option	Description
<code>BACKUP</code>	If the data file was changed during recovery, save a backup of the <code>tbl_name.MYD</code> file as <code>tbl_name-datetime.BAK</code> .
<code>FORCE</code>	Run recovery even if we would lose more than one row from the <code>.MYD</code> file.
<code>QUICK</code>	Do not check the rows in the table if there are not any delete blocks.

Before the server automatically repairs a table, it writes a note about the repair to the error log. If you want to be able to recover from most problems without user intervention, you should use the options `BACKUP`, `FORCE`. This forces a repair of a table even if some rows would be deleted, but it keeps the old data file as a backup so that you can later examine what happened.

This option was named `--myisam-recover`, before MySQL 5.5.3. The old option name still works because it is recognized as an unambiguous prefix of the new name, `--myisam-recover-options`. (Option prefix recognition occurs as described in [Section 4.2.3, “Specifying Program Options”](#).)

The option value `OFF` is available as of MySQL 5.5.3.

See [Section 15.3.1, “MyISAM Startup Options”](#).

- `--no-defaults`

Do not read any option files. If program startup fails due to reading unknown options from an option file, `--no-defaults` can be used to prevent them from being read.

- `--old-alter-table`

Command-Line Format	<code>--old-alter-table</code>	
Option-File Format	<code>old-alter-table</code>	
System Variable Name	<code>old_alter_table</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>OFF</code>

When this option is given, the server does not use the optimized method of processing an `ALTER TABLE` operation. It reverts to using a temporary table, copying over the data, and then renaming the temporary table to the original, as used by MySQL 5.0 and earlier. For more information on the operation of `ALTER TABLE`, see [Section 13.1.7, “ALTER TABLE Syntax”](#).

- `--old-style-user-limits`

Command-Line Format	<code>--old-style-user-limits</code>	
Option-File Format	<code>old-style-user-limits</code>	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>FALSE</code>

Enable old-style user limits. (Before MySQL 5.0.3, account resource limits were counted separately for each host from which a user connected rather than per account row in the `user` table.) See [Section 6.3.4, “Setting Account Resource Limits”](#).

- `--one-thread`

Command-Line Format	<code>--one-thread</code>
Option-File Format	<code>one-thread</code>

Only use one thread (for debugging under Linux). This option is available only if the server is built with debugging enabled. See [Section 24.4, “Debugging and Porting MySQL”](#).

This option is deprecated and is removed in MySQL 5.6. Use `--thread_handling=no-threads` instead.

- `--open-files-limit=count`

Command-Line Format	<code>--open-files-limit=#</code>	
Option-File Format	<code>open-files-limit</code>	
System Variable Name	<code>open_files_limit</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>0</code>
	Range	<code>0 .. platform dependent</code>

Changes the number of file descriptors available to `mysqld`. You should try increasing the value of this option if `mysqld` gives you the error `Too many open files`. `mysqld` uses the option value to reserve descriptors with `setrlimit()`. Internally, the maximum value for this option is the maximum unsigned integer value, but the actual maximum is platform dependent. If the requested number of file descriptors cannot be allocated, `mysqld` writes a warning to the error log.

`mysqld` may attempt to allocate more than the requested number of descriptors (if they are available), using the values of `max_connections` and `table_open_cache` to estimate whether more descriptors will be needed.

On Unix, the value cannot be set less than `ulimit -n`.

- `--partition[=value]`

Command-Line Format	<code>--partition</code>	
Option-File Format	<code>partition</code>	
Disabled by	<code>skip-partition</code>	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>ON</code>

Enables or disables user-defined partitioning support in the MySQL Server.

- `--pid-file=path`

Command-Line Format	<code>--pid-file=file_name</code>	
Option-File Format	<code>pid-file</code>	
System Variable Name	<code>pid_file</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>file name</code>

The path name of the process ID file. The server creates the file in the data directory unless an absolute path name is given to specify a different directory. This file is used by other programs such as `mysqld_safe` to determine the server's process ID.

- `--plugin-xxx`

Specifies an option that pertains to a server plugin. For example, many storage engines can be built as plugins, and for such engines, options for them can be specified with a `--plugin` prefix. Thus, the `--innodb_file_per_table` option for InnoDB can be specified as `--plugin-innodb_file_per_table`.

For boolean options that can be enabled or disabled, the `--skip` prefix and other alternative formats are supported as well (see [Section 4.2.5, “Program Option Modifiers”](#)). For example, `--skip-plugin-innodb_file_per_table` disables `innodb_file_per_table`.

The rationale for the `--plugin` prefix is that it enables plugin options to be specified unambiguously if there is a name conflict with a built-in server option. For example, were a plugin writer to name a plugin “sql” and implement a “mode” option, the option name might be `--sql-mode`, which would conflict with the built-in option of the same name. In such cases, references to the conflicting name are resolved in favor of the built-in option. To avoid the ambiguity, users can specify the plugin option as `--plugin-sql-mode`. Use of the `--plugin` prefix for plugin options is recommended to avoid any question of ambiguity.

- `--plugin-load=plugin_list`

Command-Line Format	<code>--plugin-load=plugin_list</code>	
Option-File Format	<code>plugin-load</code>	
	Permitted Values	
	Type	<code>string</code>

This option tells the server to load the named plugins at startup. The option value is a semicolon-separated list of `name=plugin_library` pairs. Each `name` is the name of the plugin, and `plugin_library` is the name of the shared library that contains the plugin code. Each library file must be located in the directory named by the `plugin_dir` system variable. For example, if plugins named `myplug1` and `myplug2` have library files `myplug1.so` and `myplug2.so`, use this option to load them at startup:

```
shell> mysqld --plugin-load="myplug1=myplug1.so;myplug2=myplug2.so"
```

Quotes are used around the argument value here because semicolon (;) is interpreted as a special character by some command interpreters. (Unix shells treat it as a command terminator, for example.)

All plugins to load must be named in the same `--plugin-load` option. If multiple `--plugin-load` options are given, only the last one is used.

If a plugin library is named without any preceding plugin name, the server loads all plugins in the library.

Each plugin is loaded for a single invocation of `mysqld` only. After a restart, the plugin is not loaded unless `--plugin-load` is used again. This is in contrast to `INSTALL PLUGIN`, which adds an entry to the `mysql.plugins` table to cause the plugin to be loaded for every normal server startup.

Under normal startup, the server determines which plugins to load by reading the `mysql.plugins` system table. If the server is started with the `--skip-grant-tables` option, it does not consult the `mysql.plugins` table and does not load plugins listed there. `--plugin-load` enables plugins to be loaded even when `--skip-grant-tables` is given. `--plugin-load` also enables plugins to be loaded at startup under configurations when plugins cannot be loaded at runtime.

For additional information about plugin loading, see [Section 5.1.8.1, “Installing and Uninstalling Plugins”](#).

- `--port=port_num, -P port_num`

Command-Line Format	<code>--port=#</code>	
	<code>-P</code>	
Option-File Format	<code>port</code>	
System Variable Name	<code>port</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>3306</code>
	Range	<code>0 .. 65535</code>

The port number to use when listening for TCP/IP connections. The port number must be 1024 or higher unless the server is started by the `root` system user.

- `--port-open-timeout=num`

Command-Line Format	<code>--port-open-timeout=#</code>	
Option-File Format	<code>port-open-timeout</code>	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>0</code>

On some systems, when the server is stopped, the TCP/IP port might not become available immediately. If the server is restarted quickly afterward, its attempt to reopen the port can fail. This option indicates how many seconds the server should wait for the TCP/IP port to become free if it cannot be opened. The default is not to wait.

- `--print-defaults`

Print the program name and all options that it gets from option files.

- `--remove [service_name]`

Command-Line Format	<code>--remove [service_name]</code>
----------------------------	--------------------------------------

(Windows only) Remove a MySQL Windows service. The default service name is `MySQL` if no `service_name` value is given. For more information, see [Section 2.3.7.7, “Starting MySQL as a Windows Service”](#).

- `--safe-mode`

Deprecated	5.5.26
Command-Line Format	<code>--safe-mode</code>
Option-File Format	<code>safe-mode</code>

Skip some optimization stages. This option is deprecated and is removed in MySQL 5.6.

- `--safe-show-database`

Deprecated	4.0.2
Removed	5.5.3
Command-Line Format	<code>--safe-show-database</code>
Option-File Format	<code>safe-show-database</code>
System Variable Name	<code>safe_show_database</code>
Variable Scope	Global
Dynamic Variable	Yes
	Permitted Values
	Type <code>boolean</code>

This option is deprecated and does not do anything because there is a `SHOW DATABASES` privilege that can be used to control access to database names on a per-account basis. See [Section 6.2.1, “Privileges Provided by MySQL”](#). `--safe-show-database` was removed in MySQL 5.5.3.

- `--safe-user-create`

Command-Line Format	<code>--safe-user-create</code>
Option-File Format	<code>safe-user-create</code>
	Permitted Values
	Type <code>boolean</code>
	Default <code>FALSE</code>

If this option is enabled, a user cannot create new MySQL users by using the `GRANT` statement unless the user has the `INSERT` privilege for the `mysql.user` table or any column in the table. If you want a user to have the ability to create new users that have those privileges that the user has the right to grant, you should grant the user the following privilege:

```
GRANT INSERT(user) ON mysql.user TO 'user_name'@'host_name' ;
```

This ensures that the user cannot change any privilege columns directly, but has to use the `GRANT` statement to give privileges to other users.

- `--secure-auth`

Command-Line Format	<code>--secure-auth</code>	
Option-File Format	<code>secure-auth</code>	
System Variable Name	<code>secure_auth</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>OFF</code>

This option causes the server to block connections by clients that attempt to use accounts that have passwords stored in the old (pre-4.1) format. Use it to prevent all use of passwords employing the old format (and hence insecure communication over the network).

Server startup fails with an error if this option is enabled and the privilege tables are in pre-4.1 format. See [Section B.5.2.4](#), “Client does not support authentication protocol”.

The `mysql` client also has a `--secure-auth` option, which prevents connections to a server if the server requires a password in old format for the client account.

Note

Passwords that use the pre-4.1 hashing method are less secure than passwordss that use the native password hashing method and should be avoided.

- `--secure-file-priv=path`

Command-Line Format	<code>--secure-file-priv=path</code>	
Option-File Format	<code>secure-file-priv</code>	
System Variable Name	<code>secure_file_priv</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>string</code>

This option limits the effect of the `LOAD_FILE()` function and the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements to work only with files in the specified directory.

- `--shared-memory`

System Variable Name	<code>shared_memory</code>
Variable Scope	Global
Dynamic Variable	No
Platform Specific	Windows

Enable shared-memory connections by local clients. This option is available only on Windows.

- `--shared-memory-base-name=name`

System Variable Name	<code>shared_memory_base_name</code>
Variable Scope	Global
Dynamic Variable	No
Platform Specific	Windows

The name of shared memory to use for shared-memory connections. This option is available only on Windows. The default name is `MYSQL`. The name is case sensitive.

- `--skip-concurrent-insert`

Turn off the ability to select and insert at the same time on `MyISAM` tables. (This is to be used only if you think you have found a bug in this feature.) See [Section 8.10.3, “Concurrent Inserts”](#).

- `--skip-event-scheduler`

Command-Line Format	<code>--skip-event-scheduler</code>
	<code>--disable-event-scheduler</code>
Option-File Format	<code>skip-event-scheduler</code>

Turns the Event Scheduler `OFF`. This is not the same as disabling the Event Scheduler, which requires setting `--event-scheduler=DISABLED`; see [The `--event-scheduler` Option \[2618\]](#), for more information.

- `--skip-grant-tables`

This option causes the server to start without using the privilege system at all, which gives anyone with access to the server *unrestricted access to all databases*. You can cause a running server to start using the grant tables again by executing `mysqladmin flush-privileges` or `mysqladmin reload` command from a system shell, or by issuing a MySQL `FLUSH PRIVILEGES` statement after connecting to the server. This option also suppresses loading of plugins that were installed with the `INSTALL PLUGIN` statement, user-defined functions (UDFs), and scheduled events. To cause plugins to be loaded anyway, use the `--plugin-load` option.

Note that `FLUSH PRIVILEGES` might be executed implicitly by other actions performed after startup. For example, `mysql_upgrade` flushes the privileges during the upgrade procedure.

- `--skip-host-cache`

Disable use of the internal host cache for faster name-to-IP resolution. In this case, the server performs a DNS lookup every time a client connects. See [Section 8.11.5.2, “DNS Lookup Optimization and the Host Cache”](#).

- `--skip-innodb`

Disable the `InnoDB` storage engine. In this case, if the default storage engine is `InnoDB`, the server will not start unless you also use `--default-storage-engine` to set the default to some other engine.

- `--skip-name-resolve`

Do not resolve host names when checking client connections. Use only IP addresses. If you use this option, all `Host` column values in the grant tables must be IP addresses or `localhost`. See [Section 8.11.5.2, “DNS Lookup Optimization and the Host Cache”](#).

Depending on the network configuration of your system and the [Host](#) values for your accounts, clients may need to connect using an explicit `--host` option, such as `--host=localhost`, `--host=127.0.0.1`, or `--host=::1`.

- `--skip-networking`

Do not listen for TCP/IP connections at all. All interaction with `mysqld` must be made using named pipes or shared memory (on Windows) or Unix socket files (on Unix). This option is highly recommended for systems where only local clients are permitted. See [Section 8.11.5.2, “DNS Lookup Optimization and the Host Cache”](#).

- `--skip-partition`

Command-Line Format	<code>--skip-partition</code>
	<code>--disable-partition</code>
Option-File Format	<code>skip-partition</code>

Disables user-defined partitioning. Partitioned tables can be seen using `SHOW TABLES` or by querying the `INFORMATION_SCHEMA.TABLES` table, but cannot be created or modified, nor can data in such tables be accessed. All partition-specific columns in the `INFORMATION_SCHEMA.PARTITIONS` table display `NULL`.

Since `DROP TABLE` removes table definition (`.frm`) files, this statement works on partitioned tables even when partitioning is disabled using the option. The statement, however, does not remove `.par` files associated with partitioned tables in such cases. For this reason, you should avoid dropping partitioned tables with partitioning disabled, or take action to remove the orphaned `.par` files manually.

- `--ssl*`

Options that begin with `--ssl` specify whether to permit clients to connect using SSL and indicate where to find SSL keys and certificates. See [Section 6.3.9.4, “SSL Command Options”](#).

- `--standalone`

Command-Line Format	<code>--standalone</code>
Option-File Format	<code>standalone</code>
Platform Specific	Windows

Available on Windows only; instructs the MySQL server not to run as a service.

- `--super-large-pages`

Introduced	5.5.3	
Command-Line Format	<code>--super-large-pages</code>	
Option-File Format	<code>super-large-pages</code>	
Platform Specific	Solaris	
	Permitted Values	
	Type (Solaris)	<code>boolean</code>
	Default	<code>FALSE</code>

Standard use of large pages in MySQL attempts to use the largest size supported, up to 4MB. Under Solaris, a “super large pages” feature enables uses of pages up to 256MB. This feature is available for recent SPARC platforms. It can be enabled or disabled by using the `--super-large-pages` or `--skip-super-large-pages` option.

- `--symbolic-links, --skip-symbolic-links`

Command-Line Format	<code>--symbolic-links</code>
Option-File Format	<code>symbolic-links</code>

Enable or disable symbolic link support. This option has different effects on Windows and Unix:

- On Windows, enabling symbolic links enables you to establish a symbolic link to a database directory by creating a `db_name.sym` file that contains the path to the real directory. See [Using Symbolic Links for Databases on Windows](#).
- On Unix, enabling symbolic links means that you can link a [MyISAM](#) index file or data file to another directory with the `INDEX DIRECTORY` or `DATA DIRECTORY` options of the `CREATE TABLE` statement. If you delete or rename the table, the files that its symbolic links point to also are deleted or renamed. See [Using Symbolic Links for MyISAM Tables on Unix](#).
- `--skip-safemalloc`

Removed	5.5.6
Command-Line Format	<code>--skip-safemalloc</code>
Option-File Format	<code>skip-safemalloc</code>

Previously, if MySQL was configured with full debugging support, all MySQL programs check for memory overruns during each memory allocation and memory freeing operation. This checking is very slow, so for the server you can avoid it when you do not need it by using the `--skip-safemalloc` option.

`safemalloc`, along with this option, was removed in MySQL 5.5.6.

- `--skip-show-database`

Command-Line Format	<code>--skip-show-database</code>
Option-File Format	<code>skip-show-database</code>
System Variable Name	<code>skip_show_database</code>
Variable Scope	Global
Dynamic Variable	No

This option sets the `skip_show_database` system variable that controls who is permitted to use the `SHOW DATABASES` statement. See [Section 5.1.4, “Server System Variables”](#).

- `--skip-stack-trace`

Command-Line Format	<code>--skip-stack-trace</code>
Option-File Format	<code>skip-stack-trace</code>

Do not write stack traces. This option is useful when you are running `mysqld` under a debugger. On some systems, you also must use this option to get a core file. See [Section 24.4, “Debugging and Porting MySQL”](#).

- `--skip-thread-priority`

Deprecated	5.1.29
Command-Line Format	<code>--skip-thread-priority</code>
Option-File Format	<code>skip-thread-priority</code>

Disable using thread priorities for faster response time. This option is deprecated and is removed in MySQL 5.6.

- `--slow-query-log[={0|1}]`

Command-Line Format	<code>--slow-query-log</code>	
Option-File Format	<code>slow-query-log</code>	
System Variable Name	<code>slow_query_log</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>OFF</code>

Specify the initial slow query log state. With no argument or an argument of 1, the `--slow-query-log` option enables the log. If omitted or given with an argument of 0, the option disables the log.

- `--slow-start-timeout=timeout`

Introduced	5.5.20	
Command-Line Format	<code>--slow-start-timeout=#</code>	
Option-File Format	<code>slow-start-timeout</code>	
	Permitted Values	
	Type (Windows)	<code>numeric</code>
	Default	<code>15000</code>

This option controls the Windows service control manager's service start timeout. The value is the maximum number of milliseconds that the service control manager waits before trying to kill the windows service during startup. The default value is 15000 (15 seconds). If the MySQL service takes too long to start, you may need to increase this value. A value of 0 means there is no timeout.

- `--socket=path`

Command-Line Format	<code>--socket=name</code>
Option-File Format	<code>socket</code>
System Variable Name	<code>socket</code>

Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	file name
	Default	/tmp/mysql.sock

On Unix, this option specifies the Unix socket file to use when listening for local connections. The default value is `/tmp/mysql.sock`. If this option is given, the server creates the file in the data directory unless an absolute path name is given to specify a different directory. On Windows, the option specifies the pipe name to use when listening for local connections that use a named pipe. The default value is `MySQL` (not case sensitive).

- `--sql-mode=value[,value[,value...]]`

Command-Line Format	<code>--sql-mode=name</code>	
Option-File Format	<code>sql-mode</code>	
System Variable Name	<code>sql_mode</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	set
	Default	''
	Valid Values	ALLOW_INVALID_DATES
		ANSI_QUOTES
		ERROR_FOR_DIVISION_BY_ZERO
		HIGH_NOT_PRECEDENCE
		IGNORE_SPACE
		NO_AUTO_CREATE_USER
		NO_AUTO_VALUE_ON_ZERO
		NO_BACKSLASH_ESCAPES
		NO_DIR_IN_CREATE
		NO_ENGINE_SUBSTITUTION
		NO_FIELD_OPTIONS
		NO_KEY_OPTIONS
		NO_TABLE_OPTIONS
		NO_UNSIGNED_SUBTRACTION
		NO_ZERO_DATE
		NO_ZERO_IN_DATE
		ONLY_FULL_GROUP_BY
		PAD_CHAR_TO_FULL_LENGTH
		PIPES_AS_CONCAT
		REAL_AS_FLOAT

		STRICT_ALL_TABLES
		STRICT_TRANS_TABLES

Set the SQL mode. See [Section 5.1.7, “Server SQL Modes”](#).

Note

MySQL installation programs may configure the SQL mode during the installation process. If the SQL mode differs from the default or from what you expect, check for a setting in an option file that the server reads at startup.

- `--sysdate-is-now`

Command-Line Format	<code>--sysdate-is-now</code>	
Option-File Format	<code>sysdate-is-now</code>	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>FALSE</code>

`SYSDATE()` by default returns the time at which it executes, not the time at which the statement in which it occurs begins executing. This differs from the behavior of `NOW()`. This option causes `SYSDATE()` to be an alias for `NOW()`. For information about the implications for binary logging and replication, see the description for `SYSDATE()` in [Section 12.7, “Date and Time Functions”](#) and for `SET TIMESTAMP` in [Section 5.1.4, “Server System Variables”](#).

- `--tc-heuristic-recover={COMMIT|ROLLBACK}`

Command-Line Format	<code>--tc-heuristic-recover=name</code>	
Option-File Format	<code>tc-heuristic-recover</code>	
	Permitted Values	
	Type	<code>enumeration</code>
	Default	<code>COMMIT</code>
	Valid Values	<code>COMMIT</code> <code>ROLLBACK</code>

The type of decision to use in the heuristic recovery process. Currently, this option is unused.

- `--temp-pool`

Command-Line Format	<code>--temp-pool</code>	
Option-File Format	<code>temp-pool</code>	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>TRUE</code>

This option causes most temporary files created by the server to use a small set of names, rather than a unique name for each new file. This works around a problem in the Linux kernel dealing with creating many new files with different names. With the old behavior, Linux seems to “leak” memory, because it is

being allocated to the directory entry cache rather than to the disk cache. This option is ignored except on Linux.

- `--transaction-isolation=level`

Command-Line Format	<code>--transaction-isolation=name</code>	
Option-File Format	<code>transaction-isolation</code>	
	Permitted Values	
	Type	enumeration
	Default	REPEATABLE-READ
	Valid Values	READ-UNCOMMITTED
		READ-COMMITTED
		REPEATABLE-READ
		SERIALIZABLE

Sets the default transaction isolation level. The `level` value can be `READ-UNCOMMITTED`, `READ-COMMITTED`, `REPEATABLE-READ`, or `SERIALIZABLE`. See [Section 13.3.6, “SET TRANSACTION Syntax”](#).

The default transaction isolation level can also be set at runtime using the `SET TRANSACTION` statement or by setting the `tx_isolation` system variable.

- `--tmpdir=path, -t path`

Command-Line Format	<code>--tmpdir=path</code>	
	<code>-t</code>	
Option-File Format	<code>tmpdir</code>	
System Variable Name	<code>tmpdir</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	directory name

The path of the directory to use for creating temporary files. It might be useful if your default `/tmp` directory resides on a partition that is too small to hold temporary tables. This option accepts several paths that are used in round-robin fashion. Paths should be separated by colon characters (":") on Unix and semicolon characters (";") on Windows. If the MySQL server is acting as a replication slave, you should not set `--tmpdir` to point to a directory on a memory-based file system or to a directory that is cleared when the server host restarts. For more information about the storage location of temporary files, see [Section B.5.4.4, “Where MySQL Stores Temporary Files”](#). A replication slave needs some of its temporary files to survive a machine restart so that it can replicate temporary tables or `LOAD DATA INFILE` operations. If files in the temporary file directory are lost when the server restarts, replication fails.

- `--user={user_name|user_id}, -u {user_name|user_id}`

Command-Line Format	<code>--user=name</code>	
	<code>-u name</code>	

Option-File Format	user	
	Permitted Values	
	Type	string

Run the `mysqld` server as the user having the name `user_name` or the numeric user ID `user_id`. (“User” in this context refers to a system login account, not a MySQL user listed in the grant tables.)

This option is *mandatory* when starting `mysqld` as `root`. The server changes its user ID during its startup sequence, causing it to run as that particular user rather than as `root`. See [Section 6.1.1, “Security Guidelines”](#).

To avoid a possible security hole where a user adds a `--user=root` option to a `my.cnf` file (thus causing the server to run as `root`), `mysqld` uses only the first `--user` option specified and produces a warning if there are multiple `--user` options. Options in `/etc/my.cnf` and `$MYSQL_HOME/my.cnf` are processed before command-line options, so it is recommended that you put a `--user` option in `/etc/my.cnf` and specify a value other than `root`. The option in `/etc/my.cnf` is found before any other `--user` options, which ensures that the server runs as a user other than `root`, and that a warning results if any other `--user` option is found.

- `--verbose, -v`

Use this option with the `--help` option for detailed help.

- `--version, -V`

Display version information and exit.

You can assign a value to a server system variable by using an option of the form `--var_name=value`. For example, `--key_buffer_size=32M` sets the `key_buffer_size` variable to a value of 32MB.

Note that when you assign a value to a variable, MySQL might automatically correct the value to stay within a given range, or adjust the value to the closest permissible value if only certain values are permitted.

If you want to restrict the maximum value to which a variable can be set at runtime with `SET`, you can define this by using the `--maximum-var_name=value` command-line option.

You can change the values of most system variables for a running server with the `SET` statement. See [Section 13.7.4, “SET Syntax”](#).

[Section 5.1.4, “Server System Variables”](#), provides a full description for all variables, and additional information for setting them at server startup and runtime. [Section 8.11.2, “Tuning Server Parameters”](#), includes information on optimizing the server by tuning system variables.

5.1.4 Server System Variables

The MySQL server maintains many system variables that indicate how it is configured. Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. Most of them can be changed dynamically while the server is running by means of the `SET` statement, which enables you to modify operation of the server without having to stop and restart it. You can refer to system variable values in expressions.

There are several ways to see the names and values of system variables:

- To see the values that a server will use based on its compiled-in defaults and any option files that it reads, use this command:

```
mysqld --verbose --help
```

- To see the values that a server will use based on its compiled-in defaults, ignoring the settings in any option files, use this command:

```
mysqld --no-defaults --verbose --help
```

- To see the current values used by a running server, use the `SHOW VARIABLES` statement.

This section provides a description of each system variable. Variables with no version indicated are present in all MySQL 5.5 releases. For historical information concerning their implementation, please see <http://dev.mysql.com/doc/refman/5.0/en/>, and <http://dev.mysql.com/doc/refman/4.1/en/>.

The following table lists all available system variables.

Table 5.2 System Variable Summary

Name	Cmd-Line	Option file	System Var	Var Scope	Dynamic
audit_log_buffer_size			Yes	Global	No
audit_log_file			Yes	Global	No
audit_log_flush			Yes	Global	Yes
audit_log_format			Yes	Global	No
audit_log_policy			Yes	Global	Yes
audit_log_rotate_on_size			Yes	Global	Yes
audit_log_strategy			Yes	Global	No
auto_increment_increment			Yes	Both	Yes
auto_increment_offset			Yes	Both	Yes
autocommit	Yes	Yes	Yes	Both	Yes
automatic_sp_privileges			Yes	Global	Yes
back_log			Yes	Global	No
basedir	Yes	Yes	Yes	Global	No
big-tables	Yes	Yes			Yes
- <i>Variable:</i> big_tables			Yes	Both	Yes
bind-address	Yes	Yes	Yes	Global	No
binlog_cache_size	Yes	Yes	Yes	Global	Yes
binlog_direct_non_transactional_updates	Yes	Yes	Yes	Both	Yes
binlog-format	Yes	Yes			Yes
- <i>Variable:</i> binlog_format			Yes	Both	Yes
binlog_stmt_cache_size	Yes	Yes	Yes	Global	Yes
bulk_insert_buffer_size	Yes	Yes	Yes	Both	Yes
character_set_client			Yes	Both	Yes
character_set_connection			Yes	Both	Yes
character_set_database ^a			Yes	Both	Yes

Name	Cmd-Line	Option file	System Var	Var Scope	Dynamic
character-set-filesystem	Yes	Yes			Yes
- Variable: character_set_filesystem			Yes	Both	Yes
character_set_results			Yes	Both	Yes
character-set-server	Yes	Yes			Yes
- Variable: character_set_server			Yes	Both	Yes
character_set_system			Yes	Global	No
character-sets-dir	Yes	Yes			No
- Variable: character_sets_dir			Yes	Global	No
collation_connection			Yes	Both	Yes
collation_database^b			Yes	Both	Yes
collation-server	Yes	Yes			Yes
- Variable: collation_server			Yes	Both	Yes
completion_type	Yes	Yes	Yes	Both	Yes
concurrent_insert	Yes	Yes	Yes	Global	Yes
connect_timeout	Yes	Yes	Yes	Global	Yes
datadir	Yes	Yes	Yes	Global	No
date_format			Yes	Global	No
datetime_format			Yes	Global	No
debug	Yes	Yes	Yes	Both	Yes
debug_sync			Yes	Session	Yes
default-storage-engine	Yes	Yes			Yes
- Variable: default_storage_engine			Yes	Both	Yes
default_week_format	Yes	Yes	Yes	Both	Yes
delay-key-write	Yes	Yes			Yes
- Variable: delay_key_write			Yes	Global	Yes
delayed_insert_limit	Yes	Yes	Yes	Global	Yes
delayed_insert_timeout	Yes	Yes	Yes	Global	Yes
delayed_queue_size	Yes	Yes	Yes	Global	Yes
div_precision_increment	Yes	Yes	Yes	Both	Yes
engine-condition-pushdown	Yes	Yes			Yes
- Variable: engine_condition_pushdown			Yes	Both	Yes

Name	Cmd-Line	Option file	System Var	Var Scope	Dynamic
error_count			Yes	Session	No
event-scheduler	Yes	Yes			Yes
- Variable: event_scheduler			Yes	Global	Yes
expire_logs_days	Yes	Yes	Yes	Global	Yes
external_user			Yes	Session	No
flush	Yes	Yes	Yes	Global	Yes
flush_time	Yes	Yes	Yes	Global	Yes
foreign_key_checks			Yes	Both	Yes
ft_boolean_syntax	Yes	Yes	Yes	Global	Yes
ft_max_word_len	Yes	Yes	Yes	Global	No
ft_min_word_len	Yes	Yes	Yes	Global	No
ft_query_expansion_limit	Yes	Yes	Yes	Global	No
ft_stopword_file	Yes	Yes	Yes	Global	No
general-log	Yes	Yes			Yes
- Variable: general_log			Yes	Global	Yes
general_log_file	Yes	Yes	Yes	Global	Yes
group_concat_max_len	Yes	Yes	Yes	Both	Yes
have_compress			Yes	Global	No
have_crypt			Yes	Global	No
have_csv			Yes	Global	No
have_dynamic_loading			Yes	Global	No
have_geometry			Yes	Global	No
have_innodb			Yes	Global	No
have_ndbcluster			Yes	Global	No
have_openssl			Yes	Global	No
have_partitioning			Yes	Global	No
have_profiling			Yes	Global	No
have_query_cache			Yes	Global	No
have_rtree_keys			Yes	Global	No
have_ssl			Yes	Global	No
have_symlink			Yes	Global	No
hostname			Yes	Global	No
identity			Yes	Session	Yes
ignore-builtin-innodb	Yes	Yes			No
- Variable: ignore_builtin_innodb			Yes	Global	No
init_connect	Yes	Yes	Yes	Global	Yes

Name	Cmd-Line	Option file	System Var	Var Scope	Dynamic
init-file	Yes	Yes			No
- Variable: init_file			Yes	Global	No
init_slave	Yes	Yes	Yes	Global	Yes
innodb_adaptive_flushing	Yes	Yes	Yes	Global	Yes
innodb_adaptive_hash_index	Yes	Yes	Yes	Global	Yes
innodb_additional_mem_pool_size	Yes	Yes	Yes	Global	No
innodb_autoextend_innodb	Yes	Yes	Yes	Global	Yes
innodb_autoinc_lock_mode	Yes	Yes	Yes	Global	No
innodb_buffer_pool_instances	Yes	Yes	Yes	Global	No
innodb_buffer_pool_size	Yes	Yes	Yes	Global	No
innodb_change_buffering	Yes	Yes	Yes	Global	Yes
innodb_checksums	Yes	Yes	Yes	Global	No
innodb_commit_concurrency	Yes	Yes	Yes	Global	Yes
innodb_concurrency_tickets	Yes	Yes	Yes	Global	Yes
innodb_data_file_path	Yes	Yes	Yes	Global	No
innodb_data_home_dir	Yes	Yes	Yes	Global	No
innodb_doublewrite	Yes	Yes	Yes	Global	No
innodb_fast_shutdown	Yes	Yes	Yes	Global	Yes
innodb_file_format	Yes	Yes	Yes	Global	Yes
innodb_file_format_check	Yes	Yes	Yes	Global	No
innodb_file_format_max	Yes	Yes	Yes	Global	Yes
innodb_file_per_table	Yes	Yes	Yes	Global	Yes
innodb_flush_log_at_trx_commit	Yes	Yes	Yes	Global	Yes
innodb_flush_method	Yes	Yes	Yes	Global	No
innodb_force_load_consistency	Yes	Yes	Yes	Global	No
innodb_force_recovery	Yes	Yes	Yes	Global	No
innodb_io_capacity	Yes	Yes	Yes	Global	Yes
innodb_large_prefix	Yes	Yes	Yes	Global	Yes
innodb_lock_wait_timeout	Yes	Yes	Yes	Both	Yes
innodb_locks_unsafe_for_binlog	Yes	Yes	Yes	Global	No
innodb_log_buffer_size	Yes	Yes	Yes	Global	No
innodb_log_file_size	Yes	Yes	Yes	Global	No
innodb_log_files_in_group	Yes	Yes	Yes	Global	No
innodb_log_group_home_dir	Yes	Yes	Yes	Global	No
innodb_max_dirty_pages_pct	Yes	Yes	Yes	Global	Yes
innodb_max_purge_lag	Yes	Yes	Yes	Global	Yes
innodb_mirrored_log_groups	Yes	Yes	Yes	Global	No
innodb_old_blocks_pct	Yes	Yes	Yes	Global	Yes

Name	Cmd-Line	Option file	System Var	Var Scope	Dynamic
innodb_old_blocks_time	Yes	Yes	Yes	Global	Yes
innodb_open_files	Yes	Yes	Yes	Global	No
innodb_print_all_deadlocks	Yes	Yes	Yes	Global	Yes
innodb_purge_batch_size	Yes	Yes	Yes	Global	Yes
innodb_purge_threads	Yes	Yes	Yes	Global	No
innodb_random_read_ahead	Yes	Yes	Yes	Global	Yes

^aThis option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

^bThis option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

For additional system variable information, see these sections:

- [Section 5.1.5, “Using System Variables”](#), discusses the syntax for setting and displaying system variable values.
- [Section 5.1.5.2, “Dynamic System Variables”](#), lists the variables that can be set at runtime.
- Information on tuning system variables can be found in [Section 8.11.2, “Tuning Server Parameters”](#).
- [Section 14.15, “InnoDB Startup Options and System Variables”](#), lists [InnoDB](#) system variables.
- [Section 18.3.4.3, “MySQL Cluster System Variables”](#), lists system variables which are specific to MySQL Cluster.
- For information on server system variables specific to replication, see [Section 17.1.3, “Replication and Binary Logging Options and Variables”](#).

**Note**

Some of the following variable descriptions refer to “enabling” or “disabling” a variable. These variables can be enabled with the `SET` statement by setting them to `ON` or `1`, or disabled by setting them to `OFF` or `0`. However, before MySQL 5.5.10, to set such a variable on the command line or in an option file, you must set it to `1` or `0`; setting it to `ON` or `OFF` will not work. For example, on the command line, `--delay_key_write=1` works but `--delay_key_write=ON` does not. As of MySQL 5.5.10, boolean variables can be set at startup to the values `ON`, `TRUE`, `OFF`, and `FALSE` (not case sensitive). See [Section 4.2.5, “Program Option Modifiers”](#).

Some system variables control the size of buffers or caches. For a given buffer, the server might need to allocate internal data structures. These structures typically are allocated from the total memory allocated to the buffer, and the amount of space required might be platform dependent. This means that when you assign a value to a system variable that controls a buffer size, the amount of space actually available might differ from the value assigned. In some cases, the amount might be less than the value assigned. It is also possible that the server will adjust a value upward. For example, if you assign a value of 0 to a variable for which the minimal value is 1024, the server will set the value to 1024.

Values for buffer sizes, lengths, and stack sizes are given in bytes unless otherwise specified.

Some system variables take file name values. Unless otherwise specified, the default file location is the data directory if the value is a relative path name. To specify the location explicitly, use an absolute path name. Suppose that the data directory is `/var/mysql/data`. If a file-valued variable is given as a relative path name, it will be located under `/var/mysql/data`. If the value is an absolute path name, its location is as given by the path name.

- `authentication_windows_log_level`

Introduced	5.5.16	
Command-Line Format	<code>--authentication_windows_log_level</code>	
Option-File Format	<code>authentication_windows_log_level</code>	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>0</code>
	Range	<code>0 .. 4</code>

This variable is available only if the `authentication_windows` Windows authentication plugin is enabled and debugging code is enabled. See [Section 6.3.7.4, “The Windows Native Authentication Plugin”](#).

This variable sets the logging level for the Windows authentication plugin. The following table shows the permitted values.

Value	Description
0	No logging
1	Log only error messages
2	Log level 1 messages and warning messages
3	Log level 2 messages and information notes
4	Log level 3 messages and debug messages

This variable was added in MySQL 5.5.16.

- `authentication_windows_use_principal_name`

Introduced	5.5.16	
Command-Line Format	<code>--authentication_windows_use_principal_name</code>	
Option-File Format	<code>authentication_windows_use_principal_name</code>	
	Permitted Values	
	Type	boolean
	Default	ON

This variable is available only if the `authentication_windows` Windows authentication plugin is enabled. See [Section 6.3.7.4, “The Windows Native Authentication Plugin”](#).

A client that authenticates using the `InitSecurityContext()` function should provide a string identifying the service to which it connects (*targetName*). MySQL uses the principal name (UPN) of the account under which the server is running. The UPN has the form `user_id@computer_name` and need not be registered anywhere to be used. This UPN is sent by the server at the beginning of authentication handshake.

This variable controls whether the server sends the UPN in the initial challenge. By default, the variable is enabled. For security reasons, it can be disabled to avoid sending the server's account name to a client in clear text. If the variable is disabled, the server always sends a `0x00` byte in the first challenge, the client does not specify *targetName*, and as a result, NTLM authentication is used.

If the server fails to obtain its UPN (which will happen primarily in environments that do not support Kerberos authentication), the UPN is not sent by the server and NTLM authentication is used.

This variable was added in MySQL 5.5.16.

- `autocommit`

Command-Line Format	<code>--</code>	from 5.5.8
	<code>autocommit[=#]</code>	
Option-File Format	<code>autocommit</code>	from 5.5.8
System Variable Name	<code>autocommit</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	boolean
	Default	ON

The autocommit mode. If set to 1, all changes to a table take effect immediately. If set to 0, you must use `COMMIT` to accept a transaction or `ROLLBACK` to cancel it. If `autocommit` is 0 and you change it to 1, MySQL performs an automatic `COMMIT` of any open transaction. Another way to begin a transaction is to use a `START TRANSACTION` or `BEGIN` statement. See [Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#).

By default, client connections begin with `autocommit` set to 1. To cause clients to begin with a default of 0, set the global `autocommit` value by starting the server with the `--autocommit=0` option. To set the variable using an option file, include these lines:

```
[mysqld]
autocommit=0
```

Before MySQL 5.5.8, the global `autocommit` value cannot be set at startup. As a workaround, set the `init_connect` system variable:

```
SET GLOBAL init_connect='SET autocommit=0';
```

The `init_connect` variable can also be set on the command line or in an option file. To set the variable as just shown using an option file, include these lines:

```
[mysqld]
init_connect='SET autocommit=0'
```

The content of `init_connect` is not executed for users that have the `SUPER` privilege (unlike the effect of setting the global `autocommit` value at startup).

- `automatic_sp_privileges`

System Variable Name	<code>automatic_sp_privileges</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>TRUE</code>

When this variable has a value of 1 (the default), the server automatically grants the `EXECUTE` and `ALTER ROUTINE` privileges to the creator of a stored routine, if the user cannot already execute and alter or drop the routine. (The `ALTER ROUTINE` privilege is required to drop the routine.) The server also automatically drops those privileges from the creator when the routine is dropped. If `automatic_sp_privileges` is 0, the server does not automatically add or drop these privileges.

The creator of a routine is the account used to execute the `CREATE` statement for it. This might not be the same as the account named as the `DEFINER` in the routine definition.

See also [Section 20.2.2, “Stored Routines and MySQL Privileges”](#).

- `back_log`

System Variable Name	<code>back_log</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>50</code>

	Range	1 .. 65535
--	--------------	------------

The number of outstanding connection requests MySQL can have. This comes into play when the main MySQL thread gets very many connection requests in a very short time. It then takes some time (although very little) for the main thread to check the connection and start a new thread. The `back_log` value indicates how many requests can be stacked during this short time before MySQL momentarily stops answering new requests. You need to increase this only if you expect a large number of connections in a short period of time.

In other words, this value is the size of the listen queue for incoming TCP/IP connections. Your operating system has its own limit on the size of this queue. The manual page for the Unix `listen()` system call should have more details. Check your OS documentation for the maximum value for this variable. `back_log` cannot be set higher than your operating system limit.

- `basedir`

Command-Line Format	<code>--basedir=path</code>	
	<code>-b</code>	
Option-File Format	<code>basedir</code>	
System Variable Name	<code>basedir</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	directory name

The MySQL installation base directory. This variable can be set with the `--basedir` option. Relative path names for other variables usually are resolved relative to the base directory.

- `big_tables`

Command-Line Format	<code>--big-tables</code>	
Option-File Format	<code>big-tables</code>	
System Variable Name	<code>big_tables</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	boolean
	Default	OFF

If set to 1, all temporary tables are stored on disk rather than in memory. This is a little slower, but the error `The table tbl_name is full` does not occur for `SELECT` operations that require a large temporary table. The default value for a new connection is 0 (use in-memory temporary tables). Normally, you should never need to set this variable, because in-memory tables are automatically converted to disk-based tables as required.

Note

This variable was formerly named `sql_big_tables`.

- `bulk_insert_buffer_size`

Command-Line Format	<code>--bulk_insert_buffer_size=#</code>	
Option-File Format	<code>bulk_insert_buffer_size</code>	
System Variable Name	<code>bulk_insert_buffer_size</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Platform Bit Size	32
	Type	numeric
	Default	8388608
	Range	0 .. 4294967295
	Permitted Values	
	Platform Bit Size	64
	Type	numeric
	Default	8388608
	Range	0 .. 18446744073709547520

MyISAM uses a special tree-like cache to make bulk inserts faster for `INSERT ... SELECT`, `INSERT ... VALUES (...), (...), ...`, and `LOAD DATA INFILE` when adding data to nonempty tables. This variable limits the size of the cache tree in bytes per thread. Setting it to 0 disables this optimization. The default value is 8MB.

- `character_set_client`

System Variable Name	<code>character_set_client</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	string

The character set for statements that arrive from the client. The session value of this variable is set using the character set requested by the client when the client connects to the server. (Many clients support a `--default-character-set` option to enable this character set to be specified explicitly. See also [Section 10.1.4, “Connection Character Sets and Collations”](#).) The global value of the variable is used to set the session value in cases when the client-requested value is unknown or not available, or the server is configured to ignore client requests:

- The client is from a version of MySQL older than MySQL 4.1, and thus does not request a character set.
- The client requests a character set not known to the server. For example, a Japanese-enabled client requests `sjis` when connecting to a server not configured with `sjis` support.

- `mysqld` was started with the `--skip-character-set-client-handshake` option, which causes it to ignore client character set configuration. This reproduces MySQL 4.0 behavior and is useful should you wish to upgrade the server without upgrading all the clients.

`ucs2`, `utf16`, and `utf32` cannot be used as a client character set, which means that they also do not work for `SET NAMES` or `SET CHARACTER SET`.

- `character_set_connection`

System Variable Name	<code>character_set_connection</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>string</code>

The character set used for literals that do not have a character set introducer and for number-to-string conversion.

- `character_set_database`

System Variable Name	<code>character_set_database</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
Footnote	This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.	
	Permitted Values	
	Type	<code>string</code>

The character set used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as `character_set_server`.

- `character_set_filesystem`

Command-Line Format	<code>--character-set-filesystem=name</code>	
Option-File Format	<code>character-set-filesystem</code>	
System Variable Name	<code>character_set_filesystem</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>string</code>
	Default	<code>binary</code>

The file system character set. This variable is used to interpret string literals that refer to file names, such as in the `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` function. Such file names are converted from `character_set_client` to `character_set_filesystem` before the file opening attempt occurs. The default value is `binary`, which means that no conversion occurs. For systems on which multi-byte file names are permitted, a

different value may be more appropriate. For example, if the system represents file names using UTF-8, set `character_set_filesystem` to `'utf8'`.

- `character_set_results`

System Variable Name	<code>character_set_results</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>string</code>

The character set used for returning query results such as result sets or error messages to the client.

- `character_set_server`

Command-Line Format	<code>--character-set-server</code>	
Option-File Format	<code>character-set-server</code>	
System Variable Name	<code>character_set_server</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>string</code>
	Default	<code>latin1</code>

The server's default character set.

- `character_set_system`

System Variable Name	<code>character_set_system</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>string</code>
	Default	<code>utf8</code>

The character set used by the server for storing identifiers. The value is always `utf8`.

- `character_sets_dir`

Command-Line Format	<code>--character-sets-dir=path</code>	
Option-File Format	<code>character-sets-dir</code>	
System Variable Name	<code>character_sets_dir</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>directory name</code>

The directory where character sets are installed.

- `collation_connection`

System Variable Name	<code>collation_connection</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>string</code>

The collation of the connection character set.

- `collation_database`

System Variable Name	<code>collation_database</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
Footnote	This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.	
	Permitted Values	
	Type	<code>string</code>

The collation used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as `collation_server`.

- `collation_server`

Command-Line Format	<code>--collation-server</code>	
Option-File Format	<code>collation-server</code>	
System Variable Name	<code>collation_server</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>string</code>
	Default	<code>latin1_swedish_ci</code>

The server's default collation.

- `completion_type`

Command-Line Format	<code>--completion_type=#</code>	
Option-File Format	<code>completion_type</code>	
System Variable Name	<code>completion_type</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values (<= 5.5.2)	

	Type	numeric
	Default	0
	Valid Values	0
		1
2		
	Permitted Values (>= 5.5.3)	
	Type	enumeration
	Default	NO_CHAIN
	Valid Values	NO_CHAIN
		CHAIN
		RELEASE
		0
		1
		2

The transaction completion type. This variable can take the values shown in the following table. As of MySQL 5.5.3, the variable can be assigned using either the name values or corresponding integer values. Before 5.5.3, only the integer values can be used.

Value	Description
NO_CHAIN (or 0)	COMMIT and ROLLBACK are unaffected. This is the default value.
CHAIN (or 1)	COMMIT and ROLLBACK are equivalent to COMMIT AND CHAIN and ROLLBACK AND CHAIN, respectively. (A new transaction starts immediately with the same isolation level as the just-terminated transaction.)
RELEASE (or 2)	COMMIT and ROLLBACK are equivalent to COMMIT RELEASE and ROLLBACK RELEASE, respectively. (The server disconnects after terminating the transaction.)

`completion_type` affects transactions that begin with `START TRANSACTION` or `BEGIN` and end with `COMMIT` or `ROLLBACK`. It does not apply to implicit commits resulting from execution of the statements listed in [Section 13.3.3, “Statements That Cause an Implicit Commit”](#). It also does not apply for `XA COMMIT`, `XA ROLLBACK`, or when `autocommit=1`.

- `concurrent_insert`

Command-Line Format	<code>--concurrent_insert[=#]</code>	
Option-File Format	<code>concurrent_insert</code>	
System Variable Name	<code>concurrent_insert</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values (<= 5.5.2)	
	Type	<code>numeric</code>
	Default	<code>1</code>
	Valid Values	<code>0</code>

		1
		2
	Permitted Values (>= 5.5.3)	
	Type	enumeration
	Default	AUTO
	Valid Values	NEVER
		AUTO
		ALWAYS
		0
		1
		2

If **AUTO** (the default), MySQL permits **INSERT** and **SELECT** statements to run concurrently for **MyISAM** tables that have no free blocks in the middle of the data file. If you start **mysqld** with **--skip-new**, this variable is set to **NEVER**.

This variable can take the values shown in the following table. As of MySQL 5.5.3, the variable can be assigned using either the name values or corresponding integer values. Before 5.5.3, only the integer values can be used.

Value	Description
NEVER (or 0)	Disables concurrent inserts
AUTO (or 1)	(Default) Enables concurrent insert for MyISAM tables that do not have holes
ALWAYS (or 2)	Enables concurrent inserts for all MyISAM tables, even those that have holes. For a table with a hole, new rows are inserted at the end of the table if it is in use by another thread. Otherwise, MySQL acquires a normal write lock and inserts the row into the hole.

See also [Section 8.10.3, “Concurrent Inserts”](#).

- `connect_timeout`

Command-Line Format	--connect_timeout=#	
Option-File Format	<code>connect_timeout</code>	
System Variable Name	<code>connect_timeout</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	numeric
	Default	10
	Range	2 .. 31536000

The number of seconds that the **mysqld** server waits for a connect packet before responding with **Bad handshake**. The default value is 10 seconds.

Increasing the `connect_timeout` value might help if clients frequently encounter errors of the form `Lost connection to MySQL server at 'XXX', system error: errno`.

- `datadir`

Command-Line Format	<code>--datadir=path</code>	
	<code>-h</code>	
Option-File Format	<code>datadir</code>	
System Variable Name	<code>datadir</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>directory name</code>

The MySQL data directory. This variable can be set with the `--datadir` option.

- `date_format`

This variable is unused.

- `datetime_format`

This variable is unused.

- `debug`

Command-Line Format	<code>--debug[=debug_options]</code>	
Option-File Format	<code>debug</code>	
System Variable Name	<code>debug</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type (Unix)	<code>string</code>
	Default	<code>d:t:i:o,/tmp/mysqld.trace</code>
	Permitted Values	
	Type (Windows)	<code>string</code>
	Default	<code>d:t:i:O,\mysqld.trace</code>

This variable indicates the current debugging settings. It is available only for servers built with debugging support. The initial value comes from the value of instances of the `--debug` option given at server startup. The global and session values may be set at runtime; the `SUPER` privilege is required, even for the session value.

Assigning a value that begins with `+` or `-` cause the value to added to or subtracted from the current value:

```

mysql> SET debug = 'T';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| T       |
+-----+

mysql> SET debug = '+P';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| P:T     |
+-----+

mysql> SET debug = '-P';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| T       |
+-----+

```

For more information, see [Section 24.4.3, “The DEBUG Package”](#).

- `debug_sync`

System Variable Name	<code>debug_sync</code>	
Variable Scope	Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>string</code>

This variable is the user interface to the Debug Sync facility. Use of Debug Sync requires that MySQL be configured with the `-DENABLE_DEBUG_SYNC=1` option (see [Section 2.9.4, “MySQL Source-Configuration Options”](#)). If Debug Sync is not compiled in, this system variable is not available.

The global variable value is read only and indicates whether the facility is enabled. By default, Debug Sync is disabled and the value of `debug_sync` is `OFF`. If the server is started with `--debug-sync-timeout=N`, where `N` is a timeout value greater than 0, Debug Sync is enabled and the value of `debug_sync` is `ON - current signal` followed by the signal name. Also, `N` becomes the default timeout for individual synchronization points.

The session value can be read by any user and will have the same value as the global variable. The session value can be set by users that have the `SUPER` privilege to control synchronization points.

For a description of the Debug Sync facility and how to use synchronization points, see [MySQL Internals: Test Synchronization](#).

- `default_storage_engine`

Command-Line Format	<code>--default-storage-engine=name</code>
Option-File Format	<code>default-storage-engine</code>
System Variable Name	<code>default_storage_engine</code>

Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values (<= 5.5.4)	
	Type	enumeration
	Default	MyISAM
	Permitted Values (>= 5.5.5)	
	Type	enumeration
	Default	InnoDB

The default storage engine. To set the storage engine at server startup, use the `--default-storage-engine` option. See [Section 5.1.3, “Server Command Options”](#).

To see which storage engines are available and enabled, use the `SHOW ENGINES` statement or query the `INFORMATION_SCHEMA.ENGINES` table.

If you disable the default storage engine at server startup, you must set the default engine to a different engine or the server will not start.

This variable was added in MySQL 5.5.3 to be used in preference to `storage_engine`, which is now deprecated.

- `default_week_format`

Command-Line Format	<code>--default_week_format=#</code>	
Option-File Format	<code>default_week_format</code>	
System Variable Name	<code>default_week_format</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	numeric
	Default	0
	Range	0 .. 7

The default mode value to use for the `WEEK()` function. See [Section 12.7, “Date and Time Functions”](#).

- `delay_key_write`

Command-Line Format	<code>--delay-key-write[=name]</code>	
Option-File Format	<code>delay-key-write</code>	
System Variable Name	<code>delay_key_write</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	enumeration
	Default	ON

	Valid Values	ON
		OFF
		ALL

This option applies only to [MyISAM](#) tables. It can have one of the following values to affect handling of the [DELAY_KEY_WRITE](#) table option that can be used in [CREATE TABLE](#) statements.

Option	Description
OFF	DELAY_KEY_WRITE is ignored.
ON	MySQL honors any DELAY_KEY_WRITE option specified in CREATE TABLE statements. This is the default value.
ALL	All new opened tables are treated as if they were created with the DELAY_KEY_WRITE option enabled.

If [DELAY_KEY_WRITE](#) is enabled for a table, the key buffer is not flushed for the table on every index update, but only when the table is closed. This speeds up writes on keys a lot, but if you use this feature, you should add automatic checking of all [MyISAM](#) tables by starting the server with the [--myisam-recover-options](#) option (for example, [--myisam-recover-options=BACKUP,FORCE](#)). See [Section 5.1.3, “Server Command Options”](#), and [Section 15.3.1, “MyISAM Startup Options”](#).

Warning

If you enable external locking with [--external-locking](#), there is no protection against index corruption for tables that use delayed key writes.

- [delayed_insert_limit](#)

Command-Line Format	--delayed_insert_limit=#	
Option-File Format	delayed_insert_limit	
System Variable Name	delayed_insert_limit	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Platform Bit Size	32
	Type	numeric
	Default	100
	Range	1 .. 4294967295
	Permitted Values	
	Platform Bit Size	64
	Type	numeric
	Default	100
	Range	1 .. 18446744073709547520

After inserting `delayed_insert_limit` delayed rows, the `INSERT DELAYED` handler thread checks whether there are any `SELECT` statements pending. If so, it permits them to execute before continuing to insert delayed rows.

- `delayed_insert_timeout`

Command-Line Format	<code>--delayed_insert_timeout=#</code>	
Option-File Format	<code>delayed_insert_timeout</code>	
System Variable Name	<code>delayed_insert_timeout</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>300</code>

How many seconds an `INSERT DELAYED` handler thread should wait for `INSERT` statements before terminating.

- `delayed_queue_size`

Command-Line Format	<code>--delayed_queue_size=#</code>	
Option-File Format	<code>delayed_queue_size</code>	
System Variable Name	<code>delayed_queue_size</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Platform Bit Size	<code>32</code>
	Type	<code>numeric</code>
	Default	<code>1000</code>
	Range	<code>1 .. 4294967295</code>
	Permitted Values	
	Platform Bit Size	<code>64</code>
	Type	<code>numeric</code>
	Default	<code>1000</code>
	Range	<code>1 .. 18446744073709547520</code>

This is a per-table limit on the number of rows to queue when handling `INSERT DELAYED` statements. If the queue becomes full, any client that issues an `INSERT DELAYED` statement waits until there is room in the queue again.

- `div_precision_increment`

Command-Line Format	<code>--div_precision_increment=#</code>
----------------------------	------------------------------------------

Option-File Format	<code>div_precision_increment</code>
System Variable Name	<code>div_precision_increment</code>
Variable Scope	Global, Session
Dynamic Variable	Yes
	Permitted Values
	Type <code>numeric</code>
	Default <code>4</code>
	Range <code>0 .. 30</code>

This variable indicates the number of digits by which to increase the scale of the result of division operations performed with the `/` operator. The default value is 4. The minimum and maximum values are 0 and 30, respectively. The following example illustrates the effect of increasing the default value.

```
mysql> SELECT 1/7;
+-----+
| 1/7    |
+-----+
| 0.1429 |
+-----+
mysql> SET div_precision_increment = 12;
mysql> SELECT 1/7;
+-----+
| 1/7          |
+-----+
| 0.142857142857 |
+-----+
```

- `engine_condition_pushdown`

Deprecated	5.5.3, by <code>optimizer_switch</code>
Command-Line Format	<code>--engine-condition-pushdown</code>
Option-File Format	<code>engine-condition-pushdown</code>
System Variable Name	<code>engine_condition_pushdown</code>
Variable Scope	Global, Session
Dynamic Variable	Yes
	Permitted Values
	Type <code>boolean</code>
	Default <code>ON</code>

The engine condition pushdown optimization enables processing for certain comparisons to be “pushed down” to the storage engine level for more efficient execution. For more information, see [Section 8.2.1.5, “Engine Condition Pushdown Optimization”](#).

Engine condition pushdown is used only by the `NDBCLUSTER` storage engine. Enabling this optimization on a MySQL Server acting as a MySQL Cluster SQL node causes `WHERE` conditions on unindexed columns to be evaluated on the cluster's data nodes and only the rows that match to be sent back to the SQL node that issued the query. This greatly reduces the amount of cluster data that must be sent over the network, increasing the efficiency with which results are returned.

The `engine_condition_pushdown` variable controls whether engine condition pushdown is enabled. By default, this variable is `ON` (1). Setting it to `OFF` (0) disables pushdown.

This variable is deprecated as of MySQL 5.5.3 and is removed in MySQL 5.6. Use the `engine_condition_pushdown` flag of the `optimizer_switch` variable instead. See [Section 8.8.5.2, “Controlling Switchable Optimizations”](#).

- `error_count`

The number of errors that resulted from the last statement that generated messages. This variable is read only. See [Section 13.7.5.18, “SHOW ERRORS Syntax”](#).

- `event_scheduler`

Command-Line Format	<code>--event-scheduler[=value]</code>	
Option-File Format	<code>event-scheduler</code>	
System Variable Name	<code>event_scheduler</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>enumeration</code>
	Default	<code>OFF</code>
	Valid Values	<code>ON</code>
		<code>OFF</code>
		<code>DISABLED</code>

This variable indicates the status of the Event Scheduler; possible values are `ON`, `OFF`, and `DISABLED`, with the default being `OFF`. This variable and its effects on the Event Scheduler's operation are discussed in greater detail in the [Overview section of the Events chapter \[2618\]](#).

- `expire_logs_days`

Command-Line Format	<code>--expire_logs_days=#</code>	
Option-File Format	<code>expire_logs_days</code>	
System Variable Name	<code>expire_logs_days</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>0</code>
	Range	<code>0 .. 99</code>

The number of days for automatic binary log file removal. The default is 0, which means “no automatic removal.” Possible removals happen at startup and when the binary log is flushed. Log flushing occurs as indicated in [Section 5.2, “MySQL Server Logs”](#).

To remove binary log files manually, use the `PURGE BINARY LOGS` statement. See [Section 13.4.1.1, “PURGE BINARY LOGS Syntax”](#).

- `external_user`

Introduced	5.5.7	
System Variable Name	<code>external_user</code>	
Variable Scope	Session	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>string</code>

The external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this variable is `NULL`. See [Section 6.3.8, “Proxy Users”](#).

This variable was added in MySQL 5.5.7.

- `flush`

Command-Line Format	<code>--flush</code>	
Option-File Format	<code>flush</code>	
System Variable Name	<code>flush</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>OFF</code>

If `ON`, the server flushes (synchronizes) all changes to disk after each SQL statement. Normally, MySQL does a write of all changes to disk only after each SQL statement and lets the operating system handle the synchronizing to disk. See [Section B.5.4.2, “What to Do If MySQL Keeps Crashing”](#). This variable is set to `ON` if you start `mysqld` with the `--flush` option.

- `flush_time`

Command-Line Format	<code>--flush_time=#</code>	
Option-File Format	<code>flush_time</code>	
System Variable Name	<code>flush_time</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>0</code>
	Min Value	<code>0</code>

If this is set to a nonzero value, all tables are closed every `flush_time` seconds to free up resources and synchronize unflushed data to disk. This option is best used only on systems with minimal resources.

- `foreign_key_checks`

If set to 1 (the default), foreign key constraints for `InnoDB` tables are checked. If set to 0, they are ignored. Disabling foreign key checking can be useful for reloading `InnoDB` tables in an order different from that required by their parent/child relationships. See [Section 14.9.6, “InnoDB and FOREIGN KEY Constraints”](#).

Setting `foreign_key_checks` to 0 also affects data definition statements: `DROP SCHEMA` drops a schema even if it contains tables that have foreign keys that are referred to by tables outside the schema, and `DROP TABLE` drops tables that have foreign keys that are referred to by other tables.

Note

Setting `foreign_key_checks` to 1 does not trigger a scan of the existing table data. Therefore, rows added to the table while `foreign_key_checks = 0` will not be verified for consistency.

- `ft_boolean_syntax`

Command-Line Format	<code>--ft_boolean_syntax=name</code>	
Option-File Format	<code>ft_boolean_syntax</code>	
System Variable Name	<code>ft_boolean_syntax</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>string</code>
	Default	<code>+ -><()~*: " "& </code>

The list of operators supported by boolean full-text searches performed using `IN BOOLEAN MODE`. See [Section 12.9.2, “Boolean Full-Text Searches”](#).

The default variable value is `'+ -><()~*: " "&|'`. The rules for changing the value are as follows:

- Operator function is determined by position within the string.
- The replacement value must be 14 characters.
- Each character must be an ASCII nonalphanumeric character.
- Either the first or second character must be a space.
- No duplicates are permitted except the phrase quoting operators in positions 11 and 12. These two characters are not required to be the same, but they are the only two that may be.
- Positions 10, 13, and 14 (which by default are set to `“:”`, `“&”`, and `“|”`) are reserved for future extensions.
- `ft_max_word_len`

Command-Line Format	<code>--ft_max_word_len=#</code>	
Option-File Format	<code>ft_max_word_len</code>	
System Variable Name	<code>ft_max_word_len</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>numeric</code>
	Min Value	10

The maximum length of the word to be included in a `FULLTEXT` index.

Note

`FULLTEXT` indexes must be rebuilt after changing this variable. Use `REPAIR TABLE tbl_name QUICK`.

- `ft_min_word_len`

Command-Line Format	<code>--ft_min_word_len=#</code>	
Option-File Format	<code>ft_min_word_len</code>	
System Variable Name	<code>ft_min_word_len</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>numeric</code>
	Default	4
	Min Value	1

The minimum length of the word to be included in a `FULLTEXT` index.

Note

`FULLTEXT` indexes must be rebuilt after changing this variable. Use `REPAIR TABLE tbl_name QUICK`.

- `ft_query_expansion_limit`

Command-Line Format	<code>--ft_query_expansion_limit=#</code>	
Option-File Format	<code>ft_query_expansion_limit</code>	
System Variable Name	<code>ft_query_expansion_limit</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>numeric</code>

	Default	20
	Range	0 .. 1000

The number of top matches to use for full-text searches performed using `WITH QUERY EXPANSION`.

- `ft_stopword_file`

Command-Line Format	<code>--ft_stopword_file=file_name</code>	
Option-File Format	<code>ft_stopword_file</code>	
System Variable Name	<code>ft_stopword_file</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>file name</code>

The file from which to read the list of stopwords for full-text searches. The server looks for the file in the data directory unless an absolute path name is given to specify a different directory. All the words from the file are used; comments are *not* honored. By default, a built-in list of stopwords is used (as defined in the `storage/myisam/ft_static.c` file). Setting this variable to the empty string (`' '`) disables stopwords filtering. See also [Section 12.9.4, “Full-Text Stopwords”](#).

Note

`FULLTEXT` indexes must be rebuilt after changing this variable or the contents of the stopwords file. Use `REPAIR TABLE tbl_name QUICK`.

- `general_log`

Command-Line Format	<code>--general-log</code>	
Option-File Format	<code>general-log</code>	
System Variable Name	<code>general_log</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>OFF</code>

Whether the general query log is enabled. The value can be 0 (or `OFF`) to disable the log or 1 (or `ON`) to enable the log. The default value depends on whether the `--general_log` option is given. The destination for log output is controlled by the `log_output` system variable; if that value is `NONE`, no log entries are written even if the log is enabled.

- `general_log_file`

Command-Line Format	<code>--general-log-file=file_name</code>	
Option-File Format	<code>general_log_file</code>	
System Variable Name	<code>general_log_file</code>	
Variable Scope	Global	

Dynamic Variable	Yes
	Permitted Values
	Type file name
	Default host_name.log

The name of the general query log file. The default value is `host_name.log`, but the initial value can be changed with the `--general_log_file` option.

- `group_concat_max_len`

Command-Line Format	<code>--group_concat_max_len=#</code>
Option-File Format	<code>group_concat_max_len</code>
System Variable Name	<code>group_concat_max_len</code>
Variable Scope	Global, Session
Dynamic Variable	Yes
	Permitted Values
	Platform Bit Size 32
	Type numeric
	Default 1024
	Range 4 .. 4294967295
	Permitted Values
	Platform Bit Size 64
	Type numeric
	Default 1024
	Range 4 .. 18446744073709547520

The maximum permitted result length in bytes for the `GROUP_CONCAT()` function. The default is 1024.

- `have_compress`

YES if the `zlib` compression library is available to the server, **NO** if not. If not, the `COMPRESS()` and `UNCOMPRESS()` functions cannot be used.

- `have_crypt`

YES if the `crypt()` system call is available to the server, **NO** if not. If not, the `ENCRYPT()` function cannot be used.

- `have_csv`

YES if `mysqld` supports `CSV` tables, **NO** if not.

This variable is deprecated and is removed in MySQL 5.6. Use `SHOW ENGINES` instead.

- `have_dynamic_loading`

YES if `mysqld` supports dynamic loading of plugins, **NO** if not.

- `have_geometry`

`YES` if the server supports spatial data types, `NO` if not.

- `have_innodb`

`YES` if `mysqld` supports `InnoDB` tables. `DISABLED` if `--skip-innodb` is used.

This variable is deprecated and is removed in MySQL 5.6. Use `SHOW ENGINES` instead.

- `have_openssl`

This variable is an alias for `have_ssl`.

- `have_partitioning`

`YES` if `mysqld` supports partitioning.

This variable is deprecated and is removed in MySQL 5.6. Use `SHOW PLUGINS` instead. For more information, see [Chapter 19, Partitioning](#).

- `have_profiling`

`YES` if statement profiling capability is present, `NO` if not. If present, the `profiling` system variable controls whether this capability is enabled or disabled. See [Section 13.7.5.32, “SHOW PROFILES Syntax”](#).

- `have_query_cache`

`YES` if `mysqld` supports the query cache, `NO` if not.

- `have_rtree_keys`

`YES` if `RTREE` indexes are available, `NO` if not. (These are used for spatial indexes in `MyISAM` tables.)

- `have_ssl`

`YES` if `mysqld` supports SSL connections, `NO` if not. `DISABLED` indicates that the server was compiled with SSL support, but was not started with the appropriate `--ssl-xxx` options. For more information, see [Section 6.3.9.2, “Configuring MySQL for SSL”](#).

- `have_symlink`

`YES` if symbolic link support is enabled, `NO` if not. This is required on Unix for support of the `DATA DIRECTORY` and `INDEX DIRECTORY` table options, and on Windows for support of data directory symlinks. If the server is started with the `--skip-symbolic-links` option, the value is `DISABLED`.

- `hostname`

System Variable Name	<code>hostname</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>string</code>

The server sets this variable to the server host name at startup.

- `identity`

This variable is a synonym for the `last_insert_id` variable. It exists for compatibility with other database systems. You can read its value with `SELECT @@identity`, and set it using `SET identity`.

- `init_connect`

Command-Line Format	<code>--init-connect=name</code>	
Option-File Format	<code>init_connect</code>	
System Variable Name	<code>init_connect</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>string</code>

A string to be executed by the server for each client that connects. The string consists of one or more SQL statements, separated by semicolon characters. For example, each client session begins by default with autocommit mode enabled. For older servers (before MySQL 5.5.8), there is no global `autocommit` system variable to specify that autocommit should be disabled by default, but as a workaround `init_connect` can be used to achieve the same effect:

```
SET GLOBAL init_connect='SET autocommit=0';
```

The `init_connect` variable can also be set on the command line or in an option file. To set the variable as just shown using an option file, include these lines:

```
[mysqld]
init_connect='SET autocommit=0'
```

The content of `init_connect` is not executed for users that have the `SUPER` privilege. This is done so that an erroneous value for `init_connect` does not prevent all clients from connecting. For example, the value might contain a statement that has a syntax error, thus causing client connections to fail. Not executing `init_connect` for users that have the `SUPER` privilege enables them to open a connection and fix the `init_connect` value.

- `init_file`

Command-Line Format	<code>--init-file=file_name</code>	
Option-File Format	<code>init-file</code>	
System Variable Name	<code>init_file</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>file name</code>

The name of the file specified with the `--init-file` option when you start the server. This should be a file containing SQL statements that you want the server to execute when it starts. Each statement must be on a single line and should not include comments. No statement terminator such as `;`, `\g`, or `\G` should be given at the end of each statement.

- `innodb_xxx`

InnoDB system variables are listed in [Section 14.15, “InnoDB Startup Options and System Variables”](#). These variables control many aspects of storage, memory use, and I/O patterns for InnoDB tables, and are especially important now that [InnoDB is the default storage engine](#).

- `insert_id`

The value to be used by the following `INSERT` or `ALTER TABLE` statement when inserting an `AUTO_INCREMENT` value. This is mainly used with the binary log.

- `interactive_timeout`

Command-Line Format	<code>--interactive_timeout=#</code>	
Option-File Format	<code>interactive_timeout</code>	
System Variable Name	<code>interactive_timeout</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>28800</code>
	Min Value	<code>1</code>

The number of seconds the server waits for activity on an interactive connection before closing it. An interactive client is defined as a client that uses the `CLIENT_INTERACTIVE` option to `mysql_real_connect()`. See also `wait_timeout`.

- `join_buffer_size`

Command-Line Format	<code>--join_buffer_size=#</code>	
Option-File Format	<code>join_buffer_size</code>	
System Variable Name	<code>join_buffer_size</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values (<= 5.5.2)	
	Platform Bit Size	<code>32</code>
	Type (Other)	<code>numeric</code>
	Default	<code>131072</code>
	Range	<code>8200 .. 4294967295</code>
	Permitted Values (<= 5.5.2)	
	Platform Bit Size	<code>64</code>
	Type (Other)	<code>numeric</code>

	Default	131072
	Range	8228 .. 18446744073709547520
	Permitted Values (<= 5.5.2)	
	Platform Bit Size	32
	Type (Windows)	numeric
	Default	131072
	Range	8200 .. 4294967295
	Permitted Values (<= 5.5.2)	
	Platform Bit Size	64
	Type (Windows)	numeric
	Default	131072
	Range	8228 .. 4294967295
	Permitted Values (>= 5.5.3)	
	Platform Bit Size	32
	Type (Other)	numeric
	Default	131072
	Range	128 .. 4294967295
	Permitted Values (>= 5.5.3)	
	Platform Bit Size	64
	Type (Other)	numeric
	Default	131072
	Range	128 .. 18446744073709547520
	Permitted Values (>= 5.5.3)	
	Type (Windows)	numeric
	Default	131072
	Range	128 .. 4294967295

The minimum size of the buffer that is used for plain index scans, range index scans, and joins that do not use indexes and thus perform full table scans. Normally, the best way to get fast joins is to add indexes. Increase the value of `join_buffer_size` to get a faster full join when adding indexes is not possible. One join buffer is allocated for each full join between two tables. For a complex join between several tables for which indexes are not used, multiple join buffers might be necessary.

There is no gain from setting the buffer larger than required to hold each matching row, and all joins allocate at least the minimum size, so use caution in setting this variable to a large value globally. It is

better to keep the global setting small and change to a larger setting only in sessions that are doing large joins. Memory allocation time can cause substantial performance drops if the global size is larger than needed by most queries that use it.

The maximum permissible setting for `join_buffer_size` is 4GB–1. Larger values are permitted for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB–1 with a warning).

Prior to MySQL 5.5.3, the minimum allowed value for this variable was 8200 for 32-bit platforms and 8228 for 64-bit platforms. In MySQL 5.5.3 and later, the minimum is 128 for all platforms.

For additional information about join buffering, see [Section 8.2.1.8, “Nested-Loop Join Algorithms”](#).

- `keep_files_on_create`

Command-Line Format	<code>--keep_files_on_create=#</code>	
Option-File Format	<code>keep_files_on_create</code>	
System Variable Name	<code>keep_files_on_create</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>OFF</code>

If a `MyISAM` table is created with no `DATA DIRECTORY` option, the `.MYD` file is created in the database directory. By default, if `MyISAM` finds an existing `.MYD` file in this case, it overwrites it. The same applies to `.MYI` files for tables created with no `INDEX DIRECTORY` option. To suppress this behavior, set the `keep_files_on_create` variable to `ON` (1), in which case `MyISAM` will not overwrite existing files and returns an error instead. The default value is `OFF` (0).

If a `MyISAM` table is created with a `DATA DIRECTORY` or `INDEX DIRECTORY` option and an existing `.MYD` or `.MYI` file is found, `MyISAM` always returns an error. It will not overwrite a file in the specified directory.

- `key_buffer_size`

Command-Line Format	<code>--key_buffer_size=#</code>	
Option-File Format	<code>key_buffer_size</code>	
System Variable Name	<code>key_buffer_size</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Platform Bit Size	<code>32</code>
	Type	<code>numeric</code>
	Default	<code>8388608</code>
	Range	<code>8 .. 4294967295</code>
	Permitted Values	

	Platform Bit Size	64
	Type	numeric
	Default	8388608
	Range	8 .. OS_PER_PROCESS_LIMIT

Index blocks for [MyISAM](#) tables are buffered and are shared by all threads. [key_buffer_size](#) is the size of the buffer used for index blocks. The key buffer is also known as the key cache.

The maximum permissible setting for [key_buffer_size](#) is 4GB–1 on 32-bit platforms. Larger values are permitted for 64-bit platforms. The effective maximum size might be less, depending on your available physical RAM and per-process RAM limits imposed by your operating system or hardware platform. The value of this variable indicates the amount of memory requested. Internally, the server allocates as much memory as possible up to this amount, but the actual allocation might be less.

You can increase the value to get better index handling for all reads and multiple writes; on a system whose primary function is to run MySQL using the [MyISAM](#) storage engine, 25% of the machine's total memory is an acceptable value for this variable. However, you should be aware that, if you make the value too large (for example, more than 50% of the machine's total memory), your system might start to page and become extremely slow. This is because MySQL relies on the operating system to perform file system caching for data reads, so you must leave some room for the file system cache. You should also consider the memory requirements of any other storage engines that you may be using in addition to [MyISAM](#).

For even more speed when writing many rows at the same time, use [LOCK TABLES](#). See [Section 8.2.2.1, “Speed of INSERT Statements”](#).

You can check the performance of the key buffer by issuing a [SHOW STATUS](#) statement and examining the [Key_read_requests](#), [Key_reads](#), [Key_write_requests](#), and [Key_writes](#) status variables. (See [Section 13.7.5, “SHOW Syntax”](#).) The [Key_reads/Key_read_requests](#) ratio should normally be less than 0.01. The [Key_writes/Key_write_requests](#) ratio is usually near 1 if you are using mostly updates and deletes, but might be much smaller if you tend to do updates that affect many rows at the same time or if you are using the [DELAY_KEY_WRITE](#) table option.

The fraction of the key buffer in use can be determined using [key_buffer_size](#) in conjunction with the [Key_blocks_unused](#) status variable and the buffer block size, which is available from the [key_cache_block_size](#) system variable:

```
1 - ((Key_blocks_unused * key_cache_block_size) / key_buffer_size)
```

This value is an approximation because some space in the key buffer is allocated internally for administrative structures. Factors that influence the amount of overhead for these structures include block size and pointer size. As block size increases, the percentage of the key buffer lost to overhead tends to decrease. Larger blocks results in a smaller number of read operations (because more keys are obtained per read), but conversely an increase in reads of keys that are not examined (if not all keys in a block are relevant to a query).

It is possible to create multiple [MyISAM](#) key caches. The size limit of 4GB applies to each cache individually, not as a group. See [Section 8.9.2, “The MyISAM Key Cache”](#).

- [key_cache_age_threshold](#)

Command-Line Format	<code>--key_cache_age_threshold=#</code>
----------------------------	------------------------------------------

Option-File Format	<code>key_cache_age_threshold</code>	
System Variable Name	<code>key_cache_age_threshold</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Platform Bit Size	32
	Type	numeric
	Default	300
	Range	100 .. 4294967295
	Permitted Values	
	Platform Bit Size	64
	Type	numeric
	Default	300
	Range	100 .. 18446744073709547520

This value controls the demotion of buffers from the hot sublist of a key cache to the warm sublist. Lower values cause demotion to happen more quickly. The minimum value is 100. The default value is 300. See [Section 8.9.2, “The MyISAM Key Cache”](#).

- `key_cache_block_size`

Command-Line Format	<code>--key_cache_block_size=#</code>	
Option-File Format	<code>key_cache_block_size</code>	
System Variable Name	<code>key_cache_block_size</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	numeric
	Default	1024
	Range	512 .. 16384

The size in bytes of blocks in the key cache. The default value is 1024. See [Section 8.9.2, “The MyISAM Key Cache”](#).

- `key_cache_division_limit`

Command-Line Format	<code>--key_cache_division_limit=#</code>	
Option-File Format	<code>key_cache_division_limit</code>	
System Variable Name	<code>key_cache_division_limit</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	

Type	numeric
Default	100
Range	1 .. 100

The division point between the hot and warm sublists of the key cache buffer list. The value is the percentage of the buffer list to use for the warm sublist. Permissible values range from 1 to 100. The default value is 100. See [Section 8.9.2, “The MyISAM Key Cache”](#).

- `language`

Deprecated	5.5.0, by <code>lc-messages-dir</code>
Command-Line Format	<code>--language=name</code>
	<code>-L</code>
Option-File Format	<code>language</code>
System Variable Name	<code>language</code>
Variable Scope	Global
Dynamic Variable	No
	Permitted Values
	Type directory name
	Default <code>/usr/local/mysql/share/mysql/english/</code>

The directory where error messages are located. See [Section 10.2, “Setting the Error Message Language”](#).

The `language` system variable is removed as of MySQL 5.5.0 (although the `--language` command-line option can still be used). Similar information is available from the `lc_messages_dir` and `lc_messages` variables.

- `large_files_support`

System Variable Name	<code>large_files_support</code>
Variable Scope	Global
Dynamic Variable	No

Whether `mysqld` was compiled with options for large file support.

- `large_pages`

Command-Line Format	<code>--large-pages</code>
Option-File Format	<code>large-pages</code>
System Variable Name	<code>large_pages</code>
Variable Scope	Global
Dynamic Variable	No
Platform Specific	Linux
	Permitted Values
	Type (Linux) boolean

	Default	<code>FALSE</code>
--	----------------	--------------------

Whether large page support is enabled (via the `--large-pages` option). See [Section 8.11.4.2, “Enabling Large Page Support”](#).

- `large_page_size`

System Variable Name	<code>large_page_size</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type (Linux)	<code>numeric</code>
	Default	<code>0</code>

If large page support is enabled, this shows the size of memory pages. Currently, large memory pages are supported only on Linux; on other platforms, the value of this variable is always 0. See [Section 8.11.4.2, “Enabling Large Page Support”](#).

- `last_insert_id`

The value to be returned from `LAST_INSERT_ID()`. This is stored in the binary log when you use `LAST_INSERT_ID()` in a statement that updates a table. Setting this variable does not update the value returned by the `mysql_insert_id()` C API function.

- `lc_messages`

Command-Line Format	<code>--lc-messages=name</code>	
Option-File Format	<code>lc-messages</code>	
System Variable Name	<code>lc_messages</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>string</code>

The locale to use for error messages. The server converts the value to a language name and combines it with the value of the `lc_messages_dir` to produce the location for the error message file. See [Section 10.2, “Setting the Error Message Language”](#).

- `lc_messages_dir`

Command-Line Format	<code>--lc-messages-dir=path</code>	
Option-File Format	<code>lc-messages-dir</code>	
System Variable Name	<code>lc_messages_dir</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>directory name</code>

The directory where error messages are located. The value is used together with the value of `lc_messages` to produce the location for the error message file. See [Section 10.2, “Setting the Error Message Language”](#).

- `lc_time_names`

System Variable Name	<code>lc_time_names</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>string</code>

This variable specifies the locale that controls the language used to display day and month names and abbreviations. This variable affects the output from the `DATE_FORMAT()`, `DAYNAME()` and `MONTHNAME()` functions. Locale names are POSIX-style values such as `'ja_JP'` or `'pt_BR'`. The default value is `'en_US'` regardless of your system's locale setting. For further information, see [Section 10.7, “MySQL Server Locale Support”](#).

- `license`

System Variable Name	<code>license</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>string</code>
	Default	<code>GPL</code>

The type of license the server has.

- `local_infile`

System Variable Name	<code>local_infile</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>

Whether `LOCAL` is supported for `LOAD DATA INFILE` statements. If this variable is disabled, clients cannot use `LOCAL` in `LOAD DATA` statements. See [Section 6.1.6, “Security Issues with LOAD DATA LOCAL”](#).

- `lock_wait_timeout`

Introduced	5.5.3
Command-Line Format	<code>--lock_wait_timeout=#</code>
Option-File Format	<code>lock_wait_timeout</code>
System Variable Name	<code>lock_wait_timeout</code>

Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	numeric
	Default	31536000
	Range	1 .. 31536000

This variable specifies the timeout in seconds for attempts to acquire metadata locks. The permissible values range from 1 to 31536000 (1 year). The default is 31536000.

This timeout applies to all statements that use metadata locks. These include DML and DDL operations on tables, views, stored procedures, and stored functions, as well as `LOCK TABLES`, `FLUSH TABLES WITH READ LOCK`, and `HANDLER` statements.

This timeout does not apply to implicit accesses to system tables in the `mysql` database, such as grant tables modified by `GRANT` or `REVOKE` statements or table logging statements. The timeout does apply to system tables accessed directly, such as with `SELECT` or `UPDATE`.

The timeout value applies separately for each metadata lock attempt. A given statement can require more than one lock, so it is possible for the statement to block for longer than the `lock_wait_timeout` value before reporting a timeout error. When lock timeout occurs, `ER_LOCK_WAIT_TIMEOUT` is reported.

`lock_wait_timeout` does not apply to delayed inserts, which always execute with a timeout of 1 year. This is done to avoid unnecessary timeouts because a session that issues a delayed insert receives no notification of delayed insert timeouts.

This variable was added in MySQL 5.5.3.

- `locked_in_memory`

System Variable Name	<code>locked_in_memory</code>
Variable Scope	Global
Dynamic Variable	No

Whether `mysqld` was locked in memory with `--memlock`.

- `log`

Deprecated	5.1.29, by <code>general-log</code>	
Command-Line Format	<code>--log[=name]</code>	
	-1	
Option-File Format	<code>log</code>	
System Variable Name	<code>log</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	string
	Default	OFF

Whether logging of all statements to the general query log is enabled. See [Section 5.2.3, “The General Query Log”](#).

This variable is deprecated and is removed in MySQL 5.6. Use `general_log` instead.

- `log_bin_trust_function_creators`

Command-Line Format	<code>--log-bin-trust-function-creators</code>	
Option-File Format	<code>log-bin-trust-function-creators</code>	
System Variable Name	<code>log_bin_trust_function_creators</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>FALSE</code>

This variable applies when binary logging is enabled. It controls whether stored function creators can be trusted not to create stored functions that will cause unsafe events to be written to the binary log. If set to 0 (the default), users are not permitted to create or alter stored functions unless they have the `SUPER` privilege in addition to the `CREATE ROUTINE` or `ALTER ROUTINE` privilege. A setting of 0 also enforces the restriction that a function must be declared with the `DETERMINISTIC` characteristic, or with the `READS SQL DATA` or `NO SQL` characteristic. If the variable is set to 1, MySQL does not enforce these restrictions on stored function creation. This variable also applies to trigger creation. See [Section 20.7, “Binary Logging of Stored Programs”](#).

- `log_error`

Command-Line Format	<code>--log-error[=name]</code>	
Option-File Format	<code>log-error</code>	
System Variable Name	<code>log_error</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>file name</code>

The location of the error log, or empty if the server is writing error message to the standard error output. See [Section 5.2.2, “The Error Log”](#).

- `log_output`

Command-Line Format	<code>--log-output=name</code>	
Option-File Format	<code>log-output</code>	
System Variable Name	<code>log_output</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	

	Type	set
	Default	FILE
	Valid Values	TABLE
		FILE
		NONE

The destination for general query log and slow query log output. The value can be a comma-separated list of one or more of the words `TABLE` (log to tables), `FILE` (log to files), or `NONE` (do not log to tables or files). The default value is `FILE`. `NONE`, if present, takes precedence over any other specifiers. If the value is `NONE` log entries are not written even if the logs are enabled. If the logs are not enabled, no logging occurs even if the value of `log_output` is not `NONE`. For more information, see [Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”](#).

- `log_queries_not_using_indexes`

Command-Line Format	<code>--log-queries-not-using-indexes</code>	
Option-File Format	<code>log-queries-not-using-indexes</code>	
System Variable Name	<code>log_queries_not_using_indexes</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	boolean
	Default	OFF

Whether queries that do not use indexes are logged to the slow query log. See [Section 5.2.5, “The Slow Query Log”](#).

- `log_slow_queries`

Deprecated	5.1.29, by <code>slow-query-log</code>	
Command-Line Format	<code>--log-slow-queries[=name]</code>	
Option-File Format	<code>log-slow-queries</code>	
System Variable Name	<code>log_slow_queries</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	boolean

Whether slow queries should be logged. “Slow” is determined by the value of the `long_query_time` variable. See [Section 5.2.5, “The Slow Query Log”](#).

This variable is deprecated and is removed in MySQL 5.6. Use `slow_query_log` instead.

- `log_warnings`

Command-Line Format	<code>--log-warnings[=#]</code>	
	<code>-W [#]</code>	550

Option-File Format	<code>log-warnings[=#]</code>	
System Variable Name	<code>log_warnings</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Platform Bit Size	32
	Type	numeric
	Default	1
	Range	0 .. 4294967295
	Permitted Values	
	Platform Bit Size	64
	Type	numeric
	Default	1
	Range	0 .. 18446744073709547520

Whether to produce additional warning messages to the error log. This variable is enabled (1) by default and can be disabled by setting it to 0. The server logs messages about statements that are unsafe for statement-based logging if the value is greater than 0. Aborted connections and access-denied errors for new connection attempts are logged if the value is greater than 1.

- `long_query_time`

Command-Line Format	<code>--long_query_time=#</code>	
Option-File Format	<code>long_query_time</code>	
System Variable Name	<code>long_query_time</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	numeric
	Default	10
	Min Value	0

If a query takes longer than this many seconds, the server increments the `Slow_queries` status variable. If the slow query log is enabled, the query is logged to the slow query log file. This value is measured in real time, not CPU time, so a query that is under the threshold on a lightly loaded system might be above the threshold on a heavily loaded one. The minimum and default values of `long_query_time` are 0 and 10, respectively. The value can be specified to a resolution of microseconds. For logging to a file, times are written including the microseconds part. For logging to tables, only integer times are written; the microseconds part is ignored. See [Section 5.2.5, “The Slow Query Log”](#).

- `low_priority_updates`

Command-Line Format	<code>--low-priority-updates</code>	
Option-File Format	<code>low-priority-updates</code>	
System Variable Name	<code>low_priority_updates</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>FALSE</code>

If set to `1`, all `INSERT`, `UPDATE`, `DELETE`, and `LOCK TABLE WRITE` statements wait until there is no pending `SELECT` or `LOCK TABLE READ` on the affected table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`). This variable previously was named `sql_low_priority_updates`.

- `lower_case_file_system`

System Variable Name	<code>lower_case_file_system</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>boolean</code>

This variable describes the case sensitivity of file names on the file system where the data directory is located. `OFF` means file names are case sensitive, `ON` means they are not case sensitive. This variable is read only because it reflects a file system attribute and setting it would have no effect on the file system.

- `lower_case_table_names`

Command-Line Format	<code>--lower_case_table_names[=#]</code>	
Option-File Format	<code>lower_case_table_names</code>	
System Variable Name	<code>lower_case_table_names</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>0</code>
	Range	<code>0 .. 2</code>

If set to `0`, table names are stored as specified and comparisons are case sensitive. If set to `1`, table names are stored in lowercase on disk and comparisons are not case sensitive. If set to `2`, table names are stored as given but compared in lowercase. This option also applies to database names and table aliases. For additional information, see [Section 9.2.2, “Identifier Case Sensitivity”](#).

You should *not* set this variable to `0` if you are running MySQL on a system that has case-insensitive file names (such as Windows or Mac OS X). If you set this variable to `0` on such a system and access

[MyISAM](#) tablenamees using different lettercases, index corruption may result. On Windows the default value is 1. On Mac OS X, the default value is 2.

If you are using [InnoDB](#) tables, you should set this variable to 1 on all platforms to force names to be converted to lowercase.

The setting of this variable has no effect on replication filtering options. This is a known issue which is fixed in MySQL 5.6. See [Section 17.2.3, “How Servers Evaluate Replication Filtering Rules”](#), for more information.

You should not use different settings for [lower_case_table_names](#) on replication masters and slaves. In particular, you should not do this when the slave uses a case-sensitive file system, as this can cause replication to fail. This is a known issue which is fixed in MySQL 5.6. For more information, see [Section 17.4.1.36, “Replication and Variables”](#).

- [max_allowed_packet](#)

Command-Line Format	<code>--max_allowed_packet=#</code>	
Option-File Format	<code>max_allowed_packet</code>	
System Variable Name	max_allowed_packet	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	numeric
	Default	1048576
	Range	1024 .. 1073741824

The maximum size of one packet or any generated/intermediate string.

The packet message buffer is initialized to [net_buffer_length](#) bytes, but can grow up to [max_allowed_packet](#) bytes when needed. This value by default is small, to catch large (possibly incorrect) packets.

You must increase this value if you are using large [BLOB](#) columns or long strings. It should be as big as the largest [BLOB](#) you want to use. The protocol limit for [max_allowed_packet](#) is 1GB. The value should be a multiple of 1024; nonmultiples are rounded down to the nearest multiple.

When you change the message buffer size by changing the value of the [max_allowed_packet](#) variable, you should also change the buffer size on the client side if your client program permits it. The default [max_allowed_packet](#) value built in to the client library is 1GB, but individual client programs might override this. For example, [mysql](#) and [mysqldump](#) have defaults of 16MB and 24MB, respectively. They also enable you to change the client-side value by setting [max_allowed_packet](#) on the command line or in an option file.

The session value of this variable is read only.

- [max_connect_errors](#)

Command-Line Format	<code>--max_connect_errors=#</code>
Option-File Format	<code>max_connect_errors</code>
System Variable Name	max_connect_errors

Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Platform Bit Size	32
	Type	numeric
	Default	10
	Range	1 .. 4294967295
	Permitted Values	
	Platform Bit Size	64
	Type	numeric
	Default	10
	Range	1 .. 18446744073709547520

If more than this many successive connection requests from a host are interrupted without a successful connection, the server blocks that host from further connections. You can unblock blocked hosts by flushing the host cache. To do so, issue a `FLUSH HOSTS` statement or execute a `mysqladmin flush-hosts` command. If a connection is established successfully within fewer than `max_connect_errors` attempts after a previous connection was interrupted, the error count for the host is cleared to zero. However, once a host is blocked, flushing the host cache is the only way to unblock it.

- `max_connections`

Command-Line Format	<code>--max_connections=#</code>	
Option-File Format	<code>max_connections</code>	
System Variable Name	<code>max_connections</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	numeric
	Default	151
	Range	1 .. 100000

The maximum permitted number of simultaneous client connections. By default, this is 151. See [Section B.5.2.7, “Too many connections”](#), for more information.

Increasing this value increases the number of file descriptors that `mysqld` requires. See [Section 8.4.3.1, “How MySQL Opens and Closes Tables”](#), for comments on file descriptor limits.

- `max_delayed_threads`

Command-Line Format	<code>--max_delayed_threads=#</code>	
Option-File Format	<code>max_delayed_threads</code>	
System Variable Name	<code>max_delayed_threads</code>	
Variable Scope	Global, Session	

Dynamic Variable	Yes	
	Permitted Values	
	Type	numeric
	Default	20
	Range	0 .. 16384

Do not start more than this number of threads to handle `INSERT DELAYED` statements. If you try to insert data into a new table after all `INSERT DELAYED` threads are in use, the row is inserted as if the `DELAYED` attribute was not specified. If you set this to 0, MySQL never creates a thread to handle `DELAYED` rows; in effect, this disables `DELAYED` entirely.

For the `SESSION` value of this variable, the only valid values are 0 or the `GLOBAL` value.

- `max_error_count`

Command-Line Format	<code>--max_error_count=#</code>	
Option-File Format	<code>max_error_count</code>	
System Variable Name	<code>max_error_count</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	numeric
	Default	64
	Range	0 .. 65535

The maximum number of error, warning, and note messages to be stored for display by the `SHOW ERRORS` and `SHOW WARNINGS` statements.

- `max_heap_table_size`

Command-Line Format	<code>--max_heap_table_size=#</code>	
Option-File Format	<code>max_heap_table_size</code>	
System Variable Name	<code>max_heap_table_size</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Platform Bit Size	32
	Type	numeric
	Default	16777216
	Range	16384 .. 4294967295
	Permitted Values	
	Platform Bit Size	64
	Type	numeric

	Default	16777216
	Range	16384 .. 1844674407370954752

This variable sets the maximum size to which user-created `MEMORY` tables are permitted to grow. The value of the variable is used to calculate `MEMORY` table `MAX_ROWS` values. Setting this variable has no effect on any existing `MEMORY` table, unless the table is re-created with a statement such as `CREATE TABLE` or altered with `ALTER TABLE` or `TRUNCATE TABLE`. A server restart also sets the maximum size of existing `MEMORY` tables to the global `max_heap_table_size` value.

This variable is also used in conjunction with `tmp_table_size` to limit the size of internal in-memory tables. See [Section 8.4.4, “How MySQL Uses Internal Temporary Tables”](#).

`max_heap_table_size` is not replicated. See [Section 17.4.1.21, “Replication and `MEMORY` Tables”](#), and [Section 17.4.1.36, “Replication and Variables”](#), for more information.

- `max_insert_delayed_threads`

System Variable Name	<code>max_insert_delayed_threads</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>numeric</code>

This variable is a synonym for `max_delayed_threads`.

- `max_join_size`

Command-Line Format	<code>--max_join_size=#</code>	
Option-File Format	<code>max_join_size</code>	
System Variable Name	<code>max_join_size</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>numeric</code>
	Default	18446744073709551615
	Range	1 .. 18446744073709551615

Do not permit statements that probably need to examine more than `max_join_size` rows (for single-table statements) or row combinations (for multiple-table statements) or that are likely to do more than `max_join_size` disk seeks. By setting this value, you can catch statements where keys are not used properly and that would probably take a long time. Set it if your users tend to perform joins that lack a `WHERE` clause, that take a long time, or that return millions of rows.

Setting this variable to a value other than `DEFAULT` resets the value of `sql_big_selects` to 0. If you set the `sql_big_selects` value again, the `max_join_size` variable is ignored.

If a query result is in the query cache, no result size check is performed, because the result has previously been computed and it does not burden the server to send it to the client.

This variable previously was named `sql_max_join_size`.

- `max_length_for_sort_data`

Command-Line Format	<code>--max_length_for_sort_data=#</code>	
Option-File Format	<code>max_length_for_sort_data</code>	
System Variable Name	<code>max_length_for_sort_data</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>1024</code>
	Range	<code>4 .. 8388608</code>

The cutoff on the size of index values that determines which `filesort` algorithm to use. See [Section 8.2.1.11, “ORDER BY Optimization”](#).

- `max_long_data_size`

Introduced	5.5.11	
Deprecated	5.5.11	
Command-Line Format	<code>--max_long_data_size=#</code>	
Option-File Format	<code>max_long_data_size</code>	
System Variable Name	<code>max_long_data_size</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>1048576</code>
	Range	<code>1024 .. 4294967295</code>

The maximum size of parameter values that can be sent with the `mysql_stmt_send_long_data()` C API function. If not set at server startup, the default is the value of the `max_allowed_packet` system variable. This variable is deprecated. In MySQL 5.6, it is removed and the maximum parameter size is controlled by `max_allowed_packet`.

- `max_prepared_stmt_count`

Command-Line Format	<code>--max_prepared_stmt_count=#</code>	
Option-File Format	<code>max_prepared_stmt_count</code>	
System Variable Name	<code>max_prepared_stmt_count</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>16382</code>

	Range	0 .. 1048576
--	--------------	--------------

This variable limits the total number of prepared statements in the server. (The sum of the number of prepared statements across all sessions.) It can be used in environments where there is the potential for denial-of-service attacks based on running the server out of memory by preparing huge numbers of statements. If the value is set lower than the current number of prepared statements, existing statements are not affected and can be used, but no new statements can be prepared until the current number drops below the limit. The default value is 16,382. The permissible range of values is from 0 to 1 million. Setting the value to 0 disables prepared statements.

- `max_relay_log_size`

Command-Line Format	<code>--max_relay_log_size=#</code>	
Option-File Format	<code>max_relay_log_size</code>	
System Variable Name	<code>max_relay_log_size</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>numeric</code>
	Default	0
	Range	0 .. 1073741824

If a write by a replication slave to its relay log causes the current log file size to exceed the value of this variable, the slave rotates the relay logs (closes the current file and opens the next one). If `max_relay_log_size` is 0, the server uses `max_binlog_size` for both the binary log and the relay log. If `max_relay_log_size` is greater than 0, it constrains the size of the relay log, which enables you to have different sizes for the two logs. You must set `max_relay_log_size` to between 4096 bytes and 1GB (inclusive), or to 0. The default value is 0. See [Section 17.2.1, “Replication Implementation Details”](#).

- `max_seeks_for_key`

Command-Line Format	<code>--max_seeks_for_key=#</code>	
Option-File Format	<code>max_seeks_for_key</code>	
System Variable Name	<code>max_seeks_for_key</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Platform Bit Size	32
	Type	<code>numeric</code>
	Default	4294967295
	Range	1 .. 4294967295
	Permitted Values	
	Platform Bit Size	64

Type	numeric
Default	18446744073709547520
Range	1 .. 18446744073709547520

Limit the assumed maximum number of seeks when looking up rows based on a key. The MySQL optimizer assumes that no more than this number of key seeks are required when searching for matching rows in a table by scanning an index, regardless of the actual cardinality of the index (see [Section 13.7.5.23, “SHOW INDEX Syntax”](#)). By setting this to a low value (say, 100), you can force MySQL to prefer indexes instead of table scans.

- `max_sort_length`

Command-Line Format	<code>--max_sort_length=#</code>	
Option-File Format	<code>max_sort_length</code>	
System Variable Name	<code>max_sort_length</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	numeric
	Default	1024
	Range	4 .. 8388608

The number of bytes to use when sorting data values. Only the first `max_sort_length` bytes of each value are used; the rest are ignored.

- `max_sp_recursion_depth`

Command-Line Format	<code>--max_sp_recursion_depth[=#]</code>	
Option-File Format	<code>max_sp_recursion_depth</code>	
System Variable Name	<code>max_sp_recursion_depth</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	numeric
	Default	0
	Max Value	255

The number of times that any given stored procedure may be called recursively. The default value for this option is 0, which completely disables recursion in stored procedures. The maximum value is 255.

Stored procedure recursion increases the demand on thread stack space. If you increase the value of `max_sp_recursion_depth`, it may be necessary to increase thread stack size by increasing the value of `thread_stack` at server startup.

- `max_tmp_tables`

This variable is unused.

- `max_user_connections`

Command-Line Format	<code>--max_user_connections=#</code>	
Option-File Format	<code>max_user_connections</code>	
System Variable Name	<code>max_user_connections</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>0</code>
	Range	<code>0 .. 4294967295</code>

The maximum number of simultaneous connections permitted to any given MySQL user account. A value of 0 (the default) means “no limit.”

This variable has a global value that can be set at server startup or runtime. It also has a read-only session value that indicates the effective simultaneous-connection limit that applies to the account associated with the current session. The session value is initialized as follows:

- If the user account has a nonzero `MAX_USER_CONNECTIONS` resource limit, the session `max_user_connections` value is set to that limit.
- Otherwise, the session `max_user_connections` value is set to the global value.

Account resource limits are specified using the `GRANT` statement. See [Section 6.3.4, “Setting Account Resource Limits”](#), and [Section 13.7.1.3, “GRANT Syntax”](#).

- `max_write_lock_count`

Command-Line Format	<code>--max_write_lock_count=#</code>	
Option-File Format	<code>max_write_lock_count</code>	
System Variable Name	<code>max_write_lock_count</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Platform Bit Size	<code>32</code>
	Type	<code>numeric</code>
	Default	<code>4294967295</code>
	Range	<code>1 .. 4294967295</code>
	Permitted Values	
	Platform Bit Size	<code>64</code>
	Type	<code>numeric</code>
	Default	<code>18446744073709547520</code>
	Range	<code>1 .. 18446744073709547520</code>

After this many write locks, permit some pending read lock requests to be processed in between.

- `metadata_locks_cache_size`

Introduced	5.5.19	
System Variable Name	<code>metadata_locks_cache_size</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>1024</code>
	Range	<code>1 .. 1048576</code>

The size of the metadata locks cache. The server uses this cache to avoid creation and destruction of synchronization objects. This is particularly helpful on systems where such operations are expensive, such as Windows XP. This variable was added in MySQL 5.5.19.

- `min_examined_row_limit`

Command-Line Format	<code>--min-examined-row-limit=#</code>	
Option-File Format	<code>min-examined-row-limit</code>	
System Variable Name	<code>min_examined_row_limit</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Platform Bit Size	<code>32</code>
	Type	<code>numeric</code>
	Default	<code>0</code>
	Range	<code>0 .. 4294967295</code>
	Permitted Values	
	Platform Bit Size	<code>64</code>
	Type	<code>numeric</code>
	Default	<code>0</code>
	Range	<code>0 .. 18446744073709547520</code>

Queries that examine fewer than this number of rows are not logged to the slow query log.

- `myisam_data_pointer_size`

Command-Line Format	<code>--myisam_data_pointer_size=#</code>
Option-File Format	<code>myisam_data_pointer_size</code>
System Variable Name	<code>myisam_data_pointer_size</code>

Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	numeric
	Default	6
	Range	2 .. 7

The default pointer size in bytes, to be used by `CREATE TABLE` for `MyISAM` tables when no `MAX_ROWS` option is specified. This variable cannot be less than 2 or larger than 7. The default value is 6. See [Section B.5.2.12, “The table is full”](#).

- `myisam_max_sort_file_size`

Command-Line Format	<code>--myisam_max_sort_file_size=#</code>	
Option-File Format	<code>myisam_max_sort_file_size</code>	
System Variable Name	<code>myisam_max_sort_file_size</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Platform Bit Size	32
	Type	numeric
	Default	2147483648
	Permitted Values	
	Platform Bit Size	64
	Type	numeric
	Default	9223372036854775807

The maximum size of the temporary file that MySQL is permitted to use while re-creating a `MyISAM` index (during `REPAIR TABLE`, `ALTER TABLE`, or `LOAD DATA INFILE`). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

The default value is 2GB. If `MyISAM` index files exceed this size and disk space is available, increasing the value may help performance. The space must be available in the file system containing the directory where the original index file is located.

- `myisam_mmap_size`

Introduced	5.5.1
Command-Line Format	<code>--myisam_mmap_size=#</code>
Option-File Format	<code>myisam_mmap_size</code>
System Variable Name	<code>myisam_mmap_size</code>
Variable Scope	Global
Dynamic Variable	No

	Permitted Values	
	Platform Bit Size	32
	Type	numeric
	Default	4294967295
	Range	7 .. 4294967295
	Permitted Values	
	Platform Bit Size	64
	Type	numeric
	Default	18446744073709547520
	Range	7 .. 18446744073709547520

The maximum amount of memory to use for memory mapping compressed [MyISAM](#) files. If many compressed [MyISAM](#) tables are used, the value can be decreased to reduce the likelihood of memory-swapping problems. This variable was added in MySQL 5.5.1.

- [myisam_recover_options](#)

System Variable Name	myisam_recover_options
Variable Scope	Global
Dynamic Variable	No

The value of the `--myisam-recover-options` option. See [Section 5.1.3, “Server Command Options”](#).

- [myisam_repair_threads](#)

Command-Line Format	<code>--myisam_repair_threads=#</code>	
Option-File Format	myisam_repair_threads	
System Variable Name	myisam_repair_threads	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Platform Bit Size	32
	Type	numeric
	Default	1
	Range	1 .. 4294967295
	Permitted Values	
	Platform Bit Size	64
	Type	numeric
	Default	1
	Range	1 .. 18446744073709547520

If this value is greater than 1, [MyISAM](#) table indexes are created in parallel (each index in its own thread) during the [Repair by sorting](#) process. The default value is 1.

**Note**

Multi-threaded repair is still *beta-quality* code.

- [myisam_sort_buffer_size](#)

Command-Line Format	<code>--myisam_sort_buffer_size=#</code>	
Option-File Format	<code>myisam_sort_buffer_size</code>	
System Variable Name	myisam_sort_buffer_size	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Platform Bit Size	32
	Type (Other)	numeric
	Default	8388608
	Range	4096 .. 4294967295
	Permitted Values	
	Platform Bit Size	64
	Type (Other)	numeric
	Default	8388608
	Range	4096 .. 18446744073709547520
	Permitted Values	
	Type (Windows)	numeric
	Default	8388608
	Range	4096 .. 4294967295

The size of the buffer that is allocated when sorting [MyISAM](#) indexes during a [REPAIR TABLE](#) or when creating indexes with [CREATE INDEX](#) or [ALTER TABLE](#).

The maximum permissible setting for [myisam_sort_buffer_size](#) is 4GB–1. Larger values are permitted for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB–1 with a warning).

- [myisam_stats_method](#)

Command-Line Format	<code>--myisam_stats_method=name</code>
Option-File Format	<code>myisam_stats_method</code>
System Variable Name	myisam_stats_method

Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	enumeration
	Default	nulls_unequal
	Valid Values	nulls_equal
		nulls_unequal
		nulls_ignored

How the server treats `NULL` values when collecting statistics about the distribution of index values for `MyISAM` tables. This variable has three possible values, `nulls_equal`, `nulls_unequal`, and `nulls_ignored`. For `nulls_equal`, all `NULL` index values are considered equal and form a single value group that has a size equal to the number of `NULL` values. For `nulls_unequal`, `NULL` values are considered unequal, and each `NULL` forms a distinct value group of size 1. For `nulls_ignored`, `NULL` values are ignored.

The method that is used for generating table statistics influences how the optimizer chooses indexes for query execution, as described in [Section 8.3.7, “InnoDB and MyISAM Index Statistics Collection”](#).

- `myisam_use_mmap`

Command-Line Format	<code>--myisam_use_mmap</code>	
Option-File Format	<code>myisam_use_mmap</code>	
System Variable Name	<code>myisam_use_mmap</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	boolean
	Default	OFF

Use memory mapping for reading and writing `MyISAM` tables.

- `named_pipe`

System Variable Name	<code>named_pipe</code>	
Variable Scope	Global	
Dynamic Variable	No	
Platform Specific	Windows	
	Permitted Values	
	Type (Windows)	boolean
	Default	OFF

(Windows only.) Indicates whether the server supports connections over named pipes.

- `net_buffer_length`

Command-Line Format	<code>--net_buffer_length=#</code>	
Option-File Format	<code>net_buffer_length</code>	
System Variable Name	<code>net_buffer_length</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>16384</code>
	Range	<code>1024 .. 1048576</code>

Each client thread is associated with a connection buffer and result buffer. Both begin with a size given by `net_buffer_length` but are dynamically enlarged up to `max_allowed_packet` bytes as needed. The result buffer shrinks to `net_buffer_length` after each SQL statement.

This variable should not normally be changed, but if you have very little memory, you can set it to the expected length of statements sent by clients. If statements exceed this length, the connection buffer is automatically enlarged. The maximum value to which `net_buffer_length` can be set is 1MB.

The session value of this variable is read only.

- `net_read_timeout`

Command-Line Format	<code>--net_read_timeout=#</code>	
Option-File Format	<code>net_read_timeout</code>	
System Variable Name	<code>net_read_timeout</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>30</code>
	Min Value	<code>1</code>

The number of seconds to wait for more data from a connection before aborting the read. When the server is reading from the client, `net_read_timeout` is the timeout value controlling when to abort. When the server is writing to the client, `net_write_timeout` is the timeout value controlling when to abort. See also `slave_net_timeout`.

- `net_retry_count`

Command-Line Format	<code>--net_retry_count=#</code>	
Option-File Format	<code>net_retry_count</code>	
System Variable Name	<code>net_retry_count</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	

	Permitted Values	
	Platform Bit Size	32
	Type	numeric
	Default	10
	Range	1 .. 4294967295
	Permitted Values	
	Platform Bit Size	64
	Type	numeric
	Default	10
	Range	1 .. 18446744073709547520

If a read or write on a communication port is interrupted, retry this many times before giving up. This value should be set quite high on FreeBSD because internal interrupts are sent to all threads.

- `net_write_timeout`

Command-Line Format	<code>--net_write_timeout=#</code>	
Option-File Format	<code>net_write_timeout</code>	
System Variable Name	<code>net_write_timeout</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	numeric
	Default	60
	Min Value	1

The number of seconds to wait for a block to be written to a connection before aborting the write. See also `net_read_timeout`.

- `new`

Command-Line Format	<code>--new</code>	
	<code>-n</code>	
Option-File Format	<code>new</code>	
System Variable Name	<code>new</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
Disabled by	<code>skip-new</code>	
	Permitted Values	
	Type	boolean
	Default	FALSE

This variable was used in MySQL 4.0 to turn on some 4.1 behaviors, and is retained for backward compatibility. In MySQL 5.5, its value is always `OFF`.

- `old`

Command-Line Format	<code>--old</code>
Option-File Format	<code>old</code>
System Variable Name	<code>old</code>
Variable Scope	Global
Dynamic Variable	No

`old` is a compatibility variable. It is disabled by default, but can be enabled at startup to revert the server to behaviors present in older versions.

Currently, when `old` is enabled, it changes the default scope of index hints to that used prior to MySQL 5.1.17. That is, index hints with no `FOR` clause apply only to how indexes are used for row retrieval and not to resolution of `ORDER BY` or `GROUP BY` clauses. (See [Section 13.2.9.3, “Index Hint Syntax”](#).) Take care about enabling this in a replication setup. With statement-based binary logging, having different modes for the master and slaves might lead to replication errors.

- `old_alter_table`

Command-Line Format	<code>--old-alter-table</code>	
Option-File Format	<code>old-alter-table</code>	
System Variable Name	<code>old_alter_table</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>OFF</code>

When this variable is enabled, the server does not use the optimized method of processing an `ALTER TABLE` operation. It reverts to using a temporary table, copying over the data, and then renaming the temporary table to the original, as used by MySQL 5.0 and earlier. For more information on the operation of `ALTER TABLE`, see [Section 13.1.7, “ALTER TABLE Syntax”](#).

- `old_passwords`

System Variable Name	<code>old_passwords</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>0</code>

This variable controls the password hashing method used by the `PASSWORD()` function. It also influences password hashing performed by `CREATE USER` and `GRANT` statements that specify a password using an `IDENTIFIED BY` clause.

The following table shows the permitted values of `old_passwords`, the password hashing method for each value, and which authentication plugins use passwords hashed with each method.

Value	Password Hashing Method	Associated Authentication Plugin
0 or OFF	MySQL 4.1 native hashing	<code>mysql_native_password</code>
1 or ON	Pre-4.1 (“old”) hashing	<code>mysql_old_password</code>

If `old_passwords=1`, `PASSWORD(str)` returns the same value as `OLD_PASSWORD(str)`. The latter function is not affected by the value of `old_passwords`.

For additional information about authentication plugins and hashing formats, see [Section 6.3.6, “Pluggable Authentication”](#), and [Section 6.1.2.4, “Password Hashing in MySQL”](#).

Note

Passwords that use the pre-4.1 hashing method are less secure than passwordss that use the native password hashing method and should be avoided.

- `one_shot`

This is not a variable, but it can be used when setting some variables. It is described in [Section 13.7.4, “SET Syntax”](#).

- `open_files_limit`

Command-Line Format	<code>--open-files-limit=#</code>	
Option-File Format	<code>open-files-limit</code>	
System Variable Name	<code>open_files_limit</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>0</code>
	Range	<code>0 .. platform dependent</code>

The number of files that the operating system permits `mysqld` to open. This is the real value permitted by the system and might be different from the value you gave using the `--open-files-limit` option to `mysqld` or `mysqld_safe`. The value is 0 on systems where MySQL cannot change the number of open files.

- `optimizer_prune_level`

Command-Line Format	<code>--optimizer_prune_level[=#]</code>	
Option-File Format	<code>optimizer_prune_level</code>	
System Variable Name	<code>optimizer_prune_level</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	

Type	boolean
Default	1

Controls the heuristics applied during query optimization to prune less-promising partial plans from the optimizer search space. A value of 0 disables heuristics so that the optimizer performs an exhaustive search. A value of 1 causes the optimizer to prune plans based on the number of rows retrieved by intermediate plans.

- `optimizer_search_depth`

Command-Line Format	<code>--optimizer_search_depth[=#]</code>	
Option-File Format	<code>optimizer_search_depth</code>	
System Variable Name	<code>optimizer_search_depth</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	numeric
	Default	62
	Range	0 .. 63

The maximum depth of search performed by the query optimizer. Values larger than the number of relations in a query result in better query plans, but take longer to generate an execution plan for a query. Values smaller than the number of relations in a query return an execution plan quicker, but the resulting plan may be far from being optimal. If set to 0, the system automatically picks a reasonable value. If set to 63, the optimizer switches to the algorithm used in MySQL 5.0.0 (and previous versions) for performing searches. The value of 63 is deprecated and will be treated as invalid in a future MySQL release.

- `optimizer_switch`

Command-Line Format	<code>--optimizer_switch=value</code>	
Option-File Format	<code>optimizer_switch</code>	
System Variable Name	<code>optimizer_switch</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values (<= 5.5.2)	
	Type	set
	Valid Values	<code>index_merge={on off}</code>
		<code>index_merge_intersection={on off}</code>
		<code>index_merge_sort_union={on off}</code>
		<code>index_merge_union={on off}</code>
	Permitted Values (>= 5.5.3)	
	Type	set
	Valid Values	<code>engine_condition_pushdown={on off}</code> <code>index_merge={on off}</code>

	<code>index_merge_intersection={on off}</code>
	<code>index_merge_sort_union={on off}</code>
	<code>index_merge_union={on off}</code>

The `optimizer_switch` system variable enables control over optimizer behavior. The value of this variable is a set of flags, each of which has a value of `on` or `off` to indicate whether the corresponding optimizer behavior is enabled or disabled. This variable has global and session values and can be changed at runtime. The global default can be set at server startup.

To see the current set of optimizer flags, select the variable value:

```
mysql> SELECT @@optimizer_switch\G
***** 1. row *****
@@optimizer_switch: index_merge=on,index_merge_union=on,
                    index_merge_sort_union=on,
                    index_merge_intersection=on,
                    engine_condition_pushdown=on
```

For more information about the syntax of this variable and the optimizer behaviors that it controls, see [Section 8.8.5.2, “Controlling Switchable Optimizations”](#).

- `performance_schema_xxx`

Performance Schema system variables are listed in [Section 22.9, “Performance Schema System Variables”](#). These variables may be used to configure Performance Schema operation.

- `pid_file`

Command-Line Format	<code>--pid-file=file_name</code>	
Option-File Format	<code>pid-file</code>	
System Variable Name	<code>pid_file</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>file name</code>

The path name of the process ID (PID) file. This variable can be set with the `--pid-file` option.

- `plugin_dir`

Command-Line Format	<code>--plugin_dir=path</code>	
Option-File Format	<code>plugin_dir</code>	
System Variable Name	<code>plugin_dir</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values (<= 5.5.4)	
	Type (Windows)	<code>directory name</code>
	Default	<code>BASEDIR/lib/plugin</code>

	Permitted Values (<= 5.5.4)	
	Type (Other)	directory name
	Default	BASEDIR/lib/mysql/plugin
	Permitted Values (>= 5.5.5)	
	Type	directory name
	Default	BASEDIR/lib/plugin

The path name of the plugin directory.

If the plugin directory is writable by the server, it may be possible for a user to write executable code to a file in the directory using `SELECT ... INTO DUMPFILE`. This can be prevented by making `plugin_dir` read only to the server or by setting `--secure-file-priv` to a directory where `SELECT` writes can be made safely.

- `port`

Command-Line Format	<code>--port=#</code>	
	<code>-P</code>	
Option-File Format	<code>port</code>	
System Variable Name	<code>port</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	numeric
	Default	3306
	Range	0 .. 65535

The number of the port on which the server listens for TCP/IP connections. This variable can be set with the `--port` option.

- `preload_buffer_size`

Command-Line Format	<code>--preload_buffer_size=#</code>	
Option-File Format	<code>preload_buffer_size</code>	
System Variable Name	<code>preload_buffer_size</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	numeric
	Default	32768
	Range	1024 .. 1073741824

The size of the buffer that is allocated when preloading indexes.

- `profiling`

If set to 0 or `OFF` (the default), statement profiling is disabled. If set to 1 or `ON`, statement profiling is enabled and the `SHOW PROFILE` and `SHOW PROFILES` statements provide access to profiling information. See [Section 13.7.5.32, “SHOW PROFILES Syntax”](#).

- `profiling_history_size`

The number of statements for which to maintain profiling information if `profiling` is enabled. The default value is 15. The maximum value is 100. Setting the value to 0 effectively disables profiling. See [Section 13.7.5.32, “SHOW PROFILES Syntax”](#).

- `protocol_version`

System Variable Name	<code>protocol_version</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>numeric</code>

The version of the client/server protocol used by the MySQL server.

- `proxy_user`

Introduced	5.5.7	
System Variable Name	<code>proxy_user</code>	
Variable Scope	Session	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>string</code>

If the current client is a proxy for another user, this variable is the proxy user account name. Otherwise, this variable is `NULL`. See [Section 6.3.8, “Proxy Users”](#).

This variable was added in MySQL 5.5.7.

- `pseudo_slave_mode`

Introduced	5.5.30	
System Variable Name	<code>pseudo_slave_mode</code>	
Variable Scope	Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>numeric</code>

This variable is for internal server use. It was added in MySQL 5.5.30.

- `pseudo_thread_id`

System Variable Name	<code>pseudo_thread_id</code>	
Variable Scope	Session	

Dynamic Variable	Yes	
	Permitted Values	
	Type	numeric

This variable is for internal server use.

- `query_alloc_block_size`

Command-Line Format	<code>--query_alloc_block_size=#</code>	
Option-File Format	<code>query_alloc_block_size</code>	
System Variable Name	<code>query_alloc_block_size</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Platform Bit Size	32
	Type	numeric
	Default	8192
	Range	1024 .. 4294967295
	Block Size	1024
	Permitted Values	
	Platform Bit Size	64
	Type	numeric
	Default	8192
	Range	1024 .. 18446744073709547520
	Block Size	1024

The allocation size of memory blocks that are allocated for objects created during statement parsing and execution. If you have problems with memory fragmentation, it might help to increase this parameter.

- `query_cache_limit`

Command-Line Format	<code>--query_cache_limit=#</code>	
Option-File Format	<code>query_cache_limit</code>	
System Variable Name	<code>query_cache_limit</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Platform Bit Size	32
	Type	numeric

	Default	1048576
	Range	0 .. 4294967295
	Permitted Values	
	Platform Bit Size	64
	Type	numeric
	Default	1048576
	Range	0 .. 18446744073709547520

Do not cache results that are larger than this number of bytes. The default value is 1MB.

- `query_cache_min_res_unit`

Command-Line Format	<code>--query_cache_min_res_unit=#</code>	
Option-File Format	<code>query_cache_min_res_unit</code>	
System Variable Name	<code>query_cache_min_res_unit</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Platform Bit Size	32
	Type	numeric
	Default	4096
	Range	512 .. 4294967295
	Permitted Values	
	Platform Bit Size	64
	Type	numeric
	Default	4096
	Range	512 .. 18446744073709547520

The minimum size (in bytes) for blocks allocated by the query cache. The default value is 4096 (4KB). Tuning information for this variable is given in [Section 8.9.3.3, “Query Cache Configuration”](#).

- `query_cache_size`

Command-Line Format	<code>--query_cache_size=#</code>	
Option-File Format	<code>query_cache_size</code>	
System Variable Name	<code>query_cache_size</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Platform Bit Size	32

	Type	numeric
	Default	0
	Range	0 .. 4294967295
	Permitted Values	
	Platform Bit Size	64
	Type	numeric
	Default	0
	Range	0 .. 18446744073709547520

The amount of memory allocated for caching query results. The default value is 0, which disables the query cache. To reduce overhead significantly, you should also start the server with `query_cache_type=0` if you will not be using the query cache. The permissible values are multiples of 1024; other values are rounded down to the nearest multiple. Note that `query_cache_size` bytes of memory are allocated even if `query_cache_type` is set to 0. See [Section 8.9.3.3, “Query Cache Configuration”](#), for more information.

The query cache needs a minimum size of about 40KB to allocate its structures. (The exact size depends on system architecture.) If you set the value of `query_cache_size` too small, a warning will occur, as described in [Section 8.9.3.3, “Query Cache Configuration”](#).

- `query_cache_type`

Command-Line Format	<code>--query_cache_type=#</code>	
Option-File Format	<code>query_cache_type</code>	
System Variable Name	<code>query_cache_type</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	enumeration
	Default	1
	Valid Values	0
		1
		2

Set the query cache type. Setting the `GLOBAL` value sets the type for all clients that connect thereafter. Individual clients can set the `SESSION` value to affect their own use of the query cache. Possible values are shown in the following table.

Option	Description
0 or <code>OFF</code>	Do not cache results in or retrieve results from the query cache. Note that this does not deallocate the query cache buffer. To do that, you should set <code>query_cache_size</code> to 0.
1 or <code>ON</code>	Cache all cacheable query results except for those that begin with <code>SELECT SQL_NO_CACHE</code> .
2 or <code>DEMAND</code>	Cache results only for cacheable queries that begin with <code>SELECT SQL_CACHE</code> .

This variable defaults to `ON`.

If the server is started with `query_cache_type` set to 0, it does not acquire the query cache mutex at all, which means that the query cache cannot be enabled at runtime and there is reduced overhead in query execution.

- `query_cache_wlock_invalidate`

Command-Line Format	<code>--query_cache_wlock_invalidate</code>	
Option-File Format	<code>query_cache_wlock_invalidate</code>	
System Variable Name	<code>query_cache_wlock_invalidate</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>FALSE</code>

Normally, when one client acquires a `WRITE` lock on a `MyISAM` table, other clients are not blocked from issuing statements that read from the table if the query results are present in the query cache. Setting this variable to 1 causes acquisition of a `WRITE` lock for a table to invalidate any queries in the query cache that refer to the table. This forces other clients that attempt to access the table to wait while the lock is in effect.

- `query_prealloc_size`

Command-Line Format	<code>--query_prealloc_size=#</code>	
Option-File Format	<code>query_prealloc_size</code>	
System Variable Name	<code>query_prealloc_size</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Platform Bit Size	<code>32</code>
	Type	<code>numeric</code>
	Default	<code>8192</code>
	Range	<code>8192 .. 4294967295</code>
	Block Size	<code>1024</code>
	Permitted Values	
	Platform Bit Size	<code>64</code>
	Type	<code>numeric</code>
	Default	<code>8192</code>
	Range	<code>8192 .. 18446744073709547520</code>

	Block Size	1024
--	-------------------	------

The size of the persistent buffer used for statement parsing and execution. This buffer is not freed between statements. If you are running complex queries, a larger `query_prealloc_size` value might be helpful in improving performance, because it can reduce the need for the server to perform memory allocation during query execution operations.

- `rand_seed1`

The `rand_seed1` and `rand_seed2` variables exist as session variables only, and can be set but not read. The variables—but not their values—are shown in the output of `SHOW VARIABLES`.

The purpose of these variables is to support replication of the `RAND()` function. For statements that invoke `RAND()`, the master passes two values to the slave, where they are used to seed the random number generator. The slave uses these values to set the session variables `rand_seed1` and `rand_seed2` so that `RAND()` on the slave generates the same value as on the master.

- `rand_seed2`

See the description for `rand_seed1`.

- `range_alloc_block_size`

Command-Line Format	<code>--range_alloc_block_size=#</code>	
Option-File Format	<code>range_alloc_block_size</code>	
System Variable Name	<code>range_alloc_block_size</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Platform Bit Size	32
	Type	numeric
	Default	4096
	Range	4096 .. 4294967295
	Block Size	1024
	Permitted Values	
	Platform Bit Size	64
	Type	numeric
	Default	4096
	Range	4096 .. 18446744073709547520
	Block Size	1024

The size of blocks that are allocated when doing range optimization.

- `read_buffer_size`

Command-Line Format	<code>--read_buffer_size=#</code>	
Option-File Format	<code>read_buffer_size</code>	
System Variable Name	<code>read_buffer_size</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>131072</code>
	Range	<code>8200 .. 2147479552</code>

Each thread that does a sequential scan for a [MyISAM](#) table allocates a buffer of this size (in bytes) for each table it scans. If you do many sequential scans, you might want to increase this value, which defaults to 131072. The value of this variable should be a multiple of 4KB. If it is set to a value that is not a multiple of 4KB, its value will be rounded down to the nearest multiple of 4KB.

This option is also used in the following context for all search engines:

- For caching the indexes in a temporary file (not a temporary table), when sorting rows for [ORDER BY](#).
- For bulk insert into partitions.
- For caching results of nested queries.

and in one other storage engine-specific way: to determine the memory block size for [MEMORY](#) tables.

The maximum permissible setting for `read_buffer_size` is 2GB.

For more information about memory use during different operations, see [Section 8.11.4.1, “How MySQL Uses Memory”](#).

- `read_only`

Command-Line Format	<code>--read-only</code>	
Option-File Format	<code>read_only</code>	
System Variable Name	<code>read_only</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>false</code>

This variable is off by default. When it is enabled, the server permits no updates except from users that have the [SUPER](#) privilege or (on a slave server) from updates performed by slave threads. In replication setups, it can be useful to enable `read_only` on slave servers to ensure that slaves accept updates only from the master server and not from clients.

`read_only` does not apply to [TEMPORARY](#) tables, nor does it prevent the server from inserting rows into the log tables (see [Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”](#)).

This variable does not prevent the use of `ANALYZE TABLE` or `OPTIMIZE TABLE` statements because its purpose is to prevent changes to table structure or contents. Analysis and optimization do not qualify as such changes. This means, for example, that consistency checks on read-only slaves can be performed with `mysqlcheck --all-databases --analyze`.

`read_only` exists only as a `GLOBAL` variable, so changes to its value require the `SUPER` privilege. Changes to `read_only` on a master server are not replicated to slave servers. The value can be set on a slave server independent of the setting on the master.

Important

In MySQL 5.5, enabling `read_only` prevents the use of the `SET PASSWORD` statement by any user not having the `SUPER` privilege. This is not necessarily the case for all MySQL release series. When replicating from one MySQL release series to another (for example, from a MySQL 5.0 master to a MySQL 5.1 or later slave), you should check the documentation for the versions running on both master and slave to determine whether the behavior of `read_only` in this regard is or is not the same, and, if it is different, whether this has an impact on your applications.

The following conditions apply:

- If you attempt to enable `read_only` while you have any explicit locks (acquired with `LOCK TABLES`) or have a pending transaction, an error occurs.
- If you attempt to enable `read_only` while other clients hold explicit table locks or have pending transactions, the attempt blocks until the locks are released and the transactions end. While the attempt to enable `read_only` is pending, requests by other clients for table locks or to begin transactions also block until `read_only` has been set.
- `read_only` can be enabled while you hold a global read lock (acquired with `FLUSH TABLES WITH READ LOCK`) because that does not involve table locks.

As of MySQL 5.5.3, attempts to set `read_only` block for active transactions that hold metadata locks until those transactions end.

- `read_rnd_buffer_size`

Command-Line Format	<code>--read_rnd_buffer_size=#</code>	
Option-File Format	<code>read_rnd_buffer_size</code>	
System Variable Name	<code>read_rnd_buffer_size</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values (<= 5.5.2)	
	Type	<code>numeric</code>
	Default	<code>262144</code>
	Range	<code>8200 .. 2147483647</code>
	Permitted Values (>= 5.5.3)	
	Type	<code>numeric</code>
	Default	<code>262144</code>

	Range	1 .. 2147483647
--	--------------	-----------------

When reading rows from a [MyISAM](#) table in sorted order following a key-sorting operation, the rows are read through this buffer to avoid disk seeks. See [Section 8.2.1.11, “ORDER BY Optimization”](#). Setting the variable to a large value can improve [ORDER BY](#) performance by a lot. However, this is a buffer allocated for each client, so you should not set the global variable to a large value. Instead, change the session variable only from within those clients that need to run large queries.

The maximum permissible setting for `read_rnd_buffer_size` is 2GB.

For more information about memory use during different operations, see [Section 8.11.4.1, “How MySQL Uses Memory”](#).

- `relay_log_purge`

Command-Line Format	<code>--relay_log_purge</code>	
Option-File Format	<code>relay_log_purge</code>	
System Variable Name	<code>relay_log_purge</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>TRUE</code>

Disables or enables automatic purging of relay log files as soon as they are not needed any more. The default value is 1 ([ON](#)).

- `relay_log_space_limit`

Command-Line Format	<code>--relay_log_space_limit=#</code>	
Option-File Format	<code>relay_log_space_limit</code>	
System Variable Name	<code>relay_log_space_limit</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Platform Bit Size	32
	Type	<code>numeric</code>
	Default	0
	Range	0 .. 4294967295
	Permitted Values	
	Platform Bit Size	64
	Type	<code>numeric</code>
	Default	0
	Range	0 .. 18446744073709547520

The maximum amount of space to use for all relay logs.

- `report_host`

Command-Line Format	<code>--report-host=host_name</code>	
Option-File Format	<code>report-host</code>	
System Variable Name	<code>report_host</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>string</code>

The value of the `--report-host` option.

- `report_password`

Command-Line Format	<code>--report-password=name</code>	
Option-File Format	<code>report-password</code>	
System Variable Name	<code>report_password</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>string</code>

The value of the `--report-password` option. Not the same as the password used for the MySQL replication user account.

- `report_port`

Command-Line Format	<code>--report-port=#</code>	
Option-File Format	<code>report-port</code>	
System Variable Name	<code>report_port</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values (>= 5.5.23)	
	Type	<code>numeric</code>
	Default	<code>0</code>
	Range	<code>0 .. 65535</code>

The value of the `--report-port` option.

- `report_user`

Command-Line Format	<code>--report-user=name</code>	
Option-File Format	<code>report-user</code>	

System Variable Name	<code>report_user</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>string</code>

The value of the `--report-user` option. Not the same as the name for the MySQL replication user account.

- `rpl_semi_sync_master_enabled`

System Variable Name	<code>rpl_semi_sync_master_enabled</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>OFF</code>

Controls whether semisynchronous replication is enabled on the master. To enable or disable the plugin, set this variable to `ON` or `OFF` (or 1 or 0), respectively. The default is `OFF`.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_master_timeout`

System Variable Name	<code>rpl_semi_sync_master_timeout</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>10000</code>

A value in milliseconds that controls how long the master waits on a commit for acknowledgment from a slave before timing out and reverting to asynchronous replication. The default value is 10000 (10 seconds).

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_master_trace_level`

System Variable Name	<code>rpl_semi_sync_master_trace_level</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>32</code>

The semisynchronous replication debug trace level on the master. Currently, four levels are defined:

- 1 = general level (for example, time function failures)
- 16 = detail level (more verbose information)
- 32 = net wait level (more information about network waits)
- 64 = function level (information about function entry and exit)

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_master_wait_no_slave`

System Variable Name	<code>rpl_semi_sync_master_wait_no_slave</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>ON</code>

With semisynchronous replication, for each transaction, the master waits until timeout for acknowledgment of receipt from some semisynchronous slave. If no response occurs during this period, the master reverts to normal replication. This variable controls whether the master waits for the timeout to expire before reverting to normal replication even if the slave count drops to zero during the timeout period.

If the value is `ON` (the default), it is permissible for the slave count to drop to zero during the timeout period (for example, if slaves disconnect). The master still waits for the timeout, so as long as some slave reconnects and acknowledges the transaction within the timeout interval, semisynchronous replication continues.

If the value is `OFF`, the master reverts to normal replication if the slave count drops to zero during the timeout period.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_slave_enabled`

System Variable Name	<code>rpl_semi_sync_slave_enabled</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>OFF</code>

Controls whether semisynchronous replication is enabled on the slave. To enable or disable the plugin, set this variable to `ON` or `OFF` (or 1 or 0), respectively. The default is `OFF`.

This variable is available only if the slave-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_slave_trace_level`

System Variable Name	<code>rpl_semi_sync_slave_trace_level</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>32</code>

The semisynchronous replication debug trace level on the slave. See `rpl_semi_sync_master_trace_level` for the permissible values.

This variable is available only if the slave-side semisynchronous replication plugin is installed.

- `secure_auth`

Command-Line Format	<code>--secure-auth</code>	
Option-File Format	<code>secure-auth</code>	
System Variable Name	<code>secure_auth</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>OFF</code>

If this variable is enabled, the server blocks connections by clients that attempt to use accounts that have passwords stored in the old (pre-4.1) format.

Enable this variable to prevent all use of passwords employing the old format (and hence insecure communication over the network).

Server startup fails with an error if this variable is enabled and the privilege tables are in pre-4.1 format. See [Section B.5.2.4, “Client does not support authentication protocol”](#).

**Note**

Passwords that use the pre-4.1 hashing method are less secure than passwordss that use the native password hashing method and should be avoided.

- `secure_file_priv`

Command-Line Format	<code>--secure-file-priv=path</code>	
Option-File Format	<code>secure-file-priv</code>	
System Variable Name	<code>secure_file_priv</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>string</code> ⁵⁸⁵

By default, this variable is empty. If set to the name of a directory, it limits the effect of the `LOAD_FILE()` function and the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements to work only with files in that directory.

- `server_id`

Command-Line Format	<code>--server-id=#</code>	
Option-File Format	<code>server-id</code>	
System Variable Name	<code>server_id</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>0</code>
	Range	<code>0 .. 4294967295</code>

The server ID, used in replication to give each master and slave a unique identity. This variable is set by the `--server-id` [1974] option. For each server participating in replication, you should pick a positive integer in the range from 1 to $2^{32} - 1$ to act as that server's ID.

- `shared_memory`

System Variable Name	<code>shared_memory</code>
Variable Scope	Global
Dynamic Variable	No
Platform Specific	Windows

(Windows only.) Whether the server permits shared-memory connections.

- `shared_memory_base_name`

System Variable Name	<code>shared_memory_base_name</code>
Variable Scope	Global
Dynamic Variable	No
Platform Specific	Windows

(Windows only.) The name of shared memory to use for shared-memory connections. This is useful when running multiple MySQL instances on a single physical machine. The default name is `MYSQL`. The name is case sensitive.

- `skip_external_locking`

Command-Line Format	<code>--skip-external-locking</code>
Option-File Format	<code>skip_external_locking</code>
System Variable Name	<code>skip_external_locking</code>
Variable Scope	Global
Dynamic Variable	No

	Permitted Values	
	Type	boolean
	Default	ON

This is `OFF` if `mysqld` uses external locking (system locking), `ON` if external locking is disabled. This affects only `MyISAM` table access.

This variable is set by the `--external-locking` or `--skip-external-locking` option. External locking has been disabled by default as of MySQL 4.0.

External locking affects only `MyISAM` table access. For more information, including conditions under which it can and cannot be used, see [Section 8.10.5, “External Locking”](#).

- `skip_name_resolve`

Command-Line Format	<code>--skip-name-resolve</code>	
Option-File Format	<code>skip-name-resolve</code>	
System Variable Name	<code>skip_name_resolve</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	boolean
	Default	<code>OFF</code>

This variable is set from the value of the `--skip-name-resolve` option. If it is `ON`, `mysqld` resolves host names when checking client connections. If `OFF`, `mysqld` uses only IP numbers and all `Host` column values in the grant tables must be IP addresses or `localhost`. See [Section 8.11.5.2, “DNS Lookup Optimization and the Host Cache”](#).

This variable was added in MySQL 5.5.5.

- `skip_networking`

Command-Line Format	<code>--skip-networking</code>	
Option-File Format	<code>skip-networking</code>	
System Variable Name	<code>skip_networking</code>	
Variable Scope	Global	
Dynamic Variable	No	

This is `ON` if the server permits only local (non-TCP/IP) connections. On Unix, local connections use a Unix socket file. On Windows, local connections use a named pipe or shared memory. This variable can be set to `ON` with the `--skip-networking` option.

- `skip_show_database`

Command-Line Format	<code>--skip-show-database</code>	
Option-File Format	<code>skip-show-database</code>	
System Variable Name	<code>skip_show_database</code>	
Variable Scope	Global	

Dynamic Variable	No
-------------------------	----

This prevents people from using the `SHOW DATABASES` statement if they do not have the `SHOW DATABASES` privilege. This can improve security if you have concerns about users being able to see databases belonging to other users. Its effect depends on the `SHOW DATABASES` privilege: If the variable value is `ON`, the `SHOW DATABASES` statement is permitted only to users who have the `SHOW DATABASES` privilege, and the statement displays all database names. If the value is `OFF`, `SHOW DATABASES` is permitted to all users, but displays the names of only those databases for which the user has the `SHOW DATABASES` or other privilege. (Note that *any* global privilege is considered a privilege for the database.)

- `slow_launch_time`

Command-Line Format	<code>--slow_launch_time=#</code>	
Option-File Format	<code>slow_launch_time</code>	
System Variable Name	<code>slow_launch_time</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>2</code>

If creating a thread takes longer than this many seconds, the server increments the `Slow_launch_threads` status variable.

- `slow_query_log`

Command-Line Format	<code>--slow-query-log</code>	
Option-File Format	<code>slow-query-log</code>	
System Variable Name	<code>slow_query_log</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>OFF</code>

Whether the slow query log is enabled. The value can be 0 (or `OFF`) to disable the log or 1 (or `ON`) to enable the log. The default value depends on whether the `--slow_query_log` option is given. The destination for log output is controlled by the `log_output` system variable; if that value is `NONE`, no log entries are written even if the log is enabled.

“Slow” is determined by the value of the `long_query_time` variable. See [Section 5.2.5, “The Slow Query Log”](#).

- `slow_query_log_file`

Command-Line Format	<code>--slow-query-log-file=file_name</code>
Option-File Format	<code>slow_query_log_file</code>

System Variable Name	<code>slow_query_log_file</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>file name</code>
	Default	<code>host_name-slow.log</code>

The name of the slow query log file. The default value is `host_name-slow.log`, but the initial value can be changed with the `--slow_query_log_file` option.

- `socket`

Command-Line Format	<code>--socket=name</code>	
Option-File Format	<code>socket</code>	
System Variable Name	<code>socket</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>file name</code>
	Default	<code>/tmp/mysql.sock</code>

On Unix platforms, this variable is the name of the socket file that is used for local client connections. The default is `/tmp/mysql.sock`. (For some distribution formats, the directory might be different, such as `/var/lib/mysql` for RPMs.)

On Windows, this variable is the name of the named pipe that is used for local client connections. The default value is `MySQL` (not case sensitive).

- `sort_buffer_size`

Command-Line Format	<code>--sort_buffer_size=#</code>	
Option-File Format	<code>sort_buffer_size</code>	
System Variable Name	<code>sort_buffer_size</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Platform Bit Size	32
	Type (Other)	<code>numeric</code>
	Default	2097144
	Range	32768 .. 4294967295
	Permitted Values	
	Platform Bit Size	64

	Type (Other)	numeric
	Default	2097144
	Range	32768 .. 18446744073709551615
	Permitted Values	
	Type (Windows)	numeric
	Default	2097144
	Range	32768 .. 4294967295

Each session that needs to do a sort allocates a buffer of this size. `sort_buffer_size` is not specific to any storage engine and applies in a general manner for optimization. See [Section 8.2.1.11, “ORDER BY Optimization”](#), for example.

If you see many `Sort_merge_passes` per second in `SHOW GLOBAL STATUS` output, you can consider increasing the `sort_buffer_size` value to speed up `ORDER BY` or `GROUP BY` operations that cannot be improved with query optimization or improved indexing. The entire buffer is allocated even if it is not all needed, so setting it larger than required globally will slow down most queries that sort. It is best to increase it as a session setting, and only for the sessions that need a larger size. On Linux, there are thresholds of 256KB and 2MB where larger values may significantly slow down memory allocation, so you should consider staying below one of those values. Experiment to find the best value for your workload. See [Section B.5.4.4, “Where MySQL Stores Temporary Files”](#).

The maximum permissible setting for `sort_buffer_size` is 4GB–1. Larger values are permitted for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB–1 with a warning).

- `sql_auto_is_null`

System Variable Name	<code>sql_auto_is_null</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values (<= 5.5.2)	
	Type	boolean
	Default	1
	Permitted Values (>= 5.5.3)	
	Type	boolean
	Default	0

If this variable is set to 1, then after a statement that successfully inserts an automatically generated `AUTO_INCREMENT` value, you can find that value by issuing a statement of the following form:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

If the statement returns a row, the value returned is the same as if you invoked the `LAST_INSERT_ID()` function. For details, including the return value after a multiple-row insert, see [Section 12.14, “Information Functions”](#). If no `AUTO_INCREMENT` value was successfully inserted, the `SELECT` statement returns no row.

The behavior of retrieving an `AUTO_INCREMENT` value by using an `IS NULL` comparison is used by some ODBC programs, such as Access. See [Obtaining Auto-Increment Values](#). This behavior can be disabled by setting `sql_auto_is_null` to 0.

The default value of `sql_auto_is_null` is 0 as of MySQL 5.5.3, and 1 for earlier versions.

- `sql_big_selects`

System Variable Name	<code>sql_big_selects</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>1</code>

If set to 0, MySQL aborts `SELECT` statements that are likely to take a very long time to execute (that is, statements for which the optimizer estimates that the number of examined rows exceeds the value of `max_join_size`). This is useful when an inadvisable `WHERE` statement has been issued. The default value for a new connection is 1, which permits all `SELECT` statements.

If you set the `max_join_size` system variable to a value other than `DEFAULT`, `sql_big_selects` is set to 0.

- `sql_buffer_result`

System Variable Name	<code>sql_buffer_result</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>0</code>

If set to 1, `sql_buffer_result` forces results from `SELECT` statements to be put into temporary tables. This helps MySQL free the table locks early and can be beneficial in cases where it takes a long time to send results to the client. The default value is 0.

- `sql_log_bin`

System Variable Name	<code>sql_log_bin</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>

This variable controls whether logging to the binary log is done. The default value is 1 (do logging). To change logging for the current session, change the session value of this variable. The session user must have the `SUPER` privilege to set this variable.

Beginning with MySQL 5.5.5, it is no longer possible to set `@@session.sql_log_bin` within a transaction or subquery. (Bug #53437)

- `sql_log_off`

System Variable Name	<code>sql_log_off</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>0</code>

This variable controls whether logging to the general query log is done. The default value is 0 (do logging). To change logging for the current session, change the session value of this variable. The session user must have the `SUPER` privilege to set this option. The default value is 0.

- `sql_log_update`

Deprecated	5.0.0, by <code>sql_log_bin</code>	
Removed	5.5.3	
System Variable Name	<code>sql_log_update</code>	
Variable Scope	Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>

This variable is deprecated, and is mapped to `sql_log_bin`. It was removed in MySQL 5.5.3.

- `sql_mode`

Command-Line Format	<code>--sql-mode=name</code>	
Option-File Format	<code>sql-mode</code>	
System Variable Name	<code>sql_mode</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>set</code>
	Default	<code>''</code>
	Valid Values	<code>ALLOW_INVALID_DATES</code>
		<code>ANSI_QUOTES</code>
		<code>ERROR_FOR_DIVISION_BY_ZERO</code>
		<code>HIGH_NOT_PRECEDENCE</code>
		<code>IGNORE_SPACE</code>
		<code>NO_AUTO_CREATE_USER</code>

	NO_AUTO_VALUE_ON_ZERO
	NO_BACKSLASH_ESCAPES
	NO_DIR_IN_CREATE
	NO_ENGINE_SUBSTITUTION
	NO_FIELD_OPTIONS
	NO_KEY_OPTIONS
	NO_TABLE_OPTIONS
	NO_UNSIGNED_SUBTRACTION
	NO_ZERO_DATE
	NO_ZERO_IN_DATE
	ONLY_FULL_GROUP_BY
	PAD_CHAR_TO_FULL_LENGTH
	PIPES_AS_CONCAT
	REAL_AS_FLOAT
	STRICT_ALL_TABLES
	STRICT_TRANS_TABLES

The current server SQL mode, which can be set dynamically. See [Section 5.1.7, “Server SQL Modes”](#).

Note

MySQL installation programs may configure the SQL mode during the installation process. If the SQL mode differs from the default or from what you expect, check for a setting in an option file that the server reads at startup.

- `sql_notes`

If set to 1 (the default), warnings of `Note` level increment `warning_count` and the server records them. If set to 0, `Note` warnings do not increment `warning_count` and the server does not record them. `mysqldump` includes output to set this variable to 0 so that reloading the dump file does not produce warnings for events that do not affect the integrity of the reload operation.

- `sql_quote_show_create`

If set to 1 (the default), the server quotes identifiers for `SHOW CREATE TABLE` and `SHOW CREATE DATABASE` statements. If set to 0, quoting is disabled. This option is enabled by default so that replication works for identifiers that require quoting. See [Section 13.7.5.12, “SHOW CREATE TABLE Syntax”](#), and [Section 13.7.5.8, “SHOW CREATE DATABASE Syntax”](#).

- `sql_safe_updates`

If set to 1, MySQL aborts `UPDATE` or `DELETE` statements that do not use a key in the `WHERE` clause or a `LIMIT` clause. (Specifically, `UPDATE` statements must have a `WHERE` clause that uses a key or a `LIMIT` clause, or both. `DELETE` statements must have both.) This makes it possible to catch `UPDATE` or `DELETE` statements where keys are not used properly and that would probably change or delete a large number of rows. The default value is 0.

- `sql_select_limit`

System Variable Name	<code>sql_select_limit</code>
----------------------	-------------------------------

Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	numeric

The maximum number of rows to return from `SELECT` statements. The default value for a new connection is the maximum number of rows that the server permits per table. Typical default values are $(2^{32})-1$ or $(2^{64})-1$. If you have changed the limit, the default value can be restored by assigning a value of `DEFAULT`.

If a `SELECT` has a `LIMIT` clause, the `LIMIT` takes precedence over the value of `sql_select_limit`.

- `sql_warnings`

This variable controls whether single-row `INSERT` statements produce an information string if warnings occur. The default is 0. Set the value to 1 to produce an information string.

- `ssl_ca`

Command-Line Format	<code>--ssl-ca=name</code>	
Option-File Format	<code>ssl-ca</code>	
System Variable Name	<code>ssl_ca</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	file name

The path to a file with a list of trusted SSL CAs.

- `ssl_capath`

Command-Line Format	<code>--ssl-capath=name</code>	
Option-File Format	<code>ssl-capath</code>	
System Variable Name	<code>ssl_capath</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	directory name

The path to a directory that contains trusted SSL CA certificates in PEM format.

- `ssl_cert`

Command-Line Format	<code>--ssl-cert=name</code>	
Option-File Format	<code>ssl-cert</code>	
System Variable Name	<code>ssl_cert</code>	
Variable Scope	Global	
Dynamic Variable	No	

	Permitted Values	
	Type	file name

The name of the SSL certificate file to use for establishing a secure connection.

- `ssl_cipher`

Command-Line Format	<code>--ssl-cipher=name</code>	
Option-File Format	<code>ssl-cipher</code>	
System Variable Name	<code>ssl_cipher</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	string

A list of permissible ciphers to use for SSL encryption.

- `ssl_key`

Command-Line Format	<code>--ssl-key=name</code>	
Option-File Format	<code>ssl-key</code>	
System Variable Name	<code>ssl_key</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	string

The name of the SSL key file to use for establishing a secure connection.

- `storage_engine`

System Variable Name	<code>storage_engine</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values ($\geq 5.5.3$, $\leq 5.5.4$)	
	Type	enumeration
	Default	MyISAM
	Permitted Values ($\geq 5.5.5$)	
	Type	enumeration
	Default	InnoDB

The default storage engine (table type). To set the storage engine at server startup, use the `--default-storage-engine` option. See [Section 5.1.3, “Server Command Options”](#).

This variable is deprecated as of MySQL 5.5.3. Use `default_storage_engine` instead.

- `stored_program_cache`

Introduced	5.5.21	
Command-Line Format	<code>--stored-program-cache=#</code>	
Option-File Format	<code>stored_program_cache</code>	
System Variable Name	<code>stored_program_cache</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>256</code>
	Range	<code>256 .. 524288</code>

Sets a soft upper limit for the number of cached stored routines per connection. The value of this variable is specified in terms of the number of stored routines held in each of the two caches maintained by the MySQL Server for, respectively, stored procedures and stored functions.

Whenever a stored routine is executed this cache size is checked before the first or top-level statement in the routine is parsed; if the number of routines of the same type (stored procedures or stored functions according to which is being executed) exceeds the limit specified by this variable, the corresponding cache is flushed and memory previously allocated for cached objects is freed. This allows the cache to be flushed safely, even when there are dependencies between stored routines.

- `sync_frm`

Command-Line Format	<code>--sync_frm</code>	
Option-File Format	<code>sync_frm</code>	
System Variable Name	<code>sync_frm</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>TRUE</code>

If this variable is set to 1, when any nontemporary table is created its `.frm` file is synchronized to disk (using `fdatasync()`). This is slower but safer in case of a crash. The default is 1.

- `system_time_zone`

System Variable Name	<code>system_time_zone</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>string</code>

The server system time zone. When the server begins executing, it inherits a time zone setting from the machine defaults, possibly modified by the environment of the account used for running the server or the startup script. The value is used to set `system_time_zone`. Typically the time zone is specified by the

`TZ` environment variable. It also can be specified using the `--timezone` option of the `mysqld_safe` script.

The `system_time_zone` variable differs from `time_zone`. Although they might have the same value, the latter variable is used to initialize the time zone for each client that connects. See [Section 10.6](#), “MySQL Server Time Zone Support”.

- `table_definition_cache`

System Variable Name	<code>table_definition_cache</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>numeric</code>
	Default	400
	Range	400 .. 524288

The number of table definitions (from `.frm` files) that can be stored in the definition cache. If you use a large number of tables, you can create a large table definition cache to speed up opening of tables. The table definition cache takes less space and does not use file descriptors, unlike the normal table cache. The minimum and default values are both 400.

- `table_lock_wait_timeout`

Removed	5.5.3	
Command-Line Format	<code>--table_lock_wait_timeout=#</code>	
Option-File Format	<code>table_lock_wait_timeout</code>	
System Variable Name	<code>table_lock_wait_timeout</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>numeric</code>
	Default	50
	Range	1 .. 1073741824

This variable is unused. It was removed in 5.5.3.

- `table_open_cache`

System Variable Name	<code>table_open_cache</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>numeric</code>
	Default	400
	Range	1 .. 524288

The number of open tables for all threads. Increasing this value increases the number of file descriptors that `mysqld` requires. You can check whether you need to increase the table cache by checking the `Opened_tables` status variable. See [Section 5.1.6, “Server Status Variables”](#). If the value of `Opened_tables` is large and you do not use `FLUSH TABLES` often (which just forces all tables to be closed and reopened), then you should increase the value of the `table_open_cache` variable. For more information about the table cache, see [Section 8.4.3.1, “How MySQL Opens and Closes Tables”](#).

- `table_type`

This variable was removed in MySQL 5.5.3. Use `storage_engine` instead.

- `thread_cache_size`

Command-Line Format	<code>--thread_cache_size=#</code>	
Option-File Format	<code>thread_cache_size</code>	
System Variable Name	<code>thread_cache_size</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>0</code>
	Range	<code>0 .. 16384</code>

How many threads the server should cache for reuse. When a client disconnects, the client's threads are put in the cache if there are fewer than `thread_cache_size` threads there. Requests for threads are satisfied by reusing threads taken from the cache if possible, and only when the cache is empty is a new thread created. This variable can be increased to improve performance if you have a lot of new connections. Normally, this does not provide a notable performance improvement if you have a good thread implementation. However, if your server sees hundreds of connections per second you should normally set `thread_cache_size` high enough so that most new connections use cached threads. By examining the difference between the `Connections` and `Threads_created` status variables, you can see how efficient the thread cache is. For details, see [Section 5.1.6, “Server Status Variables”](#).

- `thread_concurrency`

Command-Line Format	<code>--thread_concurrency=#</code>	
Option-File Format	<code>thread_concurrency</code>	
System Variable Name	<code>thread_concurrency</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>10</code>
	Range	<code>1 .. 512</code>

This variable is specific to Solaris 8 and earlier systems, for which `mysqld` invokes the `thr_setconcurrency()` function with the variable value. This function enables applications to give

the threads system a hint about the desired number of threads that should be run at the same time. Current Solaris versions document this as having no effect.

- `thread_handling`

Command-Line Format	<code>--thread_handling=name</code>	
Option-File Format	<code>thread_handling</code>	
System Variable Name	<code>thread_handling</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values (<= 5.5.13)	
	Type	<code>enumeration</code>
	Default	<code>one-thread-per-connection</code>
	Valid Values	<code>no-threads</code> <code>one-thread-per-connection</code>
	Permitted Values (>= 5.5.16)	
	Type	<code>enumeration</code>
	Default	<code>one-thread-per-connection</code>
	Valid Values	<code>no-threads</code> <code>one-thread-per-connection</code> <code>dynamically-loaded</code>

The thread-handling model used by the server for connection threads. The permissible user-settable values are `no-threads` (the server uses a single thread to handle one connection) and `one-thread-per-connection` (the server uses one thread to handle each client connection; this is the default). `no-threads` is useful for debugging under Linux; see [Section 24.4, “Debugging and Porting MySQL”](#).

If the thread pool plugin is enabled, the server sets the `thread_handling` value to `dynamically-loaded`. See [Section 8.11.6.1, “Thread Pool Components and Installation”](#).

- `thread_pool_algorithm`

Introduced	5.5.16	
Command-Line Format	<code>--thread_pool_algorithm=#</code>	
Option-File Format	<code>thread_pool_algorithm</code>	
System Variable Name	<code>thread_pool_algorithm</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>0</code>
	Range	<code>0 .. 1</code>

This variable controls which algorithm the thread pool plugin uses:

- A value of 0 (the default) uses a conservative low-concurrency algorithm which is most well tested and is known to produce very good results.
- A value of 1 increases the concurrency and uses a more aggressive algorithm which at times has been known to perform 5–10% better on optimal thread counts, but has degrading performance as the number of connections increases. Its use should be considered as experimental and not supported.

This variable was added in MySQL 5.5.16. It is available only if the thread pool plugin is enabled. See [Section 8.11.6, “The Thread Pool Plugin”](#)

- `thread_pool_high_priority_connection`

Introduced	5.5.16	
Command-Line Format	<code>--thread_pool_high_priority_connection=#</code>	
Option-File Format	<code>thread_pool_high_priority_connection</code>	
System Variable Name	<code>thread_pool_high_priority_connection</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>0</code>
	Range	<code>0 .. 1</code>

This variable affects queuing of new statements prior to execution. If the value is 0 (false, the default), statement queuing uses both the low-priority and high-priority queues. If the value is 1 (true), queued statements always go to the high-priority queue.

This variable was added in MySQL 5.5.16. It is available only if the thread pool plugin is enabled. See [Section 8.11.6, “The Thread Pool Plugin”](#)

- `thread_pool_max_unused_threads`

Introduced	5.5.16	
Command-Line Format	<code>--thread_pool_max_unused_threads=#</code>	
Option-File Format	<code>thread_pool_max_unused_threads</code>	
System Variable Name	<code>thread_pool_max_unused_threads</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>0</code>
	Range	<code>0 .. 4096</code>

The maximum permitted number of unused threads in the thread pool. This variable makes it possible to limit the amount of memory used by sleeping threads.

A value of 0 (the default) means no limit on the number of sleeping threads. A value of *N* where *N* is greater than 0 means 1 consumer thread and *N*–1 reserve threads. In this case, if a thread is ready to sleep but the number of sleeping threads is already at the maximum, the thread exits rather than going to sleep.

A sleeping thread is either sleeping as a consumer thread or a reserve thread. The thread pool permits one thread to be the consumer thread when sleeping. If a thread goes to sleep and there is no existing consumer thread, it will sleep as a consumer thread. When a thread must be woken up, a consumer thread is selected if there is one. A reserve thread is selected only when there is no consumer thread to wake up.

This variable was added in MySQL 5.5.16. It is available only if the thread pool plugin is enabled. See [Section 8.11.6, “The Thread Pool Plugin”](#)

- `thread_pool_prio_kickup_timer`

Introduced	5.5.16	
Command-Line Format	<code>--thread_pool_prio_kickup_timer=#</code>	
Option-File Format	<code>thread_pool_prio_kickup_timer</code>	
System Variable Name	<code>thread_pool_prio_kickup_timer</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>1000</code>
	Range	<code>0 .. 4294967294</code>

This variable affects statements waiting for execution in the low-priority queue. The value is the number of milliseconds before a waiting statement is moved to the high-priority queue. The default is 1000 (1 second). The range of values is 0 to $2^{32} - 2$.

This variable was added in MySQL 5.5.16. It is available only if the thread pool plugin is enabled. See [Section 8.11.6, “The Thread Pool Plugin”](#)

- `thread_pool_size`

Introduced	5.5.16	
Command-Line Format	<code>--thread_pool_size=#</code>	
Option-File Format	<code>thread_pool_size</code>	
System Variable Name	<code>thread_pool_size</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>16</code>
	Range	<code>1 .. 64</code>

The number of thread groups in the thread pool. This is the most important parameter controlling thread pool performance. It affects how many statements can execute simultaneously. The default value is 16, with a range from 1 to 64 of permissible values. If a value outside this range is specified, the thread pool plugin does not load and the server writes a message to the error log.

This variable was added in MySQL 5.5.16. It is available only if the thread pool plugin is enabled. See [Section 8.11.6, “The Thread Pool Plugin”](#)

- `thread_pool_stall_limit`

Introduced	5.5.16	
Command-Line Format	<code>--thread_pool_stall_limit=#</code>	
Option-File Format	<code>thread_pool_stall_limit</code>	
System Variable Name	<code>thread_pool_stall_limit</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>6</code>
	Range	<code>4 .. 600</code>

This variable affects executing statements. The value is the amount of time a statement has to finish after starting to execute before it becomes defined as stalled, at which point the thread pool permits the thread group to begin executing another statement. The value is measured in 10 millisecond units, so a value of 6 (the default) means 60ms. The range of values is 4 to 600 (40ms to 6s). Short wait values permit threads to start more quickly. Short values are also better for avoiding deadlock situations. Long wait values are useful for workloads that include long-running statements, to avoid starting too many new statements while the current ones execute.

This variable was added in MySQL 5.5.16. It is available only if the thread pool plugin is enabled. See [Section 8.11.6, “The Thread Pool Plugin”](#)

- `thread_stack`

Command-Line Format	<code>--thread_stack=#</code>	
Option-File Format	<code>thread_stack</code>	
System Variable Name	<code>thread_stack</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Platform Bit Size	<code>32</code>
	Type	<code>numeric</code>
	Default	<code>196608</code>
	Range	<code>131072 .. 4294967295</code>

	Block Size	1024
	Permitted Values	
	Platform Bit Size	64
	Type	numeric
	Default	262144
	Range	131072 .. 18446744073709547520
	Block Size	1024

The stack size for each thread. Many of the limits detected by the `crash-me` test are dependent on this value. See [Section 8.12.2, “The MySQL Benchmark Suite”](#). The default of 192KB (256KB for 64-bit systems) is large enough for normal operation. If the thread stack size is too small, it limits the complexity of the SQL statements that the server can handle, the recursion depth of stored procedures, and other memory-consuming actions.

- `time_format`

This variable is unused.

- `time_zone`

System Variable Name	<code>time_zone</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	string

The current time zone. This variable is used to initialize the time zone for each client that connects. By default, the initial value of this is 'SYSTEM' (which means, “use the value of `system_time_zone`”). The value can be specified explicitly at server startup with the `--default-time-zone` option. See [Section 10.6, “MySQL Server Time Zone Support”](#).

- `timed_mutexes`

Deprecated	5.5.39	
Command-Line Format	<code>--timed_mutexes</code>	
Option-File Format	<code>timed_mutexes</code>	
System Variable Name	<code>timed_mutexes</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	boolean
	Default	OFF

In MySQL 5.5, this variable is deprecated; it has no use. It will be removed in a future MySQL release.

- `timestamp`

System Variable Name	<code>timestamp</code>	
Variable Scope	Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>numeric</code>

Set the time for this client. This is used to get the original timestamp if you use the binary log to restore rows. `timestamp_value` should be a Unix epoch timestamp (a value like that returned by `UNIX_TIMESTAMP()`), not a value in `'YYYY-MM-DD hh:mm:ss'` format) or `DEFAULT`.

Setting `timestamp` to a constant value causes it to retain that value until it is changed again. Setting `timestamp` to `DEFAULT` causes its value to be the current date and time as of the time it is accessed.

`SET timestamp` affects the value returned by `NOW()` but not by `SYSDATE()`. This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()`. The server can be started with the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`, in which case `SET timestamp` affects both functions.

- `tmp_table_size`

Command-Line Format	<code>--tmp_table_size=#</code>	
Option-File Format	<code>tmp_table_size</code>	
System Variable Name	<code>tmp_table_size</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>numeric</code>
	Default	<code>16777216</code>
	Range	<code>1024 .. 18446744073709551615</code>

The maximum size of internal in-memory temporary tables. (The actual limit is determined as the minimum of `tmp_table_size` and `max_heap_table_size`.) If an in-memory temporary table exceeds the limit, MySQL automatically converts it to an on-disk `MyISAM` table. Increase the value of `tmp_table_size` (and `max_heap_table_size` if necessary) if you do many advanced `GROUP BY` queries and you have lots of memory. This variable does not apply to user-created `MEMORY` tables.

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing the values of the `Created_tmp_disk_tables` and `Created_tmp_tables` variables.

See also [Section 8.4.4, “How MySQL Uses Internal Temporary Tables”](#).

- `tmpdir`

Command-Line Format	<code>--tmpdir=path</code>	
	<code>-t</code>	
Option-File Format	<code>tmpdir</code>	604

System Variable Name	<code>tmpdir</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>directory name</code>

The directory used for temporary files and temporary tables. This variable can be set to a list of several paths that are used in round-robin fashion. Paths should be separated by colon characters (":") on Unix and semicolon characters (";") on Windows.

The multiple-directory feature can be used to spread the load between several physical disks. If the MySQL server is acting as a replication slave, you should not set `tmpdir` to point to a directory on a memory-based file system or to a directory that is cleared when the server host restarts. A replication slave needs some of its temporary files to survive a machine restart so that it can replicate temporary tables or `LOAD DATA INFILE` operations. If files in the temporary file directory are lost when the server restarts, replication fails. You can set the slave's temporary directory using the `slave_load_tmpdir` variable. In that case, the slave will not use the general `tmpdir` value and you can set `tmpdir` to a nonpermanent location.

- `transaction_alloc_block_size`

Command-Line Format	<code>--transaction_alloc_block_size=#</code>	
Option-File Format	<code>transaction_alloc_block_size</code>	
System Variable Name	<code>transaction_alloc_block_size</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Platform Bit Size	32
	Type	<code>numeric</code>
	Default	8192
	Range	1024 .. 4294967295
	Block Size	1024
	Permitted Values	
	Platform Bit Size	64
	Type	<code>numeric</code>
	Default	8192
	Range	1024 .. 18446744073709547520
	Block Size	1024

The amount in bytes by which to increase a per-transaction memory pool which needs memory. See the description of `transaction_prealloc_size`.

- `transaction_prealloc_size`

Command-Line Format	<code>--transaction_prealloc_size=#</code>	
Option-File Format	<code>transaction_prealloc_size</code>	
System Variable Name	<code>transaction_prealloc_size</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Platform Bit Size	32
	Type	numeric
	Default	4096
	Range	1024 .. 4294967295
	Block Size	1024
	Permitted Values	
	Platform Bit Size	64
	Type	numeric
	Default	4096
	Range	1024 .. 18446744073709547520
	Block Size	1024

There is a per-transaction memory pool from which various transaction-related allocations take memory. The initial size of the pool in bytes is `transaction_prealloc_size`. For every allocation that cannot be satisfied from the pool because it has insufficient memory available, the pool is increased by `transaction_alloc_block_size` bytes. When the transaction ends, the pool is truncated to `transaction_prealloc_size` bytes.

By making `transaction_prealloc_size` sufficiently large to contain all statements within a single transaction, you can avoid many `malloc()` calls.

- `tx_isolation`

System Variable Name	<code>tx_isolation</code>	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	enumeration
	Default	REPEATABLE-READ
	Valid Values	READ-UNCOMMITTED
		READ-COMMITTED
		REPEATABLE-READ
		SERIALIZABLE

The default transaction isolation level. Defaults to [REPEATABLE-READ](#).

This variable can be set directly, or indirectly using the [SET TRANSACTION](#) statement. See [Section 13.3.6, “SET TRANSACTION Syntax”](#). If you set `tx_isolation` directly to an isolation level name that contains a space, the name should be enclosed within quotation marks, with the space replaced by a dash. For example:

```
SET tx_isolation = 'READ-COMMITTED';
```

Any unique prefix of a valid value may be used to set the value of this variable.

The default transaction isolation level can also be set at startup using the `--transaction-isolation` server option.

- [unique_checks](#)

System Variable Name	unique_checks	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	boolean
	Default	1

If set to 1 (the default), uniqueness checks for secondary indexes in [InnoDB](#) tables are performed. If set to 0, storage engines are permitted to assume that duplicate keys are not present in input data. If you know for certain that your data does not contain uniqueness violations, you can set this to 0 to speed up large table imports to [InnoDB](#).

Note that setting this variable to 0 does not *require* storage engines to ignore duplicate keys. An engine is still permitted to check for them and issue duplicate-key errors if it detects them.

- [updatable_views_with_limit](#)

Command-Line Format	<code>--updatable_views_with_limit=#</code>	
Option-File Format	updatable_views_with_limit	
System Variable Name	updatable_views_with_limit	
Variable Scope	Global, Session	
Dynamic Variable	Yes	
	Permitted Values	
	Type	boolean
	Default	1

This variable controls whether updates to a view can be made when the view does not contain all columns of the primary key defined in the underlying table, if the update statement contains a [LIMIT](#) clause. (Such updates often are generated by GUI tools.) An update is an [UPDATE](#) or [DELETE](#) statement. Primary key here means a [PRIMARY KEY](#), or a [UNIQUE](#) index in which no column can contain [NULL](#).

The variable can have two values:

- `1` or `YES`: Issue a warning only (not an error message). This is the default value.
- `0` or `NO`: Prohibit the update.
- `version`

The version number for the server. The value might also include a suffix indicating server build or configuration information. `-log` indicates that one or more of the general log, slow query log, or binary log are enabled. `-debug` indicates that the server was built with debugging support enabled.

- `version_comment`

System Variable Name	<code>version_comment</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>string</code>

The `CMake` configuration program has a `COMPILATION_COMMENT` option that permits a comment to be specified when building MySQL. This variable contains the value of that comment. See [Section 2.9.4, “MySQL Source-Configuration Options”](#).

- `version_compile_machine`

System Variable Name	<code>version_compile_machine</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>string</code>

The type of machine or architecture on which MySQL was built.

- `version_compile_os`

System Variable Name	<code>version_compile_os</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>string</code>

The type of operating system on which MySQL was built.

- `wait_timeout`

Command-Line Format	<code>--wait_timeout=#</code>
Option-File Format	<code>wait_timeout</code>
System Variable Name	<code>wait_timeout</code>
Variable Scope	Global, Session

Dynamic Variable	Yes
	Permitted Values
	Type (Other) <code>numeric</code>
	Default <code>28800</code>
	Range <code>1 .. 31536000</code>
	Permitted Values
	Type (Windows) <code>numeric</code>
	Default <code>28800</code>
	Range <code>1 .. 2147483</code>

The number of seconds the server waits for activity on a noninteractive connection before closing it.

On thread startup, the session `wait_timeout` value is initialized from the global `wait_timeout` value or from the global `interactive_timeout` value, depending on the type of client (as defined by the `CLIENT_INTERACTIVE` connect option to `mysql_real_connect()`). See also `interactive_timeout`.

- `warning_count`

The number of errors, warnings, and notes that resulted from the last statement that generated messages. This variable is read only. See [Section 13.7.5.41](#), “`SHOW WARNINGS` Syntax”.

5.1.5 Using System Variables

The MySQL server maintains many system variables that indicate how it is configured. [Section 5.1.4](#), “[Server System Variables](#)”, describes the meaning of these variables. Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. Most of them can be changed dynamically while the server is running by means of the `SET` statement, which enables you to modify operation of the server without having to stop and restart it. You can refer to system variable values in expressions.

The server maintains two kinds of system variables. Global variables affect the overall operation of the server. Session variables affect its operation for individual client connections. A given system variable can have both a global and a session value. Global and session system variables are related as follows:

- When the server starts, it initializes all global variables to their default values. These defaults can be changed by options specified on the command line or in an option file. (See [Section 4.2.3](#), “[Specifying Program Options](#)”.)
- The server also maintains a set of session variables for each client that connects. The client's session variables are initialized at connect time using the current values of the corresponding global variables. For example, the client's SQL mode is controlled by the session `sql_mode` value, which is initialized when the client connects to the value of the global `sql_mode` value.

System variable values can be set globally at server startup by using options on the command line or in an option file. When you use a startup option to set a variable that takes a numeric value, the value can be given with a suffix of `K`, `M`, or `G` (either uppercase or lowercase) to indicate a multiplier of 1024 , 1024^2 or 1024^3 ; that is, units of kilobytes, megabytes, or gigabytes, respectively. Thus, the following command starts the server with a query cache size of 16 megabytes and a maximum packet size of one gigabyte:

```
mysqld --query_cache_size=16M --max_allowed_packet=1G
```

Within an option file, those variables are set like this:

```
[mysqld]
query_cache_size=16M
max_allowed_packet=1G
```

The lettercase of suffix letters does not matter; `16M` and `16m` are equivalent, as are `1G` and `1g`.

If you want to restrict the maximum value to which a system variable can be set at runtime with the `SET` statement, you can specify this maximum by using an option of the form `--maximum-var_name=value` at server startup. For example, to prevent the value of `query_cache_size` from being increased to more than 32MB at runtime, use the option `--maximum-query_cache_size=32M`.

Many system variables are dynamic and can be changed while the server runs by using the `SET` statement. For a list, see [Section 5.1.5.2, “Dynamic System Variables”](#). To change a system variable with `SET`, refer to it as `var_name`, optionally preceded by a modifier:

- To indicate explicitly that a variable is a global variable, precede its name by `GLOBAL` or `@@global..`. The `SUPER` privilege is required to set global variables.
- To indicate explicitly that a variable is a session variable, precede its name by `SESSION`, `@@session..`, or `@@`. Setting a session variable requires no special privilege, but a client can change only its own session variables, not those of any other client.
- `LOCAL` and `@@local.` are synonyms for `SESSION` and `@@session..`
- If no modifier is present, `SET` changes the session variable.

A `SET` statement can contain multiple variable assignments, separated by commas. If you set several system variables, the most recent `GLOBAL` or `SESSION` modifier in the statement is used for following variables that have no modifier specified.

Examples:

```
SET sort_buffer_size=10000;
SET @@local.sort_buffer_size=10000;
SET GLOBAL sort_buffer_size=1000000, SESSION sort_buffer_size=1000000;
SET @@sort_buffer_size=1000000;
SET @@global.sort_buffer_size=1000000, @@local.sort_buffer_size=1000000;
```

The `@@var_name` syntax for system variables is supported for compatibility with some other database systems.

If you change a session system variable, the value remains in effect until your session ends or until you change the variable to a different value. The change is not visible to other clients.

If you change a global system variable, the value is remembered and used for new connections until the server restarts. (To make a global system variable setting permanent, you should set it in an option file.) The change is visible to any client that accesses that global variable. However, the change affects the corresponding session variable only for clients that connect after the change. The global variable change does not affect the session variable for any client that is currently connected (not even that of the client that issues the `SET GLOBAL` statement).

To prevent incorrect usage, MySQL produces an error if you use `SET GLOBAL` with a variable that can only be used with `SET SESSION` or if you do not specify `GLOBAL` (or `@@global.`) when setting a global variable.

To set a `SESSION` variable to the `GLOBAL` value or a `GLOBAL` value to the compiled-in MySQL default value, use the `DEFAULT` keyword. For example, the following two statements are identical in setting the session value of `max_join_size` to the global value:

```
SET max_join_size=DEFAULT;
SET @@session.max_join_size=@@global.max_join_size;
```

Not all system variables can be set to `DEFAULT`. In such cases, use of `DEFAULT` results in an error.

You can refer to the values of specific global or session system variables in expressions by using one of the `@@`-modifiers. For example, you can retrieve values in a `SELECT` statement like this:

```
SELECT @@global.sql_mode, @@session.sql_mode, @@sql_mode;
```

When you refer to a system variable in an expression as `@@var_name` (that is, when you do not specify `@@global.` or `@@session.`), MySQL returns the session value if it exists and the global value otherwise. (This differs from `SET @@var_name = value`, which always refers to the session value.)

Note

Some variables displayed by `SHOW VARIABLES` may not be available using `SELECT @@var_name` syntax; an `Unknown system variable` occurs. As a workaround in such cases, you can use `SHOW VARIABLES LIKE 'var_name'`.

Suffixes for specifying a value multiplier can be used when setting a variable at server startup, but not to set the value with `SET` at runtime. On the other hand, with `SET` you can assign a variable's value using an expression, which is not true when you set a variable at server startup. For example, the first of the following lines is legal at server startup, but the second is not:

```
shell> mysql --max_allowed_packet=16M
shell> mysql --max_allowed_packet=16*1024*1024
```

Conversely, the second of the following lines is legal at runtime, but the first is not:

```
mysql> SET GLOBAL max_allowed_packet=16M;
mysql> SET GLOBAL max_allowed_packet=16*1024*1024;
```

Note

Some system variables can be enabled with the `SET` statement by setting them to `ON` or `1`, or disabled by setting them to `OFF` or `0`. However, to set such a variable on the command line or in an option file, you must set it to `1` or `0`; setting it to `ON` or `OFF` will not work. For example, on the command line, `--delay_key_write=1` works but `--delay_key_write=ON` does not.

To display system variable names and values, use the `SHOW VARIABLES` statement:

```
mysql> SHOW VARIABLES;
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 1 |
| auto_increment_offset | 1 |
| automatic_sp_privileges | ON |
| back_log | 50 |
| basedir | /home/mysql/ |
+-----+-----+
```

binlog_cache_size	32768

With a [LIKE](#) clause, the statement displays only those variables that match the pattern. To obtain a specific variable name, use a [LIKE](#) clause as shown:

```
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the “%” wildcard character in a [LIKE](#) clause:

```
SHOW VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because “_” is a wildcard that matches any single character, you should escape it as “_” to match it literally. In practice, this is rarely necessary.

For [SHOW VARIABLES](#), if you specify neither [GLOBAL](#) nor [SESSION](#), MySQL returns [SESSION](#) values.

The reason for requiring the [GLOBAL](#) keyword when setting [GLOBAL](#)-only variables but not when retrieving them is to prevent problems in the future. If we were to remove a [SESSION](#) variable that has the same name as a [GLOBAL](#) variable, a client with the [SUPER](#) privilege might accidentally change the [GLOBAL](#) variable rather than just the [SESSION](#) variable for its own connection. If we add a [SESSION](#) variable with the same name as a [GLOBAL](#) variable, a client that intends to change the [GLOBAL](#) variable might find only its own [SESSION](#) variable changed.

5.1.5.1 Structured System Variables

A structured variable differs from a regular system variable in two respects:

- Its value is a structure with components that specify server parameters considered to be closely related.
- There might be several instances of a given type of structured variable. Each one has a different name and refers to a different resource maintained by the server.

MySQL 5.5 supports one structured variable type, which specifies parameters governing the operation of key caches. A key cache structured variable has these components:

- `key_buffer_size`
- `key_cache_block_size`
- `key_cache_division_limit`
- `key_cache_age_threshold`

This section describes the syntax for referring to structured variables. Key cache variables are used for syntax examples, but specific details about how key caches operate are found elsewhere, in [Section 8.9.2, “The MyISAM Key Cache”](#).

To refer to a component of a structured variable instance, you can use a compound name in `instance_name.component_name` format. Examples:

```
hot_cache.key_buffer_size
hot_cache.key_cache_block_size
cold_cache.key_cache_block_size
```

For each structured system variable, an instance with the name of `default` is always predefined. If you refer to a component of a structured variable without any instance name, the `default` instance is used. Thus, `default.key_buffer_size` and `key_buffer_size` both refer to the same system variable.

Structured variable instances and components follow these naming rules:

- For a given type of structured variable, each instance must have a name that is unique *within* variables of that type. However, instance names need not be unique *across* structured variable types. For example, each structured variable has an instance named `default`, so `default` is not unique across variable types.
- The names of the components of each structured variable type must be unique across all system variable names. If this were not true (that is, if two different types of structured variables could share component member names), it would not be clear which default structured variable to use for references to member names that are not qualified by an instance name.
- If a structured variable instance name is not legal as an unquoted identifier, refer to it as a quoted identifier using backticks. For example, `hot-cache` is not legal, but ``hot-cache`` is.
- `global`, `session`, and `local` are not legal instance names. This avoids a conflict with notation such as `@global.var_name` for referring to nonstructured system variables.

Currently, the first two rules have no possibility of being violated because the only structured variable type is the one for key caches. These rules will assume greater significance if some other type of structured variable is created in the future.

With one exception, you can refer to structured variable components using compound names in any context where simple variable names can occur. For example, you can assign a value to a structured variable using a command-line option:

```
shell> mysqld --hot_cache.key_buffer_size=64K
```

In an option file, use this syntax:

```
[mysqld]
hot_cache.key_buffer_size=64K
```

If you start the server with this option, it creates a key cache named `hot_cache` with a size of 64KB in addition to the default key cache that has a default size of 8MB.

Suppose that you start the server as follows:

```
shell> mysqld --key_buffer_size=256K \
          --extra_cache.key_buffer_size=128K \
          --extra_cache.key_cache_block_size=2048
```

In this case, the server sets the size of the default key cache to 256KB. (You could also have written `--default.key_buffer_size=256K`.) In addition, the server creates a second key cache named `extra_cache` that has a size of 128KB, with the size of block buffers for caching table index blocks set to 2048 bytes.

The following example starts the server with three different key caches having sizes in a 3:1:1 ratio:

```
shell> mysqld --key_buffer_size=6M \
          --hot_cache.key_buffer_size=2M \
          --cold_cache.key_buffer_size=2M
```

Structured variable values may be set and retrieved at runtime as well. For example, to set a key cache named `hot_cache` to a size of 10MB, use either of these statements:

```
mysql> SET GLOBAL hot_cache.key_buffer_size = 10*1024*1024;
mysql> SET @@global.hot_cache.key_buffer_size = 10*1024*1024;
```

To retrieve the cache size, do this:

```
mysql> SELECT @@global.hot_cache.key_buffer_size;
```

However, the following statement does not work. The variable is not interpreted as a compound name, but as a simple string for a `LIKE` pattern-matching operation:

```
mysql> SHOW GLOBAL VARIABLES LIKE 'hot_cache.key_buffer_size';
```

This is the exception to being able to use structured variable names anywhere a simple variable name may occur.

5.1.5.2 Dynamic System Variables

Many server system variables are dynamic and can be set at runtime using `SET GLOBAL` or `SET SESSION`. You can also obtain their values using `SELECT`. See [Section 5.1.5, “Using System Variables”](#).

The following table shows the full list of all dynamic system variables. The last column indicates for each variable whether `GLOBAL` or `SESSION` (or both) apply. The table also lists session options that can be set with the `SET` statement. [Section 5.1.4, “Server System Variables”](#), discusses these options.

Variables that have a type of “string” take a string value. Variables that have a type of “numeric” take a numeric value. Variables that have a type of “boolean” can be set to 0, 1, `ON` or `OFF`. (If you set them on the command line or in an option file, use the numeric values.) Variables that are marked as “enumeration” normally should be set to one of the available values for the variable, but can also be set to the number that corresponds to the desired enumeration value. For enumerated system variables, the first enumeration

value corresponds to 0. This differs from [ENUM](#) columns, for which the first enumeration value corresponds to 1.

Table 5.3 Dynamic Variable Summary

Variable Name	Variable Type	Variable Scope

5.1.6 Server Status Variables

The server maintains many status variables that provide information about its operation. You can view these variables and their values by using the `SHOW [GLOBAL | SESSION] STATUS` statement (see [Section 13.7.5.36, “SHOW STATUS Syntax”](#)). The optional `GLOBAL` keyword aggregates the values over all connections, and `SESSION` shows the values for the current connection.

```
mysql> SHOW GLOBAL STATUS;
```

Variable_name	Value
Aborted_clients	0
Aborted_connects	0
Bytes_received	155372598
Bytes_sent	1176560426
...	
Connections	30023
Created_tmp_disk_tables	0
Created_tmp_files	3
Created_tmp_tables	2
...	
Threads_created	217

Threads_running	88
Uptime	1389872

Many status variables are reset to 0 by the `FLUSH STATUS` statement.

The following table lists all available server status variables:

Table 5.4 Status Variable Summary

Variable Name	Variable Type	Variable Scope

Variable Name	Variable Type	Variable Scope
<code>Uptime_since_flush_status</code>	numeric	GLOBAL

The status variables have the following meanings. For meanings of status variables specific to MySQL Cluster, see [Section 18.3.4.4, “MySQL Cluster Status Variables”](#).

- `Aborted_clients`

The number of connections that were aborted because the client died without closing the connection properly. See [Section B.5.2.11, “Communication Errors and Aborted Connections”](#).

- `Aborted_connects`

The number of failed attempts to connect to the MySQL server. See [Section B.5.2.11, “Communication Errors and Aborted Connections”](#).

- `Binlog_cache_disk_use`

The number of transactions that used the binary log cache but that exceeded the value of `binlog_cache_size` and used a temporary file to store changes from the transaction.

In MySQL versions 5.5.3 through 5.5.8, this variable also included the number of nontransactional statements that caused the binary log transaction cache to be written to disk. Beginning with MySQL 5.5.9, the number of such nontransactional statements is tracked separately in the `Binlog_stmt_cache_disk_use` status variable.

- `Binlog_cache_use`

The number of transactions that used the binary log cache.

- `Binlog_stmt_cache_disk_use`

The number of nontransaction statements that used the binary log statement cache but that exceeded the value of `binlog_stmt_cache_size` and used a temporary file to store those statements.

- `Binlog_stmt_cache_use`

The number of nontransactional statements that used the binary log statement cache.

- `Bytes_received`

The number of bytes received from all clients.

- `Bytes_sent`

The number of bytes sent to all clients.

- `Com_xxx`

The `Com_xxx` statement counter variables indicate the number of times each `xxx` statement has been executed. There is one status variable for each type of statement. For example, `Com_delete` and `Com_update` count `DELETE` and `UPDATE` statements, respectively. `Com_delete_multi` and `Com_update_multi` are similar but apply to `DELETE` and `UPDATE` statements that use multiple-table syntax.

If a query result is returned from query cache, the server increments the `Qcache_hits` status variable, not `Com_select`. See [Section 8.9.3.4, “Query Cache Status and Maintenance”](#).

All of the `Com_stmt_xxx` variables are increased even if a prepared statement argument is unknown or an error occurred during execution. In other words, their values correspond to the number of requests issued, not to the number of requests successfully completed.

The `Com_stmt_xxx` status variables are as follows:

- `Com_stmt_prepare`
- `Com_stmt_execute`
- `Com_stmt_fetch`
- `Com_stmt_send_long_data`
- `Com_stmt_reset`
- `Com_stmt_close`

Those variables stand for prepared statement commands. Their names refer to the `COM_xxx` command set used in the network layer. In other words, their values increase whenever prepared statement API calls such as `mysql_stmt_prepare()`, `mysql_stmt_execute()`, and so forth are executed. However, `Com_stmt_prepare`, `Com_stmt_execute` and `Com_stmt_close` also increase for `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE`, respectively. Additionally, the values of the older statement counter variables `Com_prepare_sql`, `Com_execute_sql`, and `Com_dealloc_sql` increase for the `PREPARE`, `EXECUTE`, and `DEALLOCATE PREPARE` statements. `Com_stmt_fetch` stands for the total number of network round-trips issued when fetching from cursors.

`Com_stmt_reprepare` indicates the number of times statements were automatically reprepared by the server after metadata changes to tables or views referred to by the statement. A reprepare operation increments `Com_stmt_reprepare`, and also `Com_stmt_prepare`.

- `Compression`

Whether the client connection uses compression in the client/server protocol.

- `Connections`

The number of connection attempts (successful or not) to the MySQL server.

- `Created_tmp_disk_tables`

The number of internal on-disk temporary tables created by the server while executing statements.

If an internal temporary table is created initially as an in-memory table but becomes too large, MySQL automatically converts it to an on-disk table. The maximum size for in-memory temporary tables is the minimum of the `tmp_table_size` and `max_heap_table_size` values. If `Created_tmp_disk_tables` is large, you may want to increase the `tmp_table_size` or `max_heap_table_size` value to lessen the likelihood that internal temporary tables in memory will be converted to on-disk tables.

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing the values of the `Created_tmp_disk_tables` and `Created_tmp_tables` variables.

See also [Section 8.4.4, “How MySQL Uses Internal Temporary Tables”](#).

- `Created_tmp_files`

How many temporary files `mysqld` has created.

- `Created_tmp_tables`

The number of internal temporary tables created by the server while executing statements.

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing the values of the `Created_tmp_disk_tables` and `Created_tmp_tables` variables.

See also [Section 8.4.4, “How MySQL Uses Internal Temporary Tables”](#).

Each invocation of the `SHOW STATUS` statement uses an internal temporary table and increments the global `Created_tmp_tables` value.

- `Delayed_errors`

The number of rows written with `INSERT DELAYED` for which some error occurred (probably `duplicate key`).

- `Delayed_insert_threads`

The number of `INSERT DELAYED` handler threads in use.

- `Delayed_writes`

The number of `INSERT DELAYED` rows written.

- `Flush_commands`

The number of times the server flushes tables, whether because a user executed a `FLUSH TABLES` statement or due to internal server operation. It is also incremented by receipt of a `COM_REFRESH` packet. This is in contrast to `Com_flush`, which indicates how many `FLUSH` statements have been executed, whether `FLUSH TABLES`, `FLUSH LOGS`, and so forth.

- `Handler_commit`

The number of internal `COMMIT` statements.

- `Handler_delete`

The number of times that rows have been deleted from tables.

- `Handler_prepare`

A counter for the prepare phase of two-phase commit operations.

- `Handler_read_first`

The number of times the first entry in an index was read. If this value is high, it suggests that the server is doing a lot of full index scans; for example, `SELECT coll FROM foo`, assuming that `coll` is indexed.

- `Handler_read_key`

The number of requests to read a row based on a key. If this value is high, it is a good indication that your tables are properly indexed for your queries.

- `Handler_read_last`

The number of requests to read the last key in an index. With `ORDER BY`, the server will issue a first-key request followed by several next-key requests, whereas with `ORDER BY DESC`, the server will issue a last-key request followed by several previous-key requests. This variable was added in MySQL 5.5.7.

- `Handler_read_next`

The number of requests to read the next row in key order. This value is incremented if you are querying an index column with a range constraint or if you are doing an index scan.

- `Handler_read_prev`

The number of requests to read the previous row in key order. This read method is mainly used to optimize `ORDER BY ... DESC`.

- `Handler_read_rnd`

The number of requests to read a row based on a fixed position. This value is high if you are doing a lot of queries that require sorting of the result. You probably have a lot of queries that require MySQL to scan entire tables or you have joins that do not use keys properly.

- `Handler_read_rnd_next`

The number of requests to read the next row in the data file. This value is high if you are doing a lot of table scans. Generally this suggests that your tables are not properly indexed or that your queries are not written to take advantage of the indexes you have.

- `Handler_rollback`

The number of requests for a storage engine to perform a rollback operation.

- `Handler_savepoint`

The number of requests for a storage engine to place a savepoint.

- `Handler_savepoint_rollback`

The number of requests for a storage engine to roll back to a savepoint.

- `Handler_update`

The number of requests to update a row in a table.

- `Handler_write`

The number of requests to insert a row in a table.

- `Innodb_buffer_pool_bytes_data`

The total number of bytes in the `InnoDB buffer pool` containing data. The number includes both `dirty` and clean pages. For more accurate memory usage calculations than with `Innodb_buffer_pool_pages_data`, when `compressed` tables cause the buffer pool to hold pages of different sizes.

- `Innodb_buffer_pool_pages_data`

The number of pages containing data (dirty or clean).

- `Innodb_buffer_pool_bytes_dirty`

The total current number of bytes held in **dirty pages** in the **InnoDB buffer pool**. For more accurate memory usage calculations than with `Innodb_buffer_pool_pages_dirty`, when **compressed** tables cause the buffer pool to hold pages of different sizes.

- `Innodb_buffer_pool_pages_dirty`

The number of pages currently dirty.

- `Innodb_buffer_pool_pages_flushed`

The number of buffer pool page-flush requests.

- `Innodb_buffer_pool_pages_free`

The number of free pages.

- `Innodb_buffer_pool_pages_latched`

The number of latched pages in **InnoDB** buffer pool. These are pages currently being read or written or that cannot be flushed or removed for some other reason. Calculation of this variable is expensive, so it is available only when the `UNIV_DEBUG` system is defined at server build time.

- `Innodb_buffer_pool_pages_misc`

The number of pages that are busy because they have been allocated for administrative overhead such as row locks or the adaptive hash index. This value can also be calculated as `Innodb_buffer_pool_pages_total - Innodb_buffer_pool_pages_free - Innodb_buffer_pool_pages_data`.

- `Innodb_buffer_pool_pages_total`

The total size of the buffer pool, in pages.

- `Innodb_buffer_pool_read_ahead`

The number of pages read into the **InnoDB** buffer pool by the read-ahead background thread.

- `Innodb_buffer_pool_read_ahead_evicted`

The number of pages read into the **InnoDB** buffer pool by the read-ahead background thread that were subsequently evicted without having been accessed by queries.

- `Innodb_buffer_pool_read_requests`

The number of logical read requests.

- `Innodb_buffer_pool_reads`

The number of logical reads that **InnoDB** could not satisfy from the buffer pool, and had to read directly from the disk.

- `Innodb_buffer_pool_wait_free`

Normally, writes to the **InnoDB** buffer pool happen in the background. However, if it is necessary to read or create a page and no clean pages are available, it is also necessary to wait for pages to be flushed first. This counter counts instances of these waits. If the buffer pool size has been set properly, this value should be small.

- `Innodb_buffer_pool_write_requests`

The number writes done to the `InnoDB` buffer pool.

- `Innodb_data_fsyncs`

The number of `fsync()` operations so far.

- `Innodb_data_pending_fsyncs`

The current number of pending `fsync()` operations.

- `Innodb_data_pending_reads`

The current number of pending reads.

- `Innodb_data_pending_writes`

The current number of pending writes.

- `Innodb_data_read`

The amount of data read since the server was started.

- `Innodb_data_reads`

The total number of data reads.

- `Innodb_data_writes`

The total number of data writes.

- `Innodb_data_written`

The amount of data written so far, in bytes.

- `Innodb_dblwr_pages_written`

The number of pages that have been written for doublewrite operations. See [Section 14.13.1, “InnoDB Disk I/O”](#).

- `Innodb_dblwr_writes`

The number of doublewrite operations that have been performed. See [Section 14.13.1, “InnoDB Disk I/O”](#).

- `Innodb_have_atomic_builtins`

Indicates whether the server was built with atomic instructions.

- `Innodb_log_waits`

The number of times that the log buffer was too small and a wait was required for it to be flushed before continuing.

- `Innodb_log_write_requests`

The number of log write requests.

- `Innodb_log_writes`

The number of physical writes to the log file.

- [Innodb_os_log_fsyncs](#)

The number of `fsync()` writes done to the log file.

- [Innodb_os_log_pending_fsyncs](#)

The number of pending log file `fsync()` operations.

- [Innodb_os_log_pending_writes](#)

The number of pending log file writes.

- [Innodb_os_log_written](#)

The number of bytes written to the log file.

- [Innodb_page_size](#)

The compiled-in [InnoDB](#) page size (default 16KB). Many values are counted in pages; the page size enables them to be easily converted to bytes.

- [Innodb_pages_created](#)

The number of pages created.

- [Innodb_pages_read](#)

The number of pages read.

- [Innodb_pages_written](#)

The number of pages written.

- [Innodb_row_lock_current_waits](#)

The number of row locks currently being waited for.

- [Innodb_row_lock_time](#)

The total time spent in acquiring row locks, in milliseconds.

- [Innodb_row_lock_time_avg](#)

The average time to acquire a row lock, in milliseconds.

- [Innodb_row_lock_time_max](#)

The maximum time to acquire a row lock, in milliseconds.

- [Innodb_row_lock_waits](#)

The number of times a row lock had to be waited for.

- [Innodb_rows_deleted](#)

The number of rows deleted from [InnoDB](#) tables.

- `Innodb_rows_inserted`

The number of rows inserted into `InnoDB` tables.

- `Innodb_rows_read`

The number of rows read from `InnoDB` tables.

- `Innodb_rows_updated`

The number of rows updated in `InnoDB` tables.

- `Innodb_truncated_status_writes`

The number of times output from the `SHOW ENGINE INNODB STATUS` is truncated. Monitoring applications that parse the output from this command can test this value before and after issuing the `SHOW ENGINE` command, to confirm if the output is complete or not.

- `Key_blocks_not_flushed`

The number of key blocks in the key cache that have changed but have not yet been flushed to disk.

- `Key_blocks_unused`

The number of unused blocks in the key cache. You can use this value to determine how much of the key cache is in use; see the discussion of `key_buffer_size` in [Section 5.1.4, “Server System Variables”](#).

- `Key_blocks_used`

The number of used blocks in the key cache. This value is a high-water mark that indicates the maximum number of blocks that have ever been in use at one time.

- `Key_read_requests`

The number of requests to read a key block from the cache.

- `Key_reads`

The number of physical reads of a key block from disk. If `Key_reads` is large, then your `key_buffer_size` value is probably too small. The cache miss rate can be calculated as `Key_reads/Key_read_requests`.

- `Key_write_requests`

The number of requests to write a key block to the cache.

- `Key_writes`

The number of physical writes of a key block to disk.

- `Last_query_cost`

The total cost of the last compiled query as computed by the query optimizer. This is useful for comparing the cost of different query plans for the same query. The default value of 0 means that no query has been compiled yet. The default value is 0. `Last_query_cost` has session scope.

The `Last_query_cost` value can be computed accurately only for simple “flat” queries, not complex queries such as those with subqueries or `UNION`. For the latter, the value is set to 0.

- `Max_used_connections`

The maximum number of connections that have been in use simultaneously since the server started.

- `Not_flushed_delayed_rows`

The number of rows waiting to be written in `INSERT DELAYED` queues.

- `Open_files`

The number of files that are open. This count includes regular files opened by the server. It does not include other types of files such as sockets or pipes. Also, the count does not include files that storage engines open using their own internal functions rather than asking the server level to do so.

- `Open_streams`

The number of streams that are open (used mainly for logging).

- `Open_table_definitions`

The number of cached `.frm` files.

- `Open_tables`

The number of tables that are open.

- `Opened_files`

The number of files that have been opened with `my_open()` (a `mysys` library function). Parts of the server that open files without using this function do not increment the count.

- `Opened_table_definitions`

The number of `.frm` files that have been cached.

- `Opened_tables`

The number of tables that have been opened. If `Opened_tables` is big, your `table_open_cache` value is probably too small.

- `Performance_schema_xxx`

Performance Schema status variables are listed in [Section 22.10, “Performance Schema Status Variables”](#). These variables provide information about instrumentation that could not be loaded or created due to memory constraints.

- `Prepared_stmt_count`

The current number of prepared statements. (The maximum number of statements is given by the `max_prepared_stmt_count` system variable.)

- `Qcache_free_blocks`

The number of free memory blocks in the query cache.

- `Qcache_free_memory`

The amount of free memory for the query cache.

- `Qcache_hits`

The number of query cache hits.

- `Qcache_inserts`

The number of queries added to the query cache.

- `Qcache_lowmem_prunes`

The number of queries that were deleted from the query cache because of low memory.

- `Qcache_not_cached`

The number of noncached queries (not cacheable, or not cached due to the `query_cache_type` setting).

- `Qcache_queries_in_cache`

The number of queries registered in the query cache.

- `Qcache_total_blocks`

The total number of blocks in the query cache.

- `Queries`

The number of statements executed by the server. This variable includes statements executed within stored programs, unlike the `Questions` variable. It does not count `COM_PING` or `COM_STATISTICS` commands.

- `Questions`

The number of statements executed by the server. This includes only statements sent to the server by clients and not statements executed within stored programs, unlike the `Queries` variable. This variable does not count `COM_PING`, `COM_STATISTICS`, `COM_STMT_PREPARE`, `COM_STMT_CLOSE`, or `COM_STMT_RESET` commands.

- `Rpl_semi_sync_master_clients`

The number of semisynchronous slaves.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_net_avg_wait_time`

The average time in microseconds the master waited for a slave reply.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_net_wait_time`

The total time in microseconds the master waited for slave replies.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_net_waits`

The total number of times the master waited for slave replies.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_no_times`

The number of times the master turned off semisynchronous replication.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_no_tx`

The number of commits that were not acknowledged successfully by a slave.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_status`

Whether semisynchronous replication currently is operational on the master. The value is `ON` if the plugin has been enabled and a commit acknowledgment has occurred. It is `OFF` if the plugin is not enabled or the master has fallen back to asynchronous replication due to commit acknowledgment timeout.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_timefunc_failures`

The number of times the master failed when calling time functions such as `gettimeofday()`.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_tx_avg_wait_time`

The average time in microseconds the master waited for each transaction.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_tx_wait_time`

The total time in microseconds the master waited for transactions.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_tx_waits`

The total number of times the master waited for transactions.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_wait_pos_backtraverse`

The total number of times the master waited for an event with binary coordinates lower than events waited for previously. This can occur when the order in which transactions start waiting for a reply is different from the order in which their binary log events are written.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_wait_sessions`

The number of sessions currently waiting for slave replies.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_yes_tx`

The number of commits that were acknowledged successfully by a slave.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_slave_status`

Whether semisynchronous replication currently is operational on the slave. This is `ON` if the plugin has been enabled and the slave I/O thread is running, `OFF` otherwise.

This variable is available only if the slave-side semisynchronous replication plugin is installed.

- `Rpl_status`

The status of fail-safe replication (not implemented). This variable is unused and is removed in MySQL 5.6.

- `Select_full_join`

The number of joins that perform table scans because they do not use indexes. If this value is not 0, you should carefully check the indexes of your tables.

- `Select_full_range_join`

The number of joins that used a range search on a reference table.

- `Select_range`

The number of joins that used ranges on the first table. This is normally not a critical issue even if the value is quite large.

- `Select_range_check`

The number of joins without keys that check for key usage after each row. If this is not 0, you should carefully check the indexes of your tables.

- `Select_scan`

The number of joins that did a full scan of the first table.

- `Slave_heartbeat_period`

Shows the replication heartbeat interval (in seconds) on a replication slave.

- `Slave_open_temp_tables`

The number of temporary tables that the slave SQL thread currently has open. If the value is greater than zero, it is not safe to shut down the slave; see [Section 17.4.1.22, “Replication and Temporary Tables”](#).

- `Slave_received_heartbeats`

This counter increments with each replication heartbeat received by a replication slave since the last time that the slave was restarted or reset, or a `CHANGE MASTER TO` statement was issued.

- `Slave_retried_transactions`

The total number of times since startup that the replication slave SQL thread has retried transactions.

- `Slave_running`

This is `ON` if this server is a replication slave that is connected to a replication master, and both the I/O and SQL threads are running; otherwise, it is `OFF`.

- `Slow_launch_threads`

The number of threads that have taken more than `slow_launch_time` seconds to create.

- `Slow_queries`

The number of queries that have taken more than `long_query_time` seconds. This counter increments regardless of whether the slow query log is enabled. For information about that log, see [Section 5.2.5, “The Slow Query Log”](#).

- `Sort_merge_passes`

The number of merge passes that the sort algorithm has had to do. If this value is large, you should consider increasing the value of the `sort_buffer_size` system variable.

- `Sort_range`

The number of sorts that were done using ranges.

- `Sort_rows`

The number of sorted rows.

- `Sort_scan`

The number of sorts that were done by scanning the table.

- `Ssl_accept_renegotiates`

The number of negotiates needed to establish the connection.

- `Ssl_accepts`

The number of accepted SSL connections.

- `Ssl_callback_cache_hits`

The number of callback cache hits.

- `Ssl_cipher`

The current SSL cipher (empty for non-SSL connections).

- `Ssl_cipher_list`

The list of possible SSL ciphers (empty for non-SSL connections).

- `Ssl_client_connects`

The number of SSL connection attempts to an SSL-enabled master.

- `Ssl_connect_renegotiates`

The number of negotiates needed to establish the connection to an SSL-enabled master.

- `Ssl_ctx_verify_depth`

The SSL context verification depth (how many certificates in the chain are tested).

- `Ssl_ctx_verify_mode`

The SSL context verification mode.

- `Ssl_default_timeout`

The default SSL timeout.

- `Ssl_finished_accepts`

The number of successful SSL connections to the server.

- `Ssl_finished_connects`

The number of successful slave connections to an SSL-enabled master.

- `Ssl_session_cache_hits`

The number of SSL session cache hits.

- `Ssl_session_cache_misses`

The number of SSL session cache misses.

- `Ssl_session_cache_mode`

The SSL session cache mode.

- `Ssl_session_cache_overflows`

The number of SSL session cache overflows.

- `Ssl_session_cache_size`

The SSL session cache size.

- `Ssl_session_cache_timeouts`

The number of SSL session cache timeouts.

- `Ssl_sessions_reused`

How many SSL connections were reused from the cache.

- `Ssl_used_session_cache_entries`

How many SSL session cache entries were used.

- `Ssl_verify_depth`

The verification depth for replication SSL connections.

- `Ssl_verify_mode`

The verification mode for replication SSL connections.

- `Ssl_version`

The SSL version number.

- [Table_locks_immediate](#)

The number of times that a request for a table lock could be granted immediately.

- [Table_locks_waited](#)

The number of times that a request for a table lock could not be granted immediately and a wait was needed. If this is high and you have performance problems, you should first optimize your queries, and then either split your table or tables or use replication.

- [Tc_log_max_pages_used](#)

For the memory-mapped implementation of the log that is used by `mysqld` when it acts as the transaction coordinator for recovery of internal XA transactions, this variable indicates the largest number of pages used for the log since the server started. If the product of [Tc_log_max_pages_used](#) and [Tc_log_page_size](#) is always significantly less than the log size, the size is larger than necessary and can be reduced. (The size is set by the `--log-tc-size` option. Currently, this variable is unused: It is unneeded for binary log-based recovery, and the memory-mapped recovery log method is not used unless the number of storage engines capable of two-phase commit is greater than one. (`InnoDB` is the only applicable engine.)

- [Tc_log_page_size](#)

The page size used for the memory-mapped implementation of the XA recovery log. The default value is determined using `getpagesize()`. Currently, this variable is unused for the same reasons as described for [Tc_log_max_pages_used](#).

- [Tc_log_page_waits](#)

For the memory-mapped implementation of the recovery log, this variable increments each time the server was not able to commit a transaction and had to wait for a free page in the log. If this value is large, you might want to increase the log size (with the `--log-tc-size` option). For binary log-based recovery, this variable increments each time the binary log cannot be closed because there are two-phase commits in progress. (The close operation waits until all such transactions are finished.)

- [Threads_cached](#)

The number of threads in the thread cache.

- [Threads_connected](#)

The number of currently open connections.

- [Threads_created](#)

The number of threads created to handle connections. If [Threads_created](#) is big, you may want to increase the [thread_cache_size](#) value. The cache miss rate can be calculated as [Threads_created/Connections](#).

- [Threads_running](#)

The number of threads that are not sleeping.

- [Uptime](#)

The number of seconds that the server has been up.

- `Uptime_since_flush_status`

The number of seconds since the most recent `FLUSH STATUS` statement.

5.1.7 Server SQL Modes

The MySQL server can operate in different SQL modes, and can apply these modes differently for different clients, depending on the value of the `sql_mode` system variable. DBAs can set the global SQL mode to match site server operating requirements, and each application can set its session SQL mode to its own requirements.

Modes affect the SQL syntax MySQL supports and the data validation checks it performs. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers.

- [Setting the SQL Mode](#)
- [The Most Important SQL Modes](#)
- [Full List of SQL Modes](#)
- [Strict SQL Mode](#)
- [Combination SQL Modes](#)

For answers to questions often asked about server SQL modes in MySQL, see [Section A.3, “MySQL 5.5 FAQ: Server SQL Mode”](#).

When working with `InnoDB` tables, consider also the `innodb_strict_mode` system variable. It enables additional error checks for `InnoDB` tables.

Setting the SQL Mode

The default SQL mode is empty (no modes set).

To set the SQL mode at server startup, use the `--sql-mode="modes"` option on the command line, or `sql-mode="modes"` in an option file such as `my.cnf` (Unix operating systems) or `my.ini` (Windows). `modes` is a list of different modes separated by commas. To clear the SQL mode explicitly, set it to an empty string using `--sql-mode=""` on the command line, or `sql-mode=""` in an option file.

Note

MySQL installation programs may configure the SQL mode during the installation process. If the SQL mode differs from the default or from what you expect, check for a setting in an option file that the server reads at startup.

To change the SQL mode at runtime, set the global or session `sql_mode` system variable using a `SET` statement:

```
SET GLOBAL sql_mode = 'modes';
SET SESSION sql_mode = 'modes';
```

Setting the `GLOBAL` variable requires the `SUPER` privilege and affects the operation of all clients that connect from that time on. Setting the `SESSION` variable affects only the current client. Each client can change its session `sql_mode` value at any time.

To determine the current global or session `sql_mode` value, use the following statements:

```
SELECT @@GLOBAL.sql_mode;
SELECT @@SESSION.sql_mode;
```

Important

SQL mode and user-defined partitioning. Changing the server SQL mode after creating and inserting data into partitioned tables can cause major changes in the behavior of such tables, and could lead to loss or corruption of data. It is strongly recommended that you never change the SQL mode once you have created tables employing user-defined partitioning.

When replicating partitioned tables, differing SQL modes on master and slave can also lead to problems. For best results, you should always use the same server SQL mode on the master and on the slave.

See [Section 19.5, “Restrictions and Limitations on Partitioning”](#), for more information.

The Most Important SQL Modes

The most important `sql_mode` values are probably these:

- `ANSI`

This mode changes syntax and behavior to conform more closely to standard SQL. It is one of the special [combination modes](#) listed at the end of this section.

- `STRICT_TRANS_TABLES`

If a value could not be inserted as given into a transactional table, abort the statement. For a nontransactional table, abort the statement if the value occurs in a single-row statement or the first row of a multiple-row statement. More details are given later in this section.

- `TRADITIONAL`

Make MySQL behave like a “traditional” SQL database system. A simple description of this mode is “give an error instead of a warning” when inserting an incorrect value into a column. It is one of the special [combination modes](#) listed at the end of this section.

Note

The `INSERT` or `UPDATE` aborts as soon as the error is noticed. This may not be what you want if you are using a nontransactional storage engine, because data changes made prior to the error may not be rolled back, resulting in a “partially done” update.

When this manual refers to “strict mode,” it means a mode with either or both `STRICT_TRANS_TABLES` or `STRICT_ALL_TABLES` enabled.

Full List of SQL Modes

The following list describes all supported SQL modes:

- `ALLOW_INVALID_DATES`

Do not perform full checking of dates. Check only that the month is in the range from 1 to 12 and the day is in the range from 1 to 31. This is very convenient for Web applications where you obtain year,

month, and day in three different fields and you want to store exactly what the user inserted (without date validation). This mode applies to `DATE` and `DATETIME` columns. It does not apply `TIMESTAMP` columns, which always require a valid date.

The server requires that month and day values be legal, and not merely in the range 1 to 12 and 1 to 31, respectively. With strict mode disabled, invalid dates such as `'2004-04-31'` are converted to `'0000-00-00'` and a warning is generated. With strict mode enabled, invalid dates generate an error. To permit such dates, enable `ALLOW_INVALID_DATES`.

- `ANSI_QUOTES`

Treat `"` as an identifier quote character (like the ``` quote character) and not as a string quote character. You can still use ``` to quote identifiers with this mode enabled. With `ANSI_QUOTES` enabled, you cannot use double quotation marks to quote literal strings, because it is interpreted as an identifier.

- `ERROR_FOR_DIVISION_BY_ZERO`

The `ERROR_FOR_DIVISION_BY_ZERO` mode affects handling of division by zero, which includes `MOD(N, 0)`. For data-change operations (`INSERT`, `UPDATE`), its effect also depends on whether strict SQL mode is enabled.

- If this mode is not enabled, division by zero inserts `NULL` and produces no warning.
- If this mode is enabled, division by zero inserts `NULL` and produces a warning.
- If this mode and strict mode are enabled, division by zero produces an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, division by zero inserts `NULL` and produces a warning.

For `SELECT`, division by zero returns `NULL`. Enabling `ERROR_FOR_DIVISION_BY_ZERO` causes a warning to be produced as well, regardless of whether strict mode is enabled.

- `HIGH_NOT_PRECEDENCE`

The precedence of the `NOT` operator is such that expressions such as `NOT a BETWEEN b AND c` are parsed as `NOT (a BETWEEN b AND c)`. In some older versions of MySQL, the expression was parsed as `(NOT a) BETWEEN b AND c`. The old higher-precedence behavior can be obtained by enabling the `HIGH_NOT_PRECEDENCE` SQL mode.

```
mysql> SET sql_mode = '';
mysql> SELECT NOT 1 BETWEEN -5 AND 5;
-> 0
mysql> SET sql_mode = 'HIGH_NOT_PRECEDENCE';
mysql> SELECT NOT 1 BETWEEN -5 AND 5;
-> 1
```

- `IGNORE_SPACE`

Permit spaces between a function name and the `(` character. This causes built-in function names to be treated as reserved words. As a result, identifiers that are the same as function names must be quoted as described in [Section 9.2, “Schema Object Names”](#). For example, because there is a `COUNT()` function, the use of `count` as a table name in the following statement causes an error:

```
mysql> CREATE TABLE count (i INT);
ERROR 1064 (42000): You have an error in your SQL syntax
```

The table name should be quoted:

```
mysql> CREATE TABLE `count` (i INT);
Query OK, 0 rows affected (0.00 sec)
```

The `IGNORE_SPACE` SQL mode applies to built-in functions, not to user-defined functions or stored functions. It is always permissible to have spaces after a UDF or stored function name, regardless of whether `IGNORE_SPACE` is enabled.

For further discussion of `IGNORE_SPACE`, see [Section 9.2.4, “Function Name Parsing and Resolution”](#).

- `NO_AUTO_CREATE_USER`

Prevent the `GRANT` statement from automatically creating new users if it would otherwise do so, unless authentication information is specified. The statement must specify a nonempty password using `IDENTIFIED BY` or an authentication plugin using `IDENTIFIED WITH`.

- `NO_AUTO_VALUE_ON_ZERO`

`NO_AUTO_VALUE_ON_ZERO` affects handling of `AUTO_INCREMENT` columns. Normally, you generate the next sequence number for the column by inserting either `NULL` or `0` into it. `NO_AUTO_VALUE_ON_ZERO` suppresses this behavior for `0` so that only `NULL` generates the next sequence number.

This mode can be useful if `0` has been stored in a table's `AUTO_INCREMENT` column. (Storing `0` is not a recommended practice, by the way.) For example, if you dump the table with `mysqldump` and then reload it, MySQL normally generates new sequence numbers when it encounters the `0` values, resulting in a table with contents different from the one that was dumped. Enabling `NO_AUTO_VALUE_ON_ZERO` before reloading the dump file solves this problem. `mysqldump` now automatically includes in its output a statement that enables `NO_AUTO_VALUE_ON_ZERO`, to avoid this problem.

- `NO_BACKSLASH_ESCAPES`

Disable the use of the backslash character (“\”) as an escape character within strings. With this mode enabled, backslash becomes an ordinary character like any other.

- `NO_DIR_IN_CREATE`

When creating a table, ignore all `INDEX DIRECTORY` and `DATA DIRECTORY` directives. This option is useful on slave replication servers.

- `NO_ENGINE_SUBSTITUTION`

Control automatic substitution of the default storage engine when a statement such as `CREATE TABLE` or `ALTER TABLE` specifies a storage engine that is disabled or not compiled in.

Because storage engines can be pluggable at runtime, unavailable engines are treated the same way:

With `NO_ENGINE_SUBSTITUTION` disabled, for `CREATE TABLE` the default engine is used and a warning occurs if the desired engine is unavailable. For `ALTER TABLE`, a warning occurs and the table is not altered.

With `NO_ENGINE_SUBSTITUTION` enabled, an error occurs and the table is not created or altered if the desired engine is unavailable.

- `NO_FIELD_OPTIONS`

Do not print MySQL-specific column options in the output of `SHOW CREATE TABLE`. This mode is used by `mysqldump` in portability mode.

- `NO_KEY_OPTIONS`

Do not print MySQL-specific index options in the output of `SHOW CREATE TABLE`. This mode is used by `mysqldump` in portability mode.

- `NO_TABLE_OPTIONS`

Do not print MySQL-specific table options (such as `ENGINE`) in the output of `SHOW CREATE TABLE`. This mode is used by `mysqldump` in portability mode.

- `NO_UNSIGNED_SUBTRACTION`

By default, subtraction between integer operands produces an `UNSIGNED` result if any operand is `UNSIGNED`. When `NO_UNSIGNED_SUBTRACTION` is enabled, the subtraction result is signed, *even if any operand is unsigned*. For example, compare the type of column `c2` in table `t1` with that of column `c2` in table `t2`:

```
mysql> SET sql_mode='';
mysql> CREATE TABLE test (c1 BIGINT UNSIGNED NOT NULL);
mysql> CREATE TABLE t1 SELECT c1 - 1 AS c2 FROM test;
mysql> DESCRIBE t1;
```

Field	Type	Null	Key	Default	Extra
c2	bigint(21) unsigned			0	

```
mysql> SET sql_mode='NO_UNSIGNED_SUBTRACTION';
mysql> CREATE TABLE t2 SELECT c1 - 1 AS c2 FROM test;
mysql> DESCRIBE t2;
```

Field	Type	Null	Key	Default	Extra
c2	bigint(21)			0	

Note that this means that `BIGINT UNSIGNED` is not 100% usable in all contexts. See [Section 12.10, “Cast Functions and Operators”](#).

```
mysql> SET sql_mode = '';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
```

CAST(0 AS UNSIGNED) - 1
18446744073709551615

```
mysql> SET sql_mode = 'NO_UNSIGNED_SUBTRACTION';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
```

CAST(0 AS UNSIGNED) - 1
-1

- `NO_ZERO_DATE`

The `NO_ZERO_DATE` mode affects whether the server permits `'0000-00-00'` as a valid date. Its effect also depends on whether strict SQL mode is enabled.

- If this mode is not enabled, `'0000-00-00'` is permitted and inserts produce no warning.

- If this mode is enabled, '0000-00-00' is permitted and inserts produce a warning.
- If this mode and strict mode are enabled, '0000-00-00' is not permitted and inserts produce an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, '0000-00-00' is permitted and inserts produce a warning.

- `NO_ZERO_IN_DATE`

The `NO_ZERO_IN_DATE` mode affects whether the server permits dates in which the year part is nonzero but the month or day part is 0. (This mode affects dates such as '2010-00-01' or '2010-01-00', but not '0000-00-00'. To control whether the server permits '0000-00-00', use the `NO_ZERO_IN_DATE` mode.) The effect of `NO_ZERO_IN_DATE` also depends on whether strict SQL mode is enabled.

- If this mode is not enabled, dates with zero parts are permitted and inserts produce no warning.
- If this mode is enabled, dates with zero parts are inserted as '0000-00-00' and produce a warning.
- If this mode and strict mode are enabled, dates with zero parts are not permitted and inserts produce an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, dates with zero parts are inserted as '0000-00-00' and produce a warning.

- `ONLY_FULL_GROUP_BY`

Do not permit queries for which the select list or `HAVING` list refers to nonaggregated columns that are not named in the `GROUP BY` clause.

The following queries are invalid with `ONLY_FULL_GROUP_BY` enabled. The first is invalid because `address` in the select list is not named in the `GROUP BY` clause, and the second because `max_age` in the `HAVING` clause is not named in the `GROUP BY` clause:

```
mysql> SELECT name, address, MAX(age) FROM t GROUP BY name;
ERROR 1055 (42000): 't.address' isn't in GROUP BY
```

```
mysql> SELECT name, MAX(age) AS max_age FROM t GROUP BY name
-> HAVING max_age < 30;
Empty set (0.00 sec)
ERROR 1463 (42000): Non-grouping field 'max_age' is used in HAVING clause
```

In the second example, the query could be rewritten to use `HAVING MAX(age)` instead, so that the reference is to a column named in an aggregate function. (`max_age` fails because it *is* an aggregate function.)

In addition, if a query has aggregate functions and no `GROUP BY` clause, it cannot have nonaggregated columns in the select list or `ORDER BY` list:

```
mysql> SELECT name, MAX(age) FROM t;
ERROR 1140 (42000): Mixing of GROUP columns (MIN(),MAX(),COUNT(),...)
with no GROUP columns is illegal if there is no GROUP BY clause
```

For more information, see [Section 12.16.3, “MySQL Extensions to GROUP BY”](#).

- `PAD_CHAR_TO_FULL_LENGTH`

By default, trailing spaces are trimmed from `CHAR` column values on retrieval. If `PAD_CHAR_TO_FULL_LENGTH` is enabled, trimming does not occur and retrieved `CHAR` values are padded to their full length. This mode does not apply to `VARCHAR` columns, for which trailing spaces are retained on retrieval.

```
mysql> CREATE TABLE t1 (c1 CHAR(10));
Query OK, 0 rows affected (0.37 sec)

mysql> INSERT INTO t1 (c1) VALUES('xy');
Query OK, 1 row affected (0.01 sec)

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT c1, CHAR_LENGTH(c1) FROM t1;
+-----+-----+
| c1    | CHAR_LENGTH(c1) |
+-----+-----+
| xy    |                2 |
+-----+-----+
1 row in set (0.00 sec)

mysql> SET sql_mode = 'PAD_CHAR_TO_FULL_LENGTH';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT c1, CHAR_LENGTH(c1) FROM t1;
+-----+-----+
| c1          | CHAR_LENGTH(c1) |
+-----+-----+
| xy          |                10 |
+-----+-----+
1 row in set (0.00 sec)
```

- `PIPES_AS_CONCAT`

Treat `||` as a string concatenation operator (same as `CONCAT()`) rather than as a synonym for `OR`.

- `REAL_AS_FLOAT`

Treat `REAL` as a synonym for `FLOAT`. By default, MySQL treats `REAL` as a synonym for `DOUBLE`.

- `STRICT_ALL_TABLES`

Enable strict mode for all storage engines. Invalid data values are rejected. Additional details follow.

- `STRICT_TRANS_TABLES`

Enable strict mode for transactional storage engines, and when possible for nontransactional storage engines. Additional details follow.

Strict SQL Mode

Strict mode controls how MySQL handles invalid or missing values in data-change statements such as `INSERT` or `UPDATE`. A value can be invalid for several reasons. For example, it might have the wrong data type for the column, or it might be out of range. A value is missing when a new row to be inserted does not contain a value for a non-`NULL` column that has no explicit `DEFAULT` clause in its definition. (For a `NULL` column, `NULL` is inserted if the value is missing.)

If strict mode is not in effect, MySQL inserts adjusted values for invalid or missing values and produces warnings (see [Section 13.7.5.41](#), “[SHOW WARNINGS Syntax](#)”). In strict mode, you can produce this behavior by using [INSERT IGNORE](#) or [UPDATE IGNORE](#).

For statements such as [SELECT](#) that do not change data, invalid values generate a warning in strict mode, not an error.

Strict mode does not affect whether foreign key constraints are checked. [foreign_key_checks](#) can be used for that. (See [Section 5.1.4](#), “[Server System Variables](#)”.)

Strict SQL mode is in effect if either [STRICT_ALL_TABLES](#) or [STRICT_TRANS_TABLES](#) is enabled, although the effects of these modes differ somewhat:

- For transactional tables, an error occurs for invalid or missing values in a data-change statement when either [STRICT_ALL_TABLES](#) or [STRICT_TRANS_TABLES](#) is enabled. The statement is aborted and rolled back.
- For nontransactional tables, the behavior is the same for either mode if the bad value occurs in the first row to be inserted or updated: The statement is aborted and the table remains unchanged. If the statement inserts or modifies multiple rows and the bad value occurs in the second or later row, the result depends on which strict mode is enabled:
 - For [STRICT_ALL_TABLES](#), MySQL returns an error and ignores the rest of the rows. However, because the earlier rows have been inserted or updated, the result is a partial update. To avoid this, use single-row statements, which can be aborted without changing the table.
 - For [STRICT_TRANS_TABLES](#), MySQL converts an invalid value to the closest valid value for the column and inserts the adjusted value. If a value is missing, MySQL inserts the implicit default value for the column data type. In either case, MySQL generates a warning rather than an error and continues processing the statement. Implicit defaults are described in [Section 11.6](#), “[Data Type Default Values](#)”.

Strict mode also affects handling of division by zero, zero dates, and zeros in dates, in conjunction with the [ERROR_FOR_DIVISION_BY_ZERO](#), [NO_ZERO_DATE](#), and [NO_ZERO_IN_DATE](#) modes. For details, see the descriptions of those modes.

Combination SQL Modes

The following special modes are provided as shorthand for combinations of mode values from the preceding list.

- [ANSI](#)

Equivalent to [REAL_AS_FLOAT](#), [PIPES_AS_CONCAT](#), [ANSI_QUOTES](#), [IGNORE_SPACE](#).

[ANSI](#) mode also causes the server to return an error for queries where a set function [S](#) with an outer reference [S\(outer_ref\)](#) cannot be aggregated in the outer query against which the outer reference has been resolved. This is such a query:

```
SELECT * FROM t1 WHERE t1.a IN (SELECT MAX(t1.b) FROM t2 WHERE ...);
```

Here, [MAX\(t1.b\)](#) cannot be aggregated in the outer query because it appears in the [WHERE](#) clause of that query. Standard SQL requires an error in this situation. If [ANSI](#) mode is not enabled, the server treats [S\(outer_ref\)](#) in such queries the same way that it would interpret [S\(const\)](#).

See [Section 1.8](#), “[MySQL Standards Compliance](#)”.

- [DB2](#)

Equivalent to [PIPES_AS_CONCAT](#), [ANSI_QUOTES](#), [IGNORE_SPACE](#), [NO_KEY_OPTIONS](#), [NO_TABLE_OPTIONS](#), [NO_FIELD_OPTIONS](#).

- [MAXDB](#)

Equivalent to [PIPES_AS_CONCAT](#), [ANSI_QUOTES](#), [IGNORE_SPACE](#), [NO_KEY_OPTIONS](#), [NO_TABLE_OPTIONS](#), [NO_FIELD_OPTIONS](#), [NO_AUTO_CREATE_USER](#).

- [MSSQL](#)

Equivalent to [PIPES_AS_CONCAT](#), [ANSI_QUOTES](#), [IGNORE_SPACE](#), [NO_KEY_OPTIONS](#), [NO_TABLE_OPTIONS](#), [NO_FIELD_OPTIONS](#).

- [MYSQL323](#)

Equivalent to [NO_FIELD_OPTIONS](#), [HIGH_NOT_PRECEDENCE](#).

- [MYSQL40](#)

Equivalent to [NO_FIELD_OPTIONS](#), [HIGH_NOT_PRECEDENCE](#).

- [ORACLE](#)

Equivalent to [PIPES_AS_CONCAT](#), [ANSI_QUOTES](#), [IGNORE_SPACE](#), [NO_KEY_OPTIONS](#), [NO_TABLE_OPTIONS](#), [NO_FIELD_OPTIONS](#), [NO_AUTO_CREATE_USER](#).

- [POSTGRESQL](#)

Equivalent to [PIPES_AS_CONCAT](#), [ANSI_QUOTES](#), [IGNORE_SPACE](#), [NO_KEY_OPTIONS](#), [NO_TABLE_OPTIONS](#), [NO_FIELD_OPTIONS](#).

- [TRADITIONAL](#)

Equivalent to [STRICT_TRANS_TABLES](#), [STRICT_ALL_TABLES](#), [NO_ZERO_IN_DATE](#), [NO_ZERO_DATE](#), [ERROR_FOR_DIVISION_BY_ZERO](#), [NO_AUTO_CREATE_USER](#), and [NO_ENGINE_SUBSTITUTION](#).

5.1.8 Server Plugins

MySQL supports a plugin API that enables creation of server components. Plugins can be loaded at server startup, or loaded and unloaded at runtime without restarting the server. The components supported by this interface include, but are not limited to, storage engines, full-text parser plugins, partitioning support, and server extensions.

5.1.8.1 Installing and Uninstalling Plugins

Server plugins must be loaded in to the server before they can be used. MySQL enables you to load a plugin at server startup or at runtime. It is also possible to control the activation of loaded plugins at startup, and to unload them at runtime.

- [Installing plugins](#)
- [Controlling plugin activation](#)
- [Uninstalling plugins](#)

Installing Plugins

Server plugins must be known to the server before they can be used. A plugin can be made known several ways, as described here. In the following descriptions, `plugin_name` stands for a plugin name such as `innodb` or `csv`.

Built-in plugins:

A plugin that is built in to the server is known by the server automatically. Normally, the server enables the plugin at startup, although this can be changed with the `--plugin_name` option.

Plugins registered in the `mysql.plugin` table:

The `mysql.plugin` table serves as a registry of plugins. The server normally enables each plugin listed in the table at startup, although whether a given plugin is enabled can be changed with the `--plugin_name` option. If the server is started with the `--skip-grant-tables` option, it does not consult this table and does not load the plugins listed there.

Plugins named with the `--plugin-load` option:

A plugin that is located in a plugin library file can be loaded at server startup with the `--plugin-load` option. Normally, the server enables the plugin at startup, although this can be changed with the `--plugin_name` option.

The option value is a semicolon-separated list of `name=plugin_library` pairs. Each `name` is the name of the plugin, and `plugin_library` is the name of the shared library that contains the plugin code. If a plugin library is named without any preceding plugin name, the server loads all plugins in the library. Each library file must be located in the directory named by the `plugin_dir` system variable.

This option does not register any plugin in the `mysql.plugin` table. For subsequent restarts, the server loads the plugin again only if `--plugin-load` is given again. That is, this option effects a one-time installation that persists only for one server invocation.

`--plugin-load` enables plugins to be loaded even when `--skip-grant-tables` is given (which causes the server to ignore the `mysql.plugin` table). `--plugin-load` also enables plugins to be loaded at startup under configurations when plugins cannot be loaded at runtime.

Plugins installed with the `INSTALL PLUGIN` statement:

A plugin that is located in a plugin library file can be loaded at runtime with the `INSTALL PLUGIN` statement. The statement also registers the plugin in the `mysql.plugin` table to cause the server to load it on subsequent restarts. For this reason, `INSTALL PLUGIN` requires the `INSERT` privilege for the `mysql.plugin` table.

If a plugin is named both using a `--plugin-load` option and in the `mysql.plugin` table, the server starts but writes these messages to the error log:

```
100310 19:15:44 [ERROR] Function 'plugin_name' already exists
100310 19:15:44 [Warning] Couldn't load plugin named 'plugin_name'
with soname 'plugin_object_file'.
```

Example: The `--plugin-load` option installs a plugin at server startup. To install a plugin named `myplugin` in a plugin library file named `somepluglib.so`, use these lines in a `my.cnf` file:

```
[mysqld]
plugin-load=myplugin=somepluglib.so
```

In this case, the plugin is not registered in `mysql.plugin`. Restarting the server without the `--plugin-load` option causes the plugin not to be loaded at startup.

Alternatively, the `INSTALL PLUGIN` statement causes the server to load the plugin code from the library file at runtime:

```
mysql> INSTALL PLUGIN myplugin SONAME 'somepluglib.so';
```

`INSTALL PLUGIN` also causes “permanent” plugin registration: The server lists the plugin in the `mysql.plugin` table to ensure that it is loaded on subsequent server restarts.

Many plugins can be loaded either at server startup or at runtime. However, if a plugin is designed such that it must be loaded and initialized during server startup, use `--plugin-load` rather than `INSTALL PLUGIN`.

While a plugin is loaded, information about it is available at runtime from several sources, such as the `INFORMATION_SCHEMA.PLUGINS` table and the `SHOW PLUGINS` statement. For more information, see [Section 5.1.8.2, “Obtaining Server Plugin Information”](#).

Controlling Plugin Activation

If the server knows about a plugin when it starts (for example, because the plugin is named using a `--plugin-load` option or registered in the `mysql.plugin` table), the server loads and enables the plugin by default. It is possible to control activation for such a plugin using a `--plugin_name[=value]` startup option named after the plugin. In the following descriptions, `plugin_name` stands for a plugin name such as `innodb` or `csv`. As with other options, dashes and underscores are interchangeable in option names. For example, `--my_plugin=ON` and `--my-plugin=ON` are equivalent.

- `--plugin_name=OFF`

Tells the server to disable the plugin.

- `--plugin_name[=ON]`

Tells the server to enable the plugin. (Specifying the option as `--plugin_name` without a value has the same effect.) If the plugin fails to initialize, the server runs with the plugin disabled.

- `--plugin_name=FORCE`

Tells the server to enable the plugin, but if plugin initialization fails, the server does not start. In other words, this option forces the server to run with the plugin enabled or not at all.

- `--plugin_name=FORCE_PLUS_PERMANENT`

Like `FORCE`, but in addition prevents the plugin from being unloaded at runtime. If a user attempts to do so with `UNINSTALL PLUGIN`, an error occurs. This value is available as of MySQL 5.5.7.

The values `OFF`, `ON`, `FORCE`, and `FORCE_PLUS_PERMANENT` are not case sensitive.

The activation state for plugins is visible in the `LOAD_OPTION` column of the `INFORMATION_SCHEMA.PLUGINS` table.

Suppose that `CSV`, `BLACKHOLE`, and `ARCHIVE` are built-in pluggable storage engines and that you want the server to load them at startup, subject to these conditions: The server is permitted to run if `CSV` initialization fails, but must require that `BLACKHOLE` initialization succeeds, and `ARCHIVE` should be disabled. To accomplish that, use these lines in an option file:

```
[mysqld]  
csv=ON  
blackhole=FORCE  
archive=OFF
```

The `--enable-plugin_name` option format is supported as a synonym for `--plugin_name=ON`. The `--disable-plugin_name` and `--skip-plugin_name` option formats are supported as synonyms for `--plugin_name=OFF`.

Before MySQL 5.1.36, plugin options are boolean options (see [Section 4.2.5, “Program Option Modifiers”](#)). That is, any of these options enable the plugin:

```
--plugin_name  
--plugin_name=1  
--enable-plugin_name
```

And these options disable the plugin:

```
--plugin_name=0  
--disable-plugin_name  
--skip-plugin_name
```

If you upgrade to MySQL 5.5 from a version older than 5.1.36 and previously used options of the form `--plugin_name=0` or `--plugin_name=1`, the equivalent options are now `--plugin_name=OFF` and `--plugin_name=ON`, respectively. You also have the choice of requiring plugins to start successfully by using `--plugin_name=FORCE` or `--plugin_name=FORCE_PLUS_PERMANENT`.

If a plugin is disabled, either explicitly with `OFF` or implicitly because it was enabled with `ON` but failed to initialize, aspects of server operation that require the plugin will change. For example, if the plugin implements a storage engine, existing tables for the storage engine become inaccessible, and attempts to create new tables for the storage engine result in tables that use the default storage engine unless the `NO_ENGINE_SUBSTITUTION` SQL mode has been enabled to cause an error to occur instead.

Disabling a plugin may require adjustment to other options. For example, if you start the server using `--skip-innodb` to disable `InnoDB`, other `innodb_XXX` options likely will need to be omitted from the startup command. In addition, because `InnoDB` is the default storage engine, it will not start unless you specify another available storage engine with `--default-storage-engine`.

Uninstalling Plugins

A plugin known to the server can be uninstalled to disable it at runtime with the `UNINSTALL PLUGIN` statement. The statement unloads the plugin and removes it from the `mysql.plugin` table if it is registered there. For this reason, `UNINSTALL PLUGIN` statement requires the `DELETE` privilege for the `mysql.plugin` table. With the plugin no longer registered in the table, the server will not load the plugin automatically for subsequent restarts.

`UNINSTALL PLUGIN` can unload plugins regardless of whether they were loaded with `INSTALL PLUGIN` or `--plugin-load`.

`UNINSTALL PLUGIN` is subject to these exceptions:

- It cannot unload plugins that are built in to the server. These can be identified as those that have a library name of `NULL` in the output from `INFORMATION_SCHEMA.PLUGINS` or `SHOW PLUGINS`.
- It cannot unload plugins for which the server was started with `--plugin_name=FORCE_PLUS_PERMANENT`, which prevents plugin unloading at runtime. These can be identified from the `LOAD_OPTION` column of the `INFORMATION_SCHEMA.PLUGINS` table.

5.1.8.2 Obtaining Server Plugin Information

There are several ways to determine which plugins are installed in the server:

- The `INFORMATION_SCHEMA.PLUGINS` table contains a row for each loaded plugin. Any that have a `PLUGIN_LIBRARY` value of `NULL` are built in and cannot be unloaded.

```
mysql> SELECT * FROM information_schema.PLUGINS\G
***** 1. row *****
      PLUGIN_NAME: binlog
      PLUGIN_VERSION: 1.0
      PLUGIN_STATUS: ACTIVE
      PLUGIN_TYPE: STORAGE ENGINE
      PLUGIN_TYPE_VERSION: 50158.0
      PLUGIN_LIBRARY: NULL
      PLUGIN_LIBRARY_VERSION: NULL
      PLUGIN_AUTHOR: MySQL AB
      PLUGIN_DESCRIPTION: This is a pseudo storage engine to represent the binlog in a transaction
      PLUGIN_LICENSE: GPL
      LOAD_OPTION: FORCE
...
***** 10. row *****
      PLUGIN_NAME: InnoDB
      PLUGIN_VERSION: 1.0
      PLUGIN_STATUS: ACTIVE
      PLUGIN_TYPE: STORAGE ENGINE
      PLUGIN_TYPE_VERSION: 50158.0
      PLUGIN_LIBRARY: ha_innodb_plugin.so
      PLUGIN_LIBRARY_VERSION: 1.0
      PLUGIN_AUTHOR: Innobase Oy
      PLUGIN_DESCRIPTION: Supports transactions, row-level locking,
                        and foreign keys
      PLUGIN_LICENSE: GPL
      LOAD_OPTION: ON
...
```

- The `SHOW PLUGINS` statement displays a row for each loaded plugin. Any that have a `Library` value of `NULL` are built in and cannot be unloaded.

```
mysql> SHOW PLUGINS\G
***** 1. row *****
      Name: binlog
      Status: ACTIVE
      Type: STORAGE ENGINE
      Library: NULL
      License: GPL
...
***** 10. row *****
      Name: InnoDB
      Status: ACTIVE
      Type: STORAGE ENGINE
      Library: ha_innodb_plugin.so
      License: GPL
...
```

- The `mysql.plugin` table shows which plugins have been registered with `INSTALL PLUGIN`. The table contains only plugin names and library file names, so it does not provide as much information as the `PLUGINS` table or the `SHOW PLUGINS` statement.

5.1.9 IPv6 Support

As of MySQL 5.5.3, support for IPv6 includes these capabilities:

- MySQL Server can accept TCP/IP connections from clients connecting over IPv6. For example, this command connects over IPv6 to the MySQL server on the local host:

```
shell> mysql -h ::1
```

To use this capability, two things must be true:

- Your system must be configured to support IPv6. See [Section 5.1.9.1, “Verifying System Support for IPv6”](#).
- The default MySQL server configuration permits only IPv4 connections, so the server must be configured for IPv6 connections. To permit IPv6 connections in addition to or instead of IPv4 connections, start the server with an appropriate `--bind-address` option. See [Section 5.1.4, “Server System Variables”](#).
- MySQL account names permit IPv6 addresses to enable DBAs to specify privileges for clients that connect to the server over IPv6. See [Section 6.2.3, “Specifying Account Names”](#). IPv6 addresses can be specified in account names in statements such as `CREATE USER`, `GRANT`, and `REVOKE`. For example:

```
mysql> CREATE USER 'bill'@':::1' IDENTIFIED BY 'secret';
mysql> GRANT SELECT ON mydb.* TO 'bill'@':::1';
```

The following sections describe how to set up MySQL so that clients can connect to the server over IPv6.

5.1.9.1 Verifying System Support for IPv6

Before MySQL Server can accept IPv6 connections, the operating system on your server host must support IPv6. As a simple test to determine whether that is true, try this command:

```
shell> ping6 ::1
16 bytes from ::1, icmp_seq=0 hlim=64 time=0.171 ms
16 bytes from ::1, icmp_seq=1 hlim=64 time=0.077 ms
...
```

To produce a description of your system's network interfaces, invoke `ifconfig -a` and look for IPv6 addresses in the output.

If your host does not support IPv6, consult your system documentation for instructions on enabling it. It might be that you need only reconfigure an existing network interface to add an IPv6 address. Or a more extensive change might be needed, such as rebuilding the kernel with IPv6 options enabled.

These links may be helpful in setting up IPv6 on various platforms:

- [Windows XP](#)
- [Gentoo Linux](#)
- [Ubuntu Linux](#)
- [Linux \(Generic\)](#)
- [Mac OS X](#)

5.1.9.2 Configuring the MySQL Server to Permit IPv6 Connections

The MySQL server listens on a single network socket for TCP/IP connections. This socket is bound to a single address, but it is possible for an address to map onto multiple network interfaces. The default address is `0.0.0.0`. To specify an address explicitly, use the `--bind-address=addr` option at server

startup, where `addr` is an IPv4 or IPv6 address or a host name. (IPv6 addresses are not supported before MySQL 5.5.3.) If `addr` is a host name, the server resolves the name to an IP address and binds to that address.

The server treats different types of addresses as follows:

- If the address is `0.0.0.0`, the server accepts TCP/IP connections on all server host IPv4 interfaces.
- If the address is `::`, the server accepts TCP/IP connections on all server host IPv4 and IPv6 interfaces. Use this address to permit both IPv4 and IPv6 connections on all server interfaces.
- If the address is an IPv4-mapped address, the server accepts TCP/IP connections for that address, in either IPv4 or IPv6 format. For example, if the server is bound to `::ffff:127.0.0.1`, clients can connect using `--host=127.0.0.1` or `--host>::ffff:127.0.0.1`.
- If the address is a “regular” IPv4 or IPv6 address (such as `127.0.0.1` or `::1`), the server accepts TCP/IP connections only for that IPv4 or IPv6 address.

If you intend to bind the server to a specific address, be sure that the `mysql.user` grant table contains an account with administrative privileges that you can use to connect to that address. Otherwise, you will not be able to shut down the server. For example, if you bind the server to `::`, you can connect to it using all existing accounts. But if you bind the server to `::1`, it accepts connections only on that address. In that case, first make sure that the `'root'@'::1'` account is present in the `mysql.user` table so you can still connect to the server to shut it down.

5.1.9.3 Connecting Using the IPv6 Local Host Address

The following procedure shows how to configure MySQL to permit IPv6 connections by clients that connect to the local server using the `::1` local host address. The instructions given here assume that your system supports IPv6.

1. Start the MySQL server with an appropriate `--bind-address` option to permit it to accept IPv6 connections. For example, put the following lines in your server option file and restart the server:

```
[mysqld]
bind-address = ::
```

Alternatively, you can bind the server to `::1`, but that makes the server more restrictive for TCP/IP connections. It accepts only IPv6 connections for that single address and rejects IPv4 connections. For more information, see [Section 5.1.9.2, “Configuring the MySQL Server to Permit IPv6 Connections”](#).

2. As an administrator, connect to the server and create an account for a local user who will connect from the `::1` local IPv6 host address:

```
mysql> CREATE USER 'ipv6user'@'::1' IDENTIFIED BY 'ipv6pass';
```

For the permitted syntax of IPv6 addresses in account names, see [Section 6.2.3, “Specifying Account Names”](#). In addition to the `CREATE USER` statement, you can issue `GRANT` statements that give specific privileges to the account, although that is not necessary for the remaining steps in this procedure.

3. Invoke the `mysql` client to connect to the server using the new account:

```
shell> mysql -h ::1 -u ipv6user -pipv6pass
```

4. Try some simple statements that show connection information:

```
mysql> STATUS
...
Connection:  ::1 via TCP/IP
...

mysql> SELECT CURRENT_USER();
+-----+
| CURRENT_USER() |
+-----+
| ipv6user@::1   |
+-----+
```

5.1.9.4 Connecting Using IPv6 Nonlocal Host Addresses

The following procedure shows how to configure MySQL to permit IPv6 connections by remote clients. It is similar to the preceding procedure for local clients, but the server and client hosts are distinct and each has its own nonlocal IPv6 address. The example uses these addresses:

```
Server host: 2001:db8:0:f101::1
Client host: 2001:db8:0:f101::2
```

These addresses are chosen from the nonroutable address range recommended by [IANA](#) for documentation purposes and suffice for testing on your local network. To accept IPv6 connections from clients outside the local network, the server host must have a public address. If your network provider assigns you an IPv6 address, you can use that. Otherwise, another way to obtain an address is to use an IPv6 broker; see [Section 5.1.9.5](#), “Obtaining an IPv6 Address from a Broker”.

1. Start the MySQL server with an appropriate `--bind-address` option to permit it to accept IPv6 connections. For example, put the following lines in your server option file and restart the server:

```
[mysqld]
bind-address = ::
```

Alternatively, you can bind the server to `2001:db8:0:f101::1`, but that makes the server more restrictive for TCP/IP connections. It accepts only IPv6 connections for that single address and rejects IPv4 connections. For more information, see [Section 5.1.9.2](#), “Configuring the MySQL Server to Permit IPv6 Connections”.

2. On the server host (`2001:db8:0:f101::1`), create an account for a user who will connect from the client host (`2001:db8:0:f101::2`):

```
mysql> CREATE USER 'remoteipv6user'@'2001:db8:0:f101::2' IDENTIFIED BY 'remoteipv6pass';
```

3. On the client host (`2001:db8:0:f101::2`), invoke the `mysql` client to connect to the server using the new account:

```
shell> mysql -h 2001:db8:0:f101::1 -u remoteipv6user -premoteipv6pass
```

4. Try some simple statements that show connection information:

```
mysql> STATUS
...
Connection: 2001:db8:0:f101::1 via TCP/IP
...

mysql> SELECT CURRENT_USER();
+-----+
| CURRENT_USER() |
+-----+
```

```
| CURRENT_USER( ) |
+-----+
| remoteipv6user@2001:db8:0:f101::2 |
+-----+
```

5.1.9.5 Obtaining an IPv6 Address from a Broker

If you do not have a public IPv6 address that enables your system to communicate over IPv6 outside your local network, you can obtain one from an IPv6 broker. The [Wikipedia IPv6 Tunnel Broker page](#) lists several brokers and their features, such as whether they provide static addresses and the supported routing protocols.

After configuring your server host to use a broker-supplied IPv6 address, start the MySQL server with an appropriate `--bind-address` option to permit the server to accept IPv6 connections. For example, put the following lines in the server option file and restart the server:

```
[mysqld]
bind-address = ::
```

Alternatively, you can bind the server to the specific IPv6 address provided by the broker, but that makes the server more restrictive for TCP/IP connections. It accepts only IPv6 connections for that single address and rejects IPv4 connections. For more information, see [Section 5.1.9.2, “Configuring the MySQL Server to Permit IPv6 Connections”](#). In addition, if the broker allocates dynamic addresses, the address provided for your system might change the next time you connect to the broker. If so, any accounts you create that name the original address become invalid. To bind to a specific address but avoid this change-of-address problem, you may be able to arrange with the broker for a static IPv6 address.

The following example shows how to use Freenet6 as the broker and the `gogoc` IPv6 client package on Gentoo Linux.

1. Create a account at Freenet6 by visiting this URL and signing up:

```
http://gogonet.gogo6.com
```

2. After creating the account, go to this URL, sign in, and create a user ID and password for the IPv6 broker:

```
http://gogonet.gogo6.com/page/freenet6-registration
```

3. As `root`, install `gogoc`:

```
shell> emerge gogoc
```

4. Edit `/etc/gogoc/gogoc.conf` to set the `userid` and `password` values. For example:

```
userid=gogouser
passwd=gogopass
```

5. Start `gogoc`:

```
shell> /etc/init.d/gogoc start
```

To start `gogoc` each time your system boots, execute this command:

```
shell> rc-update add gogoc default
```

6. Use `ping6` to try to ping a host:

```
shell> ping6 ipv6.google.com
```

7. To see your IPv6 address:

```
shell> ifconfig tun
```

5.1.10 Server-Side Help

MySQL Server supports a `HELP` statement that returns online information from the MySQL Reference manual (see [Section 13.8.3](#), “`HELP Syntax`”). The proper operation of this statement requires that the help tables in the `mysql` database be initialized with help topic information, which is done by processing the contents of the `fill_help_tables.sql` script.

If you install MySQL using a binary or source distribution on Unix, help table content initialization occurs when you run `mysql_install_db`. For an RPM distribution on Linux or binary distribution on Windows, content initialization occurs as part of the MySQL installation process.

If you upgrade MySQL using a binary distribution, help table content is not upgraded automatically, but you can upgrade it manually. Locate the `fill_help_tables.sql` file in the `share` or `share/mysql` directory. Change location into that directory and process the file with the `mysql` client as follows:

```
shell> mysql -u root mysql < fill_help_tables.sql
```

You can also obtain the latest `fill_help_tables.sql` at any time to upgrade your help tables. Download the proper file for your version of MySQL from <http://dev.mysql.com/doc/index-other.html>. After downloading and uncompressing the file, process it with `mysql` as described previously.

If you are working with Bazaar and a MySQL development source tree, you must use a downloaded copy of the `fill_help_tables.sql` file because the source tree contains only a “stub” version.

Note

For a server that participates in replication, the help table content upgrade process involves multiple servers. For details, see [Section 17.4.1.28](#), “`Replication of Server-Side Help Tables`”.

5.1.11 Server Response to Signals

On Unix, signals can be sent to processes. `mysqld` responds to signals sent to it as follows:

- `SIGTERM` causes the server to shut down.
- `SIGHUP` causes the server to reload the grant tables and to flush tables, logs, the thread cache, and the host cache. These actions are like various forms of the `FLUSH` statement. The server also writes a status report to the error log that has this format:

```
Status information:

Current dir: /var/mysql/data/
Running threads: 0  Stack size: 196608
Current locks:

Key caches:
default
```

```

Buffer_size:      8388600
Block_size:       1024
Division_limit:   100
Age_limit:        300
blocks used:      0

```

On some Mac OS X 10.3 versions, `mysqld` ignores `SIGHUP` and `SIGQUIT`.

5.1.12 The Shutdown Process

The server shutdown process takes place as follows:

1. The shutdown process is initiated.

This can occur initiated several ways. For example, a user with the `SHUTDOWN` privilege can execute a `mysqladmin shutdown` command. `mysqladmin` can be used on any platform supported by MySQL. Other operating system-specific shutdown initiation methods are possible as well: The server shuts down on Unix when it receives a `SIGTERM` signal. A server running as a service on Windows shuts down when the services manager tells it to.

2. The server creates a shutdown thread if necessary.

Depending on how shutdown was initiated, the server might create a thread to handle the shutdown process. If shutdown was requested by a client, a shutdown thread is created. If shutdown is the result of receiving a `SIGTERM` signal, the signal thread might handle shutdown itself, or it might create a separate thread to do so. If the server tries to create a shutdown thread and cannot (for example, if memory is exhausted), it issues a diagnostic message that appears in the error log:

```
Error: Can't create thread to kill server
```

3. The server stops accepting new connections.

To prevent new activity from being initiated during shutdown, the server stops accepting new client connections by closing the handlers for the network interfaces to which it normally listens for connections: the TCP/IP port, the Unix socket file, the Windows named pipe, and shared memory on Windows.

4. The server terminates current activity.

For each thread associated with a client connection, the server breaks the connection to the client and marks the thread as killed. Threads die when they notice that they are so marked. Threads for idle connections die quickly. Threads that currently are processing statements check their state periodically and take longer to die. For additional information about thread termination, see [Section 13.7.6.4, “KILL Syntax”](#), in particular for the instructions about killed [REPAIR TABLE](#) or [OPTIMIZE TABLE](#) operations on [MyISAM](#) tables.

For threads that have an open transaction, the transaction is rolled back. Note that if a thread is updating a nontransactional table, an operation such as a multiple-row [UPDATE](#) or [INSERT](#) may leave the table partially updated because the operation can terminate before completion.

If the server is a master replication server, it treats threads associated with currently connected slaves like other client threads. That is, each one is marked as killed and exits when it next checks its state.

If the server is a slave replication server, it stops the I/O and SQL threads, if they are active, before marking client threads as killed. The SQL thread is permitted to finish its current statement (to avoid causing replication problems), and then stops. If the SQL thread is in the middle of a transaction at this point, the server waits until the current replication event group (if any) has finished executing, or until the user issues a [KILL QUERY](#) or [KILL CONNECTION](#) statement. See also [Section 13.4.2.6, “STOP SLAVE Syntax”](#).

If the slave is updating a nontransactional table when it is forcibly killed, the slave's data may become inconsistent with the master.

5. The server shuts down or closes storage engines.

At this stage, the server flushes the table cache and closes all open tables.

Each storage engine performs any actions necessary for tables that it manages. For example, [MyISAM](#) flushes any pending index writes for a table. [InnoDB](#) flushes its buffer pool to disk (unless [innodb_fast_shutdown](#) is 2), writes the current LSN to the tablespace, and terminates its own internal threads.

6. The server exits.

5.2 MySQL Server Logs

MySQL Server has several logs that can help you find out what activity is taking place.

Log Type	Information Written to Log
Error log	Problems encountered starting, running, or stopping mysqld
General query log	Established client connections and statements received from clients
Binary log	Statements that change data (also used for replication)
Relay log	Data changes received from a replication master server
Slow query log	Queries that took more than long_query_time seconds to execute

By default, no logs are enabled (except the error log on Windows). The following log-specific sections provide information about the server options that enable logging.

By default, the server writes files for all enabled logs in the data directory. You can force the server to close and reopen the log files (or in some cases switch to a new log file) by flushing the logs. Log flushing occurs when you issue a [FLUSH LOGS](#) statement; execute [mysqladmin](#) with a [flush-logs](#)

or `refresh` argument; or execute `mysqldump` with a `--flush-logs` or `--master-data` option. See [Section 13.7.6.3, “FLUSH Syntax”](#), [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#), and [Section 4.5.4, “mysqldump — A Database Backup Program”](#). In addition, the binary log is flushed when its size reaches the value of the `max_binlog_size` system variable.

You can control the general query and slow query logs during runtime. You can enable or disable logging, or change the log file name. You can tell the server to write general query and slow query entries to log tables, log files, or both. For details, see [Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”](#), [Section 5.2.3, “The General Query Log”](#), and [Section 5.2.5, “The Slow Query Log”](#).

The relay log is used only on slave replication servers, to hold data changes from the master server that must also be made on the slave. For discussion of relay log contents and configuration, see [Section 17.2.2.1, “The Slave Relay Log”](#).

For information about log maintenance operations such as expiration of old log files, see [Section 5.2.6, “Server Log Maintenance”](#).

For information about keeping logs secure, see [Section 6.1.2.3, “Passwords and Logging”](#).

5.2.1 Selecting General Query and Slow Query Log Output Destinations

MySQL Server provides flexible control over the destination of output to the general query log and the slow query log, if those logs are enabled. Possible destinations for log entries are log files or the `general_log` and `slow_log` tables in the `mysql` database. Either or both destinations can be selected.

Before MySQL 5.5.7, logging to tables incurs significantly more server overhead than logging to files. If you enable the general log or slow query log and require highest performance, you should use file logging, not table logging.

Log control at server startup. The `--log-output` option specifies the destination for log output. This option does not in itself enable the logs. Its syntax is `--log-output[=value,...]`:

- If `--log-output` is given with a value, the value should be a comma-separated list of one or more of the words `TABLE` (log to tables), `FILE` (log to files), or `NONE` (do not log to tables or files). `NONE`, if present, takes precedence over any other specifiers.
- If `--log-output` is omitted, the default logging destination is `FILE`.

The `general_log` system variable controls logging to the general query log for the selected log destinations. If specified at server startup, `general_log` takes an optional argument of 1 or 0 to enable or disable the log. To specify a file name other than the default for file logging, set the `general_log_file` variable. Similarly, the `slow_query_log` variable controls logging to the slow query log for the selected destinations and setting `slow_query_log_file` specifies a file name for file logging. If either log is enabled, the server opens the corresponding log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected.

Examples:

- To write general query log entries to the log table and the log file, use `--log-output=TABLE,FILE` to select both log destinations and `--general_log` to enable the general query log.
- To write general and slow query log entries only to the log tables, use `--log-output=TABLE` to select tables as the log destination and `--general_log` and `--slow_query_log` to enable both logs.
- To write slow query log entries only to the log file, use `--log-output=FILE` to select files as the log destination and `--slow_query_log` to enable the slow query log. (In this case, because the default log destination is `FILE`, you could omit the `--log-output` option.)

Log control at runtime. The system variables associated with log tables and files enable runtime control over logging:

- The global `log_output` system variable indicates the current logging destination. It can be modified at runtime to change the destination.
- The global `general_log` and `slow_query_log` variables indicate whether the general query log and slow query log are enabled (`ON`) or disabled (`OFF`). You can set these variables at runtime to control whether the logs are enabled.
- The global `general_log_file` and `slow_query_log_file` variables indicate the names of the general query log and slow query log files. You can set these variables at server startup or at runtime to change the names of the log files.
- To disable or enable general query logging for the current connection, set the session `sql_log_off` variable to `ON` or `OFF`.

The use of tables for log output offers the following benefits:

- Log entries have a standard format. To display the current structure of the log tables, use these statements:

```
SHOW CREATE TABLE mysql.general_log;
SHOW CREATE TABLE mysql.slow_log;
```

- Log contents are accessible through SQL statements. This enables the use of queries that select only those log entries that satisfy specific criteria. For example, to select log contents associated with a particular client (which can be useful for identifying problematic queries from that client), it is easier to do this using a log table than a log file.
- Logs are accessible remotely through any client that can connect to the server and issue queries (if the client has the appropriate log table privileges). It is not necessary to log in to the server host and directly access the file system.

The log table implementation has the following characteristics:

- In general, the primary purpose of log tables is to provide an interface for users to observe the runtime execution of the server, not to interfere with its runtime execution.
- `CREATE TABLE`, `ALTER TABLE`, and `DROP TABLE` are valid operations on a log table. For `ALTER TABLE` and `DROP TABLE`, the log table cannot be in use and must be disabled, as described later.
- By default, the log tables use the `CSV` storage engine that writes data in comma-separated values format. For users who have access to the `.CSV` files that contain log table data, the files are easy to import into other programs such as spreadsheets that can process CSV input.

The log tables can be altered to use the `MyISAM` storage engine. You cannot use `ALTER TABLE` to alter a log table that is in use. The log must be disabled first. No engines other than `CSV` or `MyISAM` are legal for the log tables.

- To disable logging so that you can alter (or drop) a log table, you can use the following strategy. The example uses the general query log; the procedure for the slow query log is similar but uses the `slow_log` table and `slow_query_log` system variable.

```
SET @old_log_state = @@global.general_log;
SET GLOBAL general_log = 'OFF';
ALTER TABLE mysql.general_log ENGINE = MyISAM;
```

```
SET GLOBAL general_log = @old_log_state;
```

- `TRUNCATE TABLE` is a valid operation on a log table. It can be used to expire log entries.
- `RENAME TABLE` is a valid operation on a log table. You can atomically rename a log table (to perform log rotation, for example) using the following strategy:

```
USE mysql;
DROP TABLE IF EXISTS general_log2;
CREATE TABLE general_log2 LIKE general_log;
RENAME TABLE general_log TO general_log_backup, general_log2 TO general_log;
```

- As of MySQL 5.5.7, `CHECK TABLE` is a valid operation on a log table.
- `LOCK TABLES` cannot be used on a log table.
- `INSERT`, `DELETE`, and `UPDATE` cannot be used on a log table. These operations are permitted only internally to the server itself.
- `FLUSH TABLES WITH READ LOCK` and the state of the global `read_only` system variable have no effect on log tables. The server can always write to the log tables.
- Entries written to the log tables are not written to the binary log and thus are not replicated to slave servers.
- To flush the log tables or log files, use `FLUSH TABLES` or `FLUSH LOGS`, respectively.
- Partitioning of log tables is not permitted.
- Before MySQL 5.5.25, `mysqldump` does not dump the `general_log` or `slow_query_log` tables for dumps of the `mysql` database. As of 5.5.25, the dump includes statements to recreate those tables so that they are not missing after reloading the dump file. Log table contents are not dumped.

5.2.2 The Error Log

The error log contains information indicating when `mysqld` was started and stopped and also any critical errors that occur while the server is running. If `mysqld` notices a table that needs to be automatically checked or repaired, it writes a message to the error log.

On some operating systems, the error log contains a stack trace if `mysqld` dies. The trace can be used to determine where `mysqld` died. See [Section 24.4, “Debugging and Porting MySQL”](#).

In the following discussion, “console” means `stderr`, the standard error output; this is your terminal or console window unless the standard error output has been redirected. (For example, if invoked with the `--syslog` option, `mysqld_safe` arranges for the server's `stderr` to be sent to the `syslog` facility, as described later.)

On Windows, the `--log-error` and `--console` options both affect error logging:

- Without `--log-error`, `mysqld` writes error messages to `host_name.err` in the data directory.
- With `--log-error[=file_name]`, `mysqld` writes error messages to an error log file. The server uses the named file if present, creating it in the data directory unless an absolute path name is given to specify a different directory. If no file is named, the default name is `host_name.err` in the data directory.
- If `--console` is given, `mysqld` writes error messages to the console, unless `--log-error` is also given. If both options are present, `--console` is ignored and has no effect. Their order does not matter:

`--log-error` takes precedence and error messages go to a log file. (Before MySQL 5.5.3, if both options are given, the last one takes precedence.)

In addition, on Windows, events and error messages are written to the Windows Event Log within the Application log. Entries marked as `Warning` and `Note` are written to the Event Log, but not informational messages such as information statements from individual storage engines. These log entries have a source of `MySQL`. You cannot disable writing information to the Windows Event Log.

On Unix and Unix-like systems, `mysqld` writes error log messages as follows:

- Without `--log-error`, `mysqld` writes error messages to the console.
- With `--log-error[=file_name]`, `mysqld` writes error messages to an error log file. The server uses the named file if present, creating it in the data directory unless an absolute path name is given to specify a different directory. If no file is named, the default name is `host_name.err` in the data directory.

At runtime, `log_error` system variable indicates the error log file name if error output is written to a file.

If you flush the logs using `FLUSH LOGS` or `mysqladmin flush-logs` and `mysqld` is writing the error log to a file (for example, if it was started with the `--log-error` option), the effect is version dependent:

- As of MySQL 5.5.7, the server closes and reopens the log file. To rename the file, do so manually before flushing. Then flushing the logs reopens a new file with the original file name. For example, you can rename the file and create a new one using the following commands:

```
shell> mv host_name.err host_name.err-old
shell> mysqladmin flush-logs
shell> mv host_name.err-old backup-directory
```

On Windows, use `rename` rather than `mv`.

- Prior to MySQL 5.5.7, the server renames the current log file with the suffix `-old`, then creates a new empty log file. Be aware that a second log-flushing operation thus causes the original error log file to be lost unless you save it under a different name. On Windows, you cannot rename the error log while the server has it open before MySQL 5.5.7. To avoid a restart, flush the logs first to cause the server to rename the original file and create a new one, then save the renamed file. That also works on Unix, or you can use the commands shown earlier.

No error log renaming occurs when the logs are flushed in any case if the server is not writing to a named file.

If you use `mysqld_safe` to start `mysqld`, `mysqld_safe` arranges for `mysqld` to write error messages to a log file or to `syslog`. `mysqld_safe` has three error-logging options, `--syslog`, `--skip-syslog`, and `--log-error`. The default with no logging options or with `--skip-syslog` is to use the default log file. To explicitly specify use of an error log file, specify `--log-error=file_name` to `mysqld_safe`, and `mysqld_safe` will arrange for `mysqld` to write messages to a log file. To use `syslog` instead, specify the `--syslog` option.

If you specify `--log-error` in an option file in a `[mysqld]`, `[server]`, or `[mysqld_safe]` section, `mysqld_safe` will find and use the option.

If `mysqld_safe` is used to start `mysqld` and `mysqld` dies unexpectedly, `mysqld_safe` notices that it needs to restart `mysqld` and writes a `restarted mysqld` message to the error log.

The `--log-warnings` option or `log_warnings` system variable can be used to control warning logging to the error log. The default value is enabled (1). Warning logging can be disabled using a value of 0. If the

value is greater than 1, aborted connections are written to the error log, and access-denied errors for new connection attempts are written. See [Section B.5.2.11, “Communication Errors and Aborted Connections”](#).

5.2.3 The General Query Log

The general query log is a general record of what `mysqld` is doing. The server writes information to this log when clients connect or disconnect, and it logs each SQL statement received from clients. The general query log can be very useful when you suspect an error in a client and want to know exactly what the client sent to `mysqld`.

`mysqld` writes statements to the query log in the order that it receives them, which might differ from the order in which they are executed. This logging order is in contrast with that of the binary log, for which statements are written after they are executed but before any locks are released. In addition, the query log may contain statements that only select data while such statements are never written to the binary log.

When using statement-based logging all statements are written to the query log, but when using row-based logging, updates are sent as row changes rather than SQL statements, and thus these statements are never written to the query log when `binlog_format` is `ROW`. A given update also might not be written to the query log when this variable is set to `MIXED`, depending on the statement used. See [Section 17.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#), for more information.

By default, the general query log is disabled. To specify the initial general query log state explicitly, use `--general_log[={0|1}]`. With no argument or an argument of 1, `--general_log` enables the log. With an argument of 0, this option disables the log. To specify a log file name, use `--general_log_file=file_name`. To specify the log destination, use `--log-output` (as described in [Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”](#)). The older options to enable the general query log, `--log` and `-l`, are deprecated.

If you specify no name for the general query log file, the default name is `host_name.log`. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

To disable or enable the general query log or change the log file name at runtime, use the global `general_log` and `general_log_file` system variables. Set `general_log` to 0 (or `OFF`) to disable the log or to 1 (or `ON`) to enable it. Set `general_log_file` to specify the name of the log file. If a log file already is open, it is closed and the new file is opened.

When the general query log is enabled, the server writes output to any destinations specified by the `--log-output` option or `log_output` system variable. If you enable the log, the server opens the log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected. If the destination is `NONE`, the server writes no queries even if the general log is enabled. Setting the log file name has no effect on logging if the log destination value does not contain `FILE`.

Server restarts and log flushing do not cause a new general query log file to be generated (although flushing closes and reopens it). To rename the file and create a new one, use the following commands:

```
shell> mv host_name.log host_name-old.log
shell> mysqladmin flush-logs
shell> mv host_name-old.log backup-directory
```

On Windows, use `rename` rather than `mv`.

You can also rename the general query log file at runtime by disabling the log:

```
SET GLOBAL general_log = 'OFF';
```

With the log disabled, rename the log file externally; for example, from the command line. Then enable the log again:

```
SET GLOBAL general_log = 'ON';
```

This method works on any platform and does not require a server restart.

The session `sql_log_off` variable can be set to `ON` or `OFF` to disable or enable general query logging for the current connection.

The general query log should be protected because logged statements might contain passwords. See [Section 6.1.2.3, “Passwords and Logging”](#).

5.2.4 The Binary Log

The binary log contains “events” that describe database changes such as table creation operations or changes to table data. It also contains events for statements that potentially could have made changes (for example, a `DELETE` which matched no rows), unless row-based logging is used. The binary log also contains information about how long each statement took that updated data. The binary log has two important purposes:

- For replication, the binary log on a master replication server provides a record of the data changes to be sent to slave servers. The master server sends the events contained in its binary log to its slaves, which execute those events to make the same data changes that were made on the master. See [Section 17.2, “Replication Implementation”](#).
- Certain data recovery operations require use of the binary log. After a backup has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See [Section 7.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#).

The binary log is not used for statements such as `SELECT` or `SHOW` that do not modify data. To log all statements (for example, to identify a problem query), use the general query log. See [Section 5.2.3, “The General Query Log”](#).

Running a server with binary logging enabled makes performance slightly slower. However, the benefits of the binary log in enabling you to set up replication and for restore operations generally outweigh this minor performance decrement.

The binary log should be protected because logged statements might contain passwords. See [Section 6.1.2.3, “Passwords and Logging”](#).

The following discussion describes some of the server options and variables that affect the operation of binary logging. For a complete list, see [Section 17.1.3.4, “Binary Log Options and Variables”](#).

To enable the binary log, start the server with the `--log-bin[=base_name]` option. If no `base_name` value is given, the default name is the value of the `pid-file` option (which by default is the name of host machine) followed by `-bin`. If the basename is given, the server writes the file in the data directory unless the basename is given with a leading absolute path name to specify a different directory. It is recommended that you specify a basename explicitly rather than using the default of the host name; see [Section B.5.8, “Known Issues in MySQL”](#), for the reason.

If you supply an extension in the log name (for example, `--log-bin=base_name.extension`), the extension is silently removed and ignored.

`mysqld` appends a numeric extension to the binary log basename to generate binary log file names. The number increases each time the server creates a new log file, thus creating an ordered series of files. The

server creates a new file in the series each time it starts or flushes the logs. The server also creates a new binary log file automatically after the current log's size reaches `max_binlog_size`. A binary log file may become larger than `max_binlog_size` if you are using large transactions because a transaction is written to the file in one piece, never split between files.

To keep track of which binary log files have been used, `mysqld` also creates a binary log index file that contains the names of all used binary log files. By default, this has the same basename as the binary log file, with the extension `'.index'`. You can change the name of the binary log index file with the `--log-bin-index[=file_name]` option. You should not manually edit this file while `mysqld` is running; doing so would confuse `mysqld`.

The term “binary log file” generally denotes an individual numbered file containing database events. The term “binary log” collectively denotes the set of numbered binary log files plus the index file.

A client that has the `SUPER` privilege can disable binary logging of its own statements by using a `SET sql_log_bin=0` statement. See [Section 5.1.4, “Server System Variables”](#).

The format of the events recorded in the binary log is dependent on the binary logging format. Three format types are supported, row-based logging, statement-based logging and mixed-base logging. The binary logging format used depends on the MySQL version. For general descriptions of the logging formats, see [Section 5.2.4.1, “Binary Logging Formats”](#). For detailed information about the format of the binary log, see [MySQL Internals: The Binary Log](#).

The server evaluates the `--binlog-do-db` and `--binlog-ignore-db` options in the same way as it does the `--replicate-do-db` and `--replicate-ignore-db` options. For information about how this is done, see [Section 17.2.3.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#).

If you are replicating from a MySQL Cluster to a standalone MySQL Server, you should be aware that the `NDB` storage engine uses default values for some binary logging options (including options specific to `NDB` such as `--ndb-log-update-as-write` [2534]) that differ from those used by other storage engines. If not corrected for, these differences can lead to divergence of the master's and slave's binary logs. For more information, see [Replication from NDB to other storage engines](#). In particular, if you are using a nontransactional storage engine such as `MyISAM` on the slave, see [Replication from NDB to a nontransactional storage engine](#).

A replication slave server by default does not write to its own binary log any data modifications that are received from the replication master. To log these modifications, start the slave with the `--log-slave-updates` option in addition to the `--log-bin` option (see [Section 17.1.3.3, “Replication Slave Options and Variables”](#)). This is done when a slave is also to act as a master to other slaves in chained replication.

You can delete all binary log files with the `RESET MASTER` statement, or a subset of them with `PURGE BINARY LOGS`. See [Section 13.7.6.6, “RESET Syntax”](#), and [Section 13.4.1.1, “PURGE BINARY LOGS Syntax”](#).

If you are using replication, you should not delete old binary log files on the master until you are sure that no slave still needs to use them. For example, if your slaves never run more than three days behind, once a day you can execute `mysqladmin flush-logs` on the master and then remove any logs that are more than three days old. You can remove the files manually, but it is preferable to use `PURGE BINARY LOGS`, which also safely updates the binary log index file for you (and which can take a date argument). See [Section 13.4.1.1, “PURGE BINARY LOGS Syntax”](#).

You can display the contents of binary log files with the `mysqlbinlog` utility. This can be useful when you want to reprocess statements in the log for a recovery operation. For example, you can update a MySQL server from the binary log as follows:

```
shell> mysqlbinlog log_file | mysql -h server_name
```

`mysqlbinlog` also can be used to display replication slave relay log file contents because they are written using the same format as binary log files. For more information on the `mysqlbinlog` utility and how to use it, see [Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”](#). For more information about the binary log and recovery operations, see [Section 7.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#).

Binary logging is done immediately after a statement or transaction completes but before any locks are released or any commit is done. This ensures that the log is logged in commit order.

Updates to nontransactional tables are stored in the binary log immediately after execution.

Within an uncommitted transaction, all updates (`UPDATE`, `DELETE`, or `INSERT`) that change transactional tables such as `InnoDB` tables are cached until a `COMMIT` statement is received by the server. At that point, `mysqld` writes the entire transaction to the binary log before the `COMMIT` is executed.

Modifications to nontransactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to nontransactional tables, the entire transaction is logged with a `ROLLBACK` statement at the end to ensure that the modifications to those tables are replicated.

When a thread that handles the transaction starts, it allocates a buffer of `binlog_cache_size` to buffer statements. If a statement is bigger than this, the thread opens a temporary file to store the transaction. The temporary file is deleted when the thread ends.

The `Binlog_cache_use` status variable shows the number of transactions that used this buffer (and possibly a temporary file) for storing statements. The `Binlog_cache_disk_use` status variable shows how many of those transactions actually had to use a temporary file. These two variables can be used for tuning `binlog_cache_size` to a large enough value that avoids the use of temporary files.

The `max_binlog_cache_size` system variable (default 4GB, which is also the maximum) can be used to restrict the total size used to cache a multiple-statement transaction. If a transaction is larger than this many bytes, it fails and rolls back. The minimum value is 4096.

If you are using the binary log and row based logging, concurrent inserts are converted to normal inserts for `CREATE ... SELECT` or `INSERT ... SELECT` statements. This is done to ensure that you can re-create an exact copy of your tables by applying the log during a backup operation. If you are using statement-based logging, the original statement is written to the log.

The binary log format has some known limitations that can affect recovery from backups. See [Section 17.4.1, “Replication Features and Issues”](#).

Binary logging for stored programs is done as described in [Section 20.7, “Binary Logging of Stored Programs”](#).

Note that the binary log format differs in MySQL 5.5 from previous versions of MySQL, due to enhancements in replication. See [Section 17.4.2, “Replication Compatibility Between MySQL Versions”](#).

Writes to the binary log file and binary log index file are handled in the same way as writes to `MyISAM` tables. See [Section B.5.4.3, “How MySQL Handles a Full Disk”](#).

By default, the binary log is not synchronized to disk at each write. So if the operating system or machine (not only the MySQL server) crashes, there is a chance that the last statements of the binary log are lost. To prevent this, you can make the binary log be synchronized to disk after every `N` writes to the binary log, with the `sync_binlog` system variable. See [Section 5.1.4, “Server System Variables”](#). 1 is the safest value for `sync_binlog`, but also the slowest. Even with `sync_binlog` set to 1, there is still the chance of an inconsistency between the table content and binary log content in case of a crash. For example, if you are using `InnoDB` tables and the MySQL server processes a `COMMIT` statement, it writes the whole transaction to the binary log and then commits this transaction into `InnoDB`. If the server crashes between

those two operations, the transaction is rolled back by [InnoDB](#) at restart but still exists in the binary log. To resolve this, you should set `--innodb_support_xa` to 1. Although this option is related to the support of XA transactions in InnoDB, it also ensures that the binary log and InnoDB data files are synchronized.

For this option to provide a greater degree of safety, the MySQL server should also be configured to synchronize the binary log and the [InnoDB](#) logs to disk at every transaction. The [InnoDB](#) logs are synchronized by default, and `sync_binlog=1` can be used to synchronize the binary log. The effect of this option is that at restart after a crash, after doing a rollback of transactions, the MySQL server cuts rolled back [InnoDB](#) transactions from the binary log. This ensures that the binary log reflects the exact data of [InnoDB](#) tables, and so, that the slave remains in synchrony with the master (not receiving a statement which has been rolled back).

If the MySQL server discovers at crash recovery that the binary log is shorter than it should have been, it lacks at least one successfully committed [InnoDB](#) transaction. This should not happen if `sync_binlog=1` and the disk/file system do an actual sync when they are requested to (some do not), so the server prints an error message `The binary log file_name is shorter than its expected size`. In this case, this binary log is not correct and replication should be restarted from a fresh snapshot of the master's data.

The session values of the following system variables are written to the binary log and honored by the replication slave when parsing the binary log:

- `sql_mode` (except that the `NO_DIR_IN_CREATE` mode is not replicated; see [Section 17.4.1.36](#), “Replication and Variables”)
- `foreign_key_checks`
- `unique_checks`
- `character_set_client`
- `collation_connection`
- `collation_database`
- `collation_server`
- `sql_auto_is_null`

5.2.4.1 Binary Logging Formats

The server uses several logging formats to record information in the binary log. The exact format employed depends on the version of MySQL being used. There are three logging formats:

- Replication capabilities in MySQL originally were based on propagation of SQL statements from master to slave. This is called *statement-based logging*. You can cause this format to be used by starting the server with `--binlog-format=STATEMENT`.
- In *row-based logging*, the master writes events to the binary log that indicate how individual table rows are affected. You can cause the server to use row-based logging by starting it with `--binlog-format=ROW`.
- A third option is also available: *mixed logging*. With mixed logging, statement-based logging is used by default, but the logging mode switches automatically to row-based in certain cases as described below. You can cause MySQL to use mixed logging explicitly by starting `mysqld` with the option `--binlog-format=MIXED`.

In MySQL 5.5, the default binary logging format is `STATEMENT`.

The logging format can also be set or limited by the storage engine being used. This helps to eliminate issues when replicating certain statements between a master and slave which are using different storage engines.

With statement-based replication, there may be issues with replicating nondeterministic statements. In deciding whether or not a given statement is safe for statement-based replication, MySQL determines whether it can guarantee that the statement can be replicated using statement-based logging. If MySQL cannot make this guarantee, it marks the statement as potentially unreliable and issues the warning, *Statement may not be safe to log in statement format*.

You can avoid these issues by using MySQL's row-based replication instead.

5.2.4.2 Setting The Binary Log Format

You can select the binary logging format explicitly by starting the MySQL server with `--binlog-format=type`. The supported values for `type` are:

- `STATEMENT` causes logging to be statement based.
- `ROW` causes logging to be row based.
- `MIXED` causes logging to use mixed format.

In MySQL 5.5, the default binary logging format is `STATEMENT`. This includes MySQL Cluster NDB 7.2.1 and later MySQL Cluster NDB 7.2 releases, which are based on MySQL 5.5.

The logging format also can be switched at runtime. To specify the format globally for all clients, set the global value of the `binlog_format` system variable:

```
mysql> SET GLOBAL binlog_format = 'STATEMENT';
mysql> SET GLOBAL binlog_format = 'ROW';
mysql> SET GLOBAL binlog_format = 'MIXED';
```

An individual client can control the logging format for its own statements by setting the session value of `binlog_format`:

```
mysql> SET SESSION binlog_format = 'STATEMENT';
mysql> SET SESSION binlog_format = 'ROW';
mysql> SET SESSION binlog_format = 'MIXED';
```

Note

Each MySQL Server can set its own and only its own binary logging format (true whether `binlog_format` is set with global or session scope). This means that changing the logging format on a replication master does not cause a slave to change its logging format to match. (When using `STATEMENT` mode, the `binlog_format` system variable is not replicated; when using `MIXED` or `ROW` logging mode, it is replicated but is ignored by the slave.) Changing the binary logging format on the master while replication is ongoing, or without also changing it on the slave can thus cause unexpected results, or even cause replication to fail altogether.

To change the global or session `binlog_format` value, you must have the `SUPER` privilege.

In addition to switching the logging format manually, a slave server may switch the format *automatically*. This happens when the server is running in either `STATEMENT` or `MIXED` format and encounters an event in the binary log that is written in `ROW` logging format. In that case, the slave switches to row-based replication temporarily for that event, and switches back to the previous format afterward.

There are several reasons why a client might want to set binary logging on a per-session basis:

- A session that makes many small changes to the database might want to use row-based logging.
- A session that performs updates that match many rows in the `WHERE` clause might want to use statement-based logging because it will be more efficient to log a few statements than many rows.
- Some statements require a lot of execution time on the master, but result in just a few rows being modified. It might therefore be beneficial to replicate them using row-based logging.

There are exceptions when you cannot switch the replication format at runtime:

- From within a stored function or a trigger
- If the `NDBCLUSTER` storage engine is enabled
- If the session is currently in row-based replication mode and has open temporary tables

Trying to switch the format in any of these cases results in an error.

If you are using `InnoDB` tables and the transaction isolation level is `READ COMMITTED` or `READ UNCOMMITTED`, only row-based logging can be used. It is *possible* to change the logging format to `STATEMENT`, but doing so at runtime leads very rapidly to errors because `InnoDB` can no longer perform inserts.

Switching the replication format at runtime is not recommended when any temporary tables exist, because temporary tables are logged only when using statement-based replication, whereas with row-based replication they are not logged. With mixed replication, temporary tables are usually logged; exceptions happen with user-defined functions (UDFs) and with the `UUID()` function.

With the binary log format set to `ROW`, many changes are written to the binary log using the row-based format. Some changes, however, still use the statement-based format. Examples include all DDL (data definition language) statements such as `CREATE TABLE`, `ALTER TABLE`, or `DROP TABLE`.

The `--binlog-row-event-max-size` option is available for servers that are capable of row-based replication. Rows are stored into the binary log in chunks having a size in bytes not exceeding the value of this option. The value must be a multiple of 256. The default value is 1024.

Warning

When using *statement-based logging* for replication, it is possible for the data on the master and slave to become different if a statement is designed in such a way that the data modification is *nondeterministic*; that is, it is left to the will of the query optimizer. In general, this is not a good practice even outside of replication. For a detailed explanation of this issue, see [Section B.5.8, “Known Issues in MySQL”](#).

5.2.4.3 Mixed Binary Logging Format

When running in `MIXED` logging format, the server automatically switches from statement-based to row-based logging under the following conditions:

- When a DML statement updates an `NDBCLUSTER` table.
- When a function contains `UUID()`.
- When one or more tables with `AUTO_INCREMENT` columns are updated and a trigger or stored function is invoked. Like all other unsafe statements, this generates a warning if `binlog_format = STATEMENT`.

For more information, see [Section 17.4.1.1, “Replication and `AUTO_INCREMENT`”](#).

- When any `INSERT DELAYED` is executed.
- When the body of a view requires row-based replication, the statement creating the view also uses it. For example, this occurs when the statement creating a view uses the `UUID()` function.
- When a call to a UDF is involved.
- If a statement is logged by row and the session that executed the statement has any temporary tables, logging by row is used for all subsequent statements (except for those accessing temporary tables) until all temporary tables in use by that session are dropped.

This is true whether or not any temporary tables are actually logged.

Temporary tables cannot be logged using row-based format; thus, once row-based logging is used, all subsequent statements using that table are unsafe. The server approximates this condition by treating all statements executed during the session as unsafe until the session no longer holds any temporary tables.

- When `FOUND_ROWS()` or `ROW_COUNT()` is used. (Bug #12092, Bug #30244)
- When `USER()`, `CURRENT_USER()`, or `CURRENT_USER` is used. (Bug #28086)
- When a statement refers to one or more system variables. (Bug #31168)

Exception. The following system variables, when used with session scope (only), do not cause the logging format to switch:

- `auto_increment_increment`
- `auto_increment_offset`
- `character_set_client`
- `character_set_connection`
- `character_set_database`
- `character_set_server`
- `collation_connection`
- `collation_database`
- `collation_server`
- `foreign_key_checks`
- `identity`
- `last_insert_id`
- `lc_time_names`
- `pseudo_thread_id`
- `sql_auto_is_null`

- `time_zone`
- `timestamp`
- `unique_checks`

For information about determining system variable scope, see [Section 5.1.5, “Using System Variables”](#).

For information about how replication treats `sql_mode`, see [Section 17.4.1.36, “Replication and Variables”](#).

- When one of the tables involved is a log table in the `mysql` database.
- When the `LOAD_FILE()` function is used. (Bug #39701)

Note

A warning is generated if you try to execute a statement using statement-based logging that should be written using row-based logging. The warning is shown both in the client (in the output of `SHOW WARNINGS`) and through the `mysqld` error log. A warning is added to the `SHOW WARNINGS` table each time such a statement is executed. However, only the first statement that generated the warning for each client session is written to the error log to prevent flooding the log.

In addition to the decisions above, individual engines can also determine the logging format used when information in a table is updated. The logging capabilities of an individual engine can be defined as follows:

- If an engine supports row-based logging, the engine is said to be *row-logging capable*.
- If an engine supports statement-based logging, the engine is said to be *statement-logging capable*.

A given storage engine can support either or both logging formats. The following table lists the formats supported by each engine.

Storage Engine	Row Logging Supported	Statement Logging Supported
<code>ARCHIVE</code>	Yes	Yes
<code>BLACKHOLE</code>	Yes	Yes
<code>CSV</code>	Yes	Yes
<code>EXAMPLE</code>	Yes	No
<code>FEDERATED</code>	Yes	Yes
<code>HEAP</code>	Yes	Yes
<code>InnoDB</code>	Yes	Yes when the transaction isolation level is <code>REPEATABLE READ</code> or <code>SERIALIZABLE</code> ; No otherwise.
<code>MyISAM</code>	Yes	Yes
<code>MERGE</code>	Yes	Yes
<code>NDBCLUSTER</code>	Yes	No

In MySQL 5.5.3 and later, whether a statement is to be logged and the logging mode to be used is determined according to the type of statement (safe, unsafe, or binary injected), the binary logging format

([STATEMENT](#), [ROW](#), or [MIXED](#)), and the logging capabilities of the storage engine (statement capable, row capable, both, or neither). (Binary injection refers to logging a change that must be logged using [ROW](#) format.)

Statements may be logged with or without a warning; failed statements are not logged, but generate errors in the log. This is shown in the following decision table, where **SLC** stands for “statement-logging capable” and **RLC** stands for “row-logging capable”.

Condition				Action	
Type	binlog_format	SLC	RLC	Error / Warning	Logged as
*	*	No	No	Error: Cannot execute statement: Binary logging is impossible since at least one engine is involved that is both row-incapable and statement-incapable.	–
Safe	STATEMENT	Yes	No	–	STATEMENT
Safe	MIXED	Yes	No	–	STATEMENT
Safe	ROW	Yes	No	Error: Cannot execute statement: Binary logging is impossible since BINLOG_FORMAT = ROW and at least one table uses a storage engine that is not capable of row-based logging.	–
Unsafe	STATEMENT	Yes	No	Warning: Unsafe statement binlogged in statement format, since BINLOG_FORMAT = STATEMENT	STATEMENT
Unsafe	MIXED	Yes	No	Error: Cannot execute statement: Binary logging of an unsafe statement is impossible when the storage engine is limited to statement-based logging, even if	–

Condition				Action	
Type	binlog_format	SLC	RLC	Error / Warning	Logged as
				<code>BINLOG_FORMAT = MIXED.</code>	
Unsafe	<code>ROW</code>	Yes	No	<code>Error: Cannot execute statement:</code> Binary logging is impossible since <code>BINLOG_FORMAT = ROW</code> and at least one table uses a storage engine that is not capable of row-based logging.	-
Row Injection	<code>STATEMENT</code>	Yes	No	<code>Error: Cannot execute row injection:</code> Binary logging is not possible since at least one table uses a storage engine that is not capable of row-based logging.	-
Row Injection	<code>MIXED</code>	Yes	No	<code>Error: Cannot execute row injection:</code> Binary logging is not possible since at least one table uses a storage engine that is not capable of row-based logging.	-
Row Injection	<code>ROW</code>	Yes	No	<code>Error: Cannot execute row injection:</code> Binary logging is not possible since at least one table uses a storage engine that is not capable of row-based logging.	-
Safe	<code>STATEMENT</code>	No	Yes	<code>Error: Cannot execute statement:</code> Binary logging is impossible since <code>BINLOG_FORMAT =</code>	-

Condition				Action	
Type	binlog_format	SLC	RLC	Error / Warning	Logged as
				STATEMENT and at least one table uses a storage engine that is not capable of statement-based logging.	
Safe	MIXED	No	Yes	-	ROW
Safe	ROW	No	Yes	-	ROW
Unsafe	STATEMENT	No	Yes	Error: Cannot execute statement: Binary logging is impossible since BINLOG_FORMAT = STATEMENT and at least one table uses a storage engine that is not capable of statement-based logging.	-
Unsafe	MIXED	No	Yes	-	ROW
Unsafe	ROW	No	Yes	-	ROW
Row Injection	STATEMENT	No	Yes	Error: Cannot execute row injection: Binary logging is not possible since BINLOG_FORMAT = STATEMENT.	-
Row Injection	MIXED	No	Yes	-	ROW
Row Injection	ROW	No	Yes	-	ROW
Safe	STATEMENT	Yes	Yes	-	STATEMENT
Safe	MIXED	Yes	Yes	-	STATEMENT
Safe	ROW	Yes	Yes	-	ROW
Unsafe	STATEMENT	Yes	Yes	Warning: Unsafe statement binlogged in statement format since BINLOG_FORMAT = STATEMENT.	STATEMENT
Unsafe	MIXED	Yes	Yes	-	ROW
Unsafe	ROW	Yes	Yes	-	ROW

Condition				Action	
Type	binlog_format	SLC	RLC	Error / Warning	Logged as
Row Injection	STATEMENT	Yes	Yes	Error: Cannot execute row injection: Binary logging is not possible because BINLOG_FORMAT = STATEMENT.	-
Row Injection	MIXED	Yes	Yes	-	ROW
Row Injection	ROW	Yes	Yes	-	ROW

Handling of mixed-format logging in MySQL 5.5.2 and earlier. The decision-making process for binary logging changed in MySQL 5.5.3, due to the fix for Bug #39934. Prior to MySQL 5.5.3, when determining the logging mode to be used, the capabilities of all the tables affected by the event are combined, and the set of affected tables is then marked according to these rules:

- A set of tables is defined as *row-logging restricted* if the tables are row-logging capable but not statement-logging capable.
- A set of tables is defined as *statement-logging restricted* if the tables are statement-logging capable but not row-logging capable.

Once the determination of the possible logging formats required by the statement is complete it is compared to the current `binlog_format` setting. The following table is used in MySQL 5.5.2 and earlier to decide how the information is recorded in the binary log or, if appropriate, whether an error is raised. In the table, a safe operation is defined as one that is deterministic.

In MySQL 5.5.2 and earlier, several rules decide whether the statement is deterministic, as shown in the following table, where **SLR** stands for “statement-logging restricted” and **RLR** stands for “row-logging restricted”. A statement is *statement-logging restricted* if one or more of the tables it accesses is not row-logging capable. Similarly, a statement is *row-logging restricted* if any table accessed by the statement is not statement-logging capable.

Condition				Action	
Safe/ unsafe	binlog_format	SLR	RLR	Error/Warning	Logged as
Safe	STATEMENT	Yes	Yes	Error: not loggable	
Safe	STATEMENT	Yes	No		STATEMENT
Safe	STATEMENT	No	Yes	Error: not loggable	
Safe	STATEMENT	No	No		STATEMENT
Safe	MIXED	Yes	Yes	Error: not loggable	
Safe	MIXED	Yes	No		STATEMENT
Safe	MIXED	No	Yes		ROW

Condition				Action	
Safe/ unsafe	<code>binlog_format</code>	SLR	RLR	Error/Warning	Logged as
Safe	<code>MIXED</code>	No	No		<code>STATEMENT</code>
Safe	<code>ROW</code>	Yes	Yes	Error: not loggable	
Safe	<code>ROW</code>	Yes	No	Error: not loggable	
Safe	<code>ROW</code>	No	Yes		<code>ROW</code>
Safe	<code>ROW</code>	No	No		<code>ROW</code>
Unsafe	<code>STATEMENT</code>	Yes	Yes	Error: not loggable	
Unsafe	<code>STATEMENT</code>	Yes	No	Warning: unsafe	<code>STATEMENT</code>
Unsafe	<code>STATEMENT</code>	No	Yes	Error: not loggable	
Unsafe	<code>STATEMENT</code>	No	No	Warning: unsafe	<code>STATEMENT</code>
Unsafe	<code>MIXED</code>	Yes	Yes	Error: not loggable	
Unsafe	<code>MIXED</code>	Yes	No	Error: not loggable	
Unsafe	<code>MIXED</code>	No	Yes		<code>ROW</code>
Unsafe	<code>MIXED</code>	No	No		<code>ROW</code>
Unsafe	<code>ROW</code>	Yes	Yes	Error: not loggable	
Unsafe	<code>ROW</code>	Yes	No	Error: not loggable	
Unsafe	<code>ROW</code>	No	Yes		<code>ROW</code>
Unsafe	<code>ROW</code>	No	No		<code>ROW</code>

In all MySQL 5.5 releases, when a warning is produced by the determination, a standard MySQL warning is produced (and is available using `SHOW WARNINGS`). The information is also written to the `mysqld` error log. Only one error for each error instance per client connection is logged to prevent flooding the log. The log message includes the SQL statement that was attempted.

If a slave server was started with `--log-warnings` enabled, the slave prints messages to the error log to provide information about its status, such as the binary log and relay log coordinates where it starts its job, when it is switching to another relay log, when it reconnects after a disconnect, and so forth.

5.2.4.4 Logging Format for Changes to `mysql` Database Tables

The contents of the grant tables in the `mysql` database can be modified directly (for example, with `INSERT` or `DELETE`) or indirectly (for example, with `GRANT` or `CREATE USER`). Statements that affect `mysql` database tables are written to the binary log using the following rules:

- Data manipulation statements that change data in `mysql` database tables directly are logged according to the setting of the `binlog_format` system variable. This pertains to statements such as `INSERT`, `UPDATE`, `DELETE`, `REPLACE`, `DO`, `LOAD DATA INFILE`, `SELECT`, and `TRUNCATE TABLE`.

- Statements that change the `mysql` database indirectly are logged as statements regardless of the value of `binlog_format`. This pertains to statements such as `GRANT`, `REVOKE`, `SET PASSWORD`, `RENAME USER`, `CREATE` (all forms except `CREATE TABLE ... SELECT`), `ALTER` (all forms), and `DROP` (all forms).

`CREATE TABLE ... SELECT` is a combination of data definition and data manipulation. The `CREATE TABLE` part is logged using statement format and the `SELECT` part is logged according to the value of `binlog_format`.

5.2.5 The Slow Query Log

The slow query log consists of SQL statements that took more than `long_query_time` seconds to execute and required at least `min_examined_row_limit` rows to be examined. The minimum and default values of `long_query_time` are 0 and 10, respectively. The value can be specified to a resolution of microseconds. For logging to a file, times are written including the microseconds part. For logging to tables, only integer times are written; the microseconds part is ignored.

By default, administrative statements are not logged, nor are queries that do not use indexes for lookups. This behavior can be changed using `--log-slow-admin-statements` and `log_queries_not_using_indexes`, as described later.

The time to acquire the initial locks is not counted as execution time. `mysqld` writes a statement to the slow query log after it has been executed and after all locks have been released, so log order might differ from execution order.

By default, the slow query log is disabled. To specify the initial slow query log state explicitly, use `--slow_query_log[={0|1}]`. With no argument or an argument of 1, `--slow_query_log` enables the log. With an argument of 0, this option disables the log. To specify a log file name, use `--slow_query_log_file=file_name`. To specify the log destination, use `--log-output` (as described in Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”). The older option to enable the slow query log file, `--log-slow-queries`, is deprecated.

If you specify no name for the slow query log file, the default name is `host_name-slow.log`. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

To disable or enable the slow query log or change the log file name at runtime, use the global `slow_query_log` and `slow_query_log_file` system variables. Set `slow_query_log` to 0 (or `OFF`) to disable the log or to 1 (or `ON`) to enable it. Set `slow_query_log_file` to specify the name of the log file. If a log file already is open, it is closed and the new file is opened.

When the slow query log is enabled, the server writes output to any destinations specified by the `--log-output` option or `log_output` system variable. If you enable the log, the server opens the log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected. If the destination is `NONE`, the server writes no queries even if the slow query log is enabled. Setting the log file name has no effect on logging if the log destination value does not contain `FILE`.

The server writes less information to the slow query log (and binary log) if you use the `--log-short-format` option.

To include slow administrative statements in the statements written to the slow query log, use the `--log-slow-admin-statements` server option. Administrative statements include `ALTER TABLE`, `ANALYZE TABLE`, `CHECK TABLE`, `CREATE INDEX`, `DROP INDEX`, `OPTIMIZE TABLE`, and `REPAIR TABLE`.

To include queries that do not use indexes for row lookups in the statements written to the slow query log, enable the `log_queries_not_using_indexes` system variable. When such queries are logged, the slow query log may grow quickly.

The server uses the controlling parameters in the following order to determine whether to write a query to the slow query log:

1. The query must either not be an administrative statement, or `--log-slow-admin-statements` must have been specified.
2. The query must have taken at least `long_query_time` seconds, or `log_queries_not_using_indexes` must be enabled and the query used no indexes for row lookups.
3. The query must have examined at least `min_examined_row_limit` rows.

The server does not write queries handled by the query cache to the slow query log, nor queries that would not benefit from the presence of an index because the table has zero rows or one row.

By default, a replication slave does not write replicated queries to the slow query log. To change this, use the `--log-slow-slave-statements` server option.

The slow query log should be protected because logged statements might contain passwords. See [Section 6.1.2.3, “Passwords and Logging”](#).

The slow query log can be used to find queries that take a long time to execute and are therefore candidates for optimization. However, examining a long slow query log can become a difficult task. To make this easier, you can process a slow query log file using the `mysqldumpslow` command to summarize the queries that appear in the log. See [Section 4.6.8, “mysqldumpslow — Summarize Slow Query Log Files”](#).

5.2.6 Server Log Maintenance

As described in [Section 5.2, “MySQL Server Logs”](#), MySQL Server can create several different log files to help you see what activity is taking place. However, you must clean up these files regularly to ensure that the logs do not take up too much disk space.

When using MySQL with logging enabled, you may want to back up and remove old log files from time to time and tell MySQL to start logging to new files. See [Section 7.2, “Database Backup Methods”](#).

On a Linux (Red Hat) installation, you can use the `mysql-log-rotate` script for this. If you installed MySQL from an RPM distribution, this script should have been installed automatically. Be careful with this script if you are using the binary log for replication. You should not remove binary logs until you are certain that their contents have been processed by all slaves.

On other systems, you must install a short script yourself that you start from `cron` (or its equivalent) for handling log files.

For the binary log, you can set the `expire_logs_days` system variable to expire binary log files automatically after a given number of days (see [Section 5.1.4, “Server System Variables”](#)). If you are using replication, you should set the variable no lower than the maximum number of days your slaves might lag behind the master. To remove binary logs on demand, use the `PURGE BINARY LOGS` statement (see [Section 13.4.1.1, “PURGE BINARY LOGS Syntax”](#)).

You can force MySQL to start using new log files by flushing the logs. Log flushing occurs when you issue a `FLUSH LOGS` statement or execute a `mysqladmin flush-logs`, `mysqladmin refresh`, `mysqldump --flush-logs`, or `mysqldump --master-data` command. See [Section 13.7.6.3, “FLUSH Syntax”](#), [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#), and [Section 4.5.4, “mysqldump — A Database Backup Program”](#). In addition, the binary log is flushed when its size reaches the value of the `max_binlog_size` system variable.

As of MySQL 5.5.3, `FLUSH LOGS` supports optional modifiers to enable selective flushing of individual logs (for example, `FLUSH BINARY LOGS`).

A log-flushing operation does the following:

- If general query logging or slow query logging to a log file is enabled, the server closes and reopens the general query log file or slow query log file.
- If binary logging is enabled, the server closes the current binary log file and opens a new log file with the next sequence number.
- If the server was started with the `--log-error` option to cause the error log to be written to a file, the result of a log-flushing operation is version dependent:
 - As of MySQL 5.5.7, the server closes and reopens the log file.
 - Prior to MySQL 5.5.7, the server renames the current log file with the suffix `-old`, then creates a new empty log file.

The server creates a new binary log file when you flush the logs. However, it just closes and reopens the general and slow query log files. To cause new files to be created on Unix, rename the current log files before flushing them. At flush time, the server opens new log files with the original names. For example, if the general and slow query log files are named `mysql.log` and `mysql-slow.log`, you can use a series of commands like this:

```
shell> cd mysql-data-directory
shell> mv mysql.log mysql.old
shell> mv mysql-slow.log mysql-slow.old
shell> mysqladmin flush-logs
```

On Windows, use `rename` rather than `mv`.

At this point, you can make a backup of `mysql.old` and `mysql-slow.old` and then remove them from disk.

A similar strategy can be used to back up the error log file, if there is one, except that, on Windows, you cannot rename the error log file while the server has it open before MySQL 5.5.7. To rename the error log file, a stop and restart can be avoided by flushing the logs to cause the server to rename the current log file with the suffix `-old` and create a new empty error log file. For further information, see [Section 5.2.2, “The Error Log”](#).

You can rename the general query log or slow query log at runtime by disabling the log:

```
SET GLOBAL general_log = 'OFF';
SET GLOBAL slow_query_log = 'OFF';
```

With the logs disabled, rename the log files externally; for example, from the command line. Then enable the logs again:

```
SET GLOBAL general_log = 'ON';
SET GLOBAL slow_query_log = 'ON';
```

This method works on any platform and does not require a server restart.

5.3 Running Multiple MySQL Instances on One Machine

In some cases, you might want to run multiple instances of MySQL on a single machine. You might want to test a new MySQL release while leaving an existing production setup undisturbed. Or you might want to

give different users access to different `mysqld` servers that they manage themselves. (For example, you might be an Internet Service Provider that wants to provide independent MySQL installations for different customers.)

It is possible to use a different MySQL server binary per instance, or use the same binary for multiple instances, or any combination of the two approaches. For example, you might run a server from MySQL 5.1 and one from MySQL 5.5, to see how different versions handle a given workload. Or you might run multiple instances of the current production version, each managing a different set of databases.

Whether or not you use distinct server binaries, each instance that you run must be configured with unique values for several operating parameters. This eliminates the potential for conflict between instances. Parameters can be set on the command line, in option files, or by setting environment variables. See [Section 4.2.3, “Specifying Program Options”](#). To see the values used by a given instance, connect to it and execute a `SHOW VARIABLES` statement.

The primary resource managed by a MySQL instance is the data directory. Each instance should use a different data directory, the location of which is specified using the `--datadir=path` option. For methods of configuring each instance with its own data directory, and warnings about the dangers of failing to do so, see [Section 5.3.1, “Setting Up Multiple Data Directories”](#).

In addition to using different data directories, several other options must have different values for each server instance:

- `--port=port_num`

`--port` controls the port number for TCP/IP connections. Alternatively, if the host has multiple network addresses, you can use `--bind-address` to cause each server to listen to a different address.

- `--socket=path`

`--socket` controls the Unix socket file path on Unix or the named pipe name on Windows. On Windows, it is necessary to specify distinct pipe names only for those servers configured to permit named-pipe connections.

- `--shared-memory-base-name=name`

This option is used only on Windows. It designates the shared-memory name used by a Windows server to permit clients to connect using shared memory. It is necessary to specify distinct shared-memory names only for those servers configured to permit shared-memory connections.

- `--pid-file=file_name`

This option indicates the path name of the file in which the server writes its process ID.

If you use the following log file options, their values must differ for each server:

- `--general_log_file=file_name`
- `--log-bin[=file_name]`
- `--slow_query_log_file=file_name`
- `--log-error[=file_name]`

For further discussion of log file options, see [Section 5.2, “MySQL Server Logs”](#).

To achieve better performance, you can specify the following option differently for each server, to spread the load between several physical disks:

- `--tmpdir=path`

Having different temporary directories also makes it easier to determine which MySQL server created any given temporary file.

If you have multiple MySQL installations in different locations, you can specify the base directory for each installation with the `--basedir=path` option. This causes each instance to automatically use a different data directory, log files, and PID file because the default for each of those parameters is relative to the base directory. In that case, the only other options you need to specify are the `--socket` and `--port` options. Suppose that you install different versions of MySQL using `tar` file binary distributions. These install in different locations, so you can start the server for each installation using the command `bin/mysqld_safe` under its corresponding base directory. `mysqld_safe` determines the proper `--basedir` option to pass to `mysqld`, and you need specify only the `--socket` and `--port` options to `mysqld_safe`.

As discussed in the following sections, it is possible to start additional servers by specifying appropriate command options or by setting environment variables. However, if you need to run multiple servers on a more permanent basis, it is more convenient to use option files to specify for each server those option values that must be unique to it. The `--defaults-file` option is useful for this purpose.

5.3.1 Setting Up Multiple Data Directories

Each MySQL Instance on a machine should have its own data directory. The location is specified using the `--datadir=path` option.

There are different methods of setting up a data directory for a new instance:

- Create a new data directory.
- Copy an existing data directory.

The following discussion provides more detail about each method.

Warning

Normally, you should never have two servers that update data in the same databases. This may lead to unpleasant surprises if your operating system does not support fault-free system locking. If (despite this warning) you run multiple servers using the same data directory and they have logging enabled, you must use the appropriate options to specify log file names that are unique to each server. Otherwise, the servers try to log to the same files.

Even when the preceding precautions are observed, this kind of setup works only with `MyISAM` and `MERGE` tables, and not with any of the other storage engines. Also, this warning against sharing a data directory among servers always applies in an NFS environment. Permitting multiple MySQL servers to access a common data directory over NFS is a *very bad idea*. The primary problem is that NFS is the speed bottleneck. It is not meant for such use. Another risk with NFS is that you must devise a way to ensure that two or more servers do not interfere with each other. Usually NFS file locking is handled by the `lockd` daemon, but at the moment there is no platform that performs locking 100% reliably in every situation.

Create a New Data Directory

With this method, the data directory will be in the same state as when you first install MySQL. It will have the default set of MySQL accounts and no user data.

On Unix, initialize the data directory by running `mysql_install_db`. See [Section 2.10.1, “Postinstallation Procedures for Unix-like Systems”](#).

On Windows, the data directory is included in the MySQL distribution:

- MySQL Zip archive distributions for Windows contain an unmodified data directory. You can unpack such a distribution into a temporary location, then copy it `data` directory to where you are setting up the new instance.
- As of MySQL 5.5.5, Windows MSI package installers create and set up the data directory that the installed server will use, but also create a pristine “template” data directory named `data` under the installation directory. After an installation has been performed using an MSI package, the template data directory can be copied to set up additional MySQL instances.

Copy an Existing Data Directory

With this method, any MySQL accounts or user data present in the data directory are carried over to the new data directory.

1. Stop the existing MySQL instance using the data directory. This must be a clean shutdown so that the instance flushes any pending changes to disk.
2. Copy the data directory to the location where the new data directory should be.
3. Copy the `my.cnf` or `my.ini` option file used by the existing instance. This serves as a basis for the new instance.
4. Modify the new option file so that any pathnames referring to the original data directory refer to the new data directory. Also, modify any other options that must be unique per instance, such as the TCP/IP port number and the log files. For a list of parameters that must be unique per instance, see [Section 5.3, “Running Multiple MySQL Instances on One Machine”](#).
5. Start the new instance, telling it to use the new option file.

5.3.2 Running Multiple MySQL Instances on Windows

You can run multiple servers on Windows by starting them manually from the command line, each with appropriate operating parameters, or by installing several servers as Windows services and running them that way. General instructions for running MySQL from the command line or as a service are given in [Section 2.3, “Installing MySQL on Microsoft Windows”](#). The following sections describe how to start each server with different values for those options that must be unique per server, such as the data directory. These options are listed in [Section 5.3, “Running Multiple MySQL Instances on One Machine”](#).

5.3.2.1 Starting Multiple MySQL Instances at the Windows Command Line

The procedure for starting a single MySQL server manually from the command line is described in [Section 2.3.7.5, “Starting MySQL from the Windows Command Line”](#). To start multiple servers this way, you can specify the appropriate options on the command line or in an option file. It is more convenient to place the options in an option file, but it is necessary to make sure that each server gets its own set of options. To do this, create an option file for each server and tell the server the file name with a `--defaults-file` option when you run it.

Suppose that you want to run `mysqld` on port 3307 with a data directory of `C:\mydata1`, and `mysqld-debug` on port 3308 with a data directory of `C:\mydata2`. Use this procedure:

1. Make sure that each data directory exists, including its own copy of the `mysql` database that contains the grant tables.

2. Create two option files. For example, create one file named `C:\my-opts1.cnf` that looks like this:

```
[mysqld]
datadir = C:/mydata1
port = 3307
```

Create a second file named `C:\my-opts2.cnf` that looks like this:

```
[mysqld]
datadir = C:/mydata2
port = 3308
```

3. Use the `--defaults-file` option to start each server with its own option file:

```
C:\> C:\mysql\bin\mysqld --defaults-file=C:\my-opts1.cnf
C:\> C:\mysql\bin\mysqld-debug --defaults-file=C:\my-opts2.cnf
```

Each server starts in the foreground (no new prompt appears until the server exits later), so you will need to issue those two commands in separate console windows.

To shut down the servers, connect to each using the appropriate port number:

```
C:\> C:\mysql\bin\mysqladmin --port=3307 shutdown
C:\> C:\mysql\bin\mysqladmin --port=3308 shutdown
```

Servers configured as just described permit clients to connect over TCP/IP. If your version of Windows supports named pipes and you also want to permit named-pipe connections, use the `mysqld` or `mysqld-debug` server and specify options that enable the named pipe and specify its name. Each server that supports named-pipe connections must use a unique pipe name. For example, the `C:\my-opts1.cnf` file might be written like this:

```
[mysqld]
datadir = C:/mydata1
port = 3307
enable-named-pipe
socket = mypipe1
```

Modify `C:\my-opts2.cnf` similarly for use by the second server. Then start the servers as described previously.

A similar procedure applies for servers that you want to permit shared-memory connections. Enable such connections with the `--shared-memory` option and specify a unique shared-memory name for each server with the `--shared-memory-base-name` option.

5.3.2.2 Starting Multiple MySQL Instances as Windows Services

On Windows, a MySQL server can run as a Windows service. The procedures for installing, controlling, and removing a single MySQL service are described in [Section 2.3.7.7, “Starting MySQL as a Windows Service”](#).

To set up multiple MySQL services, you must make sure that each instance uses a different service name in addition to the other parameters that must be unique per instance.

For the following instructions, suppose that you want to run the `mysqld` server from two different versions of MySQL that are installed at `C:\mysql-5.1.55` and `C:\mysql-5.5.40`, respectively. (This might be the case if you are running 5.1.55 as your production server, but also want to conduct tests using 5.5.40.)

To install MySQL as a Windows service, use the `--install` or `--install-manual` option. For information about these options, see [Section 2.3.7.7, “Starting MySQL as a Windows Service”](#).

Based on the preceding information, you have several ways to set up multiple services. The following instructions describe some examples. Before trying any of them, shut down and remove any existing MySQL services.

- **Approach 1:** Specify the options for all services in one of the standard option files. To do this, use a different service name for each server. Suppose that you want to run the 5.1.55 `mysqld` using the service name of `mysqld1` and the 5.5.40 `mysqld` using the service name `mysqld2`. In this case, you can use the `[mysqld1]` group for 5.1.55 and the `[mysqld2]` group for 5.5.40. For example, you can set up `C:\my.cnf` like this:

```
# options for mysqld1 service
[mysqld1]
basedir = C:/mysql-5.1.55
port = 3307
enable-named-pipe
socket = mypipel

# options for mysqld2 service
[mysqld2]
basedir = C:/mysql-5.5.40
port = 3308
enable-named-pipe
socket = mypipe2
```

Install the services as follows, using the full server path names to ensure that Windows registers the correct executable program for each service:

```
C:\> C:\mysql-5.1.55\bin\mysqld --install mysqld1
C:\> C:\mysql-5.5.40\bin\mysqld --install mysqld2
```

To start the services, use the services manager, or use `NET START` with the appropriate service names:

```
C:\> NET START mysqld1
C:\> NET START mysqld2
```

To stop the services, use the services manager, or use `NET STOP` with the appropriate service names:

```
C:\> NET STOP mysqld1
C:\> NET STOP mysqld2
```

- **Approach 2:** Specify options for each server in separate files and use `--defaults-file` when you install the services to tell each server what file to use. In this case, each file should list options using a `[mysqld]` group.

With this approach, to specify options for the 5.1.55 `mysqld`, create a file `C:\my-opts1.cnf` that looks like this:

```
[mysqld]
basedir = C:/mysql-5.1.55
port = 3307
enable-named-pipe
socket = mypipel
```

For the 5.5.40 `mysqld`, create a file `C:\my-opts2.cnf` that looks like this:

```
[mysqld]
basedir = C:/mysql-5.5.40
port = 3308
enable-named-pipe
socket = mypipe2
```

Install the services as follows (enter each command on a single line):

```
C:\> C:\mysql-5.1.55\bin\mysqld --install mysql1
--defaults-file=C:\my-opts1.cnf
C:\> C:\mysql-5.5.40\bin\mysqld --install mysql2
--defaults-file=C:\my-opts2.cnf
```

When you install a MySQL server as a service and use a `--defaults-file` option, the service name must precede the option.

After installing the services, start and stop them the same way as in the preceding example.

To remove multiple services, use `mysqld --remove` for each one, specifying a service name following the `--remove` option. If the service name is the default (MySQL), you can omit it.

5.3.3 Running Multiple MySQL Instances on Unix

One way is to run multiple MySQL instances on Unix is to compile different servers with different default TCP/IP ports and Unix socket files so that each one listens on different network interfaces. Compiling in different base directories for each installation also results automatically in a separate, compiled-in data directory, log file, and PID file location for each server.

Assume that an existing 5.1 server is configured for the default TCP/IP port number (3306) and Unix socket file (`/tmp/mysql.sock`). To configure a new 5.5.40 server to have different operating parameters, use a `CMake` command something like this:

```
shell> cmake . -DMYSQL_TCP_PORT=port_number \
--DMYSQL_UNIX_ADDR=file_name \
-DCMAKE_INSTALL_PREFIX=/usr/local/mysql-5.5.40
```

Here, `port_number` and `file_name` must be different from the default TCP/IP port number and Unix socket file path name, and the `CMAKE_INSTALL_PREFIX` value should specify an installation directory different from the one under which the existing MySQL installation is located.

If you have a MySQL server listening on a given port number, you can use the following command to find out what operating parameters it is using for several important configurable variables, including the base directory and Unix socket file name:

```
shell> mysqladmin --host=host_name --port=port_number variables
```

With the information displayed by that command, you can tell what option values *not* to use when configuring an additional server.

If you specify `localhost` as the host name, `mysqladmin` defaults to using a Unix socket file connection rather than TCP/IP. To explicitly specify the connection protocol, use the `--protocol={TCP|SOCKET|PIPE|MEMORY}` option.

You need not compile a new MySQL server just to start with a different Unix socket file and TCP/IP port number. It is also possible to use the same server binary and start each invocation of it with different parameter values at runtime. One way to do so is by using command-line options:

```
shell> mysqld_safe --socket=file_name --port=port_number
```

To start a second server, provide different `--socket` and `--port` option values, and pass a `--datadir=path` option to `mysqld_safe` so that the server uses a different data directory.

Alternatively, put the options for each server in a different option file, then start each server using a `--defaults-file` option that specifies the path to the appropriate option file. For example, if the option files for two server instances are named `/usr/local/mysql/my.cnf` and `/usr/local/mysql/my.cnf2`, start the servers like this: command:

```
shell> mysqld_safe --defaults-file=/usr/local/mysql/my.cnf
shell> mysqld_safe --defaults-file=/usr/local/mysql/my.cnf2
```

Another way to achieve a similar effect is to use environment variables to set the Unix socket file name and TCP/IP port number:

```
shell> MYSQL_UNIX_PORT=/tmp/mysqld-new.sock
shell> MYSQL_TCP_PORT=3307
shell> export MYSQL_UNIX_PORT MYSQL_TCP_PORT
shell> mysql_install_db --user=mysql
shell> mysqld_safe --datadir=/path/to/datadir &
```

This is a quick way of starting a second server to use for testing. The nice thing about this method is that the environment variable settings apply to any client programs that you invoke from the same shell. Thus, connections for those clients are automatically directed to the second server.

[Section 2.12, “Environment Variables”](#), includes a list of other environment variables you can use to affect MySQL programs.

On Unix, the `mysqld_multi` script provides another way to start multiple servers. See [Section 4.3.4, “mysqld_multi — Manage Multiple MySQL Servers”](#).

5.3.4 Using Client Programs in a Multiple-Server Environment

To connect with a client program to a MySQL server that is listening to different network interfaces from those compiled into your client, you can use one of the following methods:

- Start the client with `--host=host_name --port=port_number` to connect using TCP/IP to a remote server, with `--host=127.0.0.1 --port=port_number` to connect using TCP/IP to a local server, or with `--host=localhost --socket=file_name` to connect to a local server using a Unix socket file or a Windows named pipe.
- Start the client with `--protocol=TCP` to connect using TCP/IP, `--protocol=SOCKET` to connect using a Unix socket file, `--protocol=PIPE` to connect using a named pipe, or `--protocol=MEMORY` to connect using shared memory. For TCP/IP connections, you may also need to specify `--host` and `--port` options. For the other types of connections, you may need to specify a `--socket` option to specify a Unix socket file or Windows named-pipe name, or a `--shared-memory-base-name` option to specify the shared-memory name. Shared-memory connections are supported only on Windows.
- On Unix, set the `MYSQL_UNIX_PORT` and `MYSQL_TCP_PORT` environment variables to point to the Unix socket file and TCP/IP port number before you start your clients. If you normally use a specific socket file or port number, you can place commands to set these environment variables in your `.login` file so that they apply each time you log in. See [Section 2.12, “Environment Variables”](#).
- Specify the default Unix socket file and TCP/IP port number in the `[client]` group of an option file. For example, you can use `C:\my.cnf` on Windows, or the `.my.cnf` file in your home directory on Unix. See [Section 4.2.6, “Using Option Files”](#).

- In a C program, you can specify the socket file or port number arguments in the `mysql_real_connect()` call. You can also have the program read option files by calling `mysql_options()`. See [Section 23.8.7, “C API Function Descriptions”](#).
- If you are using the Perl `DBD::mysql` module, you can read options from MySQL option files. For example:

```
$dsn = "DBI:mysql:test;mysql_read_default_group=client;"  
      . "mysql_read_default_file=/usr/local/mysql/data/my.cnf";  
$dbh = DBI->connect($dsn, $user, $password);
```

See [Section 23.10, “MySQL Perl API”](#).

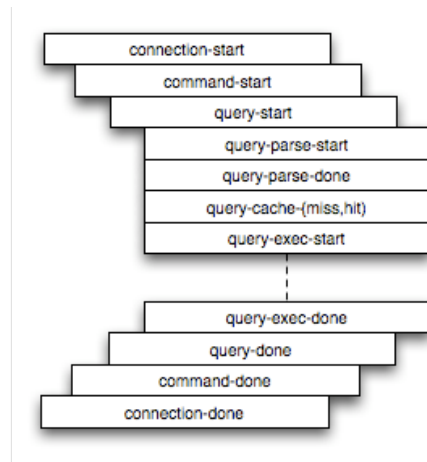

Other programming interfaces may provide similar capabilities for reading option files.

5.4 Tracing `mysqld` Using DTrace

The DTrace probes in the MySQL server are designed to provide information about the execution of queries within MySQL and the different areas of the system being utilized during that process. The organization and triggering of the probes means that the execution of an entire query can be monitored with one level of probes (`query-start` and `query-done`) but by monitoring other probes you can get successively more detailed information about the execution of the query in terms of the locks used, sort methods and even row-by-row and storage-engine level execution information.

The DTrace probes are organized so that you can follow the entire query process, from the point of connection from a client, through the query execution, row-level operations, and back out again. You can think of the probes as being fired within a specific sequence during a typical client connect/execute/disconnect sequence, as shown in the following figure.

Figure 5.1 The MySQL Architecture Using Pluggable Storage Engines

Global information is provided in the arguments to the DTrace probes at various levels. Global information, that is, the connection ID and user/host and where relevant the query string, is provided at key levels (`connection-start`, `command-start`, `query-start`, and `query-exec-start`). As you go deeper into the probes, it is assumed either you are only interested in the individual executions (row-level probes provide information on the database and table name only), or that you will combine the row-level probes with the notional parent probes to provide the information about a specific query. Examples of this will be given as the format and arguments of each probe are provided.

For more information on DTrace and writing DTrace scripts, read the [DTrace User Guide](#).

MySQL 5.5 includes support for DTrace probes on Solaris 10 Update 5 (Solaris 5/08) on SPARC, x86 and x86_64 platforms. Probes are also supported on Mac OS X 10.4 and higher. Enabling the probes should be automatic on these platforms. To explicitly enable or disable the probes during building, use the `-DENABLE_DTRACE=1` or `-DENABLE_DTRACE=0` option to CMake.

If a non-Solaris platform includes DTrace support, building `mysqld` on that platform will include DTrace support.

5.4.1 `mysqld` DTrace Probe Reference

MySQL supports the following static probes, organized into groups of functionality.

Table 5.5 MySQL DTrace Probes

Group	Probes
Connection	<code>connection-start</code> , <code>connection-done</code>
Command	<code>command-start</code> , <code>command-done</code>
Query	<code>query-start</code> , <code>query-done</code>
Query Parsing	<code>query-parse-start</code> , <code>query-parse-done</code>
Query Cache	<code>query-cache-hit</code> , <code>query-cache-miss</code>
Query Execution	<code>query-exec-start</code> , <code>query-exec-done</code>
Row Level	<code>insert-row-start</code> , <code>insert-row-done</code>
	<code>update-row-start</code> , <code>update-row-done</code>
	<code>delete-row-start</code> , <code>delete-row-done</code>
Row Reads	<code>read-row-start</code> , <code>read-row-done</code>
Index Reads	<code>index-read-row-start</code> , <code>index-read-row-done</code>
Lock	<code>handler-rdlock-start</code> , <code>handler-rdlock-done</code>
	<code>handler-wrlock-start</code> , <code>handler-wrlock-done</code>
	<code>handler-unlock-start</code> , <code>handler-unlock-done</code>
Filesort	<code>filesort-start</code> , <code>filesort-done</code>
Statement	<code>select-start</code> , <code>select-done</code>
	<code>insert-start</code> , <code>insert-done</code>
	<code>insert-select-start</code> , <code>insert-select-done</code>
	<code>update-start</code> , <code>update-done</code>
	<code>multi-update-start</code> , <code>multi-update-done</code>
	<code>delete-start</code> , <code>delete-done</code>
	<code>multi-delete-start</code> , <code>multi-delete-done</code>
Network	<code>net-read-start</code> , <code>net-read-done</code> , <code>net-write-start</code> , <code>net-write-done</code>
Keycache	<code>keycache-read-start</code> , <code>keycache-read-block</code> , <code>keycache-read-done</code> , <code>keycache-read-hit</code> , <code>keycache-read-miss</code> , <code>keycache-write-start</code> , <code>keycache-write-block</code> , <code>keycache-write-done</code>

Note

When extracting the argument data from the probes, each argument is available as `argN`, starting with `arg0`. To identify each argument within the definitions they are

provided with a descriptive name, but you must access the information using the corresponding `argN` parameter.

5.4.1.1 Connection Probes

The `connection-start` and `connection-done` probes enclose a connection from a client, regardless of whether the connection is through a socket or network connection.

```
connection-start(connectionid, user, host)
connection-done(status, connectionid)
```

- `connection-start`: Triggered after a connection and successful login/authentication have been completed by a client. The arguments contain the connection information:
 - `connectionid`: An `unsigned long` containing the connection ID. This is the same as the process ID shown as the `Id` value in the output from `SHOW PROCESSLIST`.
 - `user`: The username used when authenticating. The value will be blank for the anonymous user.
 - `host`: The host of the client connection. For a connection made using UNIX sockets, the value will be blank.
- `connection-done`: Triggered just as the connection to the client has been closed. The arguments are:
 - `status`: The status of the connection when it was closed. A logout operation will have a value of 0; any other termination of the connection has a nonzero value.
 - `connectionid`: The connection ID of the connection that was closed.

The following D script will quantify and summarize the average duration of individual connections, and provide a count, dumping the information every 60 seconds:

```
#!/usr/sbin/dtrace -s

mysql*:::connection-start
{
    self->start = timestamp;
}

mysql*:::connection-done
/self->start/
{
    @ = quantize(((timestamp - self->start)/1000000));
    self->start = 0;
}

tick-60s
{
    printa(@);
}
```

When executed on a server with a large number of clients you might see output similar to this:

```
1 57413                               :tick-60s

value  ----- Distribution ----- count
   -1 |                                0
    0 | @@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@ 30011
    1 |                                59
    2 |                                5
    4 |                                20
    8 |                                29
```

16	18
32	27
64	30
128	11
256	10
512	1
1024	6
2048	8
4096	9
8192	8
16384	2
32768	1
65536	1
131072	0
262144	1
524288	0

5.4.1.2 Command Probes

The command probes are executed before and after a client command is executed, including any SQL statement that might be executed during that period. Commands include operations such as the initialization of the DB, use of the `COM_CHANGE_USER` operation (supported by the MySQL protocol), and manipulation of prepared statements. Many of these commands are used only by the MySQL client API from various connectors such as PHP and Java.

```
command-start(connectionid, command, user, host)
command-done(status)
```

- `command-start`: Triggered when a command is submitted to the server.
- `connectionid`: The connection ID of the client executing the command.
- `command`: An integer representing the command that was executed. Possible values are shown in the following table.

Value	Name	Description
00	COM_SLEEP	Internal thread state
01	COM_QUIT	Close connection
02	COM_INIT_DB	Select database (<code>USE ...</code>)
03	COM_QUERY	Execute a query
04	COM_FIELD_LIST	Get a list of fields
05	COM_CREATE_DB	Create a database (deprecated)
06	COM_DROP_DB	Drop a database (deprecated)
07	COM_REFRESH	Refresh connection
08	COM_SHUTDOWN	Shutdown server
09	COM_STATISTICS	Get statistics
10	COM_PROCESS_INFO	Get processes (<code>SHOW PROCESSLIST</code>)
11	COM_CONNECT	Initialize connection
12	COM_PROCESS_KILL	Kill process
13	COM_DEBUG	Get debug information
14	COM_PING	Ping
15	COM_TIME	Internal thread state

Value	Name	Description
16	COM_DELAYED_INSERT	Insert a row into a delayed thread state
17	COM_CHANGE_USER	Change user
18	COM_BINLOG_DUMP	Used by a replication slave or <code>mysqlbinlog</code> to initiate a binary log read
19	COM_TABLE_DUMP	Used by a replication slave to get the master table information
20	COM_CONNECT_OUT	Used by a replication slave to log a connection to the server
21	COM_REGISTER_SLAVE	Used by a replication slave during registration
22	COM_STMT_PREPARE	Prepare a statement
23	COM_STMT_EXECUTE	Execute a statement
24	COM_STMT_SEND_LONG_DATA	Used by a client when requesting extended data
25	COM_STMT_CLOSE	Close a prepared statement
26	COM_STMT_RESET	Reset a prepared statement
27	COM_SET_OPTION	Set a server option
28	COM_STMT_FETCH	Fetch a prepared statement

- `user`: The user executing the command.
- `host`: The client host.
- `command-done`: Triggered when the command execution completes. The `status` argument contains 0 if the command executed successfully, or 1 if the statement was terminated before normal completion.

The `command-start` and `command-done` probes are best used when combined with the statement probes to get an idea of overall execution time.

5.4.1.3 Query Probes

The `query-start` and `query-done` probes are triggered when a specific query is received by the server and when the query has been completed and the information has been successfully sent to the client.

```
query-start(query, connectionid, database, user, host)
query-done(status)
```

- `query-start`: Triggered after the query string has been received from the client. The arguments are:
 - `query`: The full text of the submitted query.
 - `connectionid`: The connection ID of the client that submitted the query. The connection ID equals the connection ID returned when the client first connects and the `Id` value in the output from `SHOW PROCESSLIST`.
 - `database`: The database name on which the query is being executed.
 - `user`: The username used to connect to the server.
 - `host`: The hostname of the client.
- `query-done`: Triggered once the query has been executed and the information has been returned to the client. The probe includes a single argument, `status`, which returns 0 when the query is successfully executed and 1 if there was an error.

You can get a simple report of the execution time for each query using the following D script:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet

dtrace:::BEGIN
{
    printf("%-20s %-20s %-40s %-9s\n", "Who", "Database", "Query", "Time(ms)");
}

mysql*:::query-start
{
    self->query = copyinstr(arg0);
    self->connid = arg1;
    self->db = copyinstr(arg2);
    self->who = strjoin(copyinstr(arg3), strjoin("@", copyinstr(arg4)));
    self->querystart = timestamp;
}

mysql*:::query-done
{
    printf("%-20s %-20s %-40s %-9d\n", self->who, self->db, self->query,
        (timestamp - self->querystart) / 1000000);
}
```

When executing the above script you should get a basic idea of the execution time of your queries:

```
shell> ./query.d
```

Who	Database	Query	Time(ms)
root@localhost	test	select * from t1 order by i limit 10	0
root@localhost	test	set global query_cache_size=0	0
root@localhost	test	select * from t1 order by i limit 10	776
root@localhost	test	select * from t1 order by i limit 10	773
root@localhost	test	select * from t1 order by i desc limit 10	795

5.4.1.4 Query Parsing Probes

The query parsing probes are triggered before the original SQL statement is parsed and when the parsing of the statement and determination of the execution model required to process the statement has been completed:

```
query-parse-start(query)
query-parse-done(status)
```

- **query-parse-start**: Triggered just before the statement is parsed by the MySQL query parser. The single argument, **query**, is a string containing the full text of the original query.
- **query-parse-done**: Triggered when the parsing of the original statement has been completed. The **status** is an integer describing the status of the operation. A **0** indicates that the query was successfully parsed. A **1** indicates that the parsing of the query failed.

For example, you could monitor the execution time for parsing a given query using the following D script:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet

mysql*:::query-parse-start
{
    self->parsestart = timestamp;
    self->parsequery = copyinstr(arg0);
}
```

```
mysql*:::query-parse-done
/arg0 == 0/
{
    printf("Parsing %s: %d microseconds\n", self->parsequery, ((timestamp - self->parsestart)/1000));
}

mysql*:::query-parse-done
/arg0 != 0/
{
    printf("Error parsing %s: %d microseconds\n", self->parsequery, ((timestamp - self->parsestart)/1000));
}
```

In the above script a predicate is used on `query-parse-done` so that different output is generated based on the status value of the probe.

When running the script and monitoring the execution:

```
shell> ./query-parsing.d
Error parsing select from t1 join (t2) on (t1.i = t2.i) order by t1.s,t1.i limit 10: 36 ms
Parsing select * from t1 join (t2) on (t1.i = t2.i) order by t1.s,t1.i limit 10: 176 ms
```

5.4.1.5 Query Cache Probes

The query cache probes are fired when executing any query. The `query-cache-hit` query is triggered when a query exists in the query cache and can be used to return the query cache information. The arguments contain the original query text and the number of rows returned from the query cache for the query. If the query is not within the query cache, or the query cache is not enabled, then the `query-cache-miss` probe is triggered instead.

```
query-cache-hit(query, rows)
query-cache-miss(query)
```

- **query-cache-hit**: Triggered when the query has been found within the query cache. The first argument, `query`, contains the original text of the query. The second argument, `rows`, is an integer containing the number of rows in the cached query.
- **query-cache-miss**: Triggered when the query is not found within the query cache. The first argument, `query`, contains the original text of the query.

The query cache probes are best combined with a probe on the main query so that you can determine the differences in times between using or not using the query cache for specified queries. For example, in the following D script, the query and query cache information are combined into the information output during monitoring:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet

dtrace:::BEGIN
{
    printf("%-20s %-20s %-40s %2s %-9s\n", "Who", "Database", "Query", "QC", "Time(ms)");
}

mysql*:::query-start
{
    self->query = copyinstr(arg0);
    self->connid = arg1;
    self->db = copyinstr(arg2);
    self->who = strjoin(copyinstr(arg3), strjoin("@", copyinstr(arg4)));
    self->querystart = timestamp;
    self->qc = 0;
}
```

```
mysql*:::query-cache-hit
{
    self->qc = 1;
}

mysql*:::query-cache-miss
{
    self->qc = 0;
}

mysql*:::query-done
{
    printf("%-20s %-20s %-40s %-2s %-9d\n",self->who,self->db,self->query,(self->qc ? "Y" : "N"),
        (timestamp - self->querystart) / 1000000);
}
```

When executing the script you can see the effects of the query cache. Initially the query cache is disabled. If you set the query cache size and then execute the query multiple times you should see that the query cache is being used to return the query data:

```
shell> ./query-cache.d
root@localhost      test      select * from t1 order by i limit 10      N  1072
root@localhost      test      set global query_cache_size=262144      N   0
root@localhost      test      select * from t1 order by i limit 10      N  781
root@localhost      test      select * from t1 order by i limit 10      Y   0
```

5.4.1.6 Query Execution Probes

The query execution probe is triggered when the actual execution of the query starts, after the parsing and checking the query cache but before any privilege checks or optimization. By comparing the difference between the start and done probes you can monitor the time actually spent servicing the query (instead of just handling the parsing and other elements of the query).

```
query-exec-start(query, connectionid, database, user, host, exec_type)
query-exec-done(status)
```

Note

The information provided in the arguments for `query-start` and `query-exec-start` are almost identical and designed so that you can choose to monitor either the entire query process (using `query-start`) or only the execution (using `query-exec-start`) while exposing the core information about the user, client, and query being executed.

- `query-exec-start`: Triggered when the execution of a individual query is started. The arguments are:
 - `query`: The full text of the submitted query.
 - `connectionid`: The connection ID of the client that submitted the query. The connection ID equals the connection ID returned when the client first connects and the `Id` value in the output from `SHOW PROCESSLIST`.
 - `database`: The database name on which the query is being executed.
 - `user`: The username used to connect to the server.
 - `host`: The hostname of the client.
 - `exec_type`: The type of execution. Execution types are determined based on the contents of the query and where it was submitted. The values for each type are shown in the following table.

Value	Description
0	Executed query from sql_parse, top-level query.
1	Executed prepared statement
2	Executed cursor statement
3	Executed query in stored procedure

- `query-exec-done`: Triggered when the execution of the query has completed. The probe includes a single argument, `status`, which returns 0 when the query is successfully executed and 1 if there was an error.

5.4.1.7 Row-Level Probes

The `*row-{start,done}` probes are triggered each time a row operation is pushed down to a storage engine. For example, if you execute an `INSERT` statement with 100 rows of data, then the `insert-row-start` and `insert-row-done` probes will be triggered 100 times each, for each row insert.

```
insert-row-start(database, table)
insert-row-done(status)

update-row-start(database, table)
update-row-done(status)

delete-row-start(database, table)
delete-row-done(status)
```

- `insert-row-start`: Triggered before a row is inserted into a table.
- `insert-row-done`: Triggered after a row is inserted into a table.
- `update-row-start`: Triggered before a row is updated in a table.
- `update-row-done`: Triggered before a row is updated in a table.
- `delete-row-start`: Triggered before a row is deleted from a table.
- `delete-row-done`: Triggered before a row is deleted from a table.

The arguments supported by the probes are consistent for the corresponding `start` and `done` probes in each case:

- `database`: The database name.
- `table`: The table name.
- `status`: The status; 0 for success or 1 for failure.

Because the row-level probes are triggered for each individual row access, these probes can be triggered many thousands of times each second, which may have a detrimental effect on both the monitoring script and MySQL. The DTrace environment should limit the triggering on these probes to prevent the performance being adversely affected. Either use the probes sparingly, or use counter or aggregation functions to report on these probes and then provide a summary when the script terminates or as part of a `query-done` or `query-exec-done` probes.

The following example script summarizes the duration of each row operation within a larger query:

```
#!/usr/sbin/dtrace -s
```

```
#pragma D option quiet

dtrace::BEGIN
{
    printf("%-2s %-10s %-10s %9s %9s %-s \n",
           "St", "Who", "DB", "ConnID", "Dur ms", "Query");
}

mysql*:::query-start
{
    self->query = copyinstr(arg0);
    self->who   = strjoin(copyinstr(arg3),strjoin("@",copyinstr(arg4)));
    self->db    = copyinstr(arg2);
    self->connid = arg1;
    self->querystart = timestamp;
    self->rowdur = 0;
}

mysql*:::query-done
{
    this->elapsed = (timestamp - self->querystart) /1000000;
    printf("%2d %-10s %-10s %9d %9d %s\n",
           arg0, self->who, self->db,
           self->connid, this->elapsed, self->query);
}

mysql*:::query-done
/ self->rowdur /
{
    printf("%34s %9d %s\n", "", (self->rowdur/1000000), "-> Row ops");
}

mysql*:::insert-row-start
{
    self->rowstart = timestamp;
}

mysql*:::delete-row-start
{
    self->rowstart = timestamp;
}

mysql*:::update-row-start
{
    self->rowstart = timestamp;
}

mysql*:::insert-row-done
{
    self->rowdur += (timestamp-self->rowstart);
}

mysql*:::delete-row-done
{
    self->rowdur += (timestamp-self->rowstart);
}

mysql*:::update-row-done
{
    self->rowdur += (timestamp-self->rowstart);
}
```

Running the above script with a query that inserts data into a table, you can monitor the exact time spent performing the raw row insertion:

St	Who	DB	ConnID	Dur ms	Query
0	@localhost	test	13	20767	insert into t1(select * from t2)

5.4.1.8 Read Row Probes

The read row probes are triggered at a storage engine level each time a row read operation occurs. These probes are specified within each storage engine (as opposed to the `*row-start` probes which are in the storage engine interface). These probes can therefore be used to monitor individual storage engine row-level operations and performance. Because these probes are triggered around the storage engine row read interface, they may be hit a significant number of times during a basic query.

```
read-row-start(database, table, scan_flag)
read-row-done(status)
```

- `read-row-start`: Triggered when a row is read by the storage engine from the specified `database` and `table`. The `scan_flag` is set to 1 (true) when the read is part of a table scan (that is, a sequential read), or 0 (false) when the read is of a specific record.
- `read-row-done`: Triggered when a row read operation within a storage engine completes. The `status` returns 0 on success, or a positive value on failure.

5.4.1.9 Index Probes

The index probes are triggered each time a row is read using one of the indexes for the specified table. The probe is triggered within the corresponding storage engine for the table.

```
index-read-row-start(database, table)
index-read-row-done(status)
```

- `index-read-row-start`: Triggered when a row is read by the storage engine from the specified `database` and `table`.
- `index-read-row-done`: Triggered when an indexed row read operation within a storage engine completes. The `status` returns 0 on success, or a positive value on failure.

5.4.1.10 Lock Probes

The lock probes are called whenever an external lock is requested by MySQL for a table using the corresponding lock mechanism on the table as defined by the table's engine type. There are three different types of lock, the read lock, write lock, and unlock operations. Using the probes you can determine the duration of the external locking routine (that is, the time taken by the storage engine to implement the lock, including any time waiting for another lock to become free) and the total duration of the lock/unlock process.

```
handler-rdlock-start(database, table)
handler-rdlock-done(status)

handler-wrlock-start(database, table)
handler-wrlock-done(status)

handler-unlock-start(database, table)
handler-unlock-done(status)
```

- `handler-rdlock-start`: Triggered when a read lock is requested on the specified `database` and `table`.
- `handler-wrlock-start`: Triggered when a write lock is requested on the specified `database` and `table`.
- `handler-unlock-start`: Triggered when an unlock request is made on the specified `database` and `table`.

- `handler-rdlock-done`: Triggered when a read lock request completes. The `status` is 0 if the lock operation succeeded, or `>0` on failure.
- `handler-wrlock-done`: Triggered when a write lock request completes. The `status` is 0 if the lock operation succeeded, or `>0` on failure.
- `handler-unlock-done`: Triggered when an unlock request completes. The `status` is 0 if the unlock operation succeeded, or `>0` on failure.

You can use arrays to monitor the locking and unlocking of individual tables and then calculate the duration of the entire table lock using the following script:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet

mysql*:::handler-rdlock-start
{
    self->rdlockstart = timestamp;
    this->lockref = strjoin(copyinstr(arg0),strjoin("@",copyinstr(arg1)));
    self->lockmap[this->lockref] = self->rdlockstart;
    printf("Start: Lock->Read   %s.%s\n",copyinstr(arg0),copyinstr(arg1));
}

mysql*:::handler-wrlock-start
{
    self->wrlockstart = timestamp;
    this->lockref = strjoin(copyinstr(arg0),strjoin("@",copyinstr(arg1)));
    self->lockmap[this->lockref] = self->rdlockstart;
    printf("Start: Lock->Write  %s.%s\n",copyinstr(arg0),copyinstr(arg1));
}

mysql*:::handler-unlock-start
{
    self->unlockstart = timestamp;
    this->lockref = strjoin(copyinstr(arg0),strjoin("@",copyinstr(arg1)));
    printf("Start: Lock->Unlock %s.%s (%d ms lock duration)\n",
        copyinstr(arg0),copyinstr(arg1),
        (timestamp - self->lockmap[this->lockref])/1000000);
}

mysql*:::handler-rdlock-done
{
    printf("End:   Lock->Read   %d ms\n",
        (timestamp - self->rdlockstart)/1000000);
}

mysql*:::handler-wrlock-done
{
    printf("End:   Lock->Write  %d ms\n",
        (timestamp - self->wrlockstart)/1000000);
}

mysql*:::handler-unlock-done
{
    printf("End:   Lock->Unlock %d ms\n",
        (timestamp - self->unlockstart)/1000000);
}
```

When executed, you should get information both about the duration of the locking process itself, and of the locks on a specific table:

```
Start: Lock->Read   test.t2
End:   Lock->Read   0 ms
Start: Lock->Unlock test.t2 (25743 ms lock duration)
```

```

End:   Lock->Unlock 0 ms
Start: Lock->Read   test.t2
End:   Lock->Read   0 ms
Start: Lock->Unlock test.t2 (1 ms lock duration)
End:   Lock->Unlock 0 ms
Start: Lock->Read   test.t2
End:   Lock->Read   0 ms
Start: Lock->Unlock test.t2 (1 ms lock duration)
End:   Lock->Unlock 0 ms
Start: Lock->Read   test.t2
End:   Lock->Read   0 ms

```

5.4.1.11 Filesort Probes

The filesort probes are triggered whenever a filesort operation is applied to a table. For more information on filesort and the conditions under which it occurs, see [Section 8.2.1.11, “ORDER BY Optimization”](#).

```

filesort-start(database, table)
filesort-done(status, rows)

```

- **filesort-start**: Triggered when the filesort operation starts on a table. The two arguments to the probe, **database** and **table**, will identify the table being sorted.
- **filesort-done**: Triggered when the filesort operation completes. Two arguments are supplied, the **status** (0 for success, 1 for failure), and the number of rows sorted during the filesort process.

An example of this is in the following script, which tracks the duration of the filesort process in addition to the duration of the main query:

```

#!/usr/sbin/dtrace -s

#pragma D option quiet

dtrace:::BEGIN
{
    printf("%-2s %-10s %-10s %9s %18s %-s \n",
        "St", "Who", "DB", "ConnID", "Dur microsec", "Query");
}

mysql*:::query-start
{
    self->query = copyinstr(arg0);
    self->who   = strjoin(copyinstr(arg3), strjoin("@", copyinstr(arg4)));
    self->db    = copyinstr(arg2);
    self->connid = arg1;
    self->querystart = timestamp;
    self->filesort = 0;
    self->fsdb = "";
    self->fstable = "";
}

mysql*:::filesort-start
{
    self->filesort = timestamp;
    self->fsdb = copyinstr(arg0);
    self->fstable = copyinstr(arg1);
}

mysql*:::filesort-done
{
    this->elapsed = (timestamp - self->filesort) / 1000;
    printf("%2d %-10s %-10s %9d %18d Filesort on %s\n",
        arg0, self->who, self->fsdb,
        self->connid, this->elapsed, self->fstable);
}

```

```
mysql*:::query-done
{
    this->elapsed = (timestamp - self->querystart) /1000;
    printf("%2d %-10s %-10s %9d %18d %s\n",
        arg0, self->who, self->db,
        self->connid, this->elapsed, self->query);
}
```

Executing a query on a large table with an `ORDER BY` clause that triggers a filesort, and then creating an index on the table and then repeating the same query, you can see the difference in execution speed:

St	Who	DB	ConnID	Dur microsec	Query
0	@localhost	test	14	11335469	Filesort on t1
0	@localhost	test	14	11335787	select * from t1 order by i limit 100
0	@localhost	test	14	466734378	create index t1a on t1 (i)
0	@localhost	test	14	26472	select * from t1 order by i limit 100

5.4.1.12 Statement Probes

The individual statement probes are provided to give specific information about different statement types. For the start probes the string of the query is provided as the only argument. Depending on the statement type, the information provided by the corresponding done probe will differ. For all done probes the status of the operation (0 for success, >0 for failure) is provided. For `SELECT`, `INSERT`, `INSERT ... (SELECT FROM ...)`, `DELETE`, and `DELETE FROM t1,t2` operations the number of rows affected is returned.

For `UPDATE` and `UPDATE t1,t2 ...` statements the number of rows matched and the number of rows actually changed is provided. This is because the number of rows actually matched by the corresponding `WHERE` clause, and the number of rows changed can differ. MySQL does not update the value of a row if the value already matches the new setting.

```
select-start(query)
select-done(status,rows)

insert-start(query)
insert-done(status,rows)

insert-select-start(query)
insert-select-done(status,rows)

update-start(query)
update-done(status,rowsmatched,rowschanged)

multi-update-start(query)
multi-update-done(status,rowsmatched,rowschanged)

delete-start(query)
delete-done(status,rows)

multi-delete-start(query)
multi-delete-done(status,rows)
```

- `select-start`: Triggered before a `SELECT` statement.
- `select-done`: Triggered at the end of a `SELECT` statement.
- `insert-start`: Triggered before a `INSERT` statement.
- `insert-done`: Triggered at the end of an `INSERT` statement.
- `insert-select-start`: Triggered before an `INSERT ... SELECT` statement.
- `insert-select-done`: Triggered at the end of an `INSERT ... SELECT` statement.

- `update-start`: Triggered before an `UPDATE` statement.
- `update-done`: Triggered at the end of an `UPDATE` statement.
- `multi-update-start`: Triggered before an `UPDATE` statement involving multiple tables.
- `multi-update-done`: Triggered at the end of an `UPDATE` statement involving multiple tables.
- `delete-start`: Triggered before a `DELETE` statement.
- `delete-done`: Triggered at the end of a `DELETE` statement.
- `multi-delete-start`: Triggered before a `DELETE` statement involving multiple tables.
- `multi-delete-done`: Triggered at the end of a `DELETE` statement involving multiple tables.

The arguments for the statement probes are:

- `query`: The query string.
- `status`: The status of the query. 0 for success, and >0 for failure.
- `rows`: The number of rows affected by the statement. This returns the number rows found for `SELECT`, the number of rows deleted for `DELETE`, and the number of rows successfully inserted for `INSERT`.
- `rowsmatched`: The number of rows matched by the `WHERE` clause of an `UPDATE` operation.
- `rowschanged`: The number of rows actually changed during an `UPDATE` operation.

You use these probes to monitor the execution of these statement types without having to monitor the user or client executing the statements. A simple example of this is to track the execution times:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet

dtrace:::BEGIN
{
    printf("%-60s %-8s %-8s %-8s\n", "Query", "RowsU", "RowsM", "Dur (ms)");
}

mysql*:::update-start, mysql*:::insert-start,
mysql*:::delete-start, mysql*:::multi-delete-start,
mysql*:::multi-delete-done, mysql*:::select-start,
mysql*:::insert-select-start, mysql*:::multi-update-start
{
    self->query = copyinstr(arg0);
    self->querystart = timestamp;
}

mysql*:::insert-done, mysql*:::select-done,
mysql*:::delete-done, mysql*:::multi-delete-done, mysql*:::insert-select-done
/ self->querystart /
{
    this->elapsed = ((timestamp - self->querystart)/1000000);
    printf("%-60s %-8d %-8d %-8d\n",
        self->query,
        0,
        arg1,
        this->elapsed);
    self->querystart = 0;
}
```

```
mysql*:::update-done, mysql*:::multi-update-done
/ self->querystart /
{
    this->elapsed = ((timestamp - self->querystart)/1000000);
    printf("%-60s %-8d %-8d %d\n",
        self->query,
        arg1,
        arg2,
        this->elapsed);
    self->querystart = 0;
}
```

When executed you can see the basic execution times and rows matches:

Query	RowsU	RowsM	Dur (ms)
select * from t2	0	275	0
insert into t2 (select * from t2)	0	275	9
update t2 set i=5 where i > 75	110	110	8
update t2 set i=5 where i < 25	254	134	12
delete from t2 where i < 5	0	0	0

Another alternative is to use the aggregation functions in DTrace to aggregate the execution time of individual statements together:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet

mysql*:::update-start, mysql*:::insert-start,
mysql*:::delete-start, mysql*:::multi-delete-start,
mysql*:::multi-delete-done, mysql*:::select-start,
mysql*:::insert-select-start, mysql*:::multi-update-start
{
    self->querystart = timestamp;
}

mysql*:::select-done
{
    @statements["select"] = sum(((timestamp - self->querystart)/1000000));
}

mysql*:::insert-done, mysql*:::insert-select-done
{
    @statements["insert"] = sum(((timestamp - self->querystart)/1000000));
}

mysql*:::update-done, mysql*:::multi-update-done
{
    @statements["update"] = sum(((timestamp - self->querystart)/1000000));
}

mysql*:::delete-done, mysql*:::multi-delete-done
{
    @statements["delete"] = sum(((timestamp - self->querystart)/1000000));
}

tick-30s
{
    printa(@statements);
}
```

The script just shown aggregates the times spent doing each operation, which could be used to help benchmark a standard suite of tests.

```
delete
```

```
0
```

update	0
insert	23
select	2484
delete	0
update	0
insert	39
select	10744
delete	0
update	26
insert	56
select	10944
delete	0
update	26
insert	2287
select	15985

5.4.1.13 Network Probes

The network probes monitor the transfer of information from the MySQL server and clients of all types over the network. The probes are defined as follows:

```
net-read-start()
net-read-done(status, bytes)
net-write-start(bytes)
net-write-done(status)
```

- **net-read-start**: Triggered when a network read operation is started.
- **net-read-done**: Triggered when the network read operation completes. The `status` is an `integer` representing the return status for the operation, `0` for success and `1` for failure. The `bytes` argument is an integer specifying the number of bytes read during the process.
- **net-start-bytes**: Triggered when data is written to a network socket. The single argument, `bytes`, specifies the number of bytes written to the network socket.
- **net-write-done**: Triggered when the network write operation has completed. The single argument, `status`, is an integer representing the return status for the operation, `0` for success and `1` for failure.

You can use the network probes to monitor the time spent reading from and writing to network clients during execution. The following D script provides an example of this. Both the cumulative time for the read or write is calculated, and the number of bytes. Note that the dynamic variable size has been increased (using the `dynvarsize` option) to cope with the rapid firing of the individual probes for the network reads/writes.

```
#!/usr/sbin/dtrace -s

#pragma D option quiet
#pragma D option dynvarsize=4m

dtrace:::BEGIN
{
    printf("%-2s %-30s %-10s %9s %18s %-s \n",
        "St", "Who", "DB", "ConnID", "Dur microsec", "Query");
}

mysql*:::query-start
{
    self->query = copyinstr(arg0);
    self->who   = strjoin(copyinstr(arg3), strjoin("@", copyinstr(arg4)));
    self->db    = copyinstr(arg2);
}
```

```

    self->connid = arg1;
    self->querystart = timestamp;
    self->netwrite = 0;
    self->netwritecum = 0;
    self->netwritebase = 0;
    self->netread = 0;
    self->netreadcum = 0;
    self->netreadbase = 0;
}

mysql*:::net-write-start
{
    self->netwrite += arg0;
    self->netwritebase = timestamp;
}

mysql*:::net-write-done
{
    self->netwritecum += (timestamp - self->netwritebase);
    self->netwritebase = 0;
}

mysql*:::net-read-start
{
    self->netreadbase = timestamp;
}

mysql*:::net-read-done
{
    self->netread += arg1;
    self->netreadcum += (timestamp - self->netreadbase);
    self->netreadbase = 0;
}

mysql*:::query-done
{
    this->elapsed = (timestamp - self->querystart) / 1000000;
    printf("%2d %-30s %-10s %9d %18d %s\n",
        arg0, self->who, self->db,
        self->connid, this->elapsed, self->query);
    printf("Net read: %d bytes (%d ms) write: %d bytes (%d ms)\n",
        self->netread, (self->netreadcum/1000000),
        self->netwrite, (self->netwritecum/1000000));
}

```

When executing the above script on a machine with a remote client, you can see that approximately a third of the time spent executing the query is related to writing the query results back to the client.

St	Who	DB	ConnID	Dur microsec	Query
0	root@::ffff:192.168.0.108	test	31	3495	select * from t1 limit 1000000
Net read: 0 bytes (0 ms) write: 10000075 bytes (1220 ms)					

5.4.1.14 Keycache Probes

The keycache probes are triggered when using the index key cache used with the MyISAM storage engine. Probes exist to monitor when data is read into the keycache, cached key data is written from the cache into a cached file, or when accessing the keycache.

Keycache usage indicates when data is read or written from the index files into the cache, and can be used to monitor how efficient the memory allocated to the keycache is being used. A high number of keycache reads across a range of queries may indicate that the keycache is too small for size of data being accessed.

```
keycache-read-start(filepath, bytes, mem_used, mem_free)
```

```
keycache-read-block(bytes)
keycache-read-hit()
keycache-read-miss()
keycache-read-done(mem_used, mem_free)
keycache-write-start(filepath, bytes, mem_used, mem_free)
keycache-write-block(bytes)
keycache-write-done(mem_used, mem_free)
```

When reading data from the index files into the keycache, the process first initializes the read operation (indicated by `keycache-read-start`), then loads blocks of data (`keycache-read-block`), and then the read block is either matches the data being identified (`keycache-read-hit`) or more data needs to be read (`keycache-read-miss`). Once the read operation has completed, reading stops with the `keycache-read-done`.

Data will be read from the index file into the keycache only when the specified key is not already within the keycache.

- `keycache-read-start`: Triggered when the keycache read operation is started. Data is read from the specified `filepath`, reading the specified number of `bytes`. The `mem_used` and `mem_avail` indicate memory currently used by the keycache and the amount of memory available within the keycache.
- `keycache-read-block`: Triggered when the keycache reads a block of data, of the specified number of `bytes`, from the index file into the keycache.
- `keycache-read-hit`: Triggered when the block of data read from the index file matches the key data requested.
- `keycache-read-miss`: Triggered when the block of data read from the index file does not match the key data needed.
- `keycache-read-done`: Triggered when the keycache read operation has completed. The `mem_used` and `mem_avail` indicate memory currently used by the keycache and the amount of memory available within the keycache.

Keycache writes occur when the index information is updated during an `INSERT`, `UPDATE`, or `DELETE` operation, and the cached key information is flushed back to the index file.

- `keycache-write-start`: Triggered when the keycache write operation is started. Data is written to the specified `filepath`, reading the specified number of `bytes`. The `mem_used` and `mem_avail` indicate memory currently used by the keycache and the amount of memory available within the keycache.
- `keycache-write-block`: Triggered when the keycache writes a block of data, of the specified number of `bytes`, to the index file from the keycache.
- `keycache-write-done`: Triggered when the keycache write operation has completed. The `mem_used` and `mem_avail` indicate memory currently used by the keycache and the amount of memory available within the keycache.

When thinking about security within a MySQL installation, you should consider a wide range of possible topics and how they affect the security of your MySQL server and related applications:

- General factors that affect security. These include choosing good passwords, not granting unnecessary privileges to users, ensuring application security by preventing SQL injections and data corruption, and others. See [Section 6.1, “General Security Issues”](#).
- Security of the installation itself. The data files, log files, and the all the application files of your installation should be protected to ensure that they are not readable or writable by unauthorized parties. For more information, see [Section 2.10, “Postinstallation Setup and Testing”](#).
- Access control and security within the database system itself, including the users and databases granted with access to the databases, views and stored programs in use within the database. For more information, see [Section 6.2, “The MySQL Access Privilege System”](#), and [Section 6.3, “MySQL User Account Management”](#).
- Network security of MySQL and your system. The security is related to the grants for individual users, but you may also wish to restrict MySQL so that it is available only locally on the MySQL server host, or to a limited set of other hosts.

- Ensure that you have adequate and appropriate backups of your database files, configuration and log files. Also be sure that you have a recovery solution in place and test that you are able to successfully recover the information from your backups. See [Chapter 7, Backup and Recovery](#).

6.1 General Security Issues

This section describes general security issues to be aware of and what you can do to make your MySQL installation more secure against attack or misuse. For information specifically about the access control system that MySQL uses for setting up user accounts and checking database access, see [Section 2.10, “Postinstallation Setup and Testing”](#).

For answers to some questions that are often asked about MySQL Server security issues, see [Section A.9, “MySQL 5.5 FAQ: Security”](#).

6.1.1 Security Guidelines

Anyone using MySQL on a computer connected to the Internet should read this section to avoid the most common security mistakes.

In discussing security, it is necessary to consider fully protecting the entire server host (not just the MySQL server) against all types of applicable attacks: eavesdropping, altering, playback, and denial of service. We do not cover all aspects of availability and fault tolerance here.

MySQL uses security based on Access Control Lists (ACLs) for all connections, queries, and other operations that users can attempt to perform. There is also support for SSL-encrypted connections between MySQL clients and servers. Many of the concepts discussed here are not specific to MySQL at all; the same general ideas apply to almost all applications.

When running MySQL, follow these guidelines:

- **Do not ever give anyone (except MySQL `root` accounts) access to the `user` table in the `mysql` database!** This is critical.
- Learn how the MySQL access privilege system works (see [Section 6.2, “The MySQL Access Privilege System”](#)). Use the `GRANT` and `REVOKE` statements to control access to MySQL. Do not grant more privileges than necessary. Never grant privileges to all hosts.

Checklist:

- Try `mysql -u root`. If you are able to connect successfully to the server without being asked for a password, anyone can connect to your MySQL server as the MySQL `root` user with full privileges! Review the MySQL installation instructions, paying particular attention to the information about setting a `root` password. See [Section 2.10.2, “Securing the Initial MySQL Accounts”](#).
- Use the `SHOW GRANTS` statement to check which accounts have access to what. Then use the `REVOKE` statement to remove those privileges that are not necessary.
- Do not store cleartext passwords in your database. If your computer becomes compromised, the intruder can take the full list of passwords and use them. Instead, use `SHA2()`, `SHA1()`, `MD5()`, or some other one-way hashing function and store the hash value.

To prevent password recovery using rainbow tables, do not use these functions on a plain password; instead, choose some string to be used as a salt, and use `hash(hash(password)+salt)` values.

- Do not choose passwords from dictionaries. Special programs exist to break passwords. Even passwords like “xfish98” are very bad. Much better is “duag98” which contains the same word “fish” but typed one key to the left on a standard QWERTY keyboard. Another method is to use a password that

is taken from the first characters of each word in a sentence (for example, “Four score and seven years ago” results in a password of “Fsasya”). The password is easy to remember and type, but difficult to guess for someone who does not know the sentence. In this case, you can additionally substitute digits for the number words to obtain the phrase “4 score and 7 years ago”, yielding the password “4sa7ya” which is even more difficult to guess.

- Invest in a firewall. This protects you from at least 50% of all types of exploits in any software. Put MySQL behind the firewall or in a demilitarized zone (DMZ).

Checklist:

- Try to scan your ports from the Internet using a tool such as [nmap](#). MySQL uses port 3306 by default. This port should not be accessible from untrusted hosts. As a simple way to check whether your MySQL port is open, try the following command from some remote machine, where [server_host](#) is the host name or IP address of the host on which your MySQL server runs:

```
shell> telnet server_host 3306
```

If [telnet](#) hangs or the connection is refused, the port is blocked, which is how you want it to be. If you get a connection and some garbage characters, the port is open, and should be closed on your firewall or router, unless you really have a good reason to keep it open.

- Applications that access MySQL should not trust any data entered by users, and should be written using proper defensive programming techniques. See [Section 6.1.7, “Client Programming Security Guidelines”](#).
- Do not transmit plain (unencrypted) data over the Internet. This information is accessible to everyone who has the time and ability to intercept it and use it for their own purposes. Instead, use an encrypted protocol such as SSL or SSH. MySQL supports internal SSL connections. Another technique is to use SSH port-forwarding to create an encrypted (and compressed) tunnel for the communication.
- Learn to use the [tcpdump](#) and [strings](#) utilities. In most cases, you can check whether MySQL data streams are unencrypted by issuing a command like the following:

```
shell> tcpdump -l -i eth0 -w - src or dst port 3306 | strings
```

This works under Linux and should work with small modifications under other systems.

Warning

If you do not see cleartext data, this does not always mean that the information actually is encrypted. If you need high security, consult with a security expert.

6.1.2 Keeping Passwords Secure

Passwords occur in several contexts within MySQL. The following sections provide guidelines that enable end users and administrators to keep these passwords secure and avoid exposing them. There is also a discussion of how MySQL uses password hashing internally.

6.1.2.1 End-User Guidelines for Password Security

MySQL users should use the following guidelines to keep passwords secure.

When you run a client program to connect to the MySQL server, it is inadvisable to specify your password in a way that exposes it to discovery by other users. The methods you can use to specify your password when you run client programs are listed here, along with an assessment of the risks of each method.

In short, the safest methods are to have the client program prompt for the password or to specify the password in a properly protected option file.

- Use a `-p`*your_pass* or `--password=your_pass` option on the command line. For example:

```
shell> mysql -u francis -pfrank db_name
```

This is convenient *but insecure*. On some systems, your password becomes visible to system status programs such as `ps` that may be invoked by other users to display command lines. MySQL clients typically overwrite the command-line password argument with zeros during their initialization sequence. However, there is still a brief interval during which the value is visible. Also, on some systems this overwriting strategy is ineffective and the password remains visible to `ps`. (SystemV Unix systems and perhaps others are subject to this problem.)

If your operating environment is set up to display your current command in the title bar of your terminal window, the password remains visible as long as the command is running, even if the command has scrolled out of view in the window content area.

- Use the `-p` or `--password` option on the command line with no password value specified. In this case, the client program solicits the password interactively:

```
shell> mysql -u francis -p db_name
Enter password: *****
```

The “*” characters indicate where you enter your password. The password is not displayed as you enter it.

It is more secure to enter your password this way than to specify it on the command line because it is not visible to other users. However, this method of entering a password is suitable only for programs that you run interactively. If you want to invoke a client from a script that runs noninteractively, there is no opportunity to enter the password from the keyboard. On some systems, you may even find that the first line of your script is read and interpreted (incorrectly) as your password.

- Store your password in an option file. For example, on Unix, you can list your password in the `[client]` section of the `.my.cnf` file in your home directory:

```
[client]
password=your_pass
```

To keep the password safe, the file should not be accessible to anyone but yourself. To ensure this, set the file access mode to `400` or `600`. For example:

```
shell> chmod 600 .my.cnf
```

To name from the command line a specific option file containing the password, use the `--defaults-file=file_name` option, where `file_name` is the full path name to the file. For example:

```
shell> mysql --defaults-file=/home/francis/mysql-opts
```

[Section 4.2.6, “Using Option Files”](#), discusses option files in more detail.

- Store your password in the `MYSQLE_PWD` environment variable. See [Section 2.12, “Environment Variables”](#).

This method of specifying your MySQL password must be considered *extremely insecure* and should not be used. Some versions of `ps` include an option to display the environment of running processes. On some systems, if you set `MYSQL_PWD`, your password is exposed to any other user who runs `ps`. Even on systems without such a version of `ps`, it is unwise to assume that there are no other methods by which users can examine process environments.

On Unix, the `mysql` client writes a record of executed statements to a history file (see [Section 4.5.1.3, “mysql Logging”](#)). By default, this file is named `.mysql_history` and is created in your home directory. Passwords can be written as plain text in SQL statements such as `CREATE USER`, `GRANT`, and `SET PASSWORD`, so if you use these statements, they are logged in the history file. To keep this file safe, use a restrictive access mode, the same way as described earlier for the `.my.cnf` file.

If your command interpreter is configured to maintain a history, any file in which the commands are saved will contain MySQL passwords entered on the command line. For example, `bash` uses `~/.bash_history`. Any such file should have a restrictive access mode.

6.1.2.2 Administrator Guidelines for Password Security

Database administrators should use the following guidelines to keep passwords secure.

MySQL stores passwords for user accounts in the `mysql.user` table. Access to this table should never be granted to any nonadministrative accounts.

A user who has access to modify the plugin directory (the value of the `plugin_dir` system variable) or the `my.cnf` file that specifies the location of the plugin directory can replace plugins and modify the capabilities provided by plugins, including authentication plugins.

Files such as log files to which passwords might be written should be protected. See [Section 6.1.2.3, “Passwords and Logging”](#).

6.1.2.3 Passwords and Logging

Passwords can be written as plain text in SQL statements such as `CREATE USER`, `GRANT`, and `SET PASSWORD`, or statements that invoke the `PASSWORD()` function. If these statements are logged by the MySQL server as written, such passwords become available to anyone with access to the logs. This applies to the general query log, the slow query log, and the binary log (see [Section 5.2, “MySQL Server Logs”](#)).

Contents of the audit log file produced by the audit log plugin are not encrypted. For security reasons, this file should be written to a directory accessible only to the MySQL server and users with a legitimate reason to view the log. See [Section 6.3.11.2, “Audit Log Plugin Security Considerations”](#).

To guard against unwarranted exposure to log files, they should be located in a directory that restricts access to only the server and the database administrator. If you log to tables in the `mysql` database, access to the tables should never be granted to any nonadministrative accounts.

Replication slaves store the password for the replication master in the `master.info` file. Restrict this file to be accessible only to the database administrator.

Database backups that include tables or log files containing passwords should be protected using a restricted access mode.

6.1.2.4 Password Hashing in MySQL

MySQL lists user accounts in the `user` table of the `mysql` database. Each MySQL account can be assigned a password, although the `user` table does not store the cleartext version of the password, but a hash value computed from it.

MySQL uses passwords in two phases of client/server communication:

- When a client attempts to connect to the server, there is an initial authentication step in which the client must present a password that has a hash value matching the hash value stored in the `user` table for the account the client wants to use.
- After the client connects, it can (if it has sufficient privileges) set or change the password hash for accounts listed in the `user` table. The client can do this by using the `PASSWORD()` function to generate a password hash, or by using a password-generating statement (`CREATE USER`, `GRANT`, or `SET PASSWORD`).

In other words, the server *checks* hash values during authentication when a client first attempts to connect. The server *generates* hash values if a connected client invokes the `PASSWORD()` function or uses a password-generating statement to set or change a password.

Password hashing methods in MySQL have the history described following. These changes are illustrated by changes in the result from the `PASSWORD()` function that computes password hash values and in the structure of the `user` table where passwords are stored.

The Original (Pre-4.1) Hashing Method

The original hashing method produced a 16-byte string. Such hashes look like this:

```
mysql> SELECT PASSWORD('mypass');
+-----+
| PASSWORD('mypass') |
+-----+
| 6f8c114b58f2ce9e |
+-----+
```

To store account passwords, the `Password` column of the `user` table was at this point 16 bytes long.

The 4.1 Hashing Method

MySQL 4.1 introduced password hashing that provides better security and reduces the risk of passwords being intercepted. There were several aspects to this change:

- Different `PASSWORD()` function result format
- Widening of the `Password` column
- Control over the default hashing method
- Control over the permitted hashing methods for clients attempting to connect to the server

The changes in MySQL 4.1 took place in two stages:

- MySQL 4.1.0 used a preliminary version of the 4.1 hashing method. Because this method was so short lived, the following discussion says no more about it.
- In MySQL 4.1.1, the hashing method was modified to produce a longer 41-byte hash value:

```
mysql> SELECT PASSWORD('mypass');
+-----+
| PASSWORD('mypass') |
+-----+
```

```
+-----+
| *6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4 |
+-----+
```

The longer password hash format has better cryptographic properties, and client authentication based on long hashes is more secure than that based on the older short hashes.

To accommodate longer password hashes, the `Password` column in the `user` table was changed at this point to be 41 bytes, its current length.

A widened `Password` column can store password hashes in both the pre-4.1 and 4.1 formats. The format of any given hash value can be determined two ways:

- The length: 4.1 and pre-4.1 hashes are 41 and 16 bytes, respectively.
- Password hashes in the 4.1 format always begin with a “*” character, whereas passwords in the pre-4.1 format never do.

To permit explicit generation of pre-4.1 password hashes, two additional changes were made:

- The `OLD_PASSWORD()` function was added, which returns hash values in the 16-byte format.
- For compatibility purposes, the `old_passwords` system variable was added, to enable DBAs and applications control over the hashing method. The default `old_passwords` value of 0 causes hashing to use the 4.1 method (41-byte hash values), but setting `old_passwords=1` causes hashing to use the pre-4.1 method. In this case, `PASSWORD()` produces 16-byte values and is equivalent to `OLD_PASSWORD()`.

To permit DBAs control over how clients are permitted to connect, the `secure_auth` system variable was added. Starting the server with this variable disabled or enabled permits or prohibits clients to connect using the older pre-4.1 password hashing method. Before MySQL 5.6.5, `secure_auth` is disabled by default. As of 5.6.5, `secure_auth` is enabled by default to promote a more secure default configuration. (DBAs can disable it at their discretion, but this is not recommended.)

In addition, the `mysql` client supports a `--secure-auth` option that is analogous to `secure_auth`, but from the client side. It can be used to prevent connections to less secure accounts that use pre-4.1 password hashing. This option is disabled by default before MySQL 5.6.7, enabled thereafter.

Compatibility Issues Related to Hashing Methods

The widening of the `Password` column in MySQL 4.1 from 16 bytes to 41 bytes affects installation or upgrade operations as follows:

- If you perform a new installation of MySQL, the `Password` column is made 41 bytes long automatically.
- Upgrades from MySQL 4.1 or later to current versions of MySQL should not give rise to any issues in regard to the `Password` column because both versions use the same column length and password hashing method.
- For upgrades from a pre-4.1 release to 4.1 or later, you must upgrade the system tables after upgrading. (See [Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”](#).)

The 4.1 hashing method is understood only by MySQL 4.1 (and newer) servers and clients, which can result in some compatibility problems. A 4.1 or newer client can connect to a pre-4.1 server, because the client understands both the pre-4.1 and 4.1 password hashing methods. However, a pre-4.1 client that attempts to connect to a 4.1 or newer server may run into difficulties. For example, a 4.0 `mysql` client may fail with the following error message:

```
shell> mysql -h localhost -u root
Client does not support authentication protocol requested
by server; consider upgrading MySQL client
```

This phenomenon also occurs for attempts to use the older PHP `mysql` extension after upgrading to MySQL 4.1 or newer. (See [Common Problems with MySQL and PHP](#).)

The following discussion describes the differences between the pre-4.1 and 4.1 hashing methods, and what you should do if you upgrade your server but need to maintain backward compatibility with pre-4.1 clients. (However, permitting connections by old clients is not recommended and should be avoided if possible.) Additional information can be found in [Section B.5.2.4, “Client does not support authentication protocol”](#). This information is of particular importance to PHP programmers migrating MySQL databases from versions older than 4.1 to 4.1 or higher.

The differences between short and long password hashes are relevant both for how the server uses passwords during authentication and for how it generates password hashes for connected clients that perform password-changing operations.

The way in which the server uses password hashes during authentication is affected by the width of the `Password` column:

- If the column is short, only short-hash authentication is used.
- If the column is long, it can hold either short or long hashes, and the server can use either format:
 - Pre-4.1 clients can connect, but because they know only about the pre-4.1 hashing method, they can authenticate only using accounts that have short hashes.
 - 4.1 and later clients can authenticate using accounts that have short or long hashes.

Even for short-hash accounts, the authentication process is actually a bit more secure for 4.1 and later clients than for older clients. In terms of security, the gradient from least to most secure is:

- Pre-4.1 client authenticating with short password hash
- 4.1 or later client authenticating with short password hash
- 4.1 or later client authenticating with long password hash

The way in which the server generates password hashes for connected clients is affected by the width of the `Password` column and by the `old_passwords` system variable. A 4.1 or later server generates long hashes only if certain conditions are met: The `Password` column must be wide enough to hold long values and `old_passwords` must not be set to 1.

Those conditions apply as follows:

- The `Password` column must be wide enough to hold long hashes (41 bytes). If the column has not been updated and still has the pre-4.1 width of 16 bytes, the server notices that long hashes cannot fit into it and generates only short hashes when a client performs password-changing operations using the `PASSWORD()` function or a password-generating statement. This is the behavior that occurs if you have upgraded from a version of MySQL older than 4.1 to 4.1 or later but have not yet run the `mysql_upgrade` program to widen the `Password` column.
- If the `Password` column is wide, it can store either short or long password hashes. In this case, the `PASSWORD()` function and password-generating statements generate long hashes unless the server was started with the `old_passwords` system variable set to 1 to force the server to generate short password hashes instead.

The purpose of the `old_passwords` system variable is to permit backward compatibility with pre-4.1 clients under circumstances where the server would otherwise generate long password hashes. The option does not affect authentication (4.1 and later clients can still use accounts that have long password hashes), but it does prevent creation of a long password hash in the `user` table as the result of a password-changing operation. Were that permitted to occur, the account could no longer be used by pre-4.1 clients. With `old_passwords` disabled, the following undesirable scenario is possible:

- An old pre-4.1 client connects to an account that has a short password hash.
- The client changes its own password. With `old_passwords` disabled, this results in the account having a long password hash.
- The next time the old client attempts to connect to the account, it cannot, because the account has a long password hash that requires the 4.1 hashing method during authentication. (Once an account has a long password hash in the `user` table, only 4.1 and later clients can authenticate for it because pre-4.1 clients do not understand long hashes.)

This scenario illustrates that, if you must support older pre-4.1 clients, it is problematic to run a 4.1 or newer server without `old_passwords` set to 1. By running the server with `old_passwords=1`, password-changing operations do not generate long password hashes and thus do not cause accounts to become inaccessible to older clients. (Those clients cannot inadvertently lock themselves out by changing their password and ending up with a long password hash.)

The downside of `old_passwords=1` is that any passwords created or changed use short hashes, even for 4.1 or later clients. Thus, you lose the additional security provided by long password hashes. To create an account that has a long hash (for example, for use by 4.1 clients) or to change an existing account to use a long password hash, an administrator can set the session value of `old_passwords` set to 0 while leaving the global value set to 1:

```
mysql> SET @@session.old_passwords = 0;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@session.old_passwords, @@global.old_passwords;
+-----+-----+
| @@session.old_passwords | @@global.old_passwords |
+-----+-----+
| 0 | 1 |
+-----+-----+
1 row in set (0.00 sec)

mysql> CREATE USER 'newuser'@'localhost' IDENTIFIED BY 'newpass';
Query OK, 0 rows affected (0.03 sec)

mysql> SET PASSWORD FOR 'existinguser'@'localhost' = PASSWORD('existingpass');
Query OK, 0 rows affected (0.00 sec)
```

The following scenarios are possible in MySQL 4.1 or later. The factors are whether the `Password` column is short or long, and, if long, whether the server is started with `old_passwords` enabled or disabled.

Scenario 1: Short `Password` column in user table:

- Only short hashes can be stored in the `Password` column.
- The server uses only short hashes during client authentication.
- For connected clients, password hash-generating operations involving the `PASSWORD()` function or password-generating statements use short hashes exclusively. Any change to an account's password results in that account having a short password hash.

- The value of `old_passwords` is irrelevant because with a short `Password` column, the server generates only short password hashes anyway.

This scenario occurs when a pre-4.1 MySQL installation has been upgraded to 4.1 or later but `mysql_upgrade` has not been run to upgrade the system tables in the `mysql` database. (This is not a recommended configuration because it does not permit use of more secure 4.1 password hashing.)

Scenario 2: Long `Password` column; server started with `old_passwords=1`:

- Short or long hashes can be stored in the `Password` column.
- 4.1 and later clients can authenticate for accounts that have short or long hashes.
- Pre-4.1 clients can authenticate only for accounts that have short hashes.
- For connected clients, password hash-generating operations involving the `PASSWORD()` function or password-generating statements use short hashes exclusively. Any change to an account's password results in that account having a short password hash.

In this scenario, newly created accounts have short password hashes because `old_passwords=1` prevents generation of long hashes. Also, if you create an account with a long hash before setting `old_passwords` to 1, changing the account's password while `old_passwords=1` results in the account being given a short password, causing it to lose the security benefits of a longer hash.

To create a new account that has a long password hash, or to change the password of any existing account to use a long hash, first set the session value of `old_passwords` set to 0 while leaving the global value set to 1, as described previously.

In this scenario, the server has an up to date `Password` column, but is running with the default password hashing method set to generate pre-4.1 hash values. This is not a recommended configuration but may be useful during a transitional period in which pre-4.1 clients and passwords are upgraded to 4.1 or later. When that has been done, it is preferable to run the server with `old_passwords=0` and `secure_auth=1`.

Scenario 3: Long `Password` column; server started with `old_passwords=0`:

- Short or long hashes can be stored in the `Password` column.
- 4.1 and later clients can authenticate using accounts that have short or long hashes.
- Pre-4.1 clients can authenticate only using accounts that have short hashes.
- For connected clients, password hash-generating operations involving the `PASSWORD()` function or password-generating statements use long hashes exclusively. A change to an account's password results in that account having a long password hash.

As indicated earlier, a danger in this scenario is that it is possible for accounts that have a short password hash to become inaccessible to pre-4.1 clients. A change to such an account's password made using the `PASSWORD()` function or a password-generating statement results in the account being given a long password hash. From that point on, no pre-4.1 client can connect to the server using that account. The client must upgrade to 4.1 or later.

If this is a problem, you can change a password in a special way. For example, normally you use `SET PASSWORD` as follows to change an account password:

```
SET PASSWORD FOR 'some_user'@'some_host' = PASSWORD('mypass');
```

To change the password but create a short hash, use the `OLD_PASSWORD()` function instead:

```
SET PASSWORD FOR 'some_user'@'some_host' = OLD_PASSWORD('mypass');
```

`OLD_PASSWORD()` is useful for situations in which you explicitly want to generate a short hash.

The disadvantages for each of the preceding scenarios may be summarized as follows:

In scenario 1, you cannot take advantage of longer hashes that provide more secure authentication.

In scenario 2, `old_passwords=1` prevents accounts with short hashes from becoming inaccessible, but password-changing operations cause accounts with long hashes to revert to short hashes unless you take care to change the session value of `old_passwords` to 0 first.

In scenario 3, accounts with short hashes become inaccessible to pre-4.1 clients if you change their passwords without explicitly using `OLD_PASSWORD()`.

The best way to avoid compatibility problems related to short password hashes is to not use them:

- Upgrade all client programs to MySQL 4.1 or later.
- Run the server with `old_passwords=0`.
- Reset the password for any account with a short password hash to use a long password hash.
- For additional security, run the server with `secure_auth=1`.

6.1.2.5 Implications of Password Hashing Changes in MySQL 4.1 for Application Programs

An upgrade to MySQL version 4.1 or later can cause compatibility issues for applications that use `PASSWORD()` to generate passwords for their own purposes. Applications really should not do this, because `PASSWORD()` should be used only to manage passwords for MySQL accounts. But some applications use `PASSWORD()` for their own purposes anyway.

If you upgrade to 4.1 or later from a pre-4.1 version of MySQL and run the server under conditions where it generates long password hashes, an application using `PASSWORD()` for its own passwords breaks. The recommended course of action in such cases is to modify the application to use another function, such as `SHA2()`, `SHA1()`, or `MD5()`, to produce hashed values. If that is not possible, you can use the `OLD_PASSWORD()` function, which is provided to generate short hashes in the old format. However, you should note that `OLD_PASSWORD()` may one day no longer be supported.

If the server is running with `old_passwords=1`, it generates short hashes and `OLD_PASSWORD()` is equivalent to `PASSWORD()`.

PHP programmers migrating their MySQL databases from version 4.0 or lower to version 4.1 or higher should see [MySQL and PHP](#).

6.1.3 Making MySQL Secure Against Attackers

When you connect to a MySQL server, you should use a password. The password is not transmitted in clear text over the connection. Password handling during the client connection sequence was upgraded in MySQL 4.1.1 to be very secure. If you are still using pre-4.1.1-style passwords, the encryption algorithm is not as strong as the newer algorithm. With some effort, a clever attacker who can sniff the traffic between the client and the server can crack the password. (See [Section 6.1.2.4, “Password Hashing in MySQL”](#), for a discussion of the different password handling methods.)

All other information is transferred as text, and can be read by anyone who is able to watch the connection. If the connection between the client and the server goes through an untrusted network, and you are

concerned about this, you can use the compressed protocol to make traffic much more difficult to decipher. You can also use MySQL's internal SSL support to make the connection even more secure. See [Section 6.3.9, “Using SSL for Secure Connections”](#). Alternatively, use SSH to get an encrypted TCP/IP connection between a MySQL server and a MySQL client. You can find an Open Source SSH client at <http://www.openssh.org/>, and a comparison of both Open Source and Commercial SSH clients at http://en.wikipedia.org/wiki/Comparison_of_SSH_clients.

To make a MySQL system secure, you should strongly consider the following suggestions:

- Require all MySQL accounts to have a password. A client program does not necessarily know the identity of the person running it. It is common for client/server applications that the user can specify any user name to the client program. For example, anyone can use the `mysql` program to connect as any other person simply by invoking it as `mysql -u other_user db_name` if `other_user` has no password. If all accounts have a password, connecting using another user's account becomes much more difficult.

For a discussion of methods for setting passwords, see [Section 6.3.5, “Assigning Account Passwords”](#).

- Make sure that the only Unix user account with read or write privileges in the database directories is the account that is used for running `mysqld`.
- Never run the MySQL server as the Unix `root` user. This is extremely dangerous, because any user with the `FILE` privilege is able to cause the server to create files as `root` (for example, `~root/.bashrc`). To prevent this, `mysqld` refuses to run as `root` unless that is specified explicitly using the `--user=root` option.

`mysqld` can (and should) be run as an ordinary, unprivileged user instead. You can create a separate Unix account named `mysql` to make everything even more secure. Use this account only for administering MySQL. To start `mysqld` as a different Unix user, add a `user` option that specifies the user name in the `[mysqld]` group of the `my.cnf` option file where you specify server options. For example:

```
[mysqld]
user=mysql
```

This causes the server to start as the designated user whether you start it manually or by using `mysqld_safe` or `mysql.server`. For more details, see [Section 6.1.5, “How to Run MySQL as a Normal User”](#).

Running `mysqld` as a Unix user other than `root` does not mean that you need to change the `root` user name in the `user` table. *User names for MySQL accounts have nothing to do with user names for Unix accounts.*

- Do not grant the `FILE` privilege to nonadministrative users. Any user that has this privilege can write a file anywhere in the file system with the privileges of the `mysqld` daemon. This includes the server's data directory containing the files that implement the privilege tables. To make `FILE`-privilege operations a bit safer, files generated with `SELECT ... INTO OUTFILE` do not overwrite existing files and are writable by everyone.

The `FILE` privilege may also be used to read any file that is world-readable or accessible to the Unix user that the server runs as. With this privilege, you can read any file into a database table. This could be abused, for example, by using `LOAD DATA` to load `/etc/passwd` into a table, which then can be displayed with `SELECT`.

To limit the location in which files can be read and written, set the `secure_file_priv` system to a specific directory. See [Section 5.1.4, “Server System Variables”](#).

- Do not grant the `PROCESS` or `SUPER` privilege to nonadministrative users. The output of `mysqladmin processlist` and `SHOW PROCESSLIST` shows the text of any statements currently being executed, so any user who is permitted to see the server process list might be able to see statements issued by other users such as `UPDATE user SET password=PASSWORD('not_secure')`.

`mysqld` reserves an extra connection for users who have the `SUPER` privilege, so that a MySQL `root` user can log in and check server activity even if all normal connections are in use.

The `SUPER` privilege can be used to terminate client connections, change server operation by changing the value of system variables, and control replication servers.

- Do not permit the use of symlinks to tables. (This capability can be disabled with the `--skip-symbolic-links` option.) This is especially important if you run `mysqld` as `root`, because anyone that has write access to the server's data directory then could delete any file in the system! See [Using Symbolic Links for MyISAM Tables on Unix](#).
- Stored programs and views should be written using the security guidelines discussed in [Section 20.6, "Access Control for Stored Programs and Views"](#).
- If you do not trust your DNS, you should use IP addresses rather than host names in the grant tables. In any case, you should be very careful about creating grant table entries using host name values that contain wildcards.
- If you want to restrict the number of connections permitted to a single account, you can do so by setting the `max_user_connections` variable in `mysqld`. The `GRANT` statement also supports resource control options for limiting the extent of server use permitted to an account. See [Section 13.7.1.3, "GRANT Syntax"](#).
- If the plugin directory is writable by the server, it may be possible for a user to write executable code to a file in the directory using `SELECT ... INTO DUMPFILE`. This can be prevented by making `plugin_dir` read only to the server or by setting `--secure-file-priv` to a directory where `SELECT` writes can be made safely.

6.1.4 Security-Related `mysqld` Options and Variables

The following table shows `mysqld` options and system variables that affect security. For descriptions of each of these, see [Section 5.1.3, "Server Command Options"](#), and [Section 5.1.4, "Server System Variables"](#).

Table 6.1 Security Option/Variable Summary

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
allow-suspicious-udfs	Yes	Yes				
automatic_sp_privileges			Yes		Global	Yes
chroot	Yes	Yes				
des-key-file	Yes	Yes				
local_infile			Yes		Global	Yes
old_passwords			Yes		Both	Yes
safe-show-database	Yes	Yes	Yes		Global	Yes
safe-user-create	Yes	Yes				

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
secure-auth	Yes	Yes			Global	Yes
- Variable: secure_auth			Yes		Global	Yes
secure-file-priv	Yes	Yes			Global	No
- Variable: secure_file_priv			Yes		Global	No
skip-grant-tables	Yes	Yes				
skip-name-resolve	Yes	Yes			Global	No
- Variable: skip_name_resolve			Yes		Global	No
skip-networking	Yes	Yes			Global	No
- Variable: skip_networking			Yes		Global	No
skip-show-database	Yes	Yes			Global	No
- Variable: skip_show_database			Yes		Global	No

6.1.5 How to Run MySQL as a Normal User

On Windows, you can run the server as a Windows service using a normal user account.

On Unix, the MySQL server `mysqld` can be started and run by any user. However, you should avoid running the server as the Unix `root` user for security reasons. To change `mysqld` to run as a normal unprivileged Unix user `user_name`, you must do the following:

1. Stop the server if it is running (use `mysqladmin shutdown`).
2. Change the database directories and files so that `user_name` has privileges to read and write files in them (you might need to do this as the Unix `root` user):

```
shell> chown -R user_name /path/to/mysql/datadir
```

If you do not do this, the server will not be able to access databases or tables when it runs as `user_name`.

If directories or files within the MySQL data directory are symbolic links, `chown -R` might not follow symbolic links for you. If it does not, you will also need to follow those links and change the directories and files they point to.

3. Start the server as user `user_name`. Another alternative is to start `mysqld` as the Unix `root` user and use the `--user=user_name` option. `mysqld` starts up, then switches to run as the Unix user `user_name` before accepting any connections.
4. To start the server as the given user automatically at system startup time, specify the user name by adding a `user` option to the `[mysqld]` group of the `/etc/my.cnf` option file or the `my.cnf` option file in the server's data directory. For example:

```
[mysqld]
```

```
user=user_name
```

If your Unix machine itself is not secured, you should assign passwords to the MySQL `root` accounts in the grant tables. Otherwise, any user with a login account on that machine can run the `mysql` client with a `--user=root` option and perform any operation. (It is a good idea to assign passwords to MySQL accounts in any case, but especially so when other login accounts exist on the server host.) See [Section 2.10.2, “Securing the Initial MySQL Accounts”](#).

6.1.6 Security Issues with `LOAD DATA LOCAL`

The `LOAD DATA` statement can load a file that is located on the server host, or it can load a file that is located on the client host when the `LOCAL` keyword is specified.

There are two potential security issues with supporting the `LOCAL` version of `LOAD DATA` statements:

- The transfer of the file from the client host to the server host is initiated by the MySQL server. In theory, a patched server could be built that would tell the client program to transfer a file of the server's choosing rather than the file named by the client in the `LOAD DATA` statement. Such a server could access any file on the client host to which the client user has read access.
- In a Web environment where the clients are connecting from a Web server, a user could use `LOAD DATA LOCAL` to read any files that the Web server process has read access to (assuming that a user could run any command against the SQL server). In this environment, the client with respect to the MySQL server actually is the Web server, not the remote program being run by the user who connects to the Web server.

To deal with these problems, we changed how `LOAD DATA LOCAL` is handled as of MySQL 3.23.49 and MySQL 4.0.2 (4.0.13 on Windows):

- By default, all MySQL clients and libraries in binary distributions are compiled with the `-DENABLED_LOCAL_INFILE=1` option, to be compatible with MySQL 3.23.48 and before.
- If you build MySQL from source but do not invoke `CMake` with the `-DENABLED_LOCAL_INFILE=1` option, `LOAD DATA LOCAL` cannot be used by any client unless it is written explicitly to invoke `mysql_options(... MYSQL_OPT_LOCAL_INFILE, 0)`. See [Section 23.8.7.49, “mysql_options\(\)”](#).
- You can disable all `LOAD DATA LOCAL` statements from the server side by starting `mysqld` with the `--local-infile=0` option.
- For the `mysql` command-line client, enable `LOAD DATA LOCAL` by specifying the `--local-infile[=1]` option, or disable it with the `--local-infile=0` option. For `mysqlimport`, local data file loading is off by default; enable it with the `--local` or `-L` option. In any case, successful use of a local load operation requires that the server permits it.
- If you use `LOAD DATA LOCAL` in Perl scripts or other programs that read the `[client]` group from option files, you can add the `local-infile=1` option to that group. However, to keep this from causing problems for programs that do not understand `local-infile`, specify it using the `loose-` prefix:

```
[client]
loose-local-infile=1
```

- If `LOAD DATA LOCAL` is disabled, either in the server or the client, a client that attempts to issue such a statement receives the following error message:

```
ERROR 1148: The used command is not allowed with this MySQL version
```

6.1.7 Client Programming Security Guidelines

Applications that access MySQL should not trust any data entered by users, who can try to trick your code by entering special or escaped character sequences in Web forms, URLs, or whatever application you have built. Be sure that your application remains secure if a user enters something like “`;
DROP DATABASE mysql;`”. This is an extreme example, but large security leaks and data loss might occur as a result of hackers using similar techniques, if you do not prepare for them.

A common mistake is to protect only string data values. Remember to check numeric data as well. If an application generates a query such as `SELECT * FROM table WHERE ID=234` when a user enters the value 234, the user can enter the value `234 OR 1=1` to cause the application to generate the query `SELECT * FROM table WHERE ID=234 OR 1=1`. As a result, the server retrieves every row in the table. This exposes every row and causes excessive server load. The simplest way to protect from this type of attack is to use single quotation marks around the numeric constants: `SELECT * FROM table WHERE ID='234'`. If the user enters extra information, it all becomes part of the string. In a numeric context, MySQL automatically converts this string to a number and strips any trailing nonnumeric characters from it.

Sometimes people think that if a database contains only publicly available data, it need not be protected. This is incorrect. Even if it is permissible to display any row in the database, you should still protect against denial of service attacks (for example, those that are based on the technique in the preceding paragraph that causes the server to waste resources). Otherwise, your server becomes unresponsive to legitimate users.

Checklist:

- Enable strict SQL mode to tell the server to be more restrictive of what data values it accepts. See [Section 5.1.7, “Server SQL Modes”](#).
- Try to enter single and double quotation marks (“’” and “””) in all of your Web forms. If you get any kind of MySQL error, investigate the problem right away.
- Try to modify dynamic URLs by adding `%22` (“”), `%23` (“#”), and `%27` (“’”) to them.
- Try to modify data types in dynamic URLs from numeric to character types using the characters shown in the previous examples. Your application should be safe against these and similar attacks.
- Try to enter characters, spaces, and special symbols rather than numbers in numeric fields. Your application should remove them before passing them to MySQL or else generate an error. Passing unchecked values to MySQL is very dangerous!
- Check the size of data before passing it to MySQL.
- Have your application connect to the database using a user name different from the one you use for administrative purposes. Do not give your applications any access privileges they do not need.

Many application programming interfaces provide a means of escaping special characters in data values. Properly used, this prevents application users from entering values that cause the application to generate statements that have a different effect than you intend:

- MySQL C API: Use the `mysql_real_escape_string()` API call.
- MySQL++: Use the `escape` and `quote` modifiers for query streams.
- PHP: Use either the `mysqli` or `pdo_mysql` extensions, and not the older `ext/mysql` extension. The preferred API's support the improved MySQL authentication protocol and passwords, as well as prepared statements with placeholders. See also [Choosing an API](#).

If the older `ext/mysql` extension must be used, then for escaping use the `mysql_real_escape_string()` function and not `mysql_escape_string()` or `addslashes()` because only `mysql_real_escape_string()` is character set-aware; the other functions can be “bypassed” when using (invalid) multi-byte character sets.

- Perl DBI: Use placeholders or the `quote()` method.
- Ruby DBI: Use placeholders or the `quote()` method.
- Java JDBC: Use a `PreparedStatement` object and placeholders.

Other programming interfaces might have similar capabilities.

6.2 The MySQL Access Privilege System

The primary function of the MySQL privilege system is to authenticate a user who connects from a given host and to associate that user with privileges on a database such as `SELECT`, `INSERT`, `UPDATE`, and `DELETE`. Additional functionality includes the ability to have anonymous users and to grant privileges for MySQL-specific functions such as `LOAD DATA INFILE` and administrative operations.

There are some things that you cannot do with the MySQL privilege system:

- You cannot explicitly specify that a given user should be denied access. That is, you cannot explicitly match a user and then refuse the connection.
- You cannot specify that a user has privileges to create or drop tables in a database but not to create or drop the database itself.
- A password applies globally to an account. You cannot associate a password with a specific object such as a database, table, or routine.

The user interface to the MySQL privilege system consists of SQL statements such as `CREATE USER`, `GRANT`, and `REVOKE`. See [Section 13.7.1, “Account Management Statements”](#).

Internally, the server stores privilege information in the grant tables of the `mysql` database (that is, in the database named `mysql`). The MySQL server reads the contents of these tables into memory when it starts and bases access-control decisions on the in-memory copies of the grant tables.

The MySQL privilege system ensures that all users may perform only the operations permitted to them. As a user, when you connect to a MySQL server, your identity is determined by *the host from which you connect* and *the user name you specify*. When you issue requests after connecting, the system grants privileges according to your identity and *what you want to do*.

MySQL considers both your host name and user name in identifying you because there is no reason to assume that a given user name belongs to the same person on all hosts. For example, the user `joe` who connects from `office.example.com` need not be the same person as the user `joe` who connects from `home.example.com`. MySQL handles this by enabling you to distinguish users on different hosts that happen to have the same name: You can grant one set of privileges for connections by `joe` from `office.example.com`, and a different set of privileges for connections by `joe` from `home.example.com`. To see what privileges a given account has, use the `SHOW GRANTS` statement. For example:

```
SHOW GRANTS FOR 'joe'@'office.example.com';
SHOW GRANTS FOR 'joe'@'home.example.com';
```

MySQL access control involves two stages when you run a client program that connects to the server:

Stage 1: The server accepts or rejects the connection based on your identity and whether you can verify your identity by supplying the correct password.

Stage 2: Assuming that you can connect, the server checks each statement you issue to determine whether you have sufficient privileges to perform it. For example, if you try to select rows from a table in a database or drop a table from the database, the server verifies that you have the [SELECT](#) privilege for the table or the [DROP](#) privilege for the database.

For a more detailed description of what happens during each stage, see [Section 6.2.4, “Access Control, Stage 1: Connection Verification”](#), and [Section 6.2.5, “Access Control, Stage 2: Request Verification”](#).

If your privileges are changed (either by yourself or someone else) while you are connected, those changes do not necessarily take effect immediately for the next statement that you issue. For details about the conditions under which the server reloads the grant tables, see [Section 6.2.6, “When Privilege Changes Take Effect”](#).

For general security-related advice, see [Section 6.1, “General Security Issues”](#). For help in diagnosing privilege-related problems, see [Section 6.2.7, “Causes of Access-Denied Errors”](#).

6.2.1 Privileges Provided by MySQL

MySQL provides privileges that apply in different contexts and at different levels of operation:

- Administrative privileges enable users to manage operation of the MySQL server. These privileges are global because they are not specific to a particular database.
- Database privileges apply to a database and to all objects within it. These privileges can be granted for specific databases, or globally so that they apply to all databases.
- Privileges for database objects such as tables, indexes, views, and stored routines can be granted for specific objects within a database, for all objects of a given type within a database (for example, all tables in a database), or globally for all objects of a given type in all databases).

Information about account privileges is stored in the [user](#), [db](#), [host](#), [tables_priv](#), [columns_priv](#), and [procs_priv](#) tables in the [mysql](#) database (see [Section 6.2.2, “Privilege System Grant Tables”](#)). The MySQL server reads the contents of these tables into memory when it starts and reloads them under the circumstances indicated in [Section 6.2.6, “When Privilege Changes Take Effect”](#). Access-control decisions are based on the in-memory copies of the grant tables.

Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features. To make sure that you can take advantage of any new capabilities, update your grant tables to have the current structure whenever you update to a new version of MySQL. See [Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”](#).

The following table shows the privilege names used at the SQL level in the [GRANT](#) and [REVOKE](#) statements, along with the column name associated with each privilege in the grant tables and the context in which the privilege applies.

Table 6.2 Permissible Privileges for [GRANT](#) and [REVOKE](#)

Privilege	Column	Context
CREATE	Create_priv	databases, tables, or indexes
DROP	Drop_priv	databases, tables, or views
GRANT OPTION	Grant_priv	databases, tables, or stored routines
LOCK TABLES	Lock_tables_priv	databases
REFERENCES	References_priv	databases or tables

Privilege	Column	Context
EVENT	Event_priv	databases
ALTER	Alter_priv	tables
DELETE	Delete_priv	tables
INDEX	Index_priv	tables
INSERT	Insert_priv	tables or columns
SELECT	Select_priv	tables or columns
UPDATE	Update_priv	tables or columns
CREATE TEMPORARY TABLES	Create_tmp_table_priv	tables
TRIGGER	Trigger_priv	tables
CREATE VIEW	Create_view_priv	views
SHOW VIEW	Show_view_priv	views
ALTER ROUTINE	Alter_routine_priv	stored routines
CREATE ROUTINE	Create_routine_priv	stored routines
EXECUTE	Execute_priv	stored routines
FILE	File_priv	file access on server host
CREATE TABLESPACE	Create_tablespace_priv	server administration
CREATE USER	Create_user_priv	server administration
PROCESS	Process_priv	server administration
PROXY	see proxies_priv table	server administration
RELOAD	Reload_priv	server administration
REPLICATION CLIENT	Repl_client_priv	server administration
REPLICATION SLAVE	Repl_slave_priv	server administration
SHOW DATABASES	Show_db_priv	server administration
SHUTDOWN	Shutdown_priv	server administration
SUPER	Super_priv	server administration
ALL [PRIVILEGES]		server administration
USAGE		server administration

The following list provides a general description of each privilege available in MySQL. Particular SQL statements might have more specific privilege requirements than indicated here. If so, the description for the statement in question provides the details.

- The `ALL` or `ALL PRIVILEGES` privilege specifier is shorthand. It stands for “all privileges available at a given privilege level” (except `GRANT OPTION`). For example, granting `ALL` at the global or table level grants all global privileges or all table-level privileges.
- The `ALTER` privilege enables use of `ALTER TABLE` to change the structure of tables. `ALTER TABLE` also requires the `CREATE` and `INSERT` privileges. Renaming a table requires `ALTER` and `DROP` on the old table, `ALTER`, `CREATE`, and `INSERT` on the new table.
- The `ALTER ROUTINE` privilege is needed to alter or drop stored routines (procedures and functions).
- The `CREATE` privilege enables creation of new databases and tables.

- The `CREATE ROUTINE` privilege is needed to create stored routines (procedures and functions).
- The `CREATE TABLESPACE` privilege is needed to create, alter, or drop tablespaces and log file groups.
- The `CREATE TEMPORARY TABLES` privilege enables the creation of temporary tables using the `CREATE TEMPORARY TABLE` statement.

However, other operations on a temporary table, such as `INSERT`, `UPDATE`, or `SELECT`, require additional privileges for those operations for the database containing the temporary table, or for the nontemporary table of the same name.

To keep privileges for temporary and nontemporary tables separate, a common workaround for this situation is to create a database dedicated to the use of temporary tables. Then for that database, a user can be granted the `CREATE TEMPORARY TABLES` privilege, along with any other privileges required for temporary table operations done by that user.

- The `CREATE USER` privilege enables use of `CREATE USER`, `DROP USER`, `RENAME USER`, and `REVOKE ALL PRIVILEGES`.
- The `CREATE VIEW` privilege enables use of `CREATE VIEW`.
- The `DELETE` privilege enables rows to be deleted from tables in a database.
- The `DROP` privilege enables you to drop (remove) existing databases, tables, and views. The `DROP` privilege is required in order to use the statement `ALTER TABLE ... DROP PARTITION` on a partitioned table. The `DROP` privilege is also required for `TRUNCATE TABLE`. *If you grant the `DROP` privilege for the `mysql` database to a user, that user can drop the database in which the MySQL access privileges are stored.*
- The `EVENT` privilege is required to create, alter, drop, or see events for the Event Scheduler.
- The `EXECUTE` privilege is required to execute stored routines (procedures and functions).
- The `FILE` privilege gives you permission to read and write files on the server host using the `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` function. A user who has the `FILE` privilege can read any file on the server host that is either world-readable or readable by the MySQL server. (This implies the user can read any file in any database directory, because the server can access any of those files.) The `FILE` privilege also enables the user to create new files in any directory where the MySQL server has write access. This includes the server's data directory containing the files that implement the privilege tables. As a security measure, the server will not overwrite existing files.

To limit the location in which files can be read and written, set the `secure_file_priv` system to a specific directory. See [Section 5.1.4, “Server System Variables”](#).

- The `GRANT OPTION` privilege enables you to give to other users or remove from other users those privileges that you yourself possess.
- The `INDEX` privilege enables you to create or drop (remove) indexes. `INDEX` applies to existing tables. If you have the `CREATE` privilege for a table, you can include index definitions in the `CREATE TABLE` statement.
- The `INSERT` privilege enables rows to be inserted into tables in a database. `INSERT` is also required for the `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` table-maintenance statements.
- The `LOCK TABLES` privilege enables the use of explicit `LOCK TABLES` statements to lock tables for which you have the `SELECT` privilege. This includes the use of write locks, which prevents other sessions from reading the locked table.

- The `PROCESS` privilege pertains to display of information about the threads executing within the server (that is, information about the statements being executed by sessions). The privilege enables use of `SHOW PROCESSLIST` or `mysqladmin processlist` to see threads belonging to other accounts; you can always see your own threads. The `PROCESS` privilege also enables use of `SHOW ENGINE`.
- The `PROXY` privilege enables a user to impersonate or become known as another user. See [Section 6.3.8, “Proxy Users”](#). This privilege was added in MySQL 5.5.7.
- The `REFERENCES` privilege currently is unused.
- The `RELOAD` privilege enables use of the `FLUSH` statement. It also enables `mysqladmin` commands that are equivalent to `FLUSH` operations: `flush-hosts`, `flush-logs`, `flush-privileges`, `flush-status`, `flush-tables`, `flush-threads`, `refresh`, and `reload`.

The `reload` command tells the server to reload the grant tables into memory. `flush-privileges` is a synonym for `reload`. The `refresh` command closes and reopens the log files and flushes all tables. The other `flush-xxx` commands perform functions similar to `refresh`, but are more specific and may be preferable in some instances. For example, if you want to flush just the log files, `flush-logs` is a better choice than `refresh`.

- The `REPLICATION CLIENT` privilege enables the use of `SHOW MASTER STATUS` and `SHOW SLAVE STATUS`. In MySQL 5.5.25 and later, it also enables the use of the `SHOW BINARY LOGS` statement.
- The `REPLICATION SLAVE` privilege should be granted to accounts that are used by slave servers to connect to the current server as their master. Without this privilege, the slave cannot request updates that have been made to databases on the master server.
- The `SELECT` privilege enables you to select rows from tables in a database. `SELECT` statements require the `SELECT` privilege only if they actually retrieve rows from a table. Some `SELECT` statements do not access tables and can be executed without permission for any database. For example, you can use `SELECT` as a simple calculator to evaluate expressions that make no reference to tables:

```
SELECT 1+1;  
SELECT PI()*2;
```

The `SELECT` privilege is also needed for other statements that read column values. For example, `SELECT` is needed for columns referenced on the right hand side of `col_name=expr` assignment in `UPDATE` statements or for columns named in the `WHERE` clause of `DELETE` or `UPDATE` statements.

- The `SHOW DATABASES` privilege enables the account to see database names by issuing the `SHOW DATABASE` statement. Accounts that do not have this privilege see only databases for which they have some privileges, and cannot use the statement at all if the server was started with the `--skip-show-database` option. Note that *any* global privilege is a privilege for the database.
- The `SHOW VIEW` privilege enables use of `SHOW CREATE VIEW`.
- The `SHUTDOWN` privilege enables use of the `mysqladmin shutdown` command. There is no corresponding SQL statement.
- The `SUPER` privilege enables an account to use `CHANGE MASTER TO`, `KILL` or `mysqladmin kill` to kill threads belonging to other accounts (you can always kill your own threads), `PURGE BINARY LOGS`, configuration changes using `SET GLOBAL` to modify global system variables, the `mysqladmin debug` command, enabling or disabling logging, performing updates even if the `read_only` system variable is enabled, starting and stopping replication on slave servers, specification of any account in the `DEFINER` attribute of stored programs and views, and enables you to connect (once) even if the connection limit controlled by the `max_connections` system variable is reached.

To create or alter stored functions if binary logging is enabled, you may also need the [SUPER](#) privilege, as described in [Section 20.7, “Binary Logging of Stored Programs”](#).

- The [TRIGGER](#) privilege enables trigger operations. You must have this privilege for a table to create, drop, or execute triggers for that table.
- The [UPDATE](#) privilege enables rows to be updated in tables in a database.
- The [USAGE](#) privilege specifier stands for “no privileges.” It is used at the global level with [GRANT](#) to modify account attributes such as resource limits or SSL characteristics without affecting existing account privileges.

It is a good idea to grant to an account only those privileges that it needs. You should exercise particular caution in granting the [FILE](#) and administrative privileges:

- The [FILE](#) privilege can be abused to read into a database table any files that the MySQL server can read on the server host. This includes all world-readable files and files in the server's data directory. The table can then be accessed using [SELECT](#) to transfer its contents to the client host.
- The [GRANT OPTION](#) privilege enables users to give their privileges to other users. Two users that have different privileges and with the [GRANT OPTION](#) privilege are able to combine privileges.
- The [ALTER](#) privilege may be used to subvert the privilege system by renaming tables.
- The [SHUTDOWN](#) privilege can be abused to deny service to other users entirely by terminating the server.
- The [PROCESS](#) privilege can be used to view the plain text of currently executing statements, including statements that set or change passwords.
- The [SUPER](#) privilege can be used to terminate other sessions or change how the server operates.
- Privileges granted for the [mysql](#) database itself can be used to change passwords and other access privilege information. Passwords are stored encrypted, so a malicious user cannot simply read them to know the plain text password. However, a user with write access to the [user](#) table [Password](#) column can change an account's password, and then connect to the MySQL server using that account.

6.2.2 Privilege System Grant Tables

Normally, you manipulate the contents of the grant tables in the [mysql](#) database indirectly by using statements such as [GRANT](#) and [REVOKE](#) to set up accounts and control the privileges available to each one. See [Section 13.7.1, “Account Management Statements”](#). The discussion here describes the underlying structure of the grant tables and how the server uses their contents when interacting with clients.

These [mysql](#) database tables contain grant information:

- [user](#): Contains user accounts, global privileges, and other non-privilege columns.
- [db](#): Contains database-level privileges.
- [host](#): Obsolete.
- [tables_priv](#): Contains table-level privileges.
- [columns_priv](#): Contains column-level privileges.
- [procs_priv](#): Contains stored procedure and function privileges.

- `proxies_priv`: Contains proxy-user privileges.

Other tables in the `mysql` database do not hold grant information and are discussed elsewhere:

- `event`: Contains information about Event Scheduler events: See [Section 20.4, “Using the Event Scheduler”](#).
- `func`: Contains information about user-defined functions: See [Section 24.3, “Adding New Functions to MySQL”](#).
- `help_xxx`: These tables are used for server-side help: See [Section 5.1.10, “Server-Side Help”](#).
- `plugin`: Contains information about server plugins: See [Section 5.1.8.1, “Installing and Uninstalling Plugins”](#), and [Section 24.2, “The MySQL Plugin API”](#).
- `proc`: Contains information about stored procedures and functions: See [Section 20.2, “Using Stored Routines \(Procedures and Functions\)”](#).
- `servers`: Used by the `FEDERATED` storage engine: See [Section 15.9.2.2, “Creating a FEDERATED Table Using CREATE SERVER”](#).
- `time_zone_xxx`: These tables contain time zone information: See [Section 10.6, “MySQL Server Time Zone Support”](#).
- Tables with `_log` in their name are used for logging: See [Section 5.2, “MySQL Server Logs”](#).

Note

Modifications to tables in the `mysql` database normally are made by the server in response to statements such as `CREATE USER`, `GRANT`, or `CREATE PROCEDURE`. Direct modification of these tables using statements such as `INSERT`, `UPDATE`, or `DELETE` is not encouraged. The server is free to ignore rows that become malformed as a result of such modifications.

Each grant table contains scope columns and privilege columns:

- Scope columns determine the scope of each row (entry) in the tables; that is, the context in which the row applies. For example, a `user` table row with `Host` and `User` values of `'thomas.loc.gov'` and `'bob'` would be used for authenticating connections made to the server from the host `thomas.loc.gov` by a client that specifies a user name of `bob`. Similarly, a `db` table row with `Host`, `User`, and `Db` column values of `'thomas.loc.gov'`, `'bob'` and `'reports'` would be used when `bob` connects from the host `thomas.loc.gov` to access the `reports` database. The `tables_priv` and `columns_priv` tables contain scope columns indicating tables or table/column combinations to which each row applies. The `procs_priv` scope columns indicate the stored routine to which each row applies.
- Privilege columns indicate which privileges are granted by a table row; that is, what operations can be performed. The server combines the information in the various grant tables to form a complete description of a user's privileges. [Section 6.2.5, “Access Control, Stage 2: Request Verification”](#), describes the rules that are used to do this.

The server uses the grant tables in the following manner:

- The `user` table scope columns determine whether to reject or permit incoming connections. For permitted connections, any privileges granted in the `user` table indicate the user's global privileges. Any privilege granted in this table applies to *all* databases on the server.

Note

Because any global privilege is considered a privilege for all databases, any global privilege enables a user to see all database names with [SHOW DATABASES](#) or by examining the [SCHEMATA](#) table of [INFORMATION_SCHEMA](#).

- The [db](#) table scope columns determine which users can access which databases from which hosts. The privilege columns determine which operations are permitted. A privilege granted at the database level applies to the database and to all objects in the database, such as tables and stored programs.
- The [host](#) table is used in conjunction with the [db](#) table when you want a given [db](#) table row to apply to several hosts. For example, if you want a user to be able to use a database from several hosts in your network, leave the [Host](#) value empty in the user's [db](#) table row, then populate the [host](#) table with a row for each of those hosts. This mechanism is described more detail in [Section 6.2.5, “Access Control, Stage 2: Request Verification”](#).

Note

The [host](#) table must be modified directly with statements such as [INSERT](#), [UPDATE](#), and [DELETE](#). It is not affected by statements such as [GRANT](#) and [REVOKE](#) that modify the grant tables indirectly. Most MySQL installations need not use this table at all.

- The [tables_priv](#) and [columns_priv](#) tables are similar to the [db](#) table, but are more fine-grained: They apply at the table and column levels rather than at the database level. A privilege granted at the table level applies to the table and to all its columns. A privilege granted at the column level applies only to a specific column.
- The [procs_priv](#) table applies to stored routines. A privilege granted at the routine level applies only to a single routine.
- The [proxies_priv](#) table indicates which users can act as proxies for other users and whether proxy users can grant the [PROXY](#) privilege to other users.

The server uses the [user](#), [db](#), and [host](#) tables in the [mysql](#) database at both the first and second stages of access control (see [Section 6.2, “The MySQL Access Privilege System”](#)). The columns in the [user](#) and [db](#) tables are shown here. The [host](#) table is similar to the [db](#) table but has a specialized use as described in [Section 6.2.5, “Access Control, Stage 2: Request Verification”](#).

Table 6.3 [user](#) and [db](#) Table Columns

Table Name	user	db
Scope columns		
	Host	Host
	User	Db
	Password	User
Privilege columns		
	Select_priv	Select_priv
	Insert_priv	Insert_priv
	Update_priv	Update_priv
	Delete_priv	Delete_priv
	Index_priv	Index_priv
	Alter_priv	Alter_priv
	Create_priv	Create_priv

Table Name	user	db
	Drop_priv	Drop_priv
	Grant_priv	Grant_priv
	Create_view_priv	Create_view_priv
	Show_view_priv	Show_view_priv
	Create_routine_priv	Create_routine_priv
	Alter_routine_priv	Alter_routine_priv
	Execute_priv	Execute_priv
	Trigger_priv	Trigger_priv
	Event_priv	Event_priv
	Create_tmp_table_priv	Create_tmp_table_priv
	Lock_tables_priv	Lock_tables_priv
	References_priv	References_priv
	Reload_priv	
	Shutdown_priv	
	Process_priv	
	File_priv	
	Show_db_priv	
	Super_priv	
	Repl_slave_priv	
	Repl_client_priv	
	Create_user_priv	
	Create_tablespace_priv	
Security columns	ssl_type	
	ssl_cipher	
	x509_issuer	
	x509_subject	
	plugin	
	authentication_string	
Resource control columns	max_questions	
	max_updates	
	max_connections	
	max_user_connections	

As of MySQL 5.5.7, the `mysql.user` table has `plugin` and `authentication_string` columns for storing authentication plugin information.

If the `plugin` column for an account row is empty, the server authenticates the account using either the `mysql_native_password` or `mysql_old_password` plugin, depending on whether the password hash value in the `Password` column used native hashing or the older pre-4.1 hashing method. Clients must match the password in the `Password` column of the account row.

If an account row names a plugin in the `plugin` column, the server uses it to authenticate connection attempts for the account. Whether the plugin uses the value in the `Password` column is up to the plugin.

Prior to MySQL 5.5.11, the length of the `plugin` column was 60 characters. This was increased to 64 characters in MySQL 5.5.11 for compatibility with the `mysql.plugin` table's `name` column. (Bug #11766610, Bug #59752)

During the second stage of access control, the server performs request verification to make sure that each client has sufficient privileges for each request that it issues. In addition to the `user`, `db`, and `host` grant tables, the server may also consult the `tables_priv` and `columns_priv` tables for requests that involve tables. The latter tables provide finer privilege control at the table and column levels. They have the columns shown in the following table.

Table 6.4 `tables_priv` and `columns_priv` Table Columns

Table Name	<code>tables_priv</code>	<code>columns_priv</code>
Scope columns	<code>Host</code>	<code>Host</code>
	<code>Db</code>	<code>Db</code>
	<code>User</code>	<code>User</code>
	<code>Table_name</code>	<code>Table_name</code>
		<code>Column_name</code>
Privilege columns	<code>Table_priv</code>	<code>Column_priv</code>
	<code>Column_priv</code>	
Other columns	<code>Timestamp</code>	<code>Timestamp</code>
	<code>Grantor</code>	

The `Timestamp` and `Grantor` columns are set to the current timestamp and the `CURRENT_USER` value, respectively. However, they are unused and are discussed no further here.

For verification of requests that involve stored routines, the server may consult the `procs_priv` table, which has the columns shown in the following table.

Table 6.5 `procs_priv` Table Columns

Table Name	<code>procs_priv</code>
Scope columns	<code>Host</code>
	<code>Db</code>
	<code>User</code>
	<code>Routine_name</code>
	<code>Routine_type</code>
Privilege columns	<code>Proc_priv</code>
Other columns	<code>Timestamp</code>
	<code>Grantor</code>

The `Routine_type` column is an `ENUM` column with values of `'FUNCTION'` or `'PROCEDURE'` to indicate the type of routine the row refers to. This column enables privileges to be granted separately for a function and a procedure with the same name.

The `Timestamp` and `Grantor` columns currently are unused and are discussed no further here.

The `proxies_priv` table was added in MySQL 5.5.7 and records information about proxy users. It has these columns:

- `Host`, `User`: These columns indicate the user account that has the `PROXY` privilege for the proxied account.
- `Proxied_host`, `Proxied_user`: These columns indicate the account of the proxied user.
- `Grantor`: Currently unused.
- `Timestamp`: Currently unused.
- `With_grant`: This column indicates whether the proxy account can grant the `PROXY` privilege to other accounts.

Scope columns in the grant tables contain strings. They are declared as shown here; the default value for each is the empty string.

Table 6.6 Grant Table Scope Column Types

Column Name	Type
<code>Host</code> , <code>Proxied_host</code>	<code>CHAR(60)</code>
<code>User</code> , <code>Proxied_user</code>	<code>CHAR(16)</code>
<code>Password</code>	<code>CHAR(41)</code>
<code>Db</code>	<code>CHAR(64)</code>
<code>Table_name</code>	<code>CHAR(64)</code>
<code>Column_name</code>	<code>CHAR(64)</code>
<code>Routine_name</code>	<code>CHAR(64)</code>

For access-checking purposes, comparisons of `User`, `Proxied_user`, `Password`, `Db`, and `Table_name` values are case sensitive. Comparisons of `Host`, `Proxied_host`, `Column_name`, and `Routine_name` values are not case sensitive.

In the `user`, `db`, and `host` tables, each privilege is listed in a separate column that is declared as `ENUM('N', 'Y') DEFAULT 'N'`. In other words, each privilege can be disabled or enabled, with the default being disabled.

In the `tables_priv`, `columns_priv`, and `procs_priv` tables, the privilege columns are declared as `SET` columns. Values in these columns can contain any combination of the privileges controlled by the table. Only those privileges listed in the column value are enabled.

Table 6.7 Set-Type Privilege Column Values

Table Name	Column Name	Possible Set Elements
<code>tables_priv</code>	<code>Table_priv</code>	'Select', 'Insert', 'Update', 'Delete', 'Create', 'Drop', 'Grant', 'References', 'Index', 'Alter', 'Create View', 'Show view', 'Trigger'

Table Name	Column Name	Possible Set Elements
<code>tables_priv</code>	<code>Column_priv</code>	'Select', 'Insert', 'Update', 'References'
<code>columns_priv</code>	<code>Column_priv</code>	'Select', 'Insert', 'Update', 'References'
<code>procs_priv</code>	<code>Proc_priv</code>	'Execute', 'Alter Routine', 'Grant'

Administrative privileges (such as `RELOAD` or `SHUTDOWN`) are specified only in the `user` table. Administrative operations are operations on the server itself and are not database-specific, so there is no reason to list these privileges in the other grant tables. Consequently, to determine whether you can perform an administrative operation, the server need consult only the `user` table.

The `FILE` privilege also is specified only in the `user` table. It is not an administrative privilege as such, but your ability to read or write files on the server host is independent of the database you are accessing.

The `mysqld` server reads the contents of the grant tables into memory when it starts. You can tell it to reload the tables by issuing a `FLUSH PRIVILEGES` statement or executing a `mysqladmin flush-privileges` or `mysqladmin reload` command. Changes to the grant tables take effect as indicated in [Section 6.2.6, “When Privilege Changes Take Effect”](#).

When you modify an account's privileges, it is a good idea to verify that the changes set up privileges the way you want. To check the privileges for a given account, use the `SHOW GRANTS` statement (see [Section 13.7.5.22, “SHOW GRANTS Syntax”](#)). For example, to determine the privileges that are granted to an account with user name and host name values of `bob` and `pc84.example.com`, use this statement:

```
SHOW GRANTS FOR 'bob'@'pc84.example.com';
```

6.2.3 Specifying Account Names

MySQL account names consist of a user name and a host name. This enables creation of accounts for users with the same name who can connect from different hosts. This section describes how to write account names, including special values and wildcard rules.

In SQL statements such as `CREATE USER`, `GRANT`, and `SET PASSWORD`, write account names using the following rules:

- Syntax for account names is `'user_name'@'host_name'`.
- An account name consisting only of a user name is equivalent to `'user_name'@' % '`. For example, `'me'` is equivalent to `'me'@' % '`.
- The user name and host name need not be quoted if they are legal as unquoted identifiers. Quotes are necessary to specify a `user_name` string containing special characters (such as `-`), or a `host_name` string containing special characters or wildcard characters (such as `%`); for example, `'test-user'@' % .com'`.
- Quote user names and host names as identifiers or as strings, using either backticks (```), single quotation marks (`'`), or double quotation marks (`"`).
- The user name and host name parts, if quoted, must be quoted separately. That is, write `'me'@'localhost'`, not `'me@localhost'`; the latter is interpreted as `'me@localhost'@' % '`.
- A reference to the `CURRENT_USER` or `CURRENT_USER()` function is equivalent to specifying the current client's user name and host name literally.

MySQL stores account names in grant tables in the `mysql` database using separate columns for the user name and host name parts:

- The `user` table contains one row for each account. The `User` and `Host` columns store the user name and host name. This table also indicates which global privileges the account has.
- Other grant tables indicate privileges an account has for databases and objects within databases. These tables have `User` and `Host` columns to store the account name. Each row in these tables associates with the account in the `user` table that has the same `User` and `Host` values.

For additional detail about grant table structure, see [Section 6.2.2, “Privilege System Grant Tables”](#).

User names and host names have certain special values or wildcard conventions, as described following.

A user name is either a nonblank value that literally matches the user name for incoming connection attempts, or a blank value (empty string) that matches any user name. An account with a blank user name is an anonymous user. To specify an anonymous user in SQL statements, use a quoted empty user name part, such as `'@'localhost'`.

The host name part of an account name can take many forms, and wildcards are permitted:

- A host value can be a host name or an IP address (IPv4 or IPv6). The name `'localhost'` indicates the local host. The IP address `'127.0.0.1'` indicates the IPv4 loopback interface. The IP address `:::1` indicates the IPv6 loopback interface.
- You can use the wildcard characters `%` and `_` in host name or IP address values. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator. For example, a host value of `'%'` matches any host name, whereas a value of `'%.mysql.com'` matches any host in the `mysql.com` domain. `'192.168.1.%'` matches any host in the 192.168.1 class C network.

Because you can use IP wildcard values in host values (for example, `'192.168.1.%'` to match every host on a subnet), someone could try to exploit this capability by naming a host `192.168.1.somewhere.com`. To foil such attempts, MySQL disallows matching on host names that start with digits and a dot. Thus, if you have a host named something like `1.2.example.com`, its name never matches the host part of account names. An IP wildcard value can match only IP addresses, not host names.

- For a host value specified as an IPv4 address, you can specify a netmask indicating how many address bits to use for the network number. Netmask notation cannot be used for IPv6 addresses.

The syntax is `host_ip/netmask`. For example:

```
CREATE USER 'david'@'192.58.197.0/255.255.255.0';
```

This enables `david` to connect from any client host having an IP address `client_ip` for which the following condition is true:

```
client_ip & netmask = host_ip
```

That is, for the `CREATE USER` statement just shown:

```
client_ip & 255.255.255.0 = 192.58.197.0
```

IP addresses that satisfy this condition and can connect to the MySQL server are those in the range from `192.58.197.0` to `192.58.197.255`.

The netmask can only be used to tell the server to use 8, 16, 24, or 32 bits of the address. Examples:

- `192.0.0.0/255.0.0.0`: Any host on the 192 class A network
- `192.168.0.0/255.255.0.0`: Any host on the 192.168 class B network
- `192.168.1.0/255.255.255.0`: Any host on the 192.168.1 class C network
- `192.168.1.1`: Only the host with this specific IP address

The following netmask will not work because it masks 28 bits, and 28 is not a multiple of 8:

```
192.168.0.1/255.255.255.240
```

The server performs matching of host values in account names against the client host using the value returned by the system DNS resolver for the client host name or IP address. Except in the case that the account host value is specified using netmask notation, this comparison is performed as a string match, even for an account host value given as an IP address. This means that you should specify account host values in the same format used by DNS. Here are examples of problems to watch out for:

- Suppose that a host on the local network has a fully qualified name of `host1.example.com`. If DNS returns name lookups for this host as `host1.example.com`, use that name in account host values. But if DNS returns just `host1`, use `host1` instead.
- If DNS returns the IP address for a given host as `192.168.1.2`, that will match an account host value of `192.168.1.2` but not `192.168.01.2`. Similarly, it will match an account host pattern like `192.168.1.%` but not `192.168.01.%`.

To avoid problems like this, it is advisable to check the format in which your DNS returns host names and addresses, and use values in the same format in MySQL account names.

6.2.4 Access Control, Stage 1: Connection Verification

When you attempt to connect to a MySQL server, the server accepts or rejects the connection based on your identity and whether you can verify your identity by supplying the correct password. If not, the server denies access to you completely. Otherwise, the server accepts the connection, and then enters Stage 2 and waits for requests.

Your identity is based on two pieces of information:

- The client host from which you connect
- Your MySQL user name

Identity checking is performed using the three `user` table scope columns (`Host`, `User`, and `Password`). The server accepts the connection only if the `Host` and `User` columns in some `user` table row match the client host name and user name and the client supplies the password specified in that row. The rules for permissible `Host` and `User` values are given in [Section 6.2.3, "Specifying Account Names"](#).

If the `User` column value is nonblank, the user name in an incoming connection must match exactly. If the `User` value is blank, it matches any user name. If the `user` table row that matches an incoming connection has a blank user name, the user is considered to be an anonymous user with no name, not a user with the name that the client actually specified. This means that a blank user name is used for all further access checking for the duration of the connection (that is, during Stage 2).

The `Password` column can be blank. This is not a wildcard and does not mean that any password matches. It means that the user must connect without specifying a password. If the server authenticates a client using a plugin, the authentication method that the plugin implements may or may not use the password in the `Password` column. In this case, it is possible that an external password is also used to authenticate to the MySQL server.

Nonblank `Password` values in the `user` table represent encrypted passwords. MySQL does not store passwords in plaintext form for anyone to see. Rather, the password supplied by a user who is attempting to connect is encrypted (using the `PASSWORD()` function). The encrypted password then is used during the connection process when checking whether the password is correct. This is done without the encrypted password ever traveling over the connection. See [Section 6.3.1, “User Names and Passwords”](#).

From MySQL's point of view, the encrypted password is the *real* password, so you should never give anyone access to it. In particular, *do not give nonadministrative users read access to tables in the `mysql` database*.

The following table shows how various combinations of `Host` and `User` values in the `user` table apply to incoming connections.

Host Value	User Value	Permissible Connections
'thomas.loc.gov'	'fred'	fred, connecting from thomas.loc.gov
'thomas.loc.gov'	' '	Any user, connecting from thomas.loc.gov
'%'	'fred'	fred, connecting from any host
'%'	' '	Any user, connecting from any host
'%.loc.gov'	'fred'	fred, connecting from any host in the loc.gov domain
'x.y.%'	'fred'	fred, connecting from x.y.net, x.y.com, x.y.edu, and so on; this is probably not useful
'144.155.166.177'	'fred'	fred, connecting from the host with IP address 144.155.166.177
'144.155.166.%'	'fred'	fred, connecting from any host in the 144.155.166 class C subnet
'144.155.166.0/255.255.255.0'	'fred'	Same as previous example

It is possible for the client host name and user name of an incoming connection to match more than one row in the `user` table. The preceding set of examples demonstrates this: Several of the entries shown match a connection from thomas.loc.gov by fred.

When multiple matches are possible, the server must determine which of them to use. It resolves this issue as follows:

- Whenever the server reads the `user` table into memory, it sorts the rows.
- When a client attempts to connect, the server looks through the rows in sorted order.
- The server uses the first row that matches the client host name and user name.

The server uses sorting rules that order rows with the most-specific `Host` values first. Literal host names and IP addresses are the most specific. (The specificity of a literal IP address is not affected by whether it has a netmask, so 192.168.1.13 and 192.168.1.0/255.255.255.0 are considered equally specific.) The pattern '%' means “any host” and is least specific. The empty string ' ' also means “any host” but sorts after '%'. Rows with the same `Host` value are ordered with the most-specific `User` values first (a

blank `User` value means “any user” and is least specific). For rows with equally-specific `Host` and `User` values, the order is indeterminate.

To see how this works, suppose that the `user` table looks like this:

Host	User	...
%	root	...
%	jeffrey	...
localhost	root	...
localhost		...

When the server reads the table into memory, it sorts the rows using the rules just described. The result after sorting looks like this:

Host	User	...
localhost	root	...
localhost		...
%	jeffrey	...
%	root	...

When a client attempts to connect, the server looks through the sorted rows and uses the first match found. For a connection from `localhost` by `jeffrey`, two of the rows from the table match: the one with `Host` and `User` values of '`localhost`' and '`'`', and the one with values of '`%`' and '`jeffrey`'. The '`localhost`' row appears first in sorted order, so that is the one the server uses.

Here is another example. Suppose that the `user` table looks like this:

Host	User	...
%	jeffrey	...
thomas.loc.gov		...

The sorted table looks like this:

Host	User	...
thomas.loc.gov		...
%	jeffrey	...

A connection by `jeffrey` from `thomas.loc.gov` is matched by the first row, whereas a connection by `jeffrey` from any host is matched by the second.

Note

It is a common misconception to think that, for a given user name, all rows that explicitly name that user are used first when the server attempts to find a match for the connection. This is not true. The preceding example illustrates this, where

a connection from `thomas.loc.gov` by `jeffrey` is first matched not by the row containing `'jeffrey'` as the `User` column value, but by the row with no user name. As a result, `jeffrey` is authenticated as an anonymous user, even though he specified a user name when connecting.

If you are able to connect to the server, but your privileges are not what you expect, you probably are being authenticated as some other account. To find out what account the server used to authenticate you, use the `CURRENT_USER()` function. (See [Section 12.14, “Information Functions”](#).) It returns a value in `user_name@host_name` format that indicates the `User` and `Host` values from the matching `user` table row. Suppose that `jeffrey` connects and issues the following query:

```
mysql> SELECT CURRENT_USER();
+-----+
| CURRENT_USER() |
+-----+
| @localhost      |
+-----+
```

The result shown here indicates that the matching `user` table row had a blank `User` column value. In other words, the server is treating `jeffrey` as an anonymous user.

Another way to diagnose authentication problems is to print out the `user` table and sort it by hand to see where the first match is being made.

6.2.5 Access Control, Stage 2: Request Verification

After you establish a connection, the server enters Stage 2 of access control. For each request that you issue through that connection, the server determines what operation you want to perform, then checks whether you have sufficient privileges to do so. This is where the privilege columns in the grant tables come into play. These privileges can come from any of the `user`, `db`, `host`, `tables_priv`, `columns_priv`, or `procs_priv` tables. (You may find it helpful to refer to [Section 6.2.2, “Privilege System Grant Tables”](#), which lists the columns present in each of the grant tables.)

The `user` table grants privileges that are assigned to you on a global basis and that apply no matter what the default database is. For example, if the `user` table grants you the `DELETE` privilege, you can delete rows from any table in any database on the server host! It is wise to grant privileges in the `user` table only to people who need them, such as database administrators. For other users, you should leave all privileges in the `user` table set to `'N'` and grant privileges at more specific levels only. You can grant privileges for particular databases, tables, columns, or routines.

The `db` and `host` tables grant database-specific privileges. Values in the scope columns of these tables can take the following forms:

- A blank `User` value in the `db` table matches the anonymous user. A nonblank value matches literally; there are no wildcards in user names.
- The wildcard characters `“%”` and `“_”` can be used in the `Host` and `Db` columns of either table. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator. If you want to use either character literally when granting privileges, you must escape it with a backslash. For example, to include the underscore character (`“_”`) as part of a database name, specify it as `“_”` in the `GRANT` statement.
- A `'%'` `Host` value in the `db` table means “any host.” A blank `Host` value in the `db` table means “consult the `host` table for further information” (a process that is described later in this section).
- A `'%'` or blank `Host` value in the `host` table means “any host.”

- A '%' or blank `Db` value in either table means “any database.”

The server reads the `db` and `host` tables into memory and sorts them at the same time that it reads the `user` table. The server sorts the `db` table based on the `Host`, `Db`, and `User` scope columns, and sorts the `host` table based on the `Host` and `Db` scope columns. As with the `user` table, sorting puts the most-specific values first and least-specific values last, and when the server looks for matching entries, it uses the first match that it finds.

The `tables_priv`, `columns_priv`, and `procs_priv` tables grant table-specific, column-specific, and routine-specific privileges. Values in the scope columns of these tables can take the following forms:

- The wildcard characters “%” and “_” can be used in the `Host` column. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator.
- A '%' or blank `Host` value means “any host.”
- The `Db`, `Table_name`, `Column_name`, and `Routine_name` columns cannot contain wildcards or be blank.

The server sorts the `tables_priv`, `columns_priv`, and `procs_priv` tables based on the `Host`, `Db`, and `User` columns. This is similar to `db` table sorting, but simpler because only the `Host` column can contain wildcards.

The server uses the sorted tables to verify each request that it receives. For requests that require administrative privileges such as `SHUTDOWN` or `RELOAD`, the server checks only the `user` table row because that is the only table that specifies administrative privileges. The server grants access if the row permits the requested operation and denies access otherwise. For example, if you want to execute `mysqladmin shutdown` but your `user` table row does not grant the `SHUTDOWN` privilege to you, the server denies access without even checking the `db` or `host` tables. (They contain no `Shutdown_priv` column, so there is no need to do so.)

For database-related requests (`INSERT`, `UPDATE`, and so on), the server first checks the user's global privileges by looking in the `user` table row. If the row permits the requested operation, access is granted. If the global privileges in the `user` table are insufficient, the server determines the user's database-specific privileges by checking the `db` and `host` tables:

1. The server looks in the `db` table for a match on the `Host`, `Db`, and `User` columns. The `Host` and `User` columns are matched to the connecting user's host name and MySQL user name. The `Db` column is matched to the database that the user wants to access. If there is no row for the `Host` and `User`, access is denied.
2. If there is a matching `db` table row and its `Host` column is not blank, that row defines the user's database-specific privileges.
3. If the matching `db` table row's `Host` column is blank, it signifies that the `host` table enumerates which hosts should be permitted access to the database. In this case, a further lookup is done in the `host` table to find a match on the `Host` and `Db` columns. If no `host` table row matches, access is denied. If there is a match, the user's database-specific privileges are computed as the intersection (*not* the union!) of the privileges in the `db` and `host` table entries; that is, the privileges that are 'Y' in both entries. (This way you can grant general privileges in the `db` table row and then selectively restrict them on a host-by-host basis using the `host` table entries.)

After determining the database-specific privileges granted by the `db` and `host` table entries, the server adds them to the global privileges granted by the `user` table. If the result permits the requested operation, access is granted. Otherwise, the server successively checks the user's table and column privileges in

the `tables_priv` and `columns_priv` tables, adds those to the user's privileges, and permits or denies access based on the result. For stored-routine operations, the server uses the `procs_priv` table rather than `tables_priv` and `columns_priv`.

Expressed in boolean terms, the preceding description of how a user's privileges are calculated may be summarized like this:

```
global privileges
OR (database privileges AND host privileges)
OR table privileges
OR column privileges
OR routine privileges
```

It may not be apparent why, if the global `user` row privileges are initially found to be insufficient for the requested operation, the server adds those privileges to the database, table, and column privileges later. The reason is that a request might require more than one type of privilege. For example, if you execute an `INSERT INTO ... SELECT` statement, you need both the `INSERT` and the `SELECT` privileges. Your privileges might be such that the `user` table row grants one privilege and the `db` table row grants the other. In this case, you have the necessary privileges to perform the request, but the server cannot tell that from either table by itself; the privileges granted by the entries in both tables must be combined.

The `host` table is not affected by the `GRANT` or `REVOKE` statements, so it is unused in most MySQL installations. If you modify it directly, you can use it for some specialized purposes, such as to maintain a list of secure servers on the local network that are granted all privileges.

You can also use the `host` table to indicate hosts that are *not* secure. Suppose that you have a machine `public.your.domain` that is located in a public area that you do not consider secure. You can enable access to all hosts on your network except that machine by using `host` table entries like this:

Host	Db	...
public.your.domain	%	... (all privileges set to 'N')
%.your.domain	%	... (all privileges set to 'Y')

6.2.6 When Privilege Changes Take Effect

When `mysqld` starts, it reads all grant table contents into memory. The in-memory tables become effective for access control at that point.

If you modify the grant tables indirectly using account-management statements such as `GRANT`, `REVOKE`, `SET PASSWORD`, or `RENAME USER`, the server notices these changes and loads the grant tables into memory again immediately.

If you modify the grant tables directly using statements such as `INSERT`, `UPDATE`, or `DELETE`, your changes have no effect on privilege checking until you either restart the server or tell it to reload the tables. If you change the grant tables directly but forget to reload them, your changes have *no effect* until you restart the server. This may leave you wondering why your changes seem to make no difference!

To tell the server to reload the grant tables, perform a flush-privileges operation. This can be done by issuing a `FLUSH PRIVILEGES` statement or by executing a `mysqladmin flush-privileges` or `mysqladmin reload` command.

A grant table reload affects privileges for each existing client connection as follows:

- Table and column privilege changes take effect with the client's next request.

- Database privilege changes take effect the next time the client executes a `USE db_name` statement.

**Note**

Client applications may cache the database name; thus, this effect may not be visible to them without actually changing to a different database or flushing the privileges.

- Global privileges and passwords are unaffected for a connected client. These changes take effect only for subsequent connections.

If the server is started with the `--skip-grant-tables` option, it does not read the grant tables or implement any access control. Anyone can connect and do anything, *which is insecure*. To cause a server thus started to read the tables and enable access checking, flush the privileges.

6.2.7 Causes of Access-Denied Errors

If you encounter problems when you try to connect to the MySQL server, the following items describe some courses of action you can take to correct the problem.

- Make sure that the server is running. If it is not, clients cannot connect to it. For example, if an attempt to connect to the server fails with a message such as one of those following, one cause might be that the server is not running:

```
shell> mysql
ERROR 2003: Can't connect to MySQL server on 'host_name' (111)
shell> mysql
ERROR 2002: Can't connect to local MySQL server through socket
'/tmp/mysql.sock' (111)
```

- It might be that the server is running, but you are trying to connect using a TCP/IP port, named pipe, or Unix socket file different from the one on which the server is listening. To correct this when you invoke a client program, specify a `--port` option to indicate the proper port number, or a `--socket` option to indicate the proper named pipe or Unix socket file. To find out where the socket file is, you can use this command:

```
shell> netstat -ln | grep mysql
```

- Make sure that the server has not been configured to ignore network connections or (if you are attempting to connect remotely) that it has not been configured to listen only locally on its network interfaces. If the server was started with `--skip-networking`, it will not accept TCP/IP connections at all. If the server was started with `--bind-address=127.0.0.1`, it will listen for TCP/IP connections only locally on the loopback interface and will not accept remote connections.
- Check to make sure that there is no firewall blocking access to MySQL. Your firewall may be configured on the basis of the application being executed, or the port number used by MySQL for communication (3306 by default). Under Linux or Unix, check your IP tables (or similar) configuration to ensure that the port has not been blocked. Under Windows, applications such as ZoneAlarm or the Windows XP personal firewall may need to be configured not to block the MySQL port.
- The grant tables must be properly set up so that the server can use them for access control. For some distribution types (such as binary distributions on Windows, or RPM distributions on Linux), the installation process initializes the `mysql` database containing the grant tables. For distributions that do not do this, you must initialize the grant tables manually by running the `mysql_install_db` script. For details, see [Section 2.10.1, “Postinstallation Procedures for Unix-like Systems”](#).

To determine whether you need to initialize the grant tables, look for a `mysql` directory under the data directory. (The data directory normally is named `data` or `var` and is located under your MySQL installation directory.) Make sure that you have a file named `user.MYD` in the `mysql` database directory. If not, execute the `mysql_install_db` script. After running this script and starting the server, test the initial privileges by executing this command:

```
shell> mysql -u root test
```

The server should let you connect without error.

- After a fresh installation, you should connect to the server and set up your users and their access permissions:

```
shell> mysql -u root mysql
```

The server should let you connect because the MySQL `root` user has no password initially. That is also a security risk, so setting the password for the `root` accounts is something you should do while you're setting up your other MySQL accounts. For instructions on setting the initial passwords, see [Section 2.10.2, “Securing the Initial MySQL Accounts”](#).

- If you have updated an existing MySQL installation to a newer version, did you run the `mysql_upgrade` script? If not, do so. The structure of the grant tables changes occasionally when new capabilities are added, so after an upgrade you should always make sure that your tables have the current structure. For instructions, see [Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”](#).
- If a client program receives the following error message when it tries to connect, it means that the server expects passwords in a newer format than the client is capable of generating:

```
shell> mysql
Client does not support authentication protocol requested
by server; consider upgrading MySQL client
```

For information on how to deal with this, see [Section 6.1.2.4, “Password Hashing in MySQL”](#), and [Section B.5.2.4, “Client does not support authentication protocol”](#).

- Remember that client programs use connection parameters specified in option files or environment variables. If a client program seems to be sending incorrect default connection parameters when you have not specified them on the command line, check any applicable option files and your environment. For example, if you get `Access denied` when you run a client without any options, make sure that you have not specified an old password in any of your option files!

You can suppress the use of option files by a client program by invoking it with the `--no-defaults` option. For example:

```
shell> mysqladmin --no-defaults -u root version
```

The option files that clients use are listed in [Section 4.2.6, “Using Option Files”](#). Environment variables are listed in [Section 2.12, “Environment Variables”](#).

- If you get the following error, it means that you are using an incorrect `root` password:

```
shell> mysqladmin -u root -pxxxx ver
Access denied for user 'root'@'localhost' (using password: YES)
```

If the preceding error occurs even when you have not specified a password, it means that you have an incorrect password listed in some option file. Try the `--no-defaults` option as described in the previous item.

For information on changing passwords, see [Section 6.3.5, “Assigning Account Passwords”](#).

If you have lost or forgotten the `root` password, see [Section B.5.4.1, “How to Reset the Root Password”](#).

- If you change a password by using `SET PASSWORD`, `INSERT`, or `UPDATE`, you must encrypt the password using the `PASSWORD()` function. If you do not use `PASSWORD()` for these statements, the password will not work. For example, the following statement assigns a password, but fails to encrypt it, so the user is not able to connect afterward:

```
SET PASSWORD FOR 'abe'@'host_name' = 'eagle';
```

Instead, set the password like this:

```
SET PASSWORD FOR 'abe'@'host_name' = PASSWORD('eagle');
```

The `PASSWORD()` function is unnecessary when you specify a password using the `CREATE USER` or `GRANT` statements or the `mysqladmin password` command. Each of those automatically uses `PASSWORD()` to encrypt the password. See [Section 6.3.5, “Assigning Account Passwords”](#), and [Section 13.7.1.1, “CREATE USER Syntax”](#).

- `localhost` is a synonym for your local host name, and is also the default host to which clients try to connect if you specify no host explicitly.

To avoid this problem on such systems, you can use a `--host=127.0.0.1` option to name the server host explicitly. This will make a TCP/IP connection to the local `mysqld` server. You can also use TCP/IP by specifying a `--host` option that uses the actual host name of the local host. In this case, the host name must be specified in a `user` table row on the server host, even though you are running the client program on the same host as the server.

- The `Access denied` error message tells you who you are trying to log in as, the client host from which you are trying to connect, and whether you were using a password. Normally, you should have one row in the `user` table that exactly matches the host name and user name that were given in the error message. For example, if you get an error message that contains `using password: NO`, it means that you tried to log in without a password.
- If you get an `Access denied` error when trying to connect to the database with `mysql -u user_name`, you may have a problem with the `user` table. Check this by executing `mysql -u root mysql` and issuing this SQL statement:

```
SELECT * FROM user;
```

The result should include a row with the `Host` and `User` columns matching your client's host name and your MySQL user name.

- If the following error occurs when you try to connect from a host other than the one on which the MySQL server is running, it means that there is no row in the `user` table with a `Host` value that matches the client host:

```
Host ... is not allowed to connect to this MySQL server
```

You can fix this by setting up an account for the combination of client host name and user name that you are using when trying to connect.

If you do not know the IP address or host name of the machine from which you are connecting, you should put a row with `'%'` as the `Host` column value in the `user` table. After trying to connect from the client machine, use a `SELECT USER()` query to see how you really did connect. Then change the `'%'` in the `user` table row to the actual host name that shows up in the log. Otherwise, your system is left insecure because it permits connections from any host for the given user name.

On Linux, another reason that this error might occur is that you are using a binary MySQL version that is compiled with a different version of the `glibc` library than the one you are using. In this case, you should either upgrade your operating system or `glibc`, or download a source distribution of MySQL version and compile it yourself. A source RPM is normally trivial to compile and install, so this is not a big problem.

- If you specify a host name when trying to connect, but get an error message where the host name is not shown or is an IP address, it means that the MySQL server got an error when trying to resolve the IP address of the client host to a name:

```
shell> mysqladmin -u root -pXXXX -h some_hostname ver
Access denied for user 'root'@'' (using password: YES)
```

If you try to connect as `root` and get the following error, it means that you do not have a row in the `user` table with a `User` column value of `'root'` and that `mysqld` cannot resolve the host name for your client:

```
Access denied for user ''@'unknown'
```

These errors indicate a DNS problem. To fix it, execute `mysqladmin flush-hosts` to reset the internal DNS host cache. See [Section 8.11.5.2, “DNS Lookup Optimization and the Host Cache”](#).

Some permanent solutions are:

- Determine what is wrong with your DNS server and fix it.
- Specify IP addresses rather than host names in the MySQL grant tables.
- Put an entry for the client machine name in `/etc/hosts` on Unix or `\windows\hosts` on Windows.
- Start `mysqld` with the `--skip-name-resolve` option.
- Start `mysqld` with the `--skip-host-cache` option.
- On Unix, if you are running the server and the client on the same machine, connect to `localhost`. Unix connections to `localhost` use a Unix socket file rather than TCP/IP.
- On Windows, if you are running the server and the client on the same machine and the server supports named pipe connections, connect to the host name `.` (period). Connections to `.` use a named pipe rather than TCP/IP.
- If `mysql -u root test` works but `mysql -h your_hostname -u root test` results in `Access denied` (where `your_hostname` is the actual host name of the local host), you may not have the correct name for your host in the `user` table. A common problem here is that the `Host` value in the `user` table row specifies an unqualified host name, but your system's name resolution routines return a fully qualified domain name (or vice versa). For example, if you have an entry with host `'pluto'` in the

`user` table, but your DNS tells MySQL that your host name is `'pluto.example.com'`, the entry does not work. Try adding an entry to the `user` table that contains the IP address of your host as the `Host` column value. (Alternatively, you could add an entry to the `user` table with a `Host` value that contains a wildcard; for example, `'pluto.%'`. However, use of `Host` values ending with “%” is *insecure* and is *not* recommended!)

- If `mysql -u user_name test` works but `mysql -u user_name other_db` does not, you have not granted access to the given user for the database named `other_db`.
- If `mysql -u user_name` works when executed on the server host, but `mysql -h host_name -u user_name` does not work when executed on a remote client host, you have not enabled access to the server for the given user name from the remote host.
- If you cannot figure out why you get `Access denied`, remove from the `user` table all entries that have `Host` values containing wildcards (entries that contain `'%'` or `'_'` characters). A very common error is to insert a new entry with `Host='%'` and `User='some_user'`, thinking that this enables you to specify `localhost` to connect from the same machine. The reason that this does not work is that the default privileges include an entry with `Host='localhost'` and `User=''`. Because that entry has a `Host` value `'localhost'` that is more specific than `'%'`, it is used in preference to the new entry when connecting from `localhost`! The correct procedure is to insert a second entry with `Host='localhost'` and `User='some_user'`, or to delete the entry with `Host='localhost'` and `User=''`. After deleting the entry, remember to issue a `FLUSH PRIVILEGES` statement to reload the grant tables. See also [Section 6.2.4, “Access Control, Stage 1: Connection Verification”](#).
- If you are able to connect to the MySQL server, but get an `Access denied` message whenever you issue a `SELECT ... INTO OUTFILE` or `LOAD DATA INFILE` statement, your entry in the `user` table does not have the `FILE` privilege enabled.
- If you change the grant tables directly (for example, by using `INSERT`, `UPDATE`, or `DELETE` statements) and your changes seem to be ignored, remember that you must execute a `FLUSH PRIVILEGES` statement or a `mysqladmin flush-privileges` command to cause the server to reload the privilege tables. Otherwise, your changes have no effect until the next time the server is restarted. Remember that after you change the `root` password with an `UPDATE` statement, you will not need to specify the new password until after you flush the privileges, because the server will not know you've changed the password yet!
- If your privileges seem to have changed in the middle of a session, it may be that a MySQL administrator has changed them. Reloading the grant tables affects new client connections, but it also affects existing connections as indicated in [Section 6.2.6, “When Privilege Changes Take Effect”](#).
- If you have access problems with a Perl, PHP, Python, or ODBC program, try to connect to the server with `mysql -u user_name db_name` or `mysql -u user_name -pyour_pass db_name`. If you are able to connect using the `mysql` client, the problem lies with your program, not with the access privileges. (There is no space between `-p` and the password; you can also use the `--password=your_pass` syntax to specify the password. If you use the `-p` or `--password` option with no password value, MySQL prompts you for the password.)
- For testing purposes, start the `mysqld` server with the `--skip-grant-tables` option. Then you can change the MySQL grant tables and use the `mysqlaccess` script to check whether your modifications have the desired effect. When you are satisfied with your changes, execute `mysqladmin flush-privileges` to tell the `mysqld` server to reload the privileges. This enables you to begin using the new grant table contents without stopping and restarting the server.
- If you get the following error, you may have a problem with the `db` or `host` table:

```
Access to database denied
```

If the entry selected from the `db` table has an empty value in the `Host` column, make sure that there are one or more corresponding entries in the `host` table specifying which hosts the `db` table entry applies to. This problem occurs infrequently because the `host` table is rarely used.

- If everything else fails, start the `mysqld` server with a debugging option (for example, `--debug=d,general,query`). This prints host and user information about attempted connections, as well as information about each command issued. See [Section 24.4.3, “The DBUG Package”](#).
- If you have any other problems with the MySQL grant tables and feel you must post the problem to the mailing list, always provide a dump of the MySQL grant tables. You can dump the tables with the `mysqldump mysql` command. To file a bug report, see the instructions at [Section 1.7, “How to Report Bugs or Problems”](#). In some cases, you may need to restart `mysqld` with `--skip-grant-tables` to run `mysqldump`.

6.3 MySQL User Account Management

This section describes how to set up accounts for clients of your MySQL server. It discusses the following topics:

- The meaning of account names and passwords as used in MySQL and how that compares to names and passwords used by your operating system
- How to set up new accounts and remove existing accounts
- How to change passwords
- Guidelines for using passwords securely
- How to use secure connections with SSL

See also [Section 13.7.1, “Account Management Statements”](#), which describes the syntax and use for all user-management SQL statements.

6.3.1 User Names and Passwords

MySQL stores accounts in the `user` table of the `mysql` database. An account is defined in terms of a user name and the client host or hosts from which the user can connect to the server. The account may also have a password. For information about account representation in the `user` table, see [Section 6.2.2, “Privilege System Grant Tables”](#). MySQL 5.5 supports authentication plugins, so it is possible that an account authenticates using some external authentication method. See [Section 6.3.6, “Pluggable Authentication”](#).

There are several distinctions between the way user names and passwords are used by MySQL and the way they are used by your operating system:

- User names, as used by MySQL for authentication purposes, have nothing to do with user names (login names) as used by Windows or Unix. On Unix, most MySQL clients by default try to log in using the current Unix user name as the MySQL user name, but that is for convenience only. The default can be overridden easily, because client programs permit any user name to be specified with a `-u` or `--user` option. Because this means that anyone can attempt to connect to the server using any user name, you cannot make a database secure in any way unless all MySQL accounts have passwords. Anyone who specifies a user name for an account that has no password is able to connect successfully to the server.
- MySQL user names can be up to 16 characters long. Operating system user names, because they are completely unrelated to MySQL user names, may be of a different maximum length. For example, Unix user names typically are limited to eight characters.

**Warning**

The limit on MySQL user name length is hard-coded in the MySQL servers and clients, and trying to circumvent it by modifying the definitions of the tables in the `mysql` database *does not work*.

You should never alter any of the tables in the `mysql` database in any manner whatsoever except by means of the procedure that is described in [Section 4.4.7](#), “`mysql_upgrade` — Check and Upgrade MySQL Tables”. Attempting to redefine MySQL’s system tables in any other fashion results in undefined (and unsupported!) behavior.

- The server uses MySQL passwords stored in the `user` table to authenticate client connections using MySQL native authentication (against passwords stored in the `mysql.user` table). These passwords have nothing to do with passwords for logging in to your operating system. There is no necessary connection between the “external” password you use to log in to a Windows or Unix machine and the password you use to access the MySQL server on that machine.

If the server authenticates a client using a plugin, the authentication method that the plugin implements may or may not use the password in the `user` table. In this case, it is possible that an external password is also used to authenticate to the MySQL server.

- MySQL encrypts passwords stored in the `user` table using its own algorithm. This encryption is the same as that implemented by the `PASSWORD()` SQL function but differs from that used during the Unix login process. Unix password encryption is the same as that implemented by the `ENCRYPT()` SQL function. See the descriptions of the `PASSWORD()` and `ENCRYPT()` functions in [Section 12.13](#), “Encryption and Compression Functions”.

From version 4.1 on, MySQL employs a stronger authentication method that has better password protection during the connection process than in earlier versions. It is secure even if TCP/IP packets are sniffed or the `mysql` database is captured. (In earlier versions, even though passwords are stored in encrypted form in the `user` table, knowledge of the encrypted password value could be used to connect to the MySQL server.) [Section 6.1.2.4](#), “Password Hashing in MySQL”, discusses password encryption further.

- It is possible to connect to the server regardless of character set settings if the user name and password contain only ASCII characters. To connect when the user name or password contain non-ASCII characters, the client should call the `mysql_options()` C API function with the `MYSQL_SET_CHARSET_NAME` option and appropriate character set name as arguments. This causes authentication to take place using the specified character set. Otherwise, authentication will fail unless the server default character set is the same as the encoding in the authentication defaults.

Standard MySQL client programs support a `--default-character-set` option that causes `mysql_options()` to be called as just described. In addition, character set autodetection is supported as described in [Section 10.1.4](#), “Connection Character Sets and Collations”. For programs that use a connector that is not based on the C API, the connector may provide an equivalent to `mysql_options()` that can be used instead. Check the connector documentation.

The preceding notes do not apply for `ucs2`, `utf16`, and `utf32`, which are not permitted as client character sets.

When you install MySQL, the grant tables are populated with an initial set of accounts. The names and access privileges for these accounts are described in [Section 2.10.2](#), “Securing the Initial MySQL Accounts”, which also discusses how to assign passwords to them. Thereafter, you normally set up,

modify, and remove MySQL accounts using statements such as `CREATE USER`, `GRANT`, and `REVOKE`. See [Section 13.7.1, “Account Management Statements”](#).

When you connect to a MySQL server with a command-line client, specify the user name and password as necessary for the account that you want to use:

```
shell> mysql --user=monty --password=password db_name
```

If you prefer short options, the command looks like this:

```
shell> mysql -u monty -ppassword db_name
```

There must be *no space* between the `-p` option and the following password value.

If you omit the `password` value following the `--password` or `-p` option on the command line, the client prompts for one.

Specifying a password on the command line should be considered insecure. See [Section 6.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file to avoid giving the password on the command line.

For additional information about specifying user names, passwords, and other connection parameters, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

6.3.2 Adding User Accounts

You can create MySQL accounts in two ways:

- By using statements intended for creating accounts, such as `CREATE USER` or `GRANT`. These statements cause the server to make appropriate modifications to the grant tables.
- By manipulating the MySQL grant tables directly with statements such as `INSERT`, `UPDATE`, or `DELETE`.

The preferred method is to use account-creation statements because they are more concise and less error-prone than manipulating the grant tables directly. `CREATE USER` and `GRANT` are described in [Section 13.7.1, “Account Management Statements”](#).

Another option for creating accounts is to use the GUI tool MySQL Workbench. Or one of several available third-party programs that offer capabilities for MySQL account administration. `phpMyAdmin` is one such program.

The following examples show how to use the `mysql` client program to set up new accounts. These examples assume that privileges have been set up according to the defaults described in [Section 2.10.2, “Securing the Initial MySQL Accounts”](#). This means that to make changes, you must connect to the MySQL server as the MySQL `root` user, and the `root` account must have the `INSERT` privilege for the `mysql` database and the `RELOAD` administrative privilege.

As noted in the examples where appropriate, some of the statements will fail if the server's SQL mode has been set to enable certain restrictions. In particular, strict mode (`STRICT_TRANS_TABLES`, `STRICT_ALL_TABLES`) and `NO_AUTO_CREATE_USER` will prevent the server from accepting some of the statements. Workarounds are indicated for these cases. For more information about SQL modes and their effect on grant table manipulation, see [Section 5.1.7, “Server SQL Modes”](#), and [Section 13.7.1.3, “GRANT Syntax”](#).

First, use the `mysql` program to connect to the server as the MySQL `root` user:

```
shell> mysql --user=root mysql
```

If you have assigned a password to the `root` account, you will also need to supply a `--password` or `-p` option, both for this `mysql` command and for those later in this section.

After connecting to the server as `root`, you can add new accounts. The following statements use `GRANT` to set up four new accounts:

```
mysql> CREATE USER 'monty'@'localhost' IDENTIFIED BY 'some_pass';
mysql> GRANT ALL PRIVILEGES ON *.* TO 'monty'@'localhost'
-> WITH GRANT OPTION;
mysql> CREATE USER 'monty'@'%' IDENTIFIED BY 'some_pass';
mysql> GRANT ALL PRIVILEGES ON *.* TO 'monty'@'%'
-> WITH GRANT OPTION;
mysql> CREATE USER 'admin'@'localhost';
mysql> GRANT RELOAD,PROCESS ON *.* TO 'admin'@'localhost';
mysql> CREATE USER 'dummy'@'localhost';
```

The accounts created by these statements have the following properties:

- Two of the accounts have a user name of `monty` and a password of `some_pass`. Both accounts are superuser accounts with full privileges to do anything. The `'monty'@'localhost'` account can be used only when connecting from the local host. The `'monty'@'%'` account uses the `'%'` wildcard for the host part, so it can be used to connect from any host.

It is necessary to have both accounts for `monty` to be able to connect from anywhere as `monty`. Without the `localhost` account, the anonymous-user account for `localhost` that is created by `mysql_install_db` would take precedence when `monty` connects from the local host. As a result, `monty` would be treated as an anonymous user. The reason for this is that the anonymous-user account has a more specific `Host` column value than the `'monty'@'%'` account and thus comes earlier in the `user` table sort order. (`user` table sorting is discussed in [Section 6.2.4, “Access Control, Stage 1: Connection Verification”](#).)

- The `'admin'@'localhost'` account has no password. This account can be used only by `admin` to connect from the local host. It is granted the `RELOAD` and `PROCESS` administrative privileges. These privileges enable the `admin` user to execute the `mysqladmin reload`, `mysqladmin refresh`, and `mysqladmin flush-xxx` commands, as well as `mysqladmin processlist`. No privileges are granted for accessing any databases. You could add such privileges later by issuing other `GRANT` statements.
- The `'dummy'@'localhost'` account has no password. This account can be used only to connect from the local host. No privileges are granted. It is assumed that you will grant specific privileges to the account later.

The statements that create accounts with no password will fail if the `NO_AUTO_CREATE_USER` SQL mode is enabled. To deal with this, use an `IDENTIFIED BY` clause that specifies a nonempty password.

To check the privileges for an account, use `SHOW GRANTS`:

```
mysql> SHOW GRANTS FOR 'admin'@'localhost';
+-----+
| Grants for admin@localhost |
+-----+
| GRANT RELOAD, PROCESS ON *.* TO 'admin'@'localhost' |
+-----+
```

As an alternative to `CREATE USER` and `GRANT`, you can create the same accounts directly by issuing `INSERT` statements and then telling the server to reload the grant tables using `FLUSH PRIVILEGES`:

```

shell> mysql --user=root mysql
mysql> INSERT INTO user
-> VALUES('localhost','monty',PASSWORD('some_pass'),
-> 'Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y');
mysql> INSERT INTO user
-> VALUES('','monty',PASSWORD('some_pass'),
-> 'Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y',
-> 'Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y','Y',
-> '','','','',0,0,0,0);
mysql> INSERT INTO user SET Host='localhost',User='admin',
-> Reload_priv='Y', Process_priv='Y';
mysql> INSERT INTO user (Host,User,Password)
-> VALUES('localhost','dummy','');
mysql> FLUSH PRIVILEGES;

```

When you create accounts with `INSERT`, it is necessary to use `FLUSH PRIVILEGES` to tell the server to reload the grant tables. Otherwise, the changes go unnoticed until you restart the server. With `CREATE USER`, `FLUSH PRIVILEGES` is unnecessary.

The reason for using the `PASSWORD()` function with `INSERT` is to encrypt the password. The `CREATE USER` statement encrypts the password for you, so `PASSWORD()` is unnecessary.

The 'Y' values enable privileges for the accounts. Depending on your MySQL version, you may have to use a different number of 'Y' values in the first two `INSERT` statements. The `INSERT` statement for the `admin` account employs the more readable extended `INSERT` syntax using `SET`.

In the `INSERT` statement for the `dummy` account, only the `Host`, `User`, and `Password` columns in the `user` table row are assigned values. None of the privilege columns are set explicitly, so MySQL assigns them all the default value of 'N'. This is equivalent to what `CREATE USER` does.

If strict SQL mode is enabled, all columns that have no default value must have a value specified. In this case, `INSERT` statements must explicitly specify values for the `ssl_cipher`, `x509_issuer`, and `x509_subject` columns.

To set up a superuser account, it is necessary only to insert a `user` table row with all privilege columns set to 'Y'. The `user` table privileges are global, so no entries in any of the other grant tables are needed.

The next examples create three accounts and give them access to specific databases. Each of them has a user name of `custom` and password of `obscure`.

To create the accounts with `CREATE USER` and `GRANT`, use the following statements:

```

shell> mysql --user=root mysql
mysql> CREATE USER 'custom'@'localhost' IDENTIFIED BY 'obscure';
mysql> GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
-> ON bankaccount.*
-> TO 'custom'@'localhost';
mysql> CREATE USER 'custom'@'host47.example.com' IDENTIFIED BY 'obscure';
mysql> GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
-> ON expenses.*
-> TO 'custom'@'host47.example.com';
mysql> CREATE USER 'custom'@'server.domain' IDENTIFIED BY 'obscure';
mysql> GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
-> ON customer.*
-> TO 'custom'@'server.domain';

```

The three accounts can be used as follows:

- The first account can access the `bankaccount` database, but only from the local host.

- The second account can access the `expenses` database, but only from the host `host47.example.com`.
- The third account can access the `customer` database, but only from the host `server.domain`.

To set up the `custom` accounts without `GRANT`, use `INSERT` statements as follows to modify the grant tables directly:

```
shell> mysql --user=root mysql
mysql> INSERT INTO user (Host,User,Password)
-> VALUES('localhost','custom',PASSWORD('obscure'));
mysql> INSERT INTO user (Host,User,Password)
-> VALUES('host47.example.com','custom',PASSWORD('obscure'));
mysql> INSERT INTO user (Host,User,Password)
-> VALUES('server.domain','custom',PASSWORD('obscure'));
mysql> INSERT INTO db
-> (Host,Db,User,Select_priv,Insert_priv,
-> Update_priv>Delete_priv>Create_priv>Drop_priv)
-> VALUES('localhost','bankaccount','custom',
-> 'Y','Y','Y','Y','Y','Y');
mysql> INSERT INTO db
-> (Host,Db,User,Select_priv,Insert_priv,
-> Update_priv>Delete_priv>Create_priv>Drop_priv)
-> VALUES('host47.example.com','expenses','custom',
-> 'Y','Y','Y','Y','Y','Y');
mysql> INSERT INTO db
-> (Host,Db,User,Select_priv,Insert_priv,
-> Update_priv>Delete_priv>Create_priv>Drop_priv)
-> VALUES('server.domain','customer','custom',
-> 'Y','Y','Y','Y','Y','Y');
mysql> FLUSH PRIVILEGES;
```

The first three `INSERT` statements add `user` table entries that permit the user `custom` to connect from the various hosts with the given password, but grant no global privileges (all privileges are set to the default value of `'N'`). The next three `INSERT` statements add `db` table entries that grant privileges to `custom` for the `bankaccount`, `expenses`, and `customer` databases, but only when accessed from the proper hosts. As usual when you modify the grant tables directly, you must tell the server to reload them with `FLUSH PRIVILEGES` so that the privilege changes take effect.

To create a user who has access from all machines in a given domain (for example, `mydomain.com`), you can use the `"%"` wildcard character in the host part of the account name:

```
mysql> CREATE USER 'myname'@'%.mydomain.com' IDENTIFIED BY 'mypass';
```

To do the same thing by modifying the grant tables directly, do this:

```
mysql> INSERT INTO user (Host,User,Password,...)
-> VALUES('%.mydomain.com','myname',PASSWORD('mypass'),...);
mysql> FLUSH PRIVILEGES;
```

6.3.3 Removing User Accounts

To remove an account, use the `DROP USER` statement, which is described in [Section 13.7.1.2, “DROP USER Syntax”](#).

6.3.4 Setting Account Resource Limits

One means of limiting use of MySQL server resources is to set the global `max_user_connections` system variable to a nonzero value. This limits the number of simultaneous connections that can be made

by any given account, but places no limits on what a client can do once connected. In addition, setting `max_user_connections` does not enable management of individual accounts. Both types of control are of interest to many MySQL administrators, particularly those working for Internet Service Providers.

In MySQL 5.5, you can limit use of the following server resources for individual accounts:

- The number of queries that an account can issue per hour
- The number of updates that an account can issue per hour
- The number of times an account can connect to the server per hour
- The number of simultaneous connections to the server by an account

Any statement that a client can issue counts against the query limit (unless its results are served from the query cache). Only statements that modify databases or tables count against the update limit.

An “account” in this context corresponds to a row in the `mysql.user` table. That is, a connection is assessed against the `User` and `Host` values in the `user` table row that applies to the connection. For example, an account `'usera'@'%.example.com'` corresponds to a row in the `user` table that has `User` and `Host` values of `usera` and `%.example.com`, to permit `usera` to connect from any host in the `example.com` domain. In this case, the server applies resource limits in this row collectively to all connections by `usera` from any host in the `example.com` domain because all such connections use the same account.

Before MySQL 5.0.3, an “account” was assessed against the actual host from which a user connects. This older method accounting may be selected by starting the server with the `--old-style-user-limits` option. In this case, if `usera` connects simultaneously from `host1.example.com` and `host2.example.com`, the server applies the account resource limits separately to each connection. If `usera` connects again from `host1.example.com`, the server applies the limits for that connection together with the existing connection from that host.

To set resource limits for an account, use the `GRANT` statement (see [Section 13.7.1.3, “GRANT Syntax”](#)). Provide a `WITH` clause that names each resource to be limited. The default value for each limit is zero (no limit). For example, to create a new account that can access the `customer` database, but only in a limited fashion, issue these statements:

```
mysql> CREATE USER 'francis'@'localhost' IDENTIFIED BY 'frank';
mysql> GRANT ALL ON customer.* TO 'francis'@'localhost'
->     WITH MAX_QUERIES_PER_HOUR 20
->          MAX_UPDATES_PER_HOUR 10
->          MAX_CONNECTIONS_PER_HOUR 5
->          MAX_USER_CONNECTIONS 2;
```

The limit types need not all be named in the `WITH` clause, but those named can be present in any order. The value for each per-hour limit should be an integer representing a count per hour. For `MAX_USER_CONNECTIONS`, the limit is an integer representing the maximum number of simultaneous connections by the account. If this limit is set to zero, the global `max_user_connections` system variable value determines the number of simultaneous connections. If `max_user_connections` is also zero, there is no limit for the account.

To modify existing limits for an account, use a `GRANT USAGE` statement at the global level (`ON *.*`). The following statement changes the query limit for `francis` to 100:

```
mysql> GRANT USAGE ON *.* TO 'francis'@'localhost'
->     WITH MAX_QUERIES_PER_HOUR 100;
```

The statement modifies only the limit value specified and leaves the account otherwise unchanged.

To remove a limit, set its value to zero. For example, to remove the limit on how many times per hour `francis` can connect, use this statement:

```
mysql> GRANT USAGE ON *.* TO 'francis'@'localhost'
->     WITH MAX_CONNECTIONS_PER_HOUR 0;
```

As mentioned previously, the simultaneous-connection limit for an account is determined from the `MAX_USER_CONNECTIONS` limit and the `max_user_connections` system variable. Suppose that the global `max_user_connections` value is 10 and three accounts have resource limits specified with `GRANT`:

```
GRANT ... TO 'user1'@'localhost' WITH MAX_USER_CONNECTIONS 0;
GRANT ... TO 'user2'@'localhost' WITH MAX_USER_CONNECTIONS 5;
GRANT ... TO 'user3'@'localhost' WITH MAX_USER_CONNECTIONS 20;
```

`user1` has a connection limit of 10 (the global `max_user_connections` value) because it has a zero `MAX_USER_CONNECTIONS` limit). `user2` and `user3` have connection limits of 5 and 20, respectively, because they have nonzero `MAX_USER_CONNECTIONS` limits.

The server stores resource limits for an account in the `user` table row corresponding to the account. The `max_questions`, `max_updates`, and `max_connections` columns store the per-hour limits, and the `max_user_connections` column stores the `MAX_USER_CONNECTIONS` limit. (See [Section 6.2.2, “Privilege System Grant Tables”](#).)

Resource-use counting takes place when any account has a nonzero limit placed on its use of any of the resources.

As the server runs, it counts the number of times each account uses resources. If an account reaches its limit on number of connections within the last hour, further connections for the account are rejected until that hour is up. Similarly, if the account reaches its limit on the number of queries or updates, further queries or updates are rejected until the hour is up. In all such cases, an appropriate error message is issued.

Resource counting is done per account, not per client. For example, if your account has a query limit of 50, you cannot increase your limit to 100 by making two simultaneous client connections to the server. Queries issued on both connections are counted together.

The current per-hour resource-use counts can be reset globally for all accounts, or individually for a given account:

- To reset the current counts to zero for all accounts, issue a `FLUSH USER_RESOURCES` statement. The counts also can be reset by reloading the grant tables (for example, with a `FLUSH PRIVILEGES` statement or a `mysqladmin reload` command).
- The counts for an individual account can be set to zero by re-granting it any of its limits. To do this, use `GRANT USAGE` as described earlier and specify a limit value equal to the value that the account currently has.

Counter resets do not affect the `MAX_USER_CONNECTIONS` limit.

All counts begin at zero when the server starts; counts are not carried over through a restart.

For the `MAX_USER_CONNECTIONS` limit, an edge case can occur if the account currently has open the maximum number of connections permitted to it: A disconnect followed quickly by a connect can result in an error (`ER_TOO_MANY_USER_CONNECTIONS` or `ER_USER_LIMIT_REACHED`) if the server has not fully

processed the disconnect by the time the connect occurs. When the server finishes disconnect processing, another connection will once more be permitted.

6.3.5 Assigning Account Passwords

Required credentials for clients that connect to the MySQL server can include a password. This section describes how to assign passwords for MySQL accounts. Client authentication occurs using plugins; see [Section 6.3.6, “Pluggable Authentication”](#).

To assign a password when you create a new account with `CREATE USER`, include an `IDENTIFIED BY` clause:

```
mysql> CREATE USER 'jeffrey'@'localhost'
      -> IDENTIFIED BY 'mypass';
```

To assign or change a password for an existing account, one way is to issue a `SET PASSWORD` statement:

```
mysql> SET PASSWORD FOR
      -> 'jeffrey'@'localhost' = PASSWORD('mypass');
```

MySQL stores passwords in the `user` table in the `mysql` database. Only users such as `root` that have the `UPDATE` privilege for the `mysql` database can change the password for other users. If you are not connected as an anonymous user, you can change your own password by omitting the `FOR` clause:

```
mysql> SET PASSWORD = PASSWORD('mypass');
```

The `old_passwords` system variable value determines the hashing method used by `PASSWORD()`. If you specify the password using that function and `SET PASSWORD` rejects the password as not being in the correct format, it may be necessary to set `old_passwords` to change the hashing method. For descriptions of the permitted values, see [Section 5.1.4, “Server System Variables”](#).

Enabling the `read_only` system variable prevents the use of the `SET PASSWORD` statement by any user not having the `SUPER` privilege.

You can also use a `GRANT USAGE` statement at the global level (`ON *.*`) to assign a password to an account without affecting the account's current privileges:

```
mysql> GRANT USAGE ON *.* TO 'jeffrey'@'localhost'
      -> IDENTIFIED BY 'mypass';
```

To assign a password from the command line, use the `mysqladmin` command:

```
shell> mysqladmin -u user_name -h host_name password "newpwd"
```

The account for which this command sets the password is the one with a `user` table row that matches `user_name` in the `User` column and the client host *from which you connect* in the `Host` column.

During authentication when a client connects to the server, MySQL treats the password in the `user` table as an encrypted hash value (the value that `PASSWORD()` would return for the password). When assigning a password to an account, it is important to store an encrypted value, not the plaintext password. Use the following guidelines:

- When you assign a password using `CREATE USER`, `GRANT` with an `IDENTIFIED BY` clause, or the `mysqladmin password` command, they encrypt the password for you. Specify the literal plaintext password:

```
mysql> CREATE USER 'jeffrey'@'localhost'
-> IDENTIFIED BY 'mypass';
```

- For `CREATE USER` or `GRANT`, you can avoid sending the plaintext password if you know the hash value that `PASSWORD()` would return for the password. Specify the hash value preceded by the keyword `PASSWORD`:

```
mysql> CREATE USER 'jeffrey'@'localhost'
-> IDENTIFIED BY PASSWORD '*90E462C37378CED12064BB3388827D2BA3A9B689';
```

- When you assign an account a nonempty password using `SET PASSWORD`, you must use the `PASSWORD()` function to encrypt the password, otherwise the password is stored as plaintext. Suppose that you assign a password like this:

```
mysql> SET PASSWORD FOR
-> 'jeffrey'@'localhost' = 'mypass';
```

The result is that the literal value `'mypass'` is stored as the password in the `user` table, not the encrypted value. When `jeffrey` attempts to connect to the server using this password, the value is encrypted and compared to the value stored in the `user` table. However, the stored value is the literal string `'mypass'`, so the comparison fails and the server rejects the connection with an `Access denied` error.

Note

`PASSWORD()` encryption differs from Unix password encryption. See [Section 6.3.1](#), “User Names and Passwords”.

It is preferable to assign passwords using `SET PASSWORD`, `GRANT`, or `mysqladmin`, but it is also possible to modify the `user` table directly. In this case, you must also use `FLUSH PRIVILEGES` to cause the server to reread the grant tables. Otherwise, the change remains unnoticed by the server until you restart it.

6.3.6 Pluggable Authentication

When a client connects to the MySQL server, the server uses the user name provided by the client and the client host to select the appropriate account row from the `mysql.user` table. The server then consults this row to authenticate the client.

Before MySQL 5.5.7, the server authenticates the password provided by the client against the `Password` column of the account row.

As of MySQL 5.5.7, the server authenticates clients using a plugin. Selection of the proper account row from the `mysql.user` table is based on the user name and client host, as before, but the server authenticates the client by determining from the account row which authentication plugin applies for the client:

- If the account row specifies a plugin, the server invokes it to authenticate the user. If the server cannot find the plugin, an error occurs.
- If the account row specifies no plugin name, the server authenticates the account using either the `mysql_native_password` or `mysql_old_password` plugin, depending on whether the password hash value in the `Password` column used native hashing or the older pre-4.1 hashing method. Clients must match the password in the `Password` column of the account row.

The plugin returns a status to the server indicating whether the user is permitted to connect.

Pluggable authentication enables two important capabilities:

- **External authentication:** Pluggable authentication makes it possible for clients to connect to the MySQL server with credentials that are appropriate for authentication methods other than native authentication based on passwords stored in the `mysql.user` table. For example, plugins can be created to use external authentication methods such as PAM, Windows login IDs, LDAP, or Kerberos.
- **Proxy users:** If a user is permitted to connect, an authentication plugin can return to the server a user name different from the name of the connecting user, to indicate that the connecting user is a proxy for another user. While the connection lasts, the proxy user is treated, for purposes of access control, as having the privileges of a different user. In effect, one user impersonates another. For more information, see [Section 6.3.8, “Proxy Users”](#).

Several authentication plugins are available in MySQL:

- Plugins that perform native authentication that matches the password against the `Password` column of the account row. The `mysql_native_password` plugin implements authentication based on the native password hashing method. The `mysql_old_password` plugin implements native authentication based on the older (pre-4.1) password hashing method. See [Section 6.3.7.1, “The Native Authentication Plugin”](#), and [Section 6.3.7.2, “The “Old” Native Authentication Plugin”](#). Native authentication using `mysql_native_password` is the default for accounts that have no plugin named explicitly in their account row.
- A plugin that performs external authentication against PAM (Pluggable Authentication Modules), enabling MySQL Server to use PAM to authenticate MySQL users. This plugin supports proxy users as well. See [Section 6.3.7.3, “The PAM Authentication Plugin”](#).
- A plugin that performs external authentication on Windows, enabling MySQL Server to use native Windows services to authenticate client connections. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password. This plugin supports proxy users as well. See [Section 6.3.7.4, “The Windows Native Authentication Plugin”](#).
- A client-side plugin that sends the password to the server without hashing or encryption. This plugin can be used by server-side plugins that require access to the password exactly as provided by the client user. See [Section 6.3.7.5, “The Cleartext Client-Side Authentication Plugin”](#).
- A plugin that authenticates clients that connect from the local host through the Unix socket file. See [Section 6.3.7.6, “The Socket Peer-Credential Authentication Plugin”](#).
- A test plugin that authenticates using MySQL native authentication. This plugin is intended for testing and development purposes, and as an example of how to write an authentication plugin. See [Section 6.3.7.7, “The Test Authentication Plugin”](#).

**Note**

For information about current restrictions on the use of pluggable authentication, including which connectors support which plugins, see [Section D.9, “Restrictions on Pluggable Authentication”](#).

Third-party connector developers should read that section to determine the extent to which a connector can take advantage of pluggable authentication capabilities and what steps to take to become more compliant.

If you are interested in writing your own authentication plugins, see [Section 24.2.4.9, “Writing Authentication Plugins”](#).

Authentication Plugin Usage Instructions

This section provides general instructions for installing and using authentication plugins.

In general, pluggable authentication uses corresponding plugins on the server and client sides, so you use a given authentication method like this:

- On the server host, install the library containing the appropriate server plugin, if necessary, so that the server can use it to authenticate client connections. Similarly, on each client host, install the library containing the appropriate client plugin for use by client programs.
- Create MySQL accounts that specify use of the plugin for authentication.
- When a client connects, the server plugin tells the client program which client plugin to use for authentication.

The instructions here use an example authentication plugin included in MySQL distributions (see [Section 6.3.7.7, “The Test Authentication Plugin”](#)). The procedure is similar for other authentication plugins; substitute the appropriate plugin and file names.

The example authentication plugin has these characteristics:

- The server-side plugin name is `test_plugin_server`.
- The client-side plugin name is `auth_test_plugin`.
- Both plugins are located in the shared library object file named `auth_test_plugin.so` in the plugin directory (the directory named by the `plugin_dir` system variable). The file name suffix might differ on your system.

Install and use the example authentication plugin as follows:

1. Make sure that the plugin library is installed on the server and client hosts.
2. Install the server-side test plugin at server startup or at runtime:
 - To install the plugin at startup, use the `--plugin-load` option. With this plugin-loading method, the option must be given each time you start the server. For example, use these lines in a `my.cnf` option file:

```
[mysqld]
plugin-load=test_plugin_server=auth_test_plugin.so
```

- To install the plugin at runtime, use the `INSTALL PLUGIN` statement:

```
mysql> INSTALL PLUGIN test_plugin_server SONAME 'auth_test_plugin.so';
```

This installs the plugin permanently and need be done only once.

3. Verify that the plugin is installed. For example, use `SHOW PLUGINS`:

```
mysql> SHOW PLUGINS\G
...
***** 21. row *****
Name: test_plugin_server
Status: ACTIVE
Type: AUTHENTICATION
Library: auth_test_plugin.so
```

```
License: GPL
```

For other ways to check the plugin, see [Section 5.1.8.2, “Obtaining Server Plugin Information”](#).

4. To specify that a MySQL user must be authenticated using a specific server plugin, name the plugin in the `IDENTIFIED WITH` clause of the `CREATE USER` statement that creates the user:

```
CREATE USER 'testuser'@'localhost' IDENTIFIED WITH test_plugin_server;
```

5. Connect to the server using a client program. The test plugin authenticates the same way as native MySQL authentication, so provide the usual `--user` and `--password` options that you normally use to connect to the server. For example:

```
shell> mysql --user=your_name --password=your_pass
```

For connections by `testuser`, the server sees that the account must be authenticated using the server-side plugin named `test_plugin_server` and communicates to the client program which client-side plugin it must use—in this case, `auth_test_plugin`.

In the case that the account uses the authentication method that is the default for both the server and the client program, the server need not communicate to the client which plugin to use, and a round trip in client/server negotiation can be avoided. Currently this is true for accounts that use native MySQL authentication (`mysql_native_password`).

The `--default-auth=plugin_name` option can be specified on the `mysql` command line to make explicit which client-side plugin the program can expect to use, although the server will override this if the user account requires a different plugin.

If the client program does not find the plugin, specify a `--plugin-dir=dir_name` option to indicate where the plugin is located.

Note

If you start the server with the `--skip-grant-tables` option, authentication plugins are not used even if loaded because the server performs no client authentication and permits any client to connect. Because this is insecure, you might want to use `--skip-grant-tables` in conjunction with `--skip-networking` to prevent remote clients from connecting.

6.3.7 Authentication Plugins Available in MySQL

The following sections describe the authentication plugins available in MySQL.

6.3.7.1 The Native Authentication Plugin

MySQL includes two plugins that implement native authentication; that is, authentication against passwords stored in the `Password` column of the `mysql.user` table. This section describes `mysql_native_password`, which implements authentication against the `mysql.user` table using the native password hashing method. For information about `mysql_old_password`, which implements authentication using the older (pre-4.1) password hashing method, see [Section 6.3.7.2, “The “Old” Native Authentication Plugin”](#). For information about these password hashing methods, see [Section 6.1.2.4, “Password Hashing in MySQL”](#).

The `mysql_native_password` native authentication plugin is backward compatible. Clients older than MySQL 5.5.7 do not support authentication *plugins* but do use the native authentication *protocol*, so they can connect to servers from MySQL 5.5.7 and up.

The following table shows the plugin names on the server and client sides.

Table 6.8 MySQL Native Password Authentication Plugin

Server-side plugin name	<code>mysql_native_password</code>
Client-side plugin name	<code>mysql_native_password</code>
Library object file name	None (plugins are built in)

The plugin exists in both client and server form:

- The server-side plugin is built into the server, need not be loaded explicitly, and cannot be disabled by unloading it.
- The client-side plugin is built into the `libmysqlclient` client library as of MySQL 5.5.7 and available to any program linked against `libmysqlclient` from that version or newer.
- MySQL client programs use `mysql_native_password` by default. The `--default-auth` option can be used to specify the plugin explicitly:

```
shell> mysql --default-auth=mysql_native_password ...
```

If an account row specifies no plugin name, the server authenticates the account using either the `mysql_native_password` or `mysql_old_password` plugin, depending on whether the password hash value in the `Password` column used native hashing or the older pre-4.1 hashing method. Clients must match the password in the `Password` column of the account row.

For general information about pluggable authentication in MySQL, see [Section 6.3.6, “Pluggable Authentication”](#).

6.3.7.2 The “Old” Native Authentication Plugin

MySQL includes two plugins that implement native authentication; that is, authentication against passwords stored in the `Password` column of the `mysql.user` table. This section describes `mysql_old_password`, which implements authentication against the `mysql.user` table using the older (pre-4.1) password hashing method. For information about `mysql_native_password`, which implements authentication using the native password hashing method, see [Section 6.3.7.1, “The Native Authentication Plugin”](#). For information about these password hashing methods, see [Section 6.1.2.4, “Password Hashing in MySQL”](#).

Note

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided.

The `mysql_old_password` native authentication plugin is backward compatible. Clients older than MySQL 5.5.7 do not support authentication *plugins* but do use the native authentication *protocol*, so they can connect to servers from MySQL 5.5.7 and up.

The following table shows the plugin names on the server and client sides.

Table 6.9 MySQL “Old” Native Authentication Plugin

Server-side plugin name	<code>mysql_old_password</code>
Client-side plugin name	<code>mysql_old_password</code>
Library object file name	None (plugins are built in)

The plugin exists in both client and server form:

- The server-side plugin is built into the server, need not be loaded explicitly, and cannot be disabled by unloading it.
- The client-side plugin is built into the `libmysqlclient` client library as of MySQL 5.5.7 and available to any program linked against `libmysqlclient` from that version or newer.
- MySQL client programs can use the `--default-auth` option to specify the `mysql_old_password` plugin explicitly:

```
shell> mysql --default-auth=mysql_old_password ...
```

If an account row specifies no plugin name, the server authenticates the account using either the `mysql_native_password` or `mysql_old_password` plugin, depending on whether the password hash value in the `Password` column used native hashing or the older pre-4.1 hashing method. Clients must match the password in the `Password` column of the account row.

For general information about pluggable authentication in MySQL, see [Section 6.3.6, “Pluggable Authentication”](#).

6.3.7.3 The PAM Authentication Plugin

Note

The PAM authentication plugin is a commercial extension. To learn more about commercial products (MySQL Enterprise Edition), see <http://www.mysql.com/products/>.

As of MySQL 5.5.16, commercial distributions of MySQL include an authentication plugin that enables MySQL Server to use PAM (Pluggable Authentication Modules) to authenticate MySQL users. PAM enables a system to use a standard interface to access various kinds of authentication methods, such as Unix passwords or an LDAP directory.

The PAM plugin uses the information passed to it by MySQL Server (such as user name, host name, password, and authentication string), plus whatever method is available for PAM lookup. The plugin checks the user credentials against PAM and returns `'Authentication succeeded, Username is user_name'` or `'Authentication failed'`.

The PAM authentication plugin provides these capabilities:

- External authentication: The plugin enables MySQL Server to accept connections from users defined outside the MySQL grant tables.
- Proxy user support: The plugin can return to MySQL a user name different from the login user, based on the groups the external user is in and the authentication string provided. This means that the plugin can return the MySQL user that defines the privileges the external PAM-authenticated user should have. For example, a PAM user named `joe` can connect and have the privileges of the MySQL user named `developer`.

The following table shows the plugin and library file names. The file name suffix might be different on your system. The file location must be the directory named by the `plugin_dir` system variable. For installation information, see [Installing the PAM Authentication Plugin](#).

Table 6.10 MySQL PAM Authentication Plugin

Server-side plugin name	<code>authentication_pam</code>
Client-side plugin name	<code>mysql_clear_password</code>

Library object file name	<code>authentication_pam.so</code>
--------------------------	------------------------------------

The library file includes only the server-side plugin. As of MySQL 5.5.10, the client-side plugin is built into the `libmysqlclient` client library. See [Section 6.3.7.5, “The Cleartext Client-Side Authentication Plugin”](#).

The server-side PAM authentication plugin is included only in commercial distributions. It is not included in MySQL community distributions. The client-side clear-text plugin that communicates with the server-side plugin is built into the MySQL client library and is included in all distributions, including community distributions. This permits clients from any 5.5.10 or newer distribution to connect to a server that has the server-side plugin loaded.

The PAM authentication plugin has been tested on Linux and Mac OS X. It requires MySQL Server 5.5.16 or newer.

For general information about pluggable authentication in MySQL, see [Section 6.3.6, “Pluggable Authentication”](#). For proxy user information, see [Section 6.3.8, “Proxy Users”](#).

Installing the PAM Authentication Plugin

The PAM authentication plugin must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, set the value of `plugin_dir` at server startup to tell the server the location of the plugin directory.

To enable the plugin, start the server with the `--plugin-load` option. For example, put the following lines in your `my.cnf` file. If object files have a suffix different from `.so` on your system, substitute the correct suffix.

```
[mysqld]
plugin-load=authentication_pam.so
```

Use the plugin name `authentication_pam` in the `IDENTIFIED WITH` clause of `CREATE USER` or `GRANT` statements for MySQL accounts that should be authenticated with this plugin.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement. See [Section 5.1.8.2, “Obtaining Server Plugin Information”](#).

Using the PAM Authentication Plugin

This section describes how to use the PAM authentication plugin to connect from MySQL client programs to the server. It is assumed that the server-side plugin is enabled and that client programs are recent enough to include the client-side plugin.

Note

The client-side plugin with which the PAM plugin communicates simply sends the password to the server in clear text so it can be passed to PAM. This may be a security problem in some configurations, but is necessary to use the server-side PAM library. To avoid problems if there is any possibility that the password would be intercepted, clients should connect to MySQL Server using SSL. See [Section 6.3.7.5, “The Cleartext Client-Side Authentication Plugin”](#).

To refer to the PAM authentication plugin in the `IDENTIFIED WITH` clause of a `CREATE USER` or `GRANT` statement, use the name `authentication_pam`. For example:

```
CREATE USER user
  IDENTIFIED WITH authentication_pam
  AS 'authentication_string';
```

The authentication string specifies the following types of information:

- PAM supports the notion of “service name,” which is a name that the system administrator can use to configure the authentication method for a particular application. There can be several such “applications” associated with a single database server instance, so the choice of service name is left to the SQL application developer. When you define an account that should authenticate using PAM, specify the service name in the authentication string.
- PAM provides a way for a PAM module to return to the server a MySQL user name other than the login name supplied at login time. Use the authentication string to control the mapping between login name and MySQL user name. If you want to take advantage of proxy user capabilities, the authentication string must include this kind of mapping.

For example, if the service name is `mysql` and users in the `root` and `users` PAM groups should be mapped to the `developer` and `data_entry` users, respectively, use a statement like this:

```
CREATE USER user
  IDENTIFIED WITH authentication_pam
  AS 'mysql, root=developer, users=data_entry';
```

Authentication string syntax for the PAM authentication plugin follows these rules:

- The string consists of a PAM service name, optionally followed by a group mapping list consisting of one or more keyword/value pairs each specifying a group name and a SQL user name:

```
pam_service_name[,group_name=sql_user_name]...
```

- Each `group_name=sql_user_name` pair must be preceded by a comma.
- Leading and trailing spaces not inside double quotation marks are ignored.
- Unquoted `pam_service_name`, `group_name`, and `sql_user_name` values can contain anything except equal sign, comma, or space.
- If a `pam_service_name`, `group_name`, or `sql_user_name` value is quoted with double quotation marks, everything between the quotation marks is part of the value. This is necessary, for example, if the value contains space characters. All characters are legal except double quotation mark and backslash (`'\"'`). To include either character, escape it with a backslash.

The plugin parses the authentication string on each login check. To minimize overhead, keep the string as short as possible.

If the plugin successfully authenticates a login name, it looks for a group mapping list in the authentication string and uses it to return a different user name to the MySQL server based on the groups the external user is a member of:

- If the authentication string contains no group mapping list, the plugin returns the login name.
- If the authentication string does contain a group mapping list, the plugin examines each `group_name=sql_user_name` pair in the list from left to right and tries to find a match for the `group_name` value in a non-MySQL directory of the groups assigned to the authenticated user and returns `sql_user_name` for the first match it finds. If the plugin finds no match for any group, it returns the login name. If the plugin is not capable of looking up a group in a directory, it ignores the group mapping list and returns the login name.

The following sections describe how to set up several authentication scenarios that use the PAM authentication plugin:

- No proxy users. This uses PAM only to check login names and passwords. Every external user permitted to connect to MySQL Server should have a matching MySQL account that is defined to use external PAM authentication. Authentication can be performed by various PAM-supported methods. The discussion shows how to use traditional Unix passwords and LDAP.

PAM authentication, when not done through proxy users or groups, requires the MySQL account to have the same user name as the Unix account. Because MySQL user names are limited to 16 characters (see [Section 6.2.2, “Privilege System Grant Tables”](#)), this limits PAM nonproxy authentication to Unix accounts with names of at most 16 characters.

- Proxy login only and group mapping. For this scenario, create a few MySQL accounts that define different sets of privileges. (Ideally, nobody should log in through these directly.) Then define a default user authenticating through PAM that uses some mapping scheme (usually by the external groups the users are in) to map all the external logins to the few MySQL accounts holding the privilege sets. Any user that logs in is mapped to one of the MySQL accounts and uses its privileges. The discussion shows how to set this up using Unix passwords, but other PAM methods such as LDAP could be used instead.

Variations on these scenarios are possible. For example, you can permit some users to log in directly but require others to connect through proxy users.

The examples make the following assumptions. You might need to make some adjustments if your system is set up differently.

- The PAM configuration directory is `/etc/pam.d`.
- The PAM service name is `mysql`, which means that you must set up a PAM file named `mysql` in the PAM configuration directory (creating the file if it does not exist). If you use a different service name, the file name will be different and you must use a different name in the `AS` clause of `CREATE USER` and `GRANT` statements.
- The examples use a login name of `antonio` and password of `verysecret`. Change these to correspond to the users you want to authenticate.

The PAM authentication plugin checks at initialization time whether the `AUTHENTICATION_PAM_LOG` environment value is set. If so, the plugin enables logging of diagnostic messages to the standard output. These messages may be helpful for debugging PAM-related problems that occur when the plugin performs authentication. For more information, see [PAM Authentication Plugin Debugging](#).

Unix Password Authentication without Proxy Users

This authentication scenario uses PAM only to check Unix user login names and passwords. Every external user permitted to connect to MySQL Server should have a matching MySQL account that is defined to use external PAM authentication.

1. Verify that Unix authentication in PAM permits you to log in as `antonio` with password `verysecret`.
2. Set up PAM to authenticate the `mysql` service. Put the following in `/etc/pam.d/mysql`:

```
#%PAM-1.0
auth            include      password-auth
account         include      password-auth
```

3. Create a MySQL account with the same user name as the Unix login name and define it to authenticate using the PAM plugin:

```
CREATE USER 'antonio'@'localhost'
  IDENTIFIED WITH authentication_pam AS 'mysql';
```

```
GRANT ALL PRIVILEGES ON mydb.* TO 'antonio'@'localhost';
```

4. Try to connect to the MySQL server using the `mysql` command-line client. For example:

```
mysql --user=antonio --password=verysecret --enable-cleartext-plugin mydb
```

The server should permit the connection and the following query should return output as shown:

```
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-----+-----+-----+
| USER() | CURRENT_USER() | @@proxy_user |
+-----+-----+-----+
| antonio@localhost | antonio@localhost | NULL |
+-----+-----+-----+
```

This shows that `antonio` uses the privileges granted to the `antonio` MySQL account, and that no proxying has occurred.

LDAP Authentication without Proxy Users

This authentication scenario uses PAM only to check LDAP user login names and passwords. Every external user permitted to connect to MySQL Server should have a matching MySQL account that is defined to use external PAM authentication.

1. Verify that LDAP authentication in PAM permits you to log in as `antonio` with password `verysecret`.
2. Set up PAM to authenticate the `mysql` service through LDAP. Put the following in `/etc/pam.d/mysql`:

```
##PAM-1.0
auth      required      pam_ldap.so
account   required      pam_ldap.so
```

If PAM object files have a suffix different from `.so` on your system, substitute the correct suffix.

3. MySQL account creation and connecting to the server is the same as previously described in [Unix Password Authentication without Proxy Users](#).

Unix Password Authentication with Proxy Users and Group Mapping

This authentication scheme uses proxying and group mapping to map users who connect to the MySQL server through PAM onto a few MySQL accounts that define different sets of privileges. Users do not connect directly through the accounts that define the privileges. Instead, they connect through a default proxy user authenticating through PAM that uses a mapping scheme to map all the external logins to the few MySQL accounts holding the privileges. Any user who connects is mapped to one of the MySQL accounts and uses its privileges.

The procedure shown here uses Unix password authentication. To use LDAP instead, see the early steps of [LDAP Authentication without Proxy Users](#).

1. Verify that Unix authentication in PAM permits you to log in as `antonio` with password `verysecret` and that `antonio` is a member of the `root` or `users` group.
2. Set up PAM to authenticate the `mysql` service. Put the following in `/etc/pam.d/mysql`:

```
##PAM-1.0
auth      include      password-auth
account   include      password-auth
```

3. Create the default proxy user that maps the external PAM users to the proxied accounts. It maps external users from the `root` PAM group to the `developer` MySQL account and the external users from the `users` PAM group to the `data_entry` MySQL account:

```
CREATE USER ''@'
  IDENTIFIED WITH authentication_pam
  AS 'mysql, root=developer, users=data_entry';
```

The mapping list following the service name is required when you set up proxy users. Otherwise, the plugin cannot tell how to map the name of PAM groups to the proper proxied user name.

4. Create the proxied accounts that will be used to access the databases:

```
CREATE USER 'developer'@'localhost' IDENTIFIED BY 'very secret password';
GRANT ALL PRIVILEGES ON mydevdb.* TO 'developer'@'localhost';
CREATE USER 'data_entry'@'localhost' IDENTIFIED BY 'very secret password';
GRANT ALL PRIVILEGES ON mydb.* TO 'data_entry'@'localhost';
```

If you do not let anyone know the passwords for these accounts, other users cannot use them to connect directly to the MySQL server. Instead, it is expected that users will authenticate using PAM and that they will use the `developer` or `data_entry` account by proxy based on their PAM group.

5. Grant the `PROXY` privilege to the proxy account for the proxied accounts:

```
GRANT PROXY ON 'developer'@'localhost' TO ''@';
GRANT PROXY ON 'data_entry'@'localhost' TO ''@';
```

6. Try to connect to the MySQL server using the `mysql` command-line client. For example:

```
mysql --user=antonio --password=verysecret --enable-cleartext-plugin mydb
```

The server authenticates the connection using the `''@'` account. The privileges `antonio` will have depends on what PAM groups he is a member of. If `antonio` is a member of the `root` PAM group, the PAM plugin maps `root` to the `developer` MySQL user name and returns that name to the server. The server verifies that `''@'` has the `PROXY` privilege for `developer` and permits the connection. the following query should return output as shown:

```
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-----+-----+-----+
| USER()          | CURRENT_USER()    | @@proxy_user |
+-----+-----+-----+
| antonio@localhost | developer@localhost | ''@'         |
+-----+-----+-----+
```

This shows that `antonio` uses the privileges granted to the `developer` MySQL account, and that proxying occurred through the default proxy user account.

If `antonio` is not a member of the `root` PAM group but is a member of the `users` group, a similar process occurs, but the plugin maps `user` group membership to the `data_entry` MySQL user name and returns that name to the server. In this case, `antonio` uses the privileges of the `data_entry` MySQL account:

```
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-----+-----+-----+
| USER()          | CURRENT_USER()    | @@proxy_user |
+-----+-----+-----+
```

```
| antonio@localhost | data_entry@localhost | '@' |
+-----+-----+-----+
```

PAM Authentication Plugin Debugging

The PAM authentication plugin checks at initialization time whether the `AUTHENTICATION_PAM_LOG` environment value is set (the value does not matter). If so, the plugin enables logging of diagnostic messages to the standard output. These messages may be helpful for debugging PAM-related problems that occur when the plugin performs authentication.

Some messages include reference to PAM plugin source files and line numbers, which enables plugin actions to be tied more closely to the location in the code where they occur.

The following transcript demonstrates the kind of information produced by enabling logging. It resulted from a successful proxy authentication attempt.

6.3.7.4 The Windows Native Authentication Plugin

Note

The Windows authentication plugin is a commercial extension. To learn more about commercial products (MySQL Enterprise Edition), see <http://www.mysql.com/products/>.

As of MySQL 5.5.16, commercial distributions of MySQL for Windows include an authentication plugin that performs external authentication on Windows, enabling MySQL Server to use native Windows services to authenticate client connections. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password.

The client and server exchange data packets in the authentication handshake. As a result of this exchange, the server creates a security context object that represents the identity of the client in the Windows OS. This identity includes the name of the client account. The Windows authentication plugin uses the identity of the client to check whether it is a given account or a member of a group. By default, negotiation uses Kerberos to authenticate, then NTLM if Kerberos is unavailable.

The Windows authentication plugin provides these capabilities:

- **External authentication:** The plugin enables MySQL Server to accept connections from users defined outside the MySQL grant tables.
- **Proxy user support:** The plugin can return to MySQL a user name different from the client user. This means that the plugin can return the MySQL user that defines the privileges the external Windows-authenticated user should have. For example, a Windows user named `joe` can connect and have the privileges of the MySQL user named `developer`.

The following table shows the plugin and library file names. The file location must be the directory named by the `plugin_dir` system variable. For installation information, see [Installing the Windows Authentication Plugin](#).

Table 6.11 MySQL Windows Authentication Plugin

Server-side plugin name	<code>authentication_windows</code>
Client-side plugin name	<code>authentication_windows_client</code>

Library object file name	<code>authentication_windows.dll</code>
--------------------------	-----------------------------------------

The library file includes only the server-side plugin. As of MySQL 5.5.13, the client-side plugin is built into the `libmysqlclient` client library.

The server-side Windows authentication plugin is included only in commercial distributions. It is not included in MySQL community distributions. The client-side plugin is included in all distributions, including community distributions. This permits clients from any 5.5.13 or newer distribution to connect to a server that has the server-side plugin loaded.

The Windows authentication plugin is supported on any version of Windows supported by MySQL 5.5 (see <http://www.mysql.com/support/supportedplatforms/database.html>). It requires MySQL Server 5.5.16 or newer.

For general information about pluggable authentication in MySQL, see [Section 6.3.6, “Pluggable Authentication”](#). For proxy user information, see [Section 6.3.8, “Proxy Users”](#).

Installing the Windows Authentication Plugin

The Windows authentication plugin must be installed in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, set the value of `plugin_dir` at server startup to tell the server the location of the plugin directory.

To enable the plugin, start the server with the `--plugin-load` option. For example, put these lines in your `my.ini` file:

```
[mysqld]
plugin-load=authentication_windows.dll
```

Use the plugin name `authentication_windows` in the `IDENTIFIED WITH` clause of `CREATE USER` or `GRANT` statements for MySQL accounts that should be authenticated with this plugin.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement. See [Section 5.1.8.2, “Obtaining Server Plugin Information”](#).

Using the Windows Authentication Plugin

The Windows authentication plugin supports the use of MySQL accounts such that users who have logged in to Windows can connect to the MySQL server without having to specify an additional password. It is assumed that the server-side plugin is enabled and that client programs are recent enough to include the client-side plugin built into `libmysqlclient` (MySQL 5.5.13 or higher). Once the DBA has enabled the server-side plugin and set up accounts to use it, clients can connect using those accounts with no other setup required on their part.

To refer to the Windows authentication plugin in the `IDENTIFIED WITH` clause of a `CREATE USER` or `GRANT` statement, use the name `authentication_windows`. Suppose that the Windows users `Rafal` and `Tasha` should be permitted to connect to MySQL, as well as any users in the `Administrators` or `Power Users` group. To set this up, create a MySQL account named `sql_admin` that uses the Windows plugin for authentication:

```
CREATE USER sql_admin
  IDENTIFIED WITH authentication_windows
  AS 'Rafal, Tasha, Administrators, "Power Users";
```

The plugin name is `authentication_windows`. The string following the `AS` keyword is the authentication string. It specifies that the Windows users named `Rafal` or `Tasha` are permitted

to authenticate to the server as the MySQL user `sql_admin`, as are any Windows users in the `Administrators` or `Power Users` group. The latter group name contains a space, so it must be quoted with double quote characters.

After you create the `sql_admin` account, a user who has logged in to Windows can attempt to connect to the server using that account:

```
C:\> mysql --user=sql_admin
```

No password is required here. The `authentication_windows` plugin uses the Windows security API to check which Windows user is connecting. If that user is named `Rafal` or `Tasha`, or is in the `Administrators` or `Power Users` group, the server grants access and the client is authenticated as `sql_admin` and has whatever privileges are granted to the `sql_admin` account. Otherwise, the server denies access.

Authentication string syntax for the Windows authentication plugin follows these rules:

- The string consists of one or more user mappings separated by commas.
- Each user mapping associates a Windows user or group name with a MySQL user name:

```
win_user_or_group_name=sql_user_name  
win_user_or_group_name
```

For the latter syntax, with no `sql_user_name` value given, the implicit value is the MySQL user created by the `CREATE USER` statement. Thus, these statements are equivalent:

```
CREATE USER sql_admin  
  IDENTIFIED WITH authentication_windows  
  AS 'Rafal, Tasha, Administrators, "Power Users"';  
  
CREATE USER sql_admin  
  IDENTIFIED WITH authentication_windows  
  AS 'Rafal=sql_admin, Tasha=sql_admin, Administrators=sql_admin,  
      "Power Users"=sql_admin';
```

- Each backslash (`'\'`) in a value must be doubled because backslash is the escape character in MySQL strings.
- Leading and trailing spaces not inside double quotation marks are ignored.
- Unquoted `win_user_or_group_name` and `sql_user_name` values can contain anything except equal sign, comma, or space.
- If a `win_user_or_group_name` and or `sql_user_name` value is quoted with double quotation marks, everything between the quotation marks is part of the value. This is necessary, for example, if the name contains space characters. All characters within double quotes are legal except double quotation mark and backslash. To include either character, escape it with a backslash.
- `win_user_or_group_name` values use conventional syntax for Windows principals, either local or in a domain. Examples (note the doubling of backslashes):

```
domain\\user  
.\user  
domain\\group  
.\group  
BUILTIN\WellKnownGroup
```

When invoked by the server to authenticate a client, the plugin scans the authentication string left to right for a user or group match to the Windows user. If there is a match, the plugin returns the corresponding `sql_user_name` to the MySQL server. If there is no match, authentication fails.

A user name match takes preference over a group name match. Suppose that the Windows user named `win_user` is a member of `win_group` and the authentication string looks like this:

```
'win_group = sql_user1, win_user = sql_user2'
```

When `win_user` connects to the MySQL server, there is a match both to `win_group` and to `win_user`. The plugin authenticates the user as `sql_user2` because the more-specific user match takes precedence over the group match, even though the group is listed first in the authentication string.

Windows authentication always works for connections from the same computer on which the server is running. For cross-computer connections, both computers must be registered with Windows Active Directory. If they are in the same Windows domain, it is unnecessary to specify a domain name. It is also possible to permit connections from a different domain, as in this example:

```
CREATE USER sql_accounting
  IDENTIFIED WITH authentication_windows
  AS 'SomeDomain\\Accounting';
```

Here `SomeDomain` is the name of the other domain. The backslash character is doubled because it is the MySQL escape character within strings.

MySQL supports the concept of proxy users whereby a client can connect and authenticate to the MySQL server using one account but while connected has the privileges of another account (see [Section 6.3.8, “Proxy Users”](#)). Suppose that you want Windows users to connect using a single user name but be mapped based on their Windows user and group names onto specific MySQL accounts as follows:

- The `local_user` and `MyDomain\domain_user` local and domain Windows users should map to the `local_wlad` MySQL account.
- Users in the `MyDomain\Developers` domain group should map to the `local_dev` MySQL account.
- Local machine administrators should map to the `local_admin` MySQL account.

To set this up, create a proxy account for Windows users to connect to, and configure this account so that users and groups map to the appropriate MySQL accounts (`local_wlad`, `local_dev`, `local_admin`). In addition, grant the MySQL accounts the privileges appropriate to the operations they need to perform. The following instructions use `win_proxy` as the proxy account, and `local_wlad`, `local_dev`, and `local_admin` as the proxied accounts.

1. Create the proxy MySQL account:

```
CREATE USER win_proxy
  IDENTIFIED WITH authentication_windows
  AS 'local_user = local_wlad,
     MyDomain\\domain_user = local_wlad,
     MyDomain\\Developers = local_dev,
     BUILTIN\\Administrators = local_admin';
```

2. For proxying to work, the proxied accounts must exist, so create them:

```
CREATE USER local_wlad IDENTIFIED BY 'wlad_pass';
CREATE USER local_dev IDENTIFIED BY 'dev_pass';
CREATE USER local_admin IDENTIFIED BY 'admin_pass';
```

If you do not let anyone know the passwords for these accounts, other users cannot use them to connect directly to the MySQL server.

You should also issue `GRANT` statements (not shown) that grant each proxied account the privileges it needs.

3. The proxy account must have the `PROXY` privilege for each of the proxied accounts:

```
GRANT PROXY ON local_wlad TO win_proxy;  
GRANT PROXY ON local_dev TO win_proxy;  
GRANT PROXY ON local_admin TO win_proxy;
```

Now the Windows users `local_user` and `MyDomain\domain_user` can connect to the MySQL server as `win_proxy` and when authenticated have the privileges of the account given in the authentication string—in this case, `local_wlad`. A user in the `MyDomain\Developers` group who connects as `win_proxy` has the privileges of the `local_dev` account. A user in the `BUILTIN\Administrators` group has the privileges of the `local_admin` account.

To configure authentication so that all Windows users who do not have their own MySQL account go through a proxy account, substitute the default proxy user (`'@'`) for `win_proxy` in the preceding instructions. For information about the default proxy user, see [Section 6.3.8, “Proxy Users”](#).

To use the Windows authentication plugin with Connector/Net connection strings in Connector/Net 6.4.4 and higher, see [Using the Windows Native Authentication Plugin](#).

Additional control over the Windows authentication plugin is provided by the `authentication_windows_use_principal_name` and `authentication_windows_log_level` system variables. See [Section 5.1.4, “Server System Variables”](#).

6.3.7.5 The Cleartext Client-Side Authentication Plugin

As of MySQL 5.5.10, a client-side authentication plugin is available that sends the password to the server without hashing or encryption. This plugin is built into the MySQL client library.

The following table shows the plugin name.

Table 6.12 MySQL Cleartext Authentication Plugin

Server-side plugin name	None, see discussion
Client-side plugin name	<code>mysql_clear_password</code>
Library object file name	None (plugin is built in)

With native MySQL authentication, the client performs one-way hashing on the password before sending it to the server. This enables the client to avoid sending the password in clear text. See [Section 6.1.2.4, “Password Hashing in MySQL”](#). However, because the hash algorithm is one way, the original password cannot be recovered on the server side.

One-way hashing cannot be done for authentication schemes that require the server to receive the password as entered on the client side. In such cases, the `mysql_clear_password` client-side plugin can be used to send the password to the server in clear text. There is no corresponding server-side plugin. Rather, the client-side plugin can be used by any server-side plugin that needs a clear text password. (The PAM authentication plugin is one such; see [Section 6.3.7.3, “The PAM Authentication Plugin”](#).)

For general information about pluggable authentication in MySQL, see [Section 6.3.6, “Pluggable Authentication”](#).

**Note**

Sending passwords in clear text may be a security problem in some configurations. To avoid problems if there is any possibility that the password would be intercepted, clients should connect to MySQL Server using a method that protects the password. Possibilities include SSL (see [Section 6.3.9, “Using SSL for Secure Connections”](#)), IPsec, or a private network.

As of MySQL 5.5.27, to make inadvertent use of this plugin less likely, it is required that clients explicitly enable it. This can be done several ways:

- Set the `LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN` environment variable to a value that begins with `1`, `y`, or `Y`. This enables the plugin for all client connections.
- The `mysql`, `mysqladmin`, and `mysqlslap` client programs support an `--enable-cleartext-plugin` option that enables the plugin on a per-invocation basis.
- The `mysql_options()` C API function supports a `MYSQL_ENABLE_CLEARTEXT_PLUGIN` option that enables the plugin on a per-connection basis. Also, any program that uses `libmysqlclient` and reads option files can enable the plugin by including an `enable-cleartext-plugin` option in an option group read by the client library.

6.3.7.6 The Socket Peer-Credential Authentication Plugin

As of MySQL 5.5.10, a server-side authentication plugin is available that authenticates clients that connect from the local host through the Unix socket file. This plugin works only on Linux systems.

The source code for this plugin can be examined as a relatively simple example demonstrating how to write a loadable authentication plugin.

The following table shows the plugin and library file names. The file name suffix might differ on your system. The file location is the directory named by the `plugin_dir` system variable. For installation information, see [Section 6.3.6, “Pluggable Authentication”](#).

Table 6.13 MySQL Socket Peer-Credential Authentication Plugin

Server-side plugin name	<code>auth_socket</code>
Client-side plugin name	None, see discussion
Library object file name	<code>auth_socket.so</code>

The `auth_socket` authentication plugin authenticates clients that connect from the local host through the Unix socket file. The plugin uses the `SO_PEERCRED` socket option to obtain information about the user running the client program. The plugin checks whether the user name matches the MySQL user name specified by the client program to the server, and permits the connection only if the names match. The plugin can be built only on systems that support the `SO_PEERCRED` option, such as Linux.

Suppose that a MySQL account is created for a user named `valerie` who is to be authenticated by the `auth_socket` plugin for connections from the local host through the socket file:

```
CREATE USER 'valerie'@'localhost' IDENTIFIED WITH auth_socket;
```

If a user on the local host with a login name of `stefanie` invokes `mysql` with the option `--user=valerie` to connect through the socket file, the server uses `auth_socket` to authenticate the client. The plugin determines that the `--user` option value (`valerie`) differs from the client user's name (`stefanie`) and refuses the connection. If a user named `valerie` tries the same thing, the plugin finds that the user name and the MySQL user name are both `valerie` and permits the connection. However,

the plugin refuses the connection even for `valerie` if the connection is made using a different protocol, such as TCP/IP.

For general information about pluggable authentication in MySQL, see [Section 6.3.6, “Pluggable Authentication”](#).

6.3.7.7 The Test Authentication Plugin

MySQL includes a test plugin that authenticates using MySQL native authentication, but is a loadable plugin (not built in) and must be installed prior to use. It can authenticate against either normal or older (shorter) password hash values.

This plugin is intended for testing and development purposes, and not for use in production environments. The test plugin source code is separate from the server source, unlike the built-in native plugin, so it can be examined as a relatively simple example demonstrating how to write a loadable authentication plugin.

The following table shows the plugin and library file names. The file name suffix might differ on your system. The file location is the directory named by the `plugin_dir` system variable. For installation information, see [Section 6.3.6, “Pluggable Authentication”](#).

Table 6.14 MySQL Test Authentication Plugin

Server-side plugin name	<code>test_plugin_server</code>
Client-side plugin name	<code>auth_test_plugin</code>
Library object file name	<code>auth_test_plugin.so</code>

Because the test plugin authenticates the same way as native MySQL authentication, provide the usual `--user` and `--password` options that you normally use for accounts that use native authentication when you connect to the server. For example:

```
shell> mysql --user=your_name --password=your_pass
```

For general information about pluggable authentication in MySQL, see [Section 6.3.6, “Pluggable Authentication”](#).

6.3.8 Proxy Users

When authentication to the MySQL server occurs by means of an authentication plugin, the plugin may request that the connecting (external) user be treated as a different user for privilege-checking purposes. This enables the external user to be a proxy for the second user; that is, to have the privileges of the second user. In other words, the external user is a “proxy user” (a user who can impersonate or become known as another user) and the second user is a “proxied user” (a user whose identity can be taken on by a proxy user).

This section describes how the proxy user capability works. For general information about authentication plugins, see [Section 6.3.6, “Pluggable Authentication”](#). If you are interested in writing your own authentication plugins that support proxy users, see [Implementing Proxy User Support in Authentication Plugins](#).

For proxying to occur, these conditions must be satisfied:

- When a connecting client should be treated as a proxy user, the plugin must return a different name, to indicate the proxied user name.
- A proxy user account must be set up to be authenticated by the plugin. Use the `CREATE USER` or `GRANT` statement to associate an account with a plugin.

- A proxy user account must have the `PROXY` privilege for the proxied account. Use the `GRANT` statement for this.

Consider the following definitions:

```
CREATE USER 'empl_external'@'localhost'
  IDENTIFIED WITH auth_plugin AS 'auth_string';
CREATE USER 'employee'@'localhost'
  IDENTIFIED BY 'employee_pass';
GRANT PROXY
  ON 'employee'@'localhost'
  TO 'empl_external'@'localhost';
```

When a client connects as `empl_external` from the local host, MySQL uses `auth_plugin` to perform authentication. If `auth_plugin` returns the `employee` user name to the server (based on the content of `'auth_string'` and perhaps by consulting some external authentication system), that serves as a request to the server to treat this client, for purposes of privilege checking, as the `employee` local user.

In this case, `empl_external` is the proxy user and `employee` is the proxied user.

The server verifies that proxy authentication for `employee` is possible for the `empl_external` user by checking whether `empl_external` has the `PROXY` privilege for `employee`. (If this privilege had not been granted, an error would occur.)

When proxying occurs, the `USER()` and `CURRENT_USER()` functions can be used to see the difference between the connecting user and the account whose privileges apply during the current session. For the example just described, those functions return these values:

```
mysql> SELECT USER(), CURRENT_USER();
+-----+-----+
| USER()           | CURRENT_USER() |
+-----+-----+
| empl_external@localhost | employee@localhost |
+-----+-----+
```

The `IDENTIFIED WITH` clause that names the authentication plugin may be followed by an `AS` clause specifying a string that the server passes to the plugin when the user connects. It is up to each plugin whether the `AS` clause is required. If it is required, the format of the authentication string depends on how the plugin intends to use it. Consult the documentation for a given plugin for information about the authentication string values it accepts.

Granting the Proxy Privilege

A special `PROXY` privilege is needed to enable an external user to connect as and have the privileges of another user. To grant this privilege, use the `GRANT` statement. For example:

```
GRANT PROXY ON 'proxied_user' TO 'proxy_user';
```

`proxy_user` must represent a valid externally authenticated MySQL user at connection time or connection attempts fail. `proxied_user` must represent a valid locally authenticated user at connection time or connection attempts fail.

The corresponding `REVOKE` syntax is:

```
REVOKE PROXY ON 'proxied_user' FROM 'proxy_user';
```

MySQL `GRANT` and `REVOKE` syntax extensions work as usual. For example:

```
GRANT PROXY ON 'a' TO 'b', 'c', 'd';
GRANT PROXY ON 'a' TO 'd' IDENTIFIED BY ...;
GRANT PROXY ON 'a' TO 'd' WITH GRANT OPTION;
GRANT PROXY ON 'a' TO '@';
REVOKE PROXY ON 'a' FROM 'b', 'c', 'd';
```

In the preceding example, '@' is the default proxy user and means “any user.” The default proxy user is discussed later in this section.

The `PROXY` privilege can be granted in these cases:

- By *proxied_user* for itself: The value of `USER()` must exactly match `CURRENT_USER()` and *proxied_user*, for both the user name and host name parts of the account name.
- By a user that has `GRANT PROXY ... WITH GRANT OPTION` for *proxied_user*.

The `root` account created by default during MySQL installation has the `PROXY ... WITH GRANT OPTION` privilege for '@', that is, for all users. This enables `root` to set up proxy users, as well as to delegate to other accounts the authority to set up proxy users. For example, `root` can do this:

```
CREATE USER 'admin'@'localhost' IDENTIFIED BY 'test';
GRANT PROXY ON '@' TO 'admin'@'localhost' WITH GRANT OPTION;
```

Now the `admin` user can manage all the specific `GRANT PROXY` mappings. For example, `admin` can do this:

```
GRANT PROXY ON sally TO joe;
```

Default Proxy Users

To specify that some or all users should connect using a given external plugin, create a “blank” MySQL user, set it up to use that plugin for authentication, and let the plugin return the real authenticated user name (if different from the blank user). For example, suppose that there exists a hypothetical plugin named `ldap_auth` that implements LDAP authentication:

```
CREATE USER '@' IDENTIFIED WITH ldap_auth AS 'O=Oracle, OU=MySQL';
CREATE USER 'developer'@'localhost' IDENTIFIED BY 'developer_pass';
CREATE USER 'manager'@'localhost' IDENTIFIED BY 'manager_pass';
GRANT PROXY ON 'manager'@'localhost' TO '@';
GRANT PROXY ON 'developer'@'localhost' TO '@';
```

Now assume that a client tries to connect as follows:

```
mysql --user=myuser --password='myuser_pass' ...
```

The server will not find `myuser` defined as a MySQL user. But because there is a blank user account ('@'), that matches the client user name and host name, the server authenticates the client against that account: The server invokes `ldap_auth`, passing it `myuser` and `myuser_pass` as the user name and password.

If the `ldap_auth` plugin finds in the LDAP directory that `myuser_pass` is not the correct password for `myuser`, authentication fails and the server rejects the connection.

If the password is correct and `ldap_auth` finds that `myuser` is a developer, it returns the user name `developer` to the MySQL server, rather than `myuser`. The server verifies that '@' can authenticate as `developer` (because it has the `PROXY` privilege to do so) and accepts the connection. The session

proceeds with `myuser` having the privileges of `developer`. (These privileges should be set up by the DBA using `GRANT` statements, not shown.) The `USER()` and `CURRENT_USER()` functions return these values:

```
mysql> SELECT USER(), CURRENT_USER();
+-----+-----+
| USER()          | CURRENT_USER()    |
+-----+-----+
| myuser@localhost | developer@localhost |
+-----+-----+
```

If the plugin instead finds in the LDAP directory that `myuser` is a manager, it returns `manager` as the user name and the session proceeds with `myuser` having the privileges of `manager`.

```
mysql> SELECT USER(), CURRENT_USER();
+-----+-----+
| USER()          | CURRENT_USER()    |
+-----+-----+
| myuser@localhost | manager@localhost  |
+-----+-----+
```

For simplicity, external authentication cannot be multilevel: Neither the credentials for `developer` nor those for `manager` are taken into account in the preceding example. However, they are still used if a client tries to authenticate directly against the `developer` or `manager` account, which is why those accounts should be assigned passwords.

The default proxy account uses `' '` in the host part, which matches any host. If you set up a default proxy user, take care to also check for accounts with `' % '` in the host part, because that also matches any host, but has precedence over `' '` by the rules that the server uses to sort account rows internally (see [Section 6.2.4, “Access Control, Stage 1: Connection Verification”](#)).

Suppose that a MySQL installation includes these two accounts:

```
CREATE USER ''@' IDENTIFIED WITH some_plugin;
CREATE USER ''@%' IDENTIFIED BY 'some_password';
```

The intent of the first account is to serve as the default proxy user, to be used to authenticate connections for users who do not otherwise match a more-specific account. The second account might have been created, for example, to enable users without their own account as the anonymous user.

However, in this configuration, the first account will never be used because the matching rules sort `' '@' % '` ahead of `' '@' '`. For accounts that do not match any more-specific account, the server will attempt to authenticate them against `' '@' % '` rather than `' '@' '`.

If you intend to create a default proxy user, check for other existing “match any user” accounts that will take precedence over the default proxy user and thus prevent that user from working as intended. It may be necessary to remove any such accounts.

Proxy User System Variables

Two system variables help trace the proxy login process:

- `proxy_user`: This value is `NULL` if proxying is not used. Otherwise, it indicates the proxy user account. For example, if a client authenticates through the default proxy account, this variable will be set as follows:

```
mysql> SELECT @@proxy_user;
+-----+
| @@proxy_user |
+-----+
```

```
+-----+
| ' ' @ ' ' |
+-----+
```

- `external_user`: Sometimes the authentication plugin may use an external user to authenticate to the MySQL server. For example, when using Windows native authentication, a plugin that authenticates using the windows API does not need the login ID passed to it. However, it still uses an Windows user ID to authenticate. The plugin may return this external user ID (or the first 512 UTF-8 bytes of it) to the server using the `external_user` read-only session variable. If the plugin does not set this variable, its value is `NULL`.

6.3.9 Using SSL for Secure Connections

MySQL supports secure (encrypted) connections between MySQL clients and the server using the Secure Sockets Layer (SSL) protocol. This section discusses how to use SSL connections. For information on how to require users to use SSL connections, see the discussion of the `REQUIRE` clause of the `GRANT` statement in [Section 13.7.1.3, “GRANT Syntax”](#).

The standard configuration of MySQL is intended to be as fast as possible, so encrypted connections are not used by default. For applications that require the security provided by encrypted connections, the extra computation to encrypt the data is worthwhile.

MySQL enables encryption on a per-connection basis. You can choose an unencrypted connection or a secure encrypted SSL connection according the requirements of individual applications.

Secure connections are based on the OpenSSL API and are available through the MySQL C API. Replication uses the C API, so secure connections can be used between master and slave servers. See [Section 17.3.7, “Setting Up Replication Using SSL”](#).

Another way to connect securely is from within an SSH connection to the MySQL server host. For an example, see [Section 6.3.10, “Connecting to MySQL Remotely from Windows with SSH”](#).

6.3.9.1 Basic SSL Concepts

To understand how MySQL uses SSL, it is necessary to explain some basic SSL and X509 concepts. People who are familiar with these concepts can skip this part of the discussion.

By default, MySQL uses unencrypted connections between the client and the server. This means that someone with access to the network could watch all your traffic and look at the data being sent or received. They could even change the data while it is in transit between client and server. To improve security a little, you can compress client/server traffic by using the `--compress` option when invoking client programs. However, this does not foil a determined attacker.

When you need to move information over a network in a secure fashion, an unencrypted connection is unacceptable. Encryption is the way to make any kind of data unreadable. Encryption algorithms must include security elements to resist many kinds of known attacks such as changing the order of encrypted messages or replaying data twice.

SSL is a protocol that uses different encryption algorithms to ensure that data received over a public network can be trusted. It has mechanisms to detect any data change, loss, or replay. SSL also incorporates algorithms that provide identity verification using the X509 standard.

X509 makes it possible to identify someone on the Internet. It is most commonly used in e-commerce applications. In basic terms, there should be some entity called a “Certificate Authority” (or CA) that assigns electronic certificates to anyone who needs them. Certificates rely on asymmetric encryption algorithms that have two encryption keys (a public key and a secret key). A certificate owner can show the certificate to another party as proof of identity. A certificate consists of its owner's public key. Any data

encrypted with this public key can be decrypted only using the corresponding secret key, which is held by the owner of the certificate.

For more information about SSL, X509, encryption, or public-key cryptography, perform an Internet search for the keywords in which you are interested.

6.3.9.2 Configuring MySQL for SSL

To use SSL connections between the MySQL server and client programs, your system must support either OpenSSL or yaSSL, and your version of MySQL must be built with SSL support. To make it easier to use secure connections, MySQL is bundled with yaSSL, which uses the same licensing model as MySQL. (OpenSSL uses an Apache-style license.) yaSSL support is available on all MySQL platforms supported by Oracle Corporation.

To get secure connections to work with MySQL and SSL, you must do the following:

1. If you are not using a binary (precompiled) version of MySQL that has been built with SSL support, and you are going to use OpenSSL rather than the bundled yaSSL library, install OpenSSL if it has not already been installed. We have tested MySQL with OpenSSL 0.9.6. To obtain OpenSSL, visit <http://www.openssl.org>.

Building MySQL using OpenSSL requires a shared OpenSSL library, otherwise linker errors occur. Alternatively, build MySQL using yaSSL.

2. If you are not using a binary (precompiled) version of MySQL that has been built with SSL support, configure a MySQL source distribution to use SSL. When you configure MySQL, invoke `CMake` like this:

```
shell> cmake . -DWITH_SSL=bundled
```

That command configures the distribution to use the bundled yaSSL library. To use the system SSL library instead, specify the option like this instead:

```
shell> cmake . -DWITH_SSL=system
```

See [Section 2.9.4, “MySQL Source-Configuration Options”](#).

Then compile and install the distribution.

On Unix platforms, yaSSL retrieves true random numbers from either `/dev/urandom` or `/dev/random`. Bug#13164 lists workarounds for some very old platforms which do not support these devices.

3. To check whether a `mysqld` server supports SSL, examine the value of the `have_ssl` system variable:

```
mysql> SHOW VARIABLES LIKE 'have_ssl';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| have_ssl      | YES   |
+-----+-----+
```

If the value is `YES`, the server supports SSL connections. If the value is `DISABLED`, the server is capable of supporting SSL connections but was not started with the appropriate `--ssl-xxx` options to enable them to be used; see [Section 6.3.9.3, “Using SSL Connections”](#).

6.3.9.3 Using SSL Connections

To enable SSL connections, your MySQL distribution must be built with SSL support, as described in [Section 6.3.9.2, “Configuring MySQL for SSL”](#). In addition, the proper SSL-related options must be used to specify the appropriate certificate and key files. For a complete list of SSL options, see [Section 6.3.9.4, “SSL Command Options”](#).

To start the MySQL server so that it permits clients to connect using SSL, use the options that identify the certificate and key files the server uses when establishing a secure connection:

- `--ssl-ca` identifies the Certificate Authority (CA) certificate.
- `--ssl-cert` identifies the server public key certificate. This can be sent to the client and authenticated against the CA certificate that it has.
- `--ssl-key` identifies the server private key.

For example, start the server like this:

```
shell> mysqld --ssl-ca=ca-cert.pem \  
           --ssl-cert=server-cert.pem \  
           --ssl-key=server-key.pem
```

Each option names a file in PEM format. For instructions on generating the required SSL certificate and key files, see [Section 6.3.9.5, “Setting Up SSL Certificates and Keys for MySQL”](#). If you have a MySQL source distribution, you can also test your setup using the demonstration certificate and key files in the `mysql-test/std_data` directory of the distribution.

Similar options are used on the client side, but `--ssl-cert` and `--ssl-key` identify the client public and private key. The Certificate Authority certificate, if specified, must be the same as used by the server.

To establish a secure connection to a MySQL server with SSL support, the options that a client must specify depend on the SSL requirements of the MySQL account used by the client. (See the discussion of the `REQUIRE` clause in [Section 13.7.1.3, “GRANT Syntax”](#).)

Suppose that you want to connect using an account that has no special SSL requirements or was created using a `GRANT` statement that includes the `REQUIRE SSL` option. As a recommended set of SSL options, start the server with at least `--ssl-cert` and `--ssl-key`, and invoke the client with `--ssl-ca`. A client can connect securely like this:

```
shell> mysql --ssl-ca=ca-cert.pem
```

To require that a client certificate also be specified, create the account using the `REQUIRE X509` option. Then the client must also specify the proper client key and certificate files or the server will reject the connection:

```
shell> mysql --ssl-ca=ca-cert.pem \  
           --ssl-cert=client-cert.pem \  
           --ssl-key=client-key.pem
```

To prevent use of SSL and override other SSL options, invoke the client program with `--ssl=0` or a synonym (`--skip-ssl`, `--disable-ssl`):

```
shell> mysql --ssl=0
```

A client can determine whether the current connection with the server uses SSL by checking the value of the `Ssl_cipher` status variable. The value is nonempty if SSL is used, and empty otherwise. For example:

```
mysql> SHOW STATUS LIKE 'Ssl_cipher';
+-----+-----+
| Variable_name | Value                |
+-----+-----+
| Ssl_cipher    | DHE-RSA-AES256-SHA  |
+-----+-----+
```

For the `mysql` client, an alternative is to use the `STATUS` or `\s` command and check the `SSL` line:

```
mysql> \s
...
SSL: Cipher in use is DHE-RSA-AES256-SHA
...
```

Or:

```
mysql> \s
...
SSL: Not in use
...
```

The C API enables application programs to use SSL:

- To establish a secure connection, use the `mysql_ssl_set()` C API function to set the appropriate certificate options before calling `mysql_real_connect()`. See [Section 23.8.7.67](#), “`mysql_ssl_set()`”.
- To determine whether SSL is in use after the connection is established, use `mysql_get_ssl_cipher()`. A non-`NULL` return value indicates a secure connection and names the SSL cipher used for encryption. A `NULL` return value indicates that SSL is not being used. See [Section 23.8.7.33](#), “`mysql_get_ssl_cipher()`”.

Replication uses the C API, so secure connections can be used between master and slave servers. See [Section 17.3.7](#), “Setting Up Replication Using SSL”.

6.3.9.4 SSL Command Options

This section describes options that specify whether to use SSL and the names of SSL certificate and key files. These options can be given on the command line or in an option file. They are not available unless MySQL has been built with SSL support. See [Section 6.3.9.2](#), “Configuring MySQL for SSL”. For examples of suggested use and how to check whether a connection is secure, see [Section 6.3.9.3](#), “Using SSL Connections”.

Table 6.15 SSL Option/Variable Summary

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
have_openssl			Yes		Global	No
have_ssl			Yes		Global	No
skip-ssl	Yes	Yes				
ssl	Yes	Yes				
ssl-ca	Yes	Yes			Global	No
- Variable: ssl_ca			Yes		Global	No
ssl-capath	Yes	Yes			Global	No
- Variable: ssl_capath			Yes		Global	No

Name	Cmd-Line	Option file	System Var	Status Var	Var Scope	Dynamic
ssl-cert	Yes	Yes			Global	No
- Variable: ssl_cert			Yes		Global	No
ssl-cipher	Yes	Yes			Global	No
- Variable: ssl_cipher			Yes		Global	No
ssl-key	Yes	Yes			Global	No
- Variable: ssl_key			Yes		Global	No
ssl-verify-server-cert	Yes	Yes				

- `--ssl`

For the server, this option specifies that the server permits but does not require SSL connections.

For a client program, this option permits but does not require the client to connect to the server using SSL. Therefore, this option is not sufficient in itself to cause an SSL connection to be used. For example, if you specify this option for a client program but the server has not been configured to permit SSL connections, an unencrypted connection is used.

As a recommended set of options to enable SSL connections, use at least `--ssl-cert` and `--ssl-key` on the server side and `--ssl-ca` on the client side. See [Section 6.3.9.3, “Using SSL Connections”](#).

`--ssl` may be implied by other `--ssl-xxx` options, as indicated in the descriptions for those options.

The `--ssl` option can be given in its negated form to override other SSL options and indicate that SSL should *not* be used. To do this, specify the option as `--ssl=0` or a synonym (`--skip-ssl`, `--disable-ssl`). For example, you might have SSL options specified in the `[client]` group of your option file to use SSL connections by default when you invoke MySQL client programs. To use an unencrypted connection instead, invoke the client program with `--skip-ssl` on the command line to override the options in the option file.

To require use of an SSL connection for a MySQL account, issue a `GRANT` statement for the account that includes at least a `REQUIRE SSL` clause. Connections for the account will be rejected unless MySQL supports SSL connections and the server and client have been started with the proper SSL options.

The `REQUIRE` clause permits other SSL-related options, which can be used to enforce stricter requirements than `REQUIRE SSL`. For additional details about which SSL command options may or must be specified by clients that connect using accounts configured using the various `REQUIRE` options, see the description of `REQUIRE` in [Section 13.7.1.3, “GRANT Syntax”](#).

- `--ssl-ca=file_name`

The path to a file in PEM format that contains a list of trusted SSL certificate authorities. This option implies `--ssl`.

If you use SSL when establishing a client connection, to tell the client not to authenticate the server certificate, specify neither `--ssl-ca` nor `--ssl-capath`. The server still verifies the client according to any applicable requirements established using `GRANT` statements for the client account, and it still uses any `--ssl-ca` or `--ssl-capath` option values specified at server startup.

- `--ssl-capath=directory_name`

The path to a directory that contains trusted SSL certificate authority certificates in PEM format. This option implies `--ssl`.

If you use SSL when establishing a client connection, to tell the client not to authenticate the server certificate, specify neither `--ssl-ca` nor `--ssl-capath`. The server still verifies the client according to any applicable requirements established using `GRANT` statements for the client account, and it still uses any `--ssl-ca` or `--ssl-capath` option values specified at server startup.

MySQL distributions built with OpenSSL support the `--ssl-capath` option. Distributions built with yaSSL do not because yaSSL does not look in any directory and does not follow a chained certificate tree. yaSSL requires that all components of the CA certificate tree be contained within a single CA certificate tree and that each certificate in the file has a unique SubjectName value. To work around this yaSSL limitation, concatenate the individual certificate files comprising the certificate tree into a new file and specify that file as the value of the `--ssl-ca` option.

- `--ssl-cert=file_name`

The name of the SSL certificate file in PEM format to use for establishing a secure connection. This option implies `--ssl`.

- `--ssl-cipher=cipher_list`

A list of permissible ciphers to use for SSL encryption. If no cipher in the list is supported, SSL connections will not work. This option implies `--ssl`.

For greatest portability, `cipher_list` should be a list of one or more cipher names, separated by colons. This format is understood both by OpenSSL and yaSSL. Examples:

```
--ssl-cipher=AES128-SHA
--ssl-cipher=DHE-RSA-AES256-SHA:AES128-SHA
```

OpenSSL supports a more flexible syntax for specifying ciphers, as described in the OpenSSL documentation at <http://www.openssl.org/docs/apps/ciphers.html>. However, yaSSL does not, so attempts to use that extended syntax fail for a MySQL distribution built with yaSSL.

For OpenSSL, the supported ciphers may depend on which version your server is linked against. For example, the list might include these ciphers:

```
AES256-GCM-SHA384
AES256-SHA
AES256-SHA256
CAMELLIA256-SHA
DES-CBC3-SHA
DHE-DSS-AES256-GCM-SHA384
DHE-DSS-AES256-SHA
DHE-DSS-AES256-SHA256
DHE-DSS-CAMELLIA256-SHA
DHE-RSA-AES256-GCM-SHA384
DHE-RSA-AES256-SHA
DHE-RSA-AES256-SHA256
DHE-RSA-CAMELLIA256-SHA
ECDH-ECDSA-AES256-GCM-SHA384
ECDH-ECDSA-AES256-SHA
ECDH-ECDSA-AES256-SHA384
ECDH-ECDSA-DES-CBC3-SHA
ECDH-RSA-AES256-GCM-SHA384
ECDH-RSA-AES256-SHA
```

```
ECDH-RSA-AES256-SHA384
ECDH-RSA-DES-CBC3-SHA
ECDHE-ECDSA-AES128-GCM-SHA256
ECDHE-ECDSA-AES128-SHA
ECDHE-ECDSA-AES128-SHA256
ECDHE-ECDSA-AES256-GCM-SHA384
ECDHE-ECDSA-AES256-SHA
ECDHE-ECDSA-AES256-SHA384
ECDHE-ECDSA-DES-CBC3-SHA
ECDHE-RSA-AES128-GCM-SHA256
ECDHE-RSA-AES128-SHA
ECDHE-RSA-AES128-SHA256
ECDHE-RSA-AES256-GCM-SHA384
ECDHE-RSA-AES256-SHA
ECDHE-RSA-AES256-SHA384
ECDHE-RSA-DES-CBC3-SHA
EDH-DSS-DES-CBC3-SHA
EDH-RSA-DES-CBC3-SHA
PSK-3DES-EDE-CBC-SHA
PSK-AES256-CBC-SHA
SRP-DSS-3DES-EDE-CBC-SHA
SRP-DSS-AES-128-CBC-SHA
SRP-DSS-AES-256-CBC-SHA
SRP-RSA-3DES-EDE-CBC-SHA
SRP-RSA-AES-128-CBC-S
SRP-RSA-AES-256-CBC-SHA
```

yaSSL supports these ciphers:

```
AES128-RMD
AES128-SHA
AES256-RMD
AES256-SHA
DES-CBC-SHA
DES-CBC3-RMD
DES-CBC3-SHA
DHE-RSA-AES128-RMD
DHE-RSA-AES128-SHA
DHE-RSA-AES256-RMD
DHE-RSA-AES256-SHA
DHE-RSA-DES-CBC3-RMD
EDH-RSA-DES-CBC-SHA
EDH-RSA-DES-CBC3-SHA
RC4-MD5
RC4-SHA
```

To verify exactly which ciphers a given server supports, check the value of the `Ssl_cipher_list` status variable using this query:

```
SHOW STATUS LIKE 'Ssl_cipher_list';
```

- `--ssl-key=file_name`

The name of the SSL key file in PEM format to use for establishing a secure connection. This option implies `--ssl`.

If the MySQL distribution was built using OpenSSL and the key file is protected by a passphrase, the program prompts the user for the passphrase. The password must be given interactively; it cannot be stored in a file. If the passphrase is incorrect, the program continues as if it could not read the key. If the MySQL distribution was built using yaSSL and the key file is protected by a passphrase, an error occurs.

- `--ssl-verify-server-cert`

This option is available for client programs only, not the server. It causes the client to check the server's Common Name value in the certificate that the server sends to the client. The client verifies that name against the host name the client uses for connecting to the server, and the connection fails if there is a mismatch. This feature can be used to prevent man-in-the-middle attacks. Verification is disabled by default.

6.3.9.5 Setting Up SSL Certificates and Keys for MySQL

This section demonstrates how to set up SSL certificate and key files for use by MySQL servers and clients. The first example shows a simplified procedure such as you might use from the command line. The second shows a script that contains more detail. The first two examples are intended for use on Unix and both use the `openssl` command that is part of OpenSSL. The third example describes how to set up SSL files on Windows.

Important

Whatever method you use to generate the certificate and key files, the Common Name value used for the server and client certificates/keys must each differ from the Common Name value used for the CA certificate. Otherwise, the certificate and key files will not work for servers compiled using OpenSSL. A typical error in this case is:

```
ERROR 2026 (HY000): SSL connection error:
error:00000001:lib(0):func(0):reason(1)
```

Example 1: Creating SSL Files from the Command Line on Unix

The following example shows a set of commands to create MySQL server and client certificate and key files. You will need to respond to several prompts by the `openssl` commands. To generate test files, you can press Enter to all prompts. To generate files for production use, you should provide nonempty responses.

```
# Create clean environment
shell> rm -rf newcerts
shell> mkdir newcerts && cd newcerts

# Create CA certificate
shell> openssl genrsa 2048 > ca-key.pem
shell> openssl req -new -x509 -nodes -days 3600 \
    -key ca-key.pem -out ca-cert.pem

# Create server certificate, remove passphrase, and sign it
# server-cert.pem = public key, server-key.pem = private key
shell> openssl req -newkey rsa:2048 -days 3600 \
    -nodes -keyout server-key.pem -out server-req.pem
shell> openssl rsa -in server-key.pem -out server-key.pem
shell> openssl x509 -req -in server-req.pem -days 3600 \
    -CA ca-cert.pem -CAkey ca-key.pem -set_serial 01 -out server-cert.pem

# Create client certificate, remove passphrase, and sign it
# client-cert.pem = public key, client-key.pem = private key
shell> openssl req -newkey rsa:2048 -days 3600 \
    -nodes -keyout client-key.pem -out client-req.pem
shell> openssl rsa -in client-key.pem -out client-key.pem
shell> openssl x509 -req -in client-req.pem -days 3600 \
    -CA ca-cert.pem -CAkey ca-key.pem -set_serial 01 -out client-cert.pem
```

After generating the certificates, verify them:

```
shell> openssl verify -CAfile ca-cert.pem server-cert.pem client-cert.pem
server-cert.pem: OK
client-cert.pem: OK
```

Now you have a set of files that can be used as follows:

- `ca-cert.pem`: Use this as the argument to `--ssl-ca` on the server and client sides. (The CA certificate, if used, must be the same on both sides.)
- `server-cert.pem`, `server-key.pem`: Use these as the arguments to `--ssl-cert` and `--ssl-key` on the server side.
- `client-cert.pem`, `client-key.pem`: Use these as the arguments to `--ssl-cert` and `--ssl-key` on the client side.

To use the files to test SSL connections, see [Section 6.3.9.3, “Using SSL Connections”](#).

Example 2: Creating SSL Files Using a Script on Unix

Here is an example script that shows how to set up SSL certificate and key files for MySQL. After executing the script, use the files to test SSL connections as described in [Section 6.3.9.3, “Using SSL Connections”](#).

```
DIR=`pwd`/openssl
PRIV=$DIR/private

mkdir $DIR $PRIV $DIR/newcerts
cp /usr/share/ssl/openssl.cnf $DIR
replace ./demoCA $DIR -- $DIR/openssl.cnf

# Create necessary files: $database, $serial and $new_certs_dir
# directory (optional)

touch $DIR/index.txt
echo "01" > $DIR/serial

#
# Generation of Certificate Authority(CA)
#

openssl req -new -x509 -keyout $PRIV/cakey.pem -out $DIR/ca-cert.pem \
    -days 3600 -config $DIR/openssl.cnf

# Sample output:
# Using configuration from /home/monty/openssl/openssl.cnf
# Generating a 1024 bit RSA private key
# .....++++++
# .....++++++
# writing new private key to '/home/monty/openssl/private/cakey.pem'
# Enter PEM pass phrase:
# Verifying password - Enter PEM pass phrase:

```

Example 3: Creating SSL Files on Windows

Download OpenSSL for Windows if it is not installed on your system. An overview of available packages can be seen here:

<http://www.slproweb.com/products/Win32OpenSSL.html>

Choose the Win32 OpenSSL Light or Win64 OpenSSL Light package, depending on your architecture (32-bit or 64-bit). The default installation location will be `C:\OpenSSL-Win32` or `C:\OpenSSL-Win64`, depending on which package you downloaded. The following instructions assume a default location of `C:\OpenSSL-Win32`. Modify this as necessary if you are using the 64-bit package.

If a message occurs during setup indicating '`...critical component is missing: Microsoft Visual C++ 2008 Redistributables`', cancel the setup and download one of the following packages as well, again depending on your architecture (32-bit or 64-bit):

- Visual C++ 2008 Redistributables (x86), available at:

<http://www.microsoft.com/downloads/details.aspx?familyid=9B2DA534-3E03-4391-8A4D-074B9F2BC1BF>

- Visual C++ 2008 Redistributables (x64), available at:

<http://www.microsoft.com/downloads/details.aspx?familyid=bd2a6171-e2d6-4230-b809-9a8d7548c1b6>

After installing the additional package, restart the OpenSSL setup procedure.

During installation, leave the default `C:\OpenSSL-Win32` as the install path, and also leave the default option '`Copy OpenSSL DLL files to the Windows system directory`' selected.

When the installation has finished, add `C:\OpenSSL-Win32\bin` to the Windows System Path variable of your server:

1. On the Windows desktop, right-click the My Computer icon, and select Properties.
2. Select the Advanced tab from the System Properties menu that appears, and click the Environment Variables button.
3. Under **System Variables**, select Path, then click the Edit button. The Edit System Variable dialogue should appear.
4. Add '`;C:\OpenSSL-Win32\bin`' to the end (notice the semicolon).

5. Press OK 3 times.
6. Check that OpenSSL was correctly integrated into the Path variable by opening a new command console (`Start>Run>cmd.exe`) and verifying that OpenSSL is available:

```
Microsoft Windows [Version ...]
Copyright (c) 2006 Microsoft Corporation. All rights reserved.

C:\Windows\system32>cd \

C:\>openssl
OpenSSL> exit <<< If you see the OpenSSL prompt, installation was successful.

C:\>
```

Depending on your version of Windows, the preceding path-setting instructions might differ slightly.

After OpenSSL has been installed, use instructions similar to those from Example 1 (shown earlier in this section), with the following changes:

- Change the following Unix commands:

```
# Create clean environment
shell> rm -rf newcerts
shell> mkdir newcerts && cd newcerts
```

On Windows, use these commands instead:

```
# Create clean environment
shell> md c:\newcerts
shell> cd c:\newcerts
```

- When a `'\'` character is shown at the end of a command line, this `'\'` character must be removed and the command lines entered all on a single line.

After generating the certificate and key files, to use them to test SSL connections, see [Section 6.3.9.3, “Using SSL Connections”](#).

6.3.10 Connecting to MySQL Remotely from Windows with SSH

This section describes how to get a secure connection to a remote MySQL server with SSH. The information was provided by David Carlson <dcarlson@mplcomm.com>.

1. Install an SSH client on your Windows machine. For a comparison of SSH clients, see http://en.wikipedia.org/wiki/Comparison_of_SSH_clients.
2. Start your Windows SSH client. Set `Host_Name = yourmysqlserver_URL_or_IP`. Set `userid=your_userid` to log in to your server. This `userid` value might not be the same as the user name of your MySQL account.
3. Set up port forwarding. Either do a remote forward (Set `local_port: 3306`, `remote_host: yourmysqlservername_or_ip`, `remote_port: 3306`) or a local forward (Set `port: 3306`, `host: localhost`, `remote port: 3306`).
4. Save everything, otherwise you will have to redo it the next time.
5. Log in to your server with the SSH session you just created.
6. On your Windows machine, start some ODBC application (such as Access).

7. Create a new file in Windows and link to MySQL using the ODBC driver the same way you normally do, except type in `localhost` for the MySQL host server, not `yourmysqlservername`.

At this point, you should have an ODBC connection to MySQL, encrypted using SSH.

6.3.11 MySQL Enterprise Audit Log Plugin

Note

MySQL Enterprise Audit is a commercial extension. To learn more about commercial products (MySQL Enterprise Edition), see <http://www.mysql.com/products/>.

As of MySQL 5.5.28, MySQL Enterprise Edition includes MySQL Enterprise Audit, implemented using a server plugin named `audit_log`. MySQL Enterprise Audit uses the open MySQL Audit API to enable standard, policy-based monitoring and logging of connection and query activity executed on specific MySQL servers. Designed to meet the Oracle audit specification, MySQL Enterprise Audit provides an out of box, easy to use auditing and compliance solution for applications that are governed by both internal and external regulatory guidelines.

When installed, the audit plugin enables MySQL Server to produce a log file containing an audit record of server activity. The log contents include when clients connect and disconnect, and what actions they perform while connected, such as which databases and tables they access.

After you install the plugin (see [Section 6.3.11.1, “Installing the Audit Log Plugin”](#)), it writes an audit log file. By default, the file is named `audit.log` in the server data directory. To change the name of the file, set the `audit_log_file` system variable at server startup.

Audit log file contents are not encrypted. See [Section 6.3.11.2, “Audit Log Plugin Security Considerations”](#).

The audit log file is written in XML, with auditable events encoded as `<AUDIT_RECORD>` elements. To select the file format, set the `audit_log_format` system variable at server startup. For details on file format and contents, see [Section 6.3.11.3, “The Audit Log File”](#).

To control what information `audit_log` writes to its log file, set the `audit_log_policy` system variable. By default, this variable is set to `ALL` (write all auditable events), but also permits values of `LOGINS` or `QUERIES` to log only login or query events, or `NONE` to disable logging.

For more information about controlling how logging occurs, see [Section 6.3.11.4, “Audit Log Plugin Logging Control”](#). For descriptions of the parameters used to configure the audit log plugin, see [Section 6.3.11.5, “Audit Log Plugin Options and Variables”](#).

If the `audit_log` plugin is enabled, the Performance Schema (see [Chapter 22, MySQL Performance Schema](#)) has instrumentation for the audit log plugin. To identify the relevant instruments, use this query:

```
SELECT NAME FROM performance_schema.setup_instruments
WHERE NAME LIKE '%/alog/%';
```

Changes from Older Audit Log Plugin Versions

Several changes were made to the audit log plugin in MySQL 5.5.34 for better compatibility with Oracle Audit Vault.

MySQL 5.7 changed audit log file output to a new format. This format has been backported to MySQL 5.5 and it is possible to select either the old or new format using the `audit_log_format` system variable, which has permitted values of `OLD` and `NEW` (default `OLD`). The two formats differ as follows:

- Information within `<AUDIT_RECORD>` elements written in the old format using attributes is written in the new format using subelements.
- The new format includes more information in `<AUDIT_RECORD>` elements. Every element includes a `RECORD_ID` value providing a unique identifier. The `TIMESTAMP` value includes time zone information. Query records include `HOST`, `IP`, `OS_LOGIN`, and `USER` information, as well as `COMMAND_CLASS` and `STATUS_CODE` values.

Example of old `<AUDIT_RECORD>` format:

```
<AUDIT_RECORD
  TIMESTAMP="2013-09-15T15:27:27"
  NAME="Query"
  CONNECTION_ID="3"
  STATUS="0"
  SQLTEXT="SELECT 1"
/>
```

Example of new `<AUDIT_RECORD>` format:

```
<AUDIT_RECORD>
  <TIMESTAMP>2013-09-15T15:27:27 UTC</TIMESTAMP>
  <RECORD_ID>3998_2013-09-15T15:27:27</RECORD_ID>
  <NAME>Query</NAME>
  <CONNECTION_ID>3</CONNECTION_ID>
  <STATUS>0</STATUS>
  <STATUS_CODE>0</STATUS_CODE>
  <USER>root[root] @ localhost [127.0.0.1]</USER>
  <OS_LOGIN></OS_LOGIN>
  <HOST>localhost</HOST>
  <IP>127.0.0.1</IP>
  <COMMAND_CLASS>select</COMMAND_CLASS>
  <SQLTEXT>SELECT 1</SQLTEXT>
</AUDIT_RECORD>
```

When the audit log plugin rotates the audit log file, it uses a different file name format. For a log file named `audit.log`, the plugin previously renamed the file to `audit.log.TIMESTAMP`. The plugin now renames the file to `audit.log.TIMESTAMP.xml` to indicate that it is an XML file.

If you change the value of `audit_log_format`, use this procedure to avoid writing log entries in one format to an existing log file that contains entries in a different format:

1. Stop the server.
2. Rename the current audit log file manually.
3. Restart the server with the new value of `audit_log_format`. The audit log plugin will create a new log file, which will contain log entries in the selected format.

The API for writing audit plugins has also changed. The `mysql_event_general` structure has new members to represent client host name and IP address, command class, and external user. For more information, see [Section 24.2.4.8, "Writing Audit Plugins"](#).

6.3.11.1 Installing the Audit Log Plugin

The audit log plugin is named `audit_log`. To be usable by the server, the plugin library object file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, set the value of `plugin_dir` at server startup to tell the server the location of the plugin directory.

To load the plugin at server startup, use the `--plugin-load` option to name the object file that contains the plugin. With this plugin-loading method, the option must be given each time the server starts. For example, put the following lines in your `my.cnf` file:

```
[mysqld]
plugin-load=audit_log.so
```

If object files have a suffix different from `.so` on your system, substitute the correct suffix (for example, `.dll` on Windows).

Alternatively, to register the plugin at runtime, use this statement (changing the suffix as necessary):

```
mysql> INSTALL PLUGIN audit_log SONAME 'audit_log.so';
```

`INSTALL PLUGIN` loads the plugin, and also registers it in the `mysql.plugins` table to cause the plugin to be loaded for each subsequent normal server startup.

If the plugin is loaded with `--plugin-load` or has been previously registered with `INSTALL PLUGIN`, you can use the `--audit-log` option at server startup to control plugin activation. For example, to load the plugin and prevent it from being removed at runtime, use these options:

```
[mysqld]
plugin-load=audit_log.so
audit-log=FORCE_PLUS_PERMANENT
```

If it is desired to prevent the server from running without the audit plugin, use `--audit-log` with a value of `FORCE` or `FORCE_PLUS_PERMANENT` to force server startup to fail if the plugin does not initialize successfully.

For general information about installing plugins, see [Section 5.1.8, “Server Plugins”](#). To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement. See [Section 5.1.8.2, “Obtaining Server Plugin Information”](#).

Audit log file contents are not encrypted. See [Section 6.3.11.2, “Audit Log Plugin Security Considerations”](#).

For additional information about the parameters used to configure operation of the `audit_log` plugin, see [Section 6.3.11.5, “Audit Log Plugin Options and Variables”](#).

6.3.11.2 Audit Log Plugin Security Considerations

Contents of the audit log file produced by the `audit_log` audit log plugin are not encrypted and may contain sensitive information, such as the text of SQL statements. For security reasons, this file should be written to a directory accessible only to the MySQL server and users with a legitimate reason to view the log. The default file is `audit.log` in the data directory. This can be changed by setting the `audit_log_file` system variable at server startup.

6.3.11.3 The Audit Log File

Audit log file contents are not encrypted. See [Section 6.3.11.2, “Audit Log Plugin Security Considerations”](#).

The audit log file is written as XML, using UTF-8 (up to 4 bytes per character). The root element is `<AUDIT>`. The closing `</AUDIT>` tag of the root element is written when the audit log plugin terminates, so the tag is not present in the file while the plugin is active.

The root element contains `<AUDIT_RECORD>` elements. Each `<AUDIT_RECORD>` element has an empty body; all audit record fields are represented by element attributes.

MySQL 5.7 changed audit log file output to a new format that has better compatibility with Oracle Audit Vault. This new format was backported to MySQL 5.5 as of MySQL 5.5.34 and it is possible to select either the old or new format using the `audit_log_format` system variable, which has permitted values of `OLD` and `NEW` (default `OLD`).

If you change the value of `audit_log_format`, use this procedure to avoid writing log entries in one format to an existing log file that contains entries in a different format:

1. Stop the server.
2. Rename the current audit log file manually.
3. Restart the server with the new value of `audit_log_format`. The audit log plugin will create a new log file, which will contain log entries in the selected format.

Here is a sample log file in the default (old) format, reformatted slightly for readability:

```
<?xml version="1.0" encoding="UTF-8"?>
<AUDIT>
  <AUDIT_RECORD
    TIMESTAMP="2012-08-02T14:52:12"
    NAME="Audit"
    SERVER_ID="1"
    VERSION="1"
    STARTUP_OPTIONS="--port=3306"
    OS_VERSION="i686-Linux"
    MYSQL_VERSION="5.5.28-debug-log"/>
  <AUDIT_RECORD
    TIMESTAMP="2012-08-02T14:52:41"
    NAME="Connect"
    CONNECTION_ID="1"
    STATUS="0"
    USER="root"
    PRIV_USER="root"
    OS_LOGIN=" "
    PROXY_USER=" "
    HOST="localhost"
    IP="127.0.0.1"
    DB=" " />
  <AUDIT_RECORD
    TIMESTAMP="2012-08-02T14:53:45"
    NAME="Query"
    CONNECTION_ID="1"
    STATUS="0"
    SQLTEXT="INSERT INTO t1 ( ) VALUES()"/>
  <AUDIT_RECORD
    TIMESTAMP="2012-08-02T14:53:51"
    NAME="Quit"
    CONNECTION_ID="1"
    STATUS="0" />
  <AUDIT_RECORD
    TIMESTAMP="2012-08-06T14:21:03"
    NAME="NoAudit"
    SERVER_ID="1" />
</AUDIT>
```

Attributes of `<AUDIT_RECORD>` elements have these characteristics:

- Some attributes appear in every element, but most are optional and do not necessarily appear in every element.
- Order of attributes within an element is not guaranteed.

- Attribute values are not fixed length. Long values may be truncated as indicated in the attribute descriptions given later.
- The `<`, `>`, `"`, and `&` characters are encoded as `<`, `>`, `"`, and `&`, respectively. NUL bytes (U+00) are encoded as the `?` character.
- Characters not valid as XML characters are encoded using numeric character references. Valid XML characters are:

```
#x9 | #xA | #xD | [#x20-#xD7FF] | [#xE000-#xFFFF] | [#x10000-#x10FFFF]
```

New Audit Log File Format

Every `<AUDIT_RECORD>` element contains a set of mandatory elements. Other optional elements may appear, depending on the audit record type.

The following elements are mandatory in every `<AUDIT_RECORD>` element:

- `<NAME>`

A string representing the type of instruction that generated the audit event, such as a command that the server received from a client.

Example:

```
<NAME>Query</NAME>
```

Some common `<NAME>` values:

Audit	When auditing starts, which may be server startup time
Connect	When a client connects, also known as logging in
Query	An SQL statement (executed directly)
Prepare	Preparation of an SQL statement; usually followed by Execute
Execute	Execution of an SQL statement; usually follows Prepare
Shutdown	Server shutdown
Quit	When a client disconnects
NoAudit	Auditing has been turned off

The possible values are `Audit`, `Binlog Dump`, `Change user`, `Close stmt`, `Connect Out`, `Connect`, `Create DB`, `Daemon`, `Debug`, `Delayed insert`, `Drop DB`, `Execute`, `Fetch`, `Field List`, `Init DB`, `Kill`, `Long Data`, `NoAudit`, `Ping`, `Prepare`, `Processlist`, `Query`, `Quit`, `Refresh`, `Register Slave`, `Reset stmt`, `Set option`, `Shutdown`, `Sleep`, `Statistics`, `Table Dump`, `Time`.

With the exception of `Audit` and `NoAudit`, these values correspond to the `COM_xxx` command values listed in the `mysql_com.h` header file. For example, `Create DB` and `Shutdown` correspond to `COM_CREATE_DB` and `COM_SHUTDOWN`, respectively.

- `<RECORD_ID>`

A unique identifier for the audit record. The value is composed from a sequence number and timestamp, in the format `SEQ_TIMESTAMP`. The sequence number is initialized to the size of the audit log file at the time the audit log plugin opens it and increments by 1 for each record logged. The timestamp is a UTC value in `yyyy-mm-ddThh:mm:ss` format indicating the time when the audit log plugin opened the file.

Example:

```
<RECORD_ID>28743_2013-09-18T21:03:24</RECORD_ID>
```

- **<TIMESTAMP>**

The date and time that the audit event was generated. For example, the event corresponding to execution of an SQL statement received from a client has a **<TIMESTAMP>** value occurring after the statement finishes, not when it is received. The value has the format `yyyy-mm-ddThh:mm:ss UTC` (with **T**, no decimals). The format includes a time zone specifier at the end. Currently, the time zone is always UTC.

Example:

```
<TIMESTAMP>2013-09-17T15:03:49 UTC</TIMESTAMP>
```

The following elements are optional in **<AUDIT_RECORD>** elements. Many of them occur only with specific **<NAME>** values.

- **<COMMAND_CLASS>**

A string that indicates the type of action performed.

Example:

```
<COMMAND_CLASS>drop_table</COMMAND_CLASS>
```

The values come from the `com_status_vars` array in the `sql/mysqld.cc` file in a MySQL source distribution. They correspond to the status variables displayed by this statment:

```
SHOW STATUS LIKE 'Com%';
```

- **<CONNECTION_ID>**

An unsigned integer representing the client connection identifier. This is the same as the `CONNECTION_ID()` function value within the session.

Example:

```
<CONNECTION_ID>127</CONNECTION_ID>
```

- **<DB>**

A string representing the default database name. This element appears only if the **<NAME>** value is `Connect` or `Change user`.

- **<HOST>**

A string representing the client host name. This element appears only if the **<NAME>** value is `Connect`, `Change user`, or `Query`.

Example:

```
<HOST>localhost</HOST>
```

- **<IP>**

A string representing the client IP address. This element appears only if the `<NAME>` value is `Connect`, `Change user`, or `Query`.

Example:

```
<IP>127.0.0.1</IP>
```

- `<MYSQL_VERSION>`

A string representing the MySQL server version. This is the same as the value of the `VERSION()` function or `version` system variable. This element appears only if the `<NAME>` value is `Audit`.

Example:

```
<MYSQL_VERSION>5.7.1-m11-log</MYSQL_VERSION>
```

- `<OS_LOGIN>`

A string representing the external user (empty if none). The value may differ from the `<USER>` value, for example, if the server authenticates the client using an external authentication method. This element appears only if the `<NAME>` value is `Connect`, `Change user`, or `Query`.

- `<OS_VERSION>`

A string representing the operating system on which the server was built or is running. This element appears only if the `<NAME>` value is `Audit`.

Example:

```
<OS_VERSION>x86_64-Linux</OS_VERSION>
```

- `<PRIV_USER>`

A string representing the user that the server authenticated the client as. This is the user name that the server uses for privilege checking, and may differ from the `<USER>` value. This element appears only if the `<NAME>` value is `Connect` or `Change user`.

- `<PROXY_USER>`

A string representing the proxy user. The value is empty if user proxying is not in effect. This element appears only if the `<NAME>` value is `Connect` or `Change user`.

- `<SERVER_ID>`

An unsigned integer representing the server ID. This is the same as the value of the `server_id` system variable. This element appears only if the `<NAME>` value is `Audit` or `NoAudit`.

Example:

```
<SERVER_ID>1</SERVER_ID>
```

- `<SQLTEXT>`

A string representing the text of an SQL statement. The value can be empty. Long values may be truncated. This element appears only if the `<NAME>` value is `Query` or `Execute`.

The string, like the audit log file itself, is written using UTF-8 (up to 4 bytes per character), so the value may be the result of conversion. For example, the original statement might have been received from the client as an SJIS string.

Example:

```
<SQLTEXT>DELETE FROM t1</SQLTEXT>
```

- **<STARTUP_OPTIONS>**

A string representing the options that were given on the command line or in option files when the MySQL server was started. This element appears only if the **<NAME>** value is **Audit**.

Example:

```
<STARTUP_OPTIONS>/usr/local/mysql/bin/mysqld  
--port=3306 --log-output=FILE</STARTUP_OPTIONS>
```

- **<STATUS>**

An unsigned integer representing the command status: 0 for success, nonzero if an error occurred. This is the same as the value of the `mysql_errno()` C API function.

The audit log does not contain the SQLSTATE value or error message. To see the associations between error codes, SQLSTATE values, and messages, see [Section B.3, “Server Error Codes and Messages”](#).

Warnings are not logged.

See the description for **<STATUS_CODE>** for information about how it differs from **<STATUS>**.

Example:

```
<STATUS>1051</STATUS>
```

- **<STATUS_CODE>**

An unsigned integer representing the command status: 0 for success, 1 if an error occurred.

The **STATUS_CODE** value differs from the **STATUS** value: **STATUS_CODE** is 0 for success and 1 for error, which is compatible with the EZ_collector consumer for Audit Vault. **STATUS** is the value of the `mysql_errno()` C API function. This is 0 for success and nonzero for error, and thus is not necessarily 1 for error.

Example:

```
<STATUS_CODE>0</STATUS_CODE>
```

- **<USER>**

A string representing the user name sent by the client. This may differ from the **<PRIV_USER>** value. This element appears only if the **<NAME>** value is **Connect**, **Change user**, or **Query**.

Example:

```
<USER>root[root] @ localhost [127.0.0.1]</USER>
```

- **<VERSION>**

An unsigned integer representing the version of the audit log file format. This element appears only if the **<NAME>** value is **Audit**.

Example:

```
<VERSION>1</VERSION>
```

Old Audit Log File Format

Every **<AUDIT_RECORD>** element contains a set of mandatory attributes. Other optional attributes may appear depending on the audit record type.

The following attributes are mandatory in every **<AUDIT_RECORD>** element:

- **NAME**

A string representing the type of instruction that generated the audit event, such as a command that the server received from a client.

Example: **NAME="Query"**

Some common **NAME** values:

"Audit"	When auditing starts, which may be server startup time
"Connect"	When a client connects, also known as logging in
"Query"	An SQL statement (executed directly)
"Prepare"	Preparation of an SQL statement; usually followed by Execute
"Execute"	Execution of an SQL statement; usually follows Prepare
"Shutdown"	Server shutdown
"Quit"	When a client disconnects
"NoAudit"	Auditing has been turned off

The possible values are "Audit", "Binlog Dump", "Change user", "Close stmt", "Connect Out", "Connect", "Create DB", "Daemon", "Debug", "Delayed insert", "Drop DB", "Execute", "Fetch", "Field List", "Init DB", "Kill", "Long Data", "NoAudit", "Ping", "Prepare", "Processlist", "Query", "Quit", "Refresh", "Register Slave", "Reset stmt", "Set option", "Shutdown", "Sleep", "Statistics", "Table Dump", "Time".

With the exception of "Audit" and "NoAudit", these values correspond to the **COM_XXX** command values listed in the **mysql_com.h** header file. For example, "Create DB" and "Shutdown" correspond to **COM_CREATE_DB** and **COM_SHUTDOWN**, respectively.

- **TIMESTAMP**

The date and time that the audit event was generated. For example, the event corresponding to execution of an SQL statement received from a client has a **TIMESTAMP** value occurring after the statement finishes, not when it is received. The value is UTC, in the format **yyyy-mm-ddThh:mm:ss** (with **T**, no decimals).

Example: **TIMESTAMP="2012-08-09T12:55:16"**

The following attributes are optional in **<AUDIT_RECORD>** elements. Many of them occur only for elements with specific values of the **NAME** attribute.

- `CONNECTION_ID`

An unsigned integer representing the client connection identifier. This is the same as the `CONNECTION_ID()` function value within the session.

Example: `CONNECTION_ID="127"`

- `DB`

A string representing the default database name. This attribute appears only if the `NAME` value is `"Connect"` or `"Change user"`.

- `HOST`

A string representing the client host name. This attribute appears only if the `NAME` value is `"Connect"` or `"Change user"`.

Example: `HOST="localhost"`

- `IP`

A string representing the client IP address. This attribute appears only if the `NAME` value is `"Connect"` or `"Change user"`.

Example: `IP="127.0.0.1"`

- `MYSQL_VERSION`

A string representing the MySQL server version. This is the same as the value of the `VERSION()` function or `version` system variable. This attribute appears only if the `NAME` value is `"Audit"`.

Example: `MYSQL_VERSION="5.5.31-log"`

- `OS_LOGIN`

A string representing the external user (empty if none). The value may differ from `USER`, for example, if the server authenticates the client using an external authentication method. This attribute appears only if the `NAME` value is `"Connect"` or `"Change user"`.

- `OS_VERSION`

A string representing the operating system on which the server was built or is running. This attribute appears only if the `NAME` value is `"Audit"`.

Example: `OS_VERSION="x86_64-Linux"`

- `PRIV_USER`

A string representing the user that the server authenticated the client as. This is the user name that the server uses for privilege checking, and may be different from the `USER` value. This attribute appears only if the `NAME` value is `"Connect"` or `"Change user"`.

- `PROXY_USER`

A string representing the proxy user. The value is empty if user proxying is not in effect. This attribute appears only if the `NAME` value is `"Connect"` or `"Change user"`.

- `SERVER_ID`

An unsigned integer representing the server ID. This is the same as the value of the `server_id` system variable. This attribute appears only if the `NAME` value is "Audit" or "NoAudit".

Example: `SERVER_ID="1"`

- `SQLTEXT`

A string representing the text of an SQL statement. The value can be empty. Long values may be truncated. This attribute appears only if the `NAME` value is "Query" or "Execute".

The string, like the audit log file itself, is written using UTF-8 (up to 4 bytes per character), so the value may be the result of conversion. For example, the original statement might have been received from the client as an SJIS string.

Example: `SQLTEXT="DELETE FROM t1"`

- `STARTUP_OPTIONS`

A string representing the options that were given on the command line or in option files when the MySQL server was started. This attribute appears only if the `NAME` value is "Audit".

Example: `STARTUP_OPTIONS="--port=3306 --log-output=FILE"`

- `STATUS`

An unsigned integer representing the command status: 0 for success, nonzero if an error occurred. This is the same as the value of the `mysql_errno()` C API function.

The audit log does not contain the `SQLSTATE` value or error message. To see the associations between error codes, `SQLSTATE` values, and messages, see [Section B.3, "Server Error Codes and Messages"](#).

Warnings are not logged.

Example: `STATUS="1051"`

- `USER`

A string representing the user name sent by the client. This may be different from the `PRIV_USER` value. This attribute appears only if the `NAME` value is "Connect" or "Change user".

- `VERSION`

An unsigned integer representing the version of the audit log file format. This attribute appears only if the `NAME` value is "Audit".

Example: `VERSION="1"`

6.3.11.4 Audit Log Plugin Logging Control

This section describes how the `audit_log` plugin performs logging and the system variables that control how logging occurs. It assumes familiarity with the log file format described in [Section 6.3.11.3, "The Audit Log File"](#).

When the audit log plugin opens its log file, it checks whether the XML declaration and opening `<AUDIT>` root element tag must be written and writes them if so. When the audit log plugin terminates, it writes a closing `</AUDIT>` tag to the file.

If the log file exists at open time, the plugin checks whether the file ends with an `</AUDIT>` tag and truncates it if so before writing any `<AUDIT_RECORD>` elements. If the log file exists but does not end with `</AUDIT>` or the `</AUDIT>` tag cannot be truncated, the plugin considers the file malformed and fails to initialize. This can occur if the server crashes or is killed with the audit log plugin running. No logging occurs until the problem is rectified. Check the error log for diagnostic information:

```
[ERROR] Plugin 'audit_log' init function returned error.
```

To deal with this problem, you must either remove or rename the malformed log file and restart the server.

The MySQL server calls the audit log plugin to write an `<AUDIT_RECORD>` element whenever an auditable event occurs, such as when it completes execution of an SQL statement received from a client. Typically the first `<AUDIT_RECORD>` element written after server startup has the server description and startup options. Elements following that one represent events such as client connect and disconnect events, executed SQL statements, and so forth. Only top-level statements are logged, not statements within stored programs such as triggers or stored procedures. Contents of files referenced by statements such as `LOAD DATA INFILE` are not logged.

To permit control over how logging occurs, the `audit_log` plugin provides several system variables, described following. For more information, see [Section 6.3.11.5, “Audit Log Plugin Options and Variables”](#).

- `audit_log_file`: The name of the log file. By default, the name is `audit.log` in the server data directory. For security reasons, the audit log file should be written to a directory accessible only to the MySQL server and users with a legitimate reason to view the log.
- `audit_log_policy`: What kinds of information the plugin writes. By default, this variable is set to `ALL` (write all auditable events), but also permits values of `LOGINS` or `QUERIES` to log only login or query events, or `NONE` to disable logging.
- `audit_log_strategy`: The method used for log writes. By default, the strategy value is `ASYNCHRONOUS` and the plugin logs asynchronously to a buffer, waiting if the buffer is full. It's possible to tell the plugin not to wait (`PERFORMANCE`) or to log synchronously, either using file system caching (`SEMISYNCHRONOUS`) or forcing output with a `sync()` call after each write request (`SYNCHRONOUS`).

Asynchronous logging strategy has these characteristics:

- Minimal impact on server performance and scalability.
- Blocking of threads that generate audit events for the shortest possible time; that is, time to allocate the buffer plus time to copy the event to the buffer.
- Output goes to the buffer. Writes from the buffer to the log file are handled by a separate thread.

A disadvantage of `PERFORMANCE` strategy is that it drops events when the buffer is full. For a heavily loaded server, it is more likely that the audit log will be missing events.

With asynchronous logging, the integrity of the log file may be compromised if a problem occurs during a write to the file or if the plugin does not shut down cleanly (for example, in the event that the server host crashes). To reduce this risk, set `audit_log_strategy` use synchronous logging. Regardless of strategy, logging occurs on a best-effort basis, with no guarantee of consistency.

- `audit_log_buffer_size`: The size of the buffer for asynchronous logging. The plugin uses a single buffer, which it allocates when it initializes and removes when it terminates. The plugin allocates this buffer only if logging is asynchronous.
- `audit_log_rotate_on_size`, `audit_log_flush`: These variables permit audit log file rotation and flushing. The audit log file has the potential to grow very large and consume a lot of disk space. To

manage the space used, either enable automatic log rotation, or manually rename the audit file and flush the log to open a new file. The renamed file can be removed or backed up as desired.

By default, `audit_log_rotate_on_size=0` and there is no log rotation. In this case, the audit log plugin closes and reopens the log file when the `audit_log_flush` value changes from disabled to enabled. Log file renaming must be done externally to the server. Suppose that you want to maintain the three most recent log files, which cycle through the names `audit.log.1` through `audit.log.3`. On Unix, perform rotation manually like this:

1. From the command line, rename the current log files:

```
shell> mv audit.log.2 audit.log.3
shell> mv audit.log.1 audit.log.2
shell> mv audit.log audit.log.1
```

At this point, the plugin is still writing to the current log file, which has been renamed to `audit.log.1`.

2. Connect to the server and flush the log file so the plugin closes it and reopens a new `audit.log` file:

```
mysql> SET GLOBAL audit_log_flush = ON;
```

If `audit_log_rotate_on_size` is greater than 0, setting `audit_log_flush` has no effect. In this case, the audit log plugin closes and reopens its log file whenever a write to the file causes its size to exceed the `audit_log_rotate_on_size` value. The plugin renames the original file to have a timestamp extension. For example, `audit.log` might be renamed to `audit.log.13440033615657730`. The last 7 digits are a fractional second part. The first 10 digits are a Unix timestamp value that can be interpreted using the `FROM_UNIXTIME()` function:

```
mysql> SELECT FROM_UNIXTIME(1344003361);
+-----+
| FROM_UNIXTIME(1344003361) |
+-----+
| 2012-08-03 09:16:01      |
+-----+
```

6.3.11.5 Audit Log Plugin Options and Variables

This section describes the command options and system variables that control operation of the audit log plugin. If values specified at startup time are incorrect, the plugin may fail to initialize properly and the server does not load it. In this case, the server may also produce error messages for other audit log settings because it will not recognize them.

To control the activation of the `audit_log` plugin, use this option:

- `--audit-log[=value]`

Introduced	5.5.28	
Command-Line Format	<code>--audit-log[=value]</code>	
Option-File Format	<code>audit-log</code>	
	Permitted Values	
	Type	<code>enumeration</code>

	Default	ON
	Valid Values	ON
		OFF
		FORCE
		FORCE_PLUS_PERMANENT

This option controls how the server loads the `audit_log` plugin at startup. It is available only if the audit log plugin has been previously registered with `INSTALL PLUGIN` or is loaded with `--plugin-load`. See [Section 6.3.11.1, “Installing the Audit Log Plugin”](#).

The option value should be one of those available for plugin-loading options, as described in [Section 5.1.8.1, “Installing and Uninstalling Plugins”](#). For example, `--audit-log=FORCE_PLUS_PERMANENT` tells the server to load the plugin and prevent it from being removed while the server is running.

This option was added in MySQL 5.5.28.

If the `audit_log` plugin is installed, it exposes several system variables that permit control over logging:

```
mysql> SHOW VARIABLES LIKE 'audit_log%';
+-----+-----+
| Variable_name | Value          |
+-----+-----+
| audit_log_buffer_size | 1048576        |
| audit_log_file      | audit.log      |
| audit_log_flush      | OFF            |
| audit_log_policy      | ALL            |
| audit_log_rotate_on_size | 0              |
| audit_log_strategy    | ASYNCHRONOUS   |
+-----+-----+
```

You can set any of these variables at server startup, and some of them at runtime.

- `audit_log_buffer_size`

Introduced	5.5.28
System Variable Name	<code>audit_log_buffer_size</code>
Variable Scope	Global
Dynamic Variable	No
	Permitted Values
	Platform Bit Size 32
	Type numeric
	Default 1048576
	Range 4096 .. 4294967295
	Permitted Values
	Platform Bit Size 64
	Type numeric
	Default 1048576

	Range	4096 .. 18446744073709547520
--	--------------	------------------------------

When the audit log plugin writes events to the log asynchronously, it uses a buffer to store event contents prior to writing them. This variable controls the size of that buffer, in bytes. The server adjusts the value to a multiple of 4096. The plugin uses a single buffer, which it allocates when it initializes and removes when it terminates. The plugin allocates this buffer only if logging is asynchronous.

This variable was added in MySQL 5.5.28. It is available only if the `audit_log` plugin is enabled.

- `audit_log_file`

Introduced	5.5.28	
System Variable Name	<code>audit_log_file</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	<code>file name</code>
	Default	<code>audit.log</code>

The name of the file to which the audit log plugin writes events. The default value is `audit.log`. If the file name is a relative path, the server interprets it relative to the data directory. For security reasons, the audit log file should be written to a directory accessible only to the MySQL server and users with a legitimate reason to view the log.

This variable was added in MySQL 5.5.28. It is available only if the `audit_log` plugin is enabled.

- `audit_log_flush`

Introduced	5.5.28	
System Variable Name	<code>audit_log_flush</code>	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	<code>boolean</code>
	Default	<code>OFF</code>

When this variable is set to enabled (1 or `ON`), the audit log plugin closes and reopens its log file to flush it. (The value remains `OFF` so that you need not disable it explicitly before enabling it again to perform another flush.) Enabling this variable has no effect unless `audit_log_rotate_on_size` is 0.

This variable was added in MySQL 5.5.28. It is available only if the `audit_log` plugin is enabled.

- `audit_log_format`

Introduced	5.5.34	
System Variable Name	<code>audit_log_format</code>	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values (>= 5.5.34)	

	Type	enumeration
	Default	OLD
	Valid Values	OLD
		NEW

The audit log file format. Permitted values are `OLD` and `NEW` (default `OLD`). For details about each format, see [Section 6.3.11.3, “The Audit Log File”](#).

If you change the value of `audit_log_format`, use this procedure to avoid writing log entries in one format to an existing log file that contains entries in a different format:

1. Stop the server.
2. Rename the current audit log file manually.
3. Restart the server with the new value of `audit_log_format`. The audit log plugin will create a new log file, which will contain log entries in the selected format.

This variable was added in MySQL 5.5.34. It is available only if the `audit_log` plugin is enabled.

- `audit_log_policy`

Introduced	5.5.28	
System Variable Name	audit_log_policy	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	enumeration
	Default	ALL
	Valid Values	ALL
		NONE
		LOGINS
		QUERIES

The policy controlling the information written by the audit log plugin to its log file. The following table shows the permitted values.

Value	Description
ALL	Log all events
NONE	Log nothing (disable the audit stream)
LOGINS	Log only login events
QUERIES	Log only query events

This variable was added in MySQL 5.5.28. It is available only if the `audit_log` plugin is enabled.

- `audit_log_rotate_on_size`

Introduced	5.5.28	814
-------------------	--------	-----

System Variable Name	audit_log_rotate_on_size	
Variable Scope	Global	
Dynamic Variable	Yes	
	Permitted Values	
	Type	numeric
	Default	0

If the [audit_log_rotate_on_size](#) value is greater than 0, the audit log plugin closes and reopens its log file if a write to the file causes its size to exceed this value. The original file is renamed to have a timestamp extension.

If the [audit_log_rotate_on_size](#) value is 0, the plugin does not close and reopen its log based on size. Instead, use [audit_log_flush](#) to close and reopen the log on demand. In this case, rename the file externally to the server before flushing it.

For more information about audit log file rotation and timestamp interpretation, see [Section 6.3.11.4, “Audit Log Plugin Logging Control”](#).

If you set this variable to a value that is not a multiple of 4096, it is truncated to the nearest multiple. (Thus, setting it to a value less than 4096 has the effect of setting it to 0 and no rotation occurs.)

This variable was added in MySQL 5.5.28. It is available only if the [audit_log](#) plugin is enabled.

- [audit_log_strategy](#)

Introduced	5.5.28	
System Variable Name	audit_log_strategy	
Variable Scope	Global	
Dynamic Variable	No	
	Permitted Values	
	Type	enumeration
	Default	ASYNCHRONOUS
	Valid Values	ASYNCHRONOUS
		PERFORMANCE
		SEMI SYNCHRONOUS
		SYNCHRONOUS

The logging method used by the audit log plugin. The following table describes the permitted values.

Table 6.16 Audit Log Strategies

Value	Meaning
ASYNCHRONOUS	Log asynchronously, wait for space in output buffer
PERFORMANCE	Log asynchronously, drop request if insufficient space in output buffer
SEMI SYNCHRONOUS	Log synchronously, permit caching by operating system
SYNCHRONOUS	Log synchronously, call sync() after each request

This variable was added in MySQL 5.5.28. It is available only if the [audit_log](#) plugin is enabled.

6.3.11.6 Audit Log Plugin Restrictions

The audit log plugin is subject to these restrictions:

- Only top-level statements are logged, not statements within stored programs such as triggers or stored procedures.
- Contents of files referenced by statements such as `LOAD DATA INFILE` are not logged.

6.3.12 SQL-Based MySQL Account Activity Auditing

Applications can use the following guidelines to perform SQL-based auditing that ties database activity to MySQL accounts.

MySQL accounts correspond to rows in the `mysql.user` table. When a client connects successfully, the server authenticates the client to a particular row in this table. The `User` and `Host` column values in this row uniquely identify the account and correspond to the `'user_name'@'host_name'` format in which account names are written in SQL statements.

The account used to authenticate a client determines which privileges the client has. Normally, the `CURRENT_USER()` function can be invoked to determine which account this is for the client user. Its value is constructed from the `User` and `Host` columns of the `user` table row for the account.

However, there are circumstances under which the `CURRENT_USER()` value corresponds not to the client user but to a different account. This occurs in contexts when privilege checking is not based the client's account:

- Stored routines (procedures and functions) defined with the `SQL SECURITY DEFINER` characteristic
- Views defined with the `SQL SECURITY DEFINER` characteristic
- Triggers and events

In those contexts, privilege checking is done against the `DEFINER` account and `CURRENT_USER()` refers to that account, not to the account for the client who invoked the stored routine or view or who caused the trigger to activate. To determine the invoking user, you can call the `USER()` function, which returns a value indicating the actual user name provided by the client and the host from which the client connected. However, this value does not necessarily correspond directly to an account in the `user` table, because the `USER()` value never contains wildcards, whereas account values (as returned by `CURRENT_USER()`) may contain user name and host name wildcards.

For example, a blank user name matches any user, so an account of `'@'localhost'` enables clients to connect as an anonymous user from the local host with any user name. If this case, if a client connects as `user1` from the local host, `USER()` and `CURRENT_USER()` return different values:

```
mysql> SELECT USER(), CURRENT_USER();
+-----+-----+
| USER()          | CURRENT_USER() |
+-----+-----+
| user1@localhost | @localhost      |
+-----+-----+
```

The host name part of an account can contain wildcards, too. If the host name contains a `'%'` or `'_'` pattern character or uses netmask notation, the account can be used for clients connecting from multiple hosts and the `CURRENT_USER()` value will not indicate which one. For example, the account `'user2'@'%.example.com'` can be used by `user2` to connect from any host in the `example.com`

domain. If `user2` connects from `remote.example.com`, `USER()` and `CURRENT_USER()` return different values:

```
mysql> SELECT USER(), CURRENT_USER();
+-----+-----+
| USER() | CURRENT_USER() |
+-----+-----+
| user2@remote.example.com | user2@%.example.com |
+-----+-----+
```

If an application must invoke `USER()` for user auditing (for example, if it does auditing from within triggers) but must also be able to associate the `USER()` value with an account in the `user` table, it is necessary to avoid accounts that contain wildcards in the `User` or `Host` column. Specifically, do not permit `User` to be empty (which creates an anonymous-user account), and do not permit pattern characters or netmask notation in `Host` values. All accounts must have a nonempty `User` value and literal `Host` value.

With respect to the previous examples, the `'@'localhost'` and `'user2'@'%.example.com'` accounts should be changed not to use wildcards:

```
RENAME USER '@'localhost' TO 'user1'@'localhost';
RENAME USER 'user2'@'%.example.com' TO 'user2'@'remote.example.com';
```

If `user2` must be able to connect from several hosts in the `example.com` domain, there should be a separate account for each host.

To extract the user name or host name part from a `CURRENT_USER()` or `USER()` value, use the `SUBSTRING_INDEX()` function:

```
mysql> SELECT SUBSTRING_INDEX(CURRENT_USER(), '@', 1);
+-----+
| SUBSTRING_INDEX(CURRENT_USER(), '@', 1) |
+-----+
| user1 |
+-----+

mysql> SELECT SUBSTRING_INDEX(CURRENT_USER(), '@', -1);
+-----+
| SUBSTRING_INDEX(CURRENT_USER(), '@', -1) |
+-----+
| localhost |
+-----+
```

Chapter 7 Backup and Recovery

7.6.4 <code>MyISAM</code> Table Optimization	842
7.6.5 Setting Up a <code>MyISAM</code> Table Maintenance Schedule	842

It is important to back up your databases so that you can recover your data and be up and running again in case problems occur, such as system crashes, hardware failures, or users deleting data by mistake. Backups are also essential as a safeguard before upgrading a MySQL installation, and they can be used to transfer a MySQL installation to another system or to set up replication slave servers.

MySQL offers a variety of backup strategies from which you can choose the methods that best suit the requirements for your installation. This chapter discusses several backup and recovery topics with which you should be familiar:

- Types of backups: Logical versus physical, full versus incremental, and so forth.
- Methods for creating backups.
- Recovery methods, including point-in-time recovery.
- Backup scheduling, compression, and encryption.
- Table maintenance, to enable recovery of corrupt tables.

Additional Resources

Resources related to backup or to maintaining data availability include the following:

- Customers of MySQL Enterprise Edition can use the MySQL Enterprise Backup product for backups. For an overview of the MySQL Enterprise Backup product, see [Section 25.2, “MySQL Enterprise Backup”](#).
- A forum dedicated to backup issues is available at <http://forums.mysql.com/list.php?28>.

- Details for `mysqldump`, `mysqlhotcopy`, and other MySQL backup programs can be found in [Chapter 4, MySQL Programs](#).
- The syntax of the SQL statements described here is given in [Chapter 13, SQL Statement Syntax](#).
- For additional information about `InnoDB` backup procedures, see [Section 14.19, “InnoDB Backup and Recovery”](#).
- Replication enables you to maintain identical data on multiple servers. This has several benefits, such as enabling client query load to be distributed over servers, availability of data even if a given server is taken offline or fails, and the ability to make backups with no impact on the master by using a slave server. See [Chapter 17, Replication](#).
- MySQL Cluster provides a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. See [Chapter 18, MySQL Cluster NDB 7.2](#). For information specifically about MySQL Cluster backup, see [Section 18.5.3, “Online Backup of MySQL Cluster”](#).
- Distributed Replicated Block Device (DRBD) is another high-availability solution. It works by replicating a block device from a primary server to a secondary server at the block level. See [Chapter 16, High Availability and Scalability](#).

7.1 Backup and Recovery Types

This section describes the characteristics of different types of backups.

Physical (Raw) Versus Logical Backups

Physical backups consist of raw copies of the directories and files that store database contents. This type of backup is suitable for large, important databases that need to be recovered quickly when problems occur.

Logical backups save information represented as logical database structure (`CREATE DATABASE`, `CREATE TABLE` statements) and content (`INSERT` statements or delimited-text files). This type of backup is suitable for smaller amounts of data where you might edit the data values or table structure, or recreate the data on a different machine architecture.

Physical backup methods have these characteristics:

- The backup consists of exact copies of database directories and files. Typically this is a copy of all or part of the MySQL data directory.
- Physical backup methods are faster than logical because they involve only file copying without conversion.
- Output is more compact than for logical backup.
- Because backup speed and compactness are important for busy, important databases, the MySQL Enterprise Backup product performs physical backups. For an overview of the MySQL Enterprise Backup product, see [Section 25.2, “MySQL Enterprise Backup”](#).
- Backup and restore granularity ranges from the level of the entire data directory down to the level of individual files. This may or may not provide for table-level granularity, depending on storage engine. For example, `InnoDB` tables can each be in a separate file, or share file storage with other `InnoDB` tables; each `MyISAM` table corresponds uniquely to a set of files.
- In addition to databases, the backup can include any related files such as log or configuration files.

- Data from `MEMORY` tables is tricky to back up this way because their contents are not stored on disk. (The MySQL Enterprise Backup product has a feature where you can retrieve data from `MEMORY` tables during a backup.)
- Backups are portable only to other machines that have identical or similar hardware characteristics.
- Backups can be performed while the MySQL server is not running. If the server is running, it is necessary to perform appropriate locking so that the server does not change database contents during the backup. MySQL Enterprise Backup does this locking automatically for tables that require it.
- Physical backup tools include the `mysqlbackup` of MySQL Enterprise Backup for `InnoDB` or any other tables, file system-level commands (such as `cp`, `scp`, `tar`, `rsync`), or `mysqlhotcopy` for `MyISAM` tables.
- For restore:
 - MySQL Enterprise Backup restores `InnoDB` and other tables that it backed up.
 - `ndb_restore` restores `NDB` tables.
 - Files copied at the file system level or with `mysqlhotcopy` can be copied back to their original locations with file system commands.

Logical backup methods have these characteristics:

- The backup is done by querying the MySQL server to obtain database structure and content information.
- Backup is slower than physical methods because the server must access database information and convert it to logical format. If the output is written on the client side, the server must also send it to the backup program.
- Output is larger than for physical backup, particularly when saved in text format.
- Backup and restore granularity is available at the server level (all databases), database level (all tables in a particular database), or table level. This is true regardless of storage engine.
- The backup does not include log or configuration files, or other database-related files that are not part of databases.
- Backups stored in logical format are machine independent and highly portable.
- Logical backups are performed with the MySQL server running. The server is not taken offline.
- Logical backup tools include the `mysqldump` program and the `SELECT ... INTO OUTFILE` statement. These work for any storage engine, even `MEMORY`.
- To restore logical backups, SQL-format dump files can be processed using the `mysql` client. To load delimited-text files, use the `LOAD DATA INFILE` statement or the `mysqlimport` client.

Online Versus Offline Backups

Online backups take place while the MySQL server is running so that the database information can be obtained from the server. Offline backups take place while the server is stopped. This distinction can also be described as “hot” versus “cold” backups; a “warm” backup is one where the server remains running but locked against modifying data while you access database files externally.

Online backup methods have these characteristics:

- The backup is less intrusive to other clients, which can connect to the MySQL server during the backup and may be able to access data depending on what operations they need to perform.
- Care must be taken to impose appropriate locking so that data modifications do not take place that would compromise backup integrity. The MySQL Enterprise Backup product does such locking automatically.

Offline backup methods have these characteristics:

- Clients can be affected adversely because the server is unavailable during backup. For that reason, such backups are often taken from a replication slave server that can be taken offline without harming availability.
- The backup procedure is simpler because there is no possibility of interference from client activity.

A similar distinction between online and offline applies for recovery operations, and similar characteristics apply. However, it is more likely that clients will be affected for online recovery than for online backup because recovery requires stronger locking. During backup, clients might be able to read data while it is being backed up. Recovery modifies data and does not just read it, so clients must be prevented from accessing data while it is being restored.

Local Versus Remote Backups

A local backup is performed on the same host where the MySQL server runs, whereas a remote backup is done from a different host. For some types of backups, the backup can be initiated from a remote host even if the output is written locally on the server host.

- `mysqldump` can connect to local or remote servers. For SQL output (`CREATE` and `INSERT` statements), local or remote dumps can be done and generate output on the client. For delimited-text output (with the `--tab` option), data files are created on the server host.
- `mysqlhotcopy` performs only local backups: It connects to the server to lock it against data modifications and then copies local table files.
- `SELECT ... INTO OUTFILE` can be initiated from a local or remote client host, but the output file is created on the server host.
- Physical backup methods typically are initiated locally on the MySQL server host so that the server can be taken offline, although the destination for copied files might be remote.

Snapshot Backups

Some file system implementations enable “snapshots” to be taken. These provide logical copies of the file system at a given point in time, without requiring a physical copy of the entire file system. (For example, the implementation may use copy-on-write techniques so that only parts of the file system modified after the snapshot time need be copied.) MySQL itself does not provide the capability for taking file system snapshots. It is available through third-party solutions such as Veritas, LVM, or ZFS.

Full Versus Incremental Backups

A full backup includes all data managed by a MySQL server at a given point in time. An incremental backup consists of the changes made to the data during a given time span (from one point in time to another). MySQL has different ways to perform full backups, such as those described earlier in this section. Incremental backups are made possible by enabling the server's binary log, which the server uses to record data changes.

Full Versus Point-in-Time (Incremental) Recovery

A full recovery restores all data from a full backup. This restores the server instance to the state that it had when the backup was made. If that state is not sufficiently current, a full recovery can be followed by recovery of incremental backups made since the full backup, to bring the server to a more up-to-date state.

Incremental recovery is recovery of changes made during a given time span. This is also called point-in-time recovery because it makes a server's state current up to a given time. Point-in-time recovery is based on the binary log and typically follows a full recovery from the backup files that restores the server to its state when the backup was made. Then the data changes written in the binary log files are applied as incremental recovery to redo data modifications and bring the server up to the desired point in time.

Table Maintenance

Data integrity can be compromised if tables become corrupt. For [InnoDB](#) tables, this is not a typical issue. For programs to check [MyISAM](#) tables and repair them if problems are found, see [Section 7.6, “MyISAM Table Maintenance and Crash Recovery”](#).

Backup Scheduling, Compression, and Encryption

Backup scheduling is valuable for automating backup procedures. Compression of backup output reduces space requirements, and encryption of the output provides better security against unauthorized access of backed-up data. MySQL itself does not provide these capabilities. The MySQL Enterprise Backup product can compress [InnoDB](#) backups, and compression or encryption of backup output can be achieved using file system utilities. Other third-party solutions may be available.

7.2 Database Backup Methods

This section summarizes some general methods for making backups.

Making a Hot Backup with MySQL Enterprise Backup

Customers of MySQL Enterprise Edition can use the [MySQL Enterprise Backup](#) product to do [physical](#) backups of entire instances or selected databases, tables, or both. This product includes features for [incremental](#) and [compressed](#) backups. Backing up the physical database files makes restore much faster than logical techniques such as the [mysqldump](#) command. [InnoDB](#) tables are copied using a [hot backup](#) mechanism. (Ideally, the [InnoDB](#) tables should represent a substantial majority of the data.) Tables from other storage engines are copied using a [warm backup](#) mechanism. For an overview of the MySQL Enterprise Backup product, see [Section 25.2, “MySQL Enterprise Backup”](#).

Making Backups with [mysqldump](#) or [mysqlhotcopy](#)

The [mysqldump](#) program and the [mysqlhotcopy](#) script can make backups. [mysqldump](#) is more general because it can back up all kinds of tables. [mysqlhotcopy](#) works only with some storage engines. (See [Section 7.4, “Using mysqldump for Backups”](#), and [Section 4.6.9, “mysqlhotcopy — A Database Backup Program”](#).)

For [InnoDB](#) tables, it is possible to perform an online backup that takes no locks on tables using the [--single-transaction](#) option to [mysqldump](#). See [Section 7.3.1, “Establishing a Backup Policy”](#).

Making Backups by Copying Table Files

For storage engines that represent each table using its own files, tables can be backed up by copying those files. For example, [MyISAM](#) tables are stored as files, so it is easy to do a backup by copying files

(*[.frm](#), *[.MYD](#), and *[.MYI](#) files). To get a consistent backup, stop the server or lock and flush the relevant tables:

```
FLUSH TABLES tbl_list WITH READ LOCK;
```

You need only a read lock; this enables other clients to continue to query the tables while you are making a copy of the files in the database directory. The flush is needed to ensure that the all active index pages are written to disk before you start the backup. See [Section 13.3.5, “LOCK TABLES and UNLOCK TABLES Syntax”](#), and [Section 13.7.6.3, “FLUSH Syntax”](#).

You can also create a binary backup simply by copying all table files, as long as the server isn't updating anything. The [mysqlhotcopy](#) script uses this method. (But note that table file copying methods do not work if your database contains [InnoDB](#) tables. [mysqlhotcopy](#) does not work for [InnoDB](#) tables because [InnoDB](#) does not necessarily store table contents in database directories. Also, even if the server is not actively updating data, [InnoDB](#) may still have modified data cached in memory and not flushed to disk.)

Making Delimited-Text File Backups

To create a text file containing a table's data, you can use [SELECT * INTO OUTFILE 'file_name' FROM *tbl_name*](#). The file is created on the MySQL server host, not the client host. For this statement, the output file cannot already exist because permitting files to be overwritten constitutes a security risk. See [Section 13.2.9, “SELECT Syntax”](#). This method works for any kind of data file, but saves only table data, not the table structure.

Another way to create text data files (along with files containing [CREATE TABLE](#) statements for the backed up tables) is to use [mysqldump](#) with the [--tab](#) option. See [Section 7.4.3, “Dumping Data in Delimited-Text Format with mysqldump”](#).

To reload a delimited-text data file, use [LOAD DATA INFILE](#) or [mysqlimport](#).

Making Incremental Backups by Enabling the Binary Log

MySQL supports incremental backups: You must start the server with the [--log-bin](#) option to enable binary logging; see [Section 5.2.4, “The Binary Log”](#). The binary log files provide you with the information you need to replicate changes to the database that are made subsequent to the point at which you performed a backup. At the moment you want to make an incremental backup (containing all changes that happened since the last full or incremental backup), you should rotate the binary log by using [FLUSH LOGS](#). This done, you need to copy to the backup location all binary logs which range from the one of the moment of the last full or incremental backup to the last but one. These binary logs are the incremental backup; at restore time, you apply them as explained in [Section 7.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#). The next time you do a full backup, you should also rotate the binary log using [FLUSH LOGS](#), [mysqldump --flush-logs](#), or [mysqlhotcopy --flushlog](#). See [Section 4.5.4, “mysqldump — A Database Backup Program”](#), and [Section 4.6.9, “mysqlhotcopy — A Database Backup Program”](#).

Making Backups Using Replication Slaves

If you have performance problems with your master server while making backups, one strategy that can help is to set up replication and perform backups on the slave rather than on the master. See [Section 17.3.1, “Using Replication for Backups”](#).

If you are backing up a slave replication server, you should back up its [master.info](#) and [relay-log.info](#) files when you back up the slave's databases, regardless of the backup method you choose. These information files are always needed to resume replication after you restore the slave's data. If your slave is replicating [LOAD DATA INFILE](#) statements, you should also back up any [SQL_LOAD-*](#) files that

exist in the directory that the slave uses for this purpose. The slave needs these files to resume replication of any interrupted `LOAD DATA INFILE` operations. The location of this directory is the value of the `--slave-load-tmpdir` option. If the server was not started with that option, the directory location is the value of the `tmpdir` system variable.

Recovering Corrupt Tables

If you have to restore `MyISAM` tables that have become corrupt, try to recover them using `REPAIR TABLE` or `myisamchk -r` first. That should work in 99.9% of all cases. If `myisamchk` fails, see [Section 7.6, “MyISAM Table Maintenance and Crash Recovery”](#).

Making Backups Using a File System Snapshot

If you are using a Veritas file system, you can make a backup like this:

1. From a client program, execute `FLUSH TABLES WITH READ LOCK`.
2. From another shell, execute `mount vxfs snapshot`.
3. From the first client, execute `UNLOCK TABLES`.
4. Copy files from the snapshot.
5. Unmount the snapshot.

Similar snapshot capabilities may be available in other file systems, such as LVM or ZFS.

7.3 Example Backup and Recovery Strategy

This section discusses a procedure for performing backups that enables you to recover data after several types of crashes:

- Operating system crash
- Power failure
- File system crash
- Hardware problem (hard drive, motherboard, and so forth)

The example commands do not include options such as `--user` and `--password` for the `mysqldump` and `mysql` client programs. You should include such options as necessary to enable client programs to connect to the MySQL server.

Assume that data is stored in the `InnoDB` storage engine, which has support for transactions and automatic crash recovery. Assume also that the MySQL server is under load at the time of the crash. If it were not, no recovery would ever be needed.

For cases of operating system crashes or power failures, we can assume that MySQL's disk data is available after a restart. The `InnoDB` data files might not contain consistent data due to the crash, but `InnoDB` reads its logs and finds in them the list of pending committed and noncommitted transactions that have not been flushed to the data files. `InnoDB` automatically rolls back those transactions that were not committed, and flushes to its data files those that were committed. Information about this recovery process is conveyed to the user through the MySQL error log. The following is an example log excerpt:

```
InnoDB: Database was not shut down normally.
```

```
InnoDB: Starting recovery from log files...
InnoDB: Starting log scan based on checkpoint at
InnoDB: log sequence number 0 13674004
InnoDB: Doing recovery: scanned up to log sequence number 0 13739520
InnoDB: Doing recovery: scanned up to log sequence number 0 13805056
InnoDB: Doing recovery: scanned up to log sequence number 0 13870592
InnoDB: Doing recovery: scanned up to log sequence number 0 13936128
...
InnoDB: Doing recovery: scanned up to log sequence number 0 20555264
InnoDB: Doing recovery: scanned up to log sequence number 0 20620800
InnoDB: Doing recovery: scanned up to log sequence number 0 20664692
InnoDB: 1 uncommitted transaction(s) which must be rolled back
InnoDB: Starting rollback of uncommitted transactions
InnoDB: Rolling back trx no 16745
InnoDB: Rolling back of trx no 16745 completed
InnoDB: Rollback of uncommitted transactions completed
InnoDB: Starting an apply batch of log records to the database...
InnoDB: Apply batch completed
InnoDB: Started
mysqld: ready for connections
```

For the cases of file system crashes or hardware problems, we can assume that the MySQL disk data is *not* available after a restart. This means that MySQL fails to start successfully because some blocks of disk data are no longer readable. In this case, it is necessary to reformat the disk, install a new one, or otherwise correct the underlying problem. Then it is necessary to recover our MySQL data from backups, which means that backups must already have been made. To make sure that is the case, design and implement a backup policy.

7.3.1 Establishing a Backup Policy

To be useful, backups must be scheduled regularly. A full backup (a snapshot of the data at a point in time) can be done in MySQL with several tools. For example, [MySQL Enterprise Backup](#) can perform a [physical backup](#) of an entire instance, with optimizations to minimize overhead and avoid disruption when backing up [InnoDB](#) data files; [mysqldump](#) provides online [logical backup](#). This discussion uses [mysqldump](#).

Assume that we make a full backup of all our [InnoDB](#) tables in all databases using the following command on Sunday at 1 p.m., when load is low:

```
shell> mysqldump --single-transaction --all-databases > backup_sunday_1_PM.sql
```

The resulting `.sql` file produced by [mysqldump](#) contains a set of SQL `INSERT` statements that can be used to reload the dumped tables at a later time.

This backup operation acquires a global read lock on all tables at the beginning of the dump (using `FLUSH TABLES WITH READ LOCK`). As soon as this lock has been acquired, the binary log coordinates are read and the lock is released. If long updating statements are running when the `FLUSH` statement is issued, the backup operation may stall until those statements finish. After that, the dump becomes lock-free and does not disturb reads and writes on the tables.

It was assumed earlier that the tables to back up are [InnoDB](#) tables, so `--single-transaction` uses a consistent read and guarantees that data seen by [mysqldump](#) does not change. (Changes made by other clients to [InnoDB](#) tables are not seen by the [mysqldump](#) process.) If the backup operation includes nontransactional tables, consistency requires that they do not change during the backup. For example, for the [MyISAM](#) tables in the `mysql` database, there must be no administrative changes to MySQL accounts during the backup.

Full backups are necessary, but it is not always convenient to create them. They produce large backup files and take time to generate. They are not optimal in the sense that each successive full backup includes all data, even that part that has not changed since the previous full backup. It is more efficient to make an

initial full backup, and then to make incremental backups. The incremental backups are smaller and take less time to produce. The tradeoff is that, at recovery time, you cannot restore your data just by reloading the full backup. You must also process the incremental backups to recover the incremental changes.

To make incremental backups, we need to save the incremental changes. In MySQL, these changes are represented in the binary log, so the MySQL server should always be started with the `--log-bin` option to enable that log. With binary logging enabled, the server writes each data change into a file while it updates data. Looking at the data directory of a MySQL server that was started with the `--log-bin` option and that has been running for some days, we find these MySQL binary log files:

```
-rw-rw---- 1 guilhem guilhem 1277324 Nov 10 23:59 gbichot2-bin.000001
-rw-rw---- 1 guilhem guilhem      4 Nov 10 23:59 gbichot2-bin.000002
-rw-rw---- 1 guilhem guilhem    79 Nov 11 11:06 gbichot2-bin.000003
-rw-rw---- 1 guilhem guilhem   508 Nov 11 11:08 gbichot2-bin.000004
-rw-rw---- 1 guilhem guilhem 220047446 Nov 12 16:47 gbichot2-bin.000005
-rw-rw---- 1 guilhem guilhem  998412 Nov 14 10:08 gbichot2-bin.000006
-rw-rw---- 1 guilhem guilhem   361 Nov 14 10:07 gbichot2-bin.index
```

Each time it restarts, the MySQL server creates a new binary log file using the next number in the sequence. While the server is running, you can also tell it to close the current binary log file and begin a new one manually by issuing a `FLUSH LOGS` SQL statement or with a `mysqladmin flush-logs` command. `mysqldump` also has an option to flush the logs. The `.index` file in the data directory contains the list of all MySQL binary logs in the directory.

The MySQL binary logs are important for recovery because they form the set of incremental backups. If you make sure to flush the logs when you make your full backup, the binary log files created afterward contain all the data changes made since the backup. Let's modify the previous `mysqldump` command a bit so that it flushes the MySQL binary logs at the moment of the full backup, and so that the dump file contains the name of the new current binary log:

```
shell> mysqldump --single-transaction --flush-logs --master-data=2 \
        --all-databases > backup_sunday_1_PM.sql
```

After executing this command, the data directory contains a new binary log file, `gbichot2-bin.000007`, because the `--flush-logs` option causes the server to flush its logs. The `--master-data` option causes `mysqldump` to write binary log information to its output, so the resulting `.sql` dump file includes these lines:

```
-- Position to start replication or point-in-time recovery from
-- CHANGE MASTER TO MASTER_LOG_FILE='gbichot2-bin.000007',MASTER_LOG_POS=4;
```

Because the `mysqldump` command made a full backup, those lines mean two things:

- The dump file contains all changes made before any changes written to the `gbichot2-bin.000007` binary log file or newer.
- All data changes logged after the backup are not present in the dump file, but are present in the `gbichot2-bin.000007` binary log file or newer.

On Monday at 1 p.m., we can create an incremental backup by flushing the logs to begin a new binary log file. For example, executing a `mysqladmin flush-logs` command creates `gbichot2-bin.000008`. All changes between the Sunday 1 p.m. full backup and Monday 1 p.m. will be in the `gbichot2-bin.000007` file. This incremental backup is important, so it is a good idea to copy it to a safe place. (For example, back it up on tape or DVD, or copy it to another machine.) On Tuesday at 1 p.m., execute another `mysqladmin flush-logs` command. All changes between Monday 1 p.m. and Tuesday 1 p.m. will be in the `gbichot2-bin.000008` file (which also should be copied somewhere safe).

The MySQL binary logs take up disk space. To free up space, purge them from time to time. One way to do this is by deleting the binary logs that are no longer needed, such as when we make a full backup:

```
shell> mysqldump --single-transaction --flush-logs --master-data=2 \
--all-databases --delete-master-logs > backup_sunday_1_PM.sql
```

Note

Deleting the MySQL binary logs with `mysqldump --delete-master-logs` can be dangerous if your server is a replication master server, because slave servers might not yet fully have processed the contents of the binary log. The description for the `PURGE BINARY LOGS` statement explains what should be verified before deleting the MySQL binary logs. See [Section 13.4.1.1, “PURGE BINARY LOGS Syntax”](#).

7.3.2 Using Backups for Recovery

Now, suppose that we have a catastrophic crash on Wednesday at 8 a.m. that requires recovery from backups. To recover, first we restore the last full backup we have (the one from Sunday 1 p.m.). The full backup file is just a set of SQL statements, so restoring it is very easy:

```
shell> mysql < backup_sunday_1_PM.sql
```

At this point, the data is restored to its state as of Sunday 1 p.m.. To restore the changes made since then, we must use the incremental backups; that is, the `gbichot2-bin.000007` and `gbichot2-bin.000008` binary log files. Fetch the files if necessary from where they were backed up, and then process their contents like this:

```
shell> mysqlbinlog gbichot2-bin.000007 gbichot2-bin.000008 | mysql
```

We now have recovered the data to its state as of Tuesday 1 p.m., but still are missing the changes from that date to the date of the crash. To not lose them, we would have needed to have the MySQL server store its MySQL binary logs into a safe location (RAID disks, SAN, ...) different from the place where it stores its data files, so that these logs were not on the destroyed disk. (That is, we can start the server with a `--log-bin` option that specifies a location on a different physical device from the one on which the data directory resides. That way, the logs are safe even if the device containing the directory is lost.) If we had done this, we would have the `gbichot2-bin.000009` file (and any subsequent files) at hand, and we could apply them using `mysqlbinlog` and `mysql` to restore the most recent data changes with no loss up to the moment of the crash:

```
shell> mysqlbinlog gbichot2-bin.000009 ... | mysql
```

For more information about using `mysqlbinlog` to process binary log files, see [Section 7.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#).

7.3.3 Backup Strategy Summary

In case of an operating system crash or power failure, `InnoDB` itself does all the job of recovering data. But to make sure that you can sleep well, observe the following guidelines:

- Always run the MySQL server with the `--log-bin` option, or even `--log-bin=log_name`, where the log file name is located on some safe media different from the drive on which the data directory is located. If you have such safe media, this technique can also be good for disk load balancing (which results in a performance improvement).

- Make periodic full backups, using the `mysqldump` command shown earlier in [Section 7.3.1](#), “Establishing a Backup Policy”, that makes an online, nonblocking backup.
- Make periodic incremental backups by flushing the logs with `FLUSH LOGS` or `mysqladmin flush-logs`.

7.4 Using `mysqldump` for Backups

This section describes how to use `mysqldump` to produce dump files, and how to reload dump files. A dump file can be used in several ways:

- As a backup to enable data recovery in case of data loss.
- As a source of data for setting up replication slaves.
- As a source of data for experimentation:
 - To make a copy of a database that you can use without changing the original data.
 - To test potential upgrade incompatibilities.

`mysqldump` produces two types of output, depending on whether the `--tab` option is given:

- Without `--tab`, `mysqldump` writes SQL statements to the standard output. This output consists of `CREATE` statements to create dumped objects (databases, tables, stored routines, and so forth), and `INSERT` statements to load data into tables. The output can be saved in a file and reloaded later using `mysql` to recreate the dumped objects. Options are available to modify the format of the SQL statements, and to control which objects are dumped.
- With `--tab`, `mysqldump` produces two output files for each dumped table. The server writes one file as tab-delimited text, one line per table row. This file is named `tbl_name.txt` in the output directory. The server also sends a `CREATE TABLE` statement for the table to `mysqldump`, which writes it as a file named `tbl_name.sql` in the output directory.

7.4.1 Dumping Data in SQL Format with `mysqldump`

This section describes how to use `mysqldump` to create SQL-format dump files. For information about reloading such dump files, see [Section 7.4.2](#), “Reloading SQL-Format Backups”.

By default, `mysqldump` writes information as SQL statements to the standard output. You can save the output in a file:

```
shell> mysqldump [arguments] > file_name
```

To dump all databases, invoke `mysqldump` with the `--all-databases` option:

```
shell> mysqldump --all-databases > dump.sql
```

To dump only specific databases, name them on the command line and use the `--databases` option:

```
shell> mysqldump --databases db1 db2 db3 > dump.sql
```

The `--databases` option causes all names on the command line to be treated as database names. Without this option, `mysqldump` treats the first name as a database name and those following as table names.

With `--all-databases` or `--databases`, `mysqldump` writes `CREATE DATABASE` and `USE` statements prior to the dump output for each database. This ensures that when the dump file is reloaded, it creates each database if it does not exist and makes it the default database so database contents are loaded into the same database from which they came. If you want to cause the dump file to force a drop of each database before recreating it, use the `--add-drop-database` option as well. In this case, `mysqldump` writes a `DROP DATABASE` statement preceding each `CREATE DATABASE` statement.

To dump a single database, name it on the command line:

```
shell> mysqldump --databases test > dump.sql
```

In the single-database case, it is permissible to omit the `--databases` option:

```
shell> mysqldump test > dump.sql
```

The difference between the two preceding commands is that without `--databases`, the dump output contains no `CREATE DATABASE` or `USE` statements. This has several implications:

- When you reload the dump file, you must specify a default database name so that the server knows which database to reload.
- For reloading, you can specify a database name different from the original name, which enables you to reload the data into a different database.
- If the database to be reloaded does not exist, you must create it first.
- Because the output will contain no `CREATE DATABASE` statement, the `--add-drop-database` option has no effect. If you use it, it produces no `DROP DATABASE` statement.

To dump only specific tables from a database, name them on the command line following the database name:

```
shell> mysqldump test t1 t3 t7 > dump.sql
```

7.4.2 Reloading SQL-Format Backups

To reload a dump file written by `mysqldump` that consists of SQL statements, use it as input to the `mysql` client. If the dump file was created by `mysqldump` with the `--all-databases` or `--databases` option, it contains `CREATE DATABASE` and `USE` statements and it is not necessary to specify a default database into which to load the data:

```
shell> mysql < dump.sql
```

Alternatively, from within `mysql`, use a `source` command:

```
mysql> source dump.sql
```

If the file is a single-database dump not containing `CREATE DATABASE` and `USE` statements, create the database first (if necessary):

```
shell> mysqladmin create db1
```

Then specify the database name when you load the dump file:

```
shell> mysql db1 < dump.sql
```

Alternatively, from within `mysql`, create the database, select it as the default database, and load the dump file:

```
mysql> CREATE DATABASE IF NOT EXISTS db1;
mysql> USE db1;
mysql> source dump.sql
```

7.4.3 Dumping Data in Delimited-Text Format with `mysqldump`

This section describes how to use `mysqldump` to create delimited-text dump files. For information about reloading such dump files, see [Section 7.4.4, “Reloading Delimited-Text Format Backups”](#).

If you invoke `mysqldump` with the `--tab=dir_name` option, it uses `dir_name` as the output directory and dumps tables individually in that directory using two files for each table. The table name is the basename for these files. For a table named `t1`, the files are named `t1.sql` and `t1.txt`. The `.sql` file contains a `CREATE TABLE` statement for the table. The `.txt` file contains the table data, one line per table row.

The following command dumps the contents of the `db1` database to files in the `/tmp` database:

```
shell> mysqldump --tab=/tmp db1
```

The `.txt` files containing table data are written by the server, so they are owned by the system account used for running the server. The server uses `SELECT ... INTO OUTFILE` to write the files, so you must have the `FILE` privilege to perform this operation, and an error occurs if a given `.txt` file already exists.

The server sends the `CREATE` definitions for dumped tables to `mysqldump`, which writes them to `.sql` files. These files therefore are owned by the user who executes `mysqldump`.

It is best that `--tab` be used only for dumping a local server. If you use it with a remote server, the `--tab` directory must exist on both the local and remote hosts, and the `.txt` files will be written by the server in the remote directory (on the server host), whereas the `.sql` files will be written by `mysqldump` in the local directory (on the client host).

For `mysqldump --tab`, the server by default writes table data to `.txt` files one line per row with tabs between column values, no quotation marks around column values, and newline as the line terminator. (These are the same defaults as for `SELECT ... INTO OUTFILE`.)

To enable data files to be written using a different format, `mysqldump` supports these options:

- `--fields-terminated-by=str`

The string for separating column values (default: tab).

- `--fields-enclosed-by=char`

The character within which to enclose column values (default: no character).

- `--fields-optionally-enclosed-by=char`

The character within which to enclose non-numeric column values (default: no character).

- `--fields-escaped-by=char`

The character for escaping special characters (default: no escaping).

- `--lines-terminated-by=str`

The line-termination string (default: newline).

Depending on the value you specify for any of these options, it might be necessary on the command line to quote or escape the value appropriately for your command interpreter. Alternatively, specify the value using hex notation. Suppose that you want `mysqldump` to quote column values within double quotation marks. To do so, specify double quote as the value for the `--fields-enclosed-by` option. But this character is often special to command interpreters and must be treated specially. For example, on Unix, you can quote the double quote like this:

```
--fields-enclosed-by='"'
```

On any platform, you can specify the value in hex:

```
--fields-enclosed-by=0x22
```

It is common to use several of the data-formatting options together. For example, to dump tables in comma-separated values format with lines terminated by carriage-return/newline pairs (`\r\n`), use this command (enter it on a single line):

```
shell> mysqldump --tab=/tmp --fields-terminated-by=,
        --fields-enclosed-by='"' --lines-terminated-by=0x0d0a db1
```

Should you use any of the data-formatting options to dump table data, you will need to specify the same format when you reload data files later, to ensure proper interpretation of the file contents.

7.4.4 Reloading Delimited-Text Format Backups

For backups produced with `mysqldump --tab`, each table is represented in the output directory by an `.sql` file containing the `CREATE TABLE` statement for the table, and a `.txt` file containing the table data. To reload a table, first change location into the output directory. Then process the `.sql` file with `mysql` to create an empty table and process the `.txt` file to load the data into the table:

```
shell> mysql db1 < t1.sql
shell> mysqlimport db1 t1.txt
```

An alternative to using `mysqlimport` to load the data file is to use the `LOAD DATA INFILE` statement from within the `mysql` client:

```
mysql> USE db1;
mysql> LOAD DATA INFILE 't1.txt' INTO TABLE t1;
```

If you used any data-formatting options with `mysqldump` when you initially dumped the table, you must use the same options with `mysqlimport` or `LOAD DATA INFILE` to ensure proper interpretation of the data file contents:

```
shell> mysqlimport --fields-terminated-by=,
        --fields-enclosed-by='"' --lines-terminated-by=0x0d0a db1 t1.txt
```

Or:

```
mysql> USE db1;
mysql> LOAD DATA INFILE 't1.txt' INTO TABLE t1
```

```
-> FIELDS TERMINATED BY ',' FIELDS ENCLOSED BY ''  
-> LINES TERMINATED BY '\r\n';
```

7.4.5 **mysqldump** Tips

This section surveys techniques that enable you to use **mysqldump** to solve specific problems:

- How to make a copy a database
- How to copy a database from one server to another
- How to dump stored programs (stored procedures and functions, triggers, and events)
- How to dump definitions and data separately

7.4.5.1 Making a Copy of a Database

```
shell> mysqldump db1 > dump.sql  
shell> mysqladmin create db2  
shell> mysql db2 < dump.sql
```

Do not use **--databases** on the **mysqldump** command line because that causes **USE db1** to be included in the dump file, which overrides the effect of naming **db2** on the **mysql** command line.

7.4.5.2 Copy a Database from one Server to Another

On Server 1:

```
shell> mysqldump --databases db1 > dump.sql
```

Copy the dump file from Server 1 to Server 2.

On Server 2:

```
shell> mysql < dump.sql
```

Use of **--databases** with the **mysqldump** command line causes the dump file to include **CREATE DATABASE** and **USE** statements that create the database if it does exist and make it the default database for the reloaded data.

Alternatively, you can omit **--databases** from the **mysqldump** command. Then you will need to create the database on Server 2 (if necessary) and specify it as the default database when you reload the dump file.

On Server 1:

```
shell> mysqldump db1 > dump.sql
```

On Server 2:

```
shell> mysqladmin create db1  
shell> mysql db1 < dump.sql
```

You can specify a different database name in this case, so omitting **--databases** from the **mysqldump** command enables you to dump data from one database and load it into another.

7.4.5.3 Dumping Stored Programs

Several options control how `mysqldump` handles stored programs (stored procedures and functions, triggers, and events):

- `--events`: Dump Event Scheduler events
- `--routines`: Dump stored procedures and functions
- `--triggers`: Dump triggers for tables

The `--triggers` option is enabled by default so that when tables are dumped, they are accompanied by any triggers they have. The other options are disabled by default and must be specified explicitly to dump the corresponding objects. To disable any of these options explicitly, use its skip form: `--skip-events`, `--skip-routines`, or `--skip-triggers`.

7.4.5.4 Dumping Table Definitions and Content Separately

The `--no-data` option tells `mysqldump` not to dump table data, resulting in the dump file containing only statements to create the tables. Conversely, the `--no-create-info` option tells `mysqldump` to suppress `CREATE` statements from the output, so that the dump file contains only table data.

For example, to dump table definitions and data separately for the `test` database, use these commands:

```
shell> mysqldump --no-data test > dump-defs.sql
shell> mysqldump --no-create-info test > dump-data.sql
```

For a definition-only dump, add the `--routines` and `--events` options to also include stored routine and event definitions:

```
shell> mysqldump --no-data --routines --events test > dump-defs.sql
```

7.4.5.5 Using `mysqldump` to Test for Upgrade Incompatibilities

When contemplating a MySQL upgrade, it is prudent to install the newer version separately from your current production version. Then you can dump the database and database object definitions from the production server and load them into the new server to verify that they are handled properly. (This is also useful for testing downgrades.)

On the production server:

```
shell> mysqldump --all-databases --no-data --routines --events > dump-defs.sql
```

On the upgraded server:

```
shell> mysql < dump-defs.sql
```

Because the dump file does not contain table data, it can be processed quickly. This enables you to spot potential incompatibilities without waiting for lengthy data-loading operations. Look for warnings or errors while the dump file is being processed.

After you have verified that the definitions are handled properly, dump the data and try to load it into the upgraded server.

On the production server:

```
shell> mysqldump --all-databases --no-create-info > dump-data.sql
```

On the upgraded server:

```
shell> mysql < dump-data.sql
```

Now check the table contents and run some test queries.

7.5 Point-in-Time (Incremental) Recovery Using the Binary Log

Point-in-time recovery refers to recovery of data changes made since a given point in time. Typically, this type of recovery is performed after restoring a full backup that brings the server to its state as of the time the backup was made. (The full backup can be made in several ways, such as those listed in [Section 7.2, “Database Backup Methods”](#).) Point-in-time recovery then brings the server up to date incrementally from the time of the full backup to a more recent time.

Point-in-time recovery is based on these principles:

- The source of information for point-in-time recovery is the set of incremental backups represented by the binary log files generated subsequent to the full backup operation. Therefore, the server must be started with the `--log-bin` option to enable binary logging (see [Section 5.2.4, “The Binary Log”](#)).

To restore data from the binary log, you must know the name and location of the current binary log files. By default, the server creates binary log files in the data directory, but a path name can be specified with the `--log-bin` option to place the files in a different location. [Section 5.2.4, “The Binary Log”](#).

To see a listing of all binary log files, use this statement:

```
mysql> SHOW BINARY LOGS;
```

To determine the name of the current binary log file, issue the following statement:

```
mysql> SHOW MASTER STATUS;
```

- The `mysqlbinlog` utility converts the events in the binary log files from binary format to text so that they can be executed or viewed. `mysqlbinlog` has options for selecting sections of the binary log based on event times or position of events within the log. See [Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”](#).
- Executing events from the binary log causes the data modifications they represent to be redone. This enables recovery of data changes for a given span of time. To execute events from the binary log, process `mysqlbinlog` output using the `mysql` client:

```
shell> mysqlbinlog binlog_files | mysql -u root -p
```

- Viewing log contents can be useful when you need to determine event times or positions to select partial log contents prior to executing events. To view events from the log, send `mysqlbinlog` output into a paging program:

```
shell> mysqlbinlog binlog_files | more
```

Alternatively, save the output in a file and view the file in a text editor:

```
shell> mysqlbinlog binlog_files > tmpfile
shell> ... edit tmpfile ...
```

- Saving the output in a file is useful as a preliminary to executing the log contents with certain events removed, such as an accidental `DROP DATABASE`. You can delete from the file any statements not to be executed before executing its contents. After editing the file, execute the contents as follows:

```
shell> mysql -u root -p < tmpfile
```

If you have more than one binary log to execute on the MySQL server, the safe method is to process them all using a single connection to the server. Here is an example that demonstrates what may be *unsafe*:

```
shell> mysqlbinlog binlog.000001 | mysql -u root -p # DANGER!!
shell> mysqlbinlog binlog.000002 | mysql -u root -p # DANGER!!
```

Processing binary logs this way using different connections to the server causes problems if the first log file contains a `CREATE TEMPORARY TABLE` statement and the second log contains a statement that uses the temporary table. When the first `mysql` process terminates, the server drops the temporary table. When the second `mysql` process attempts to use the table, the server reports “unknown table.”

To avoid problems like this, use a *single* connection to execute the contents of all binary logs that you want to process. Here is one way to do so:

```
shell> mysqlbinlog binlog.000001 binlog.000002 | mysql -u root -p
```

Another approach is to write all the logs to a single file and then process the file:

```
shell> mysqlbinlog binlog.000001 > /tmp/statements.sql
shell> mysqlbinlog binlog.000002 >> /tmp/statements.sql
shell> mysql -u root -p -e "source /tmp/statements.sql"
```

7.5.1 Point-in-Time Recovery Using Event Times

To indicate the start and end times for recovery, specify the `--start-datetime` and `--stop-datetime` options for `mysqlbinlog`, in `DATETIME` format. As an example, suppose that exactly at 10:00 a.m. on April 20, 2005 an SQL statement was executed that deleted a large table. To restore the table and data, you could restore the previous night's backup, and then execute the following command:

```
shell> mysqlbinlog --stop-datetime="2005-04-20 9:59:59" \
/var/log/mysql/bin.123456 | mysql -u root -p
```

This command recovers all of the data up until the date and time given by the `--stop-datetime` option. If you did not detect the erroneous SQL statement that was entered until hours later, you will probably also want to recover the activity that occurred afterward. Based on this, you could run `mysqlbinlog` again with a start date and time, like so:

```
shell> mysqlbinlog --start-datetime="2005-04-20 10:01:00" \
/var/log/mysql/bin.123456 | mysql -u root -p
```

In this command, the SQL statements logged from 10:01 a.m. on will be re-executed. The combination of restoring of the previous night's dump file and the two `mysqlbinlog` commands restores everything up until one second before 10:00 a.m. and everything from 10:01 a.m. on.

To use this method of point-in-time recovery, you should examine the log to be sure of the exact times to specify for the commands. To display the log file contents without executing them, use this command:

```
shell> mysqlbinlog /var/log/mysql/bin.123456 > /tmp/mysql_restore.sql
```

Then open the `/tmp/mysql_restore.sql` file with a text editor to examine it.

Excluding specific changes by specifying times for `mysqlbinlog` does not work well if multiple statements executed at the same time as the one to be excluded.

7.5.2 Point-in-Time Recovery Using Event Positions

Instead of specifying dates and times, the `--start-position` and `--stop-position` options for `mysqlbinlog` can be used for specifying log positions. They work the same as the start and stop date options, except that you specify log position numbers rather than dates. Using positions may enable you to be more precise about which part of the log to recover, especially if many transactions occurred around the same time as a damaging SQL statement. To determine the position numbers, run `mysqlbinlog` for a range of times near the time when the unwanted transaction was executed, but redirect the results to a text file for examination. This can be done like so:

```
shell> mysqlbinlog --start-datetime="2005-04-20 9:55:00" \  
--stop-datetime="2005-04-20 10:05:00" \  
/var/log/mysql/bin.123456 > /tmp/mysql_restore.sql
```

This command creates a small text file in the `/tmp` directory that contains the SQL statements around the time that the deleterious SQL statement was executed. Open this file with a text editor and look for the statement that you do not want to repeat. Determine the positions in the binary log for stopping and resuming the recovery and make note of them. Positions are labeled as `log_pos` followed by a number. After restoring the previous backup file, use the position numbers to process the binary log file. For example, you would use commands something like these:

```
shell> mysqlbinlog --stop-position=368312 /var/log/mysql/bin.123456 \  
| mysql -u root -p  
  
shell> mysqlbinlog --start-position=368315 /var/log/mysql/bin.123456 \  
| mysql -u root -p
```

The first command recovers all the transactions up until the stop position given. The second command recovers all transactions from the starting position given until the end of the binary log. Because the output of `mysqlbinlog` includes `SET TIMESTAMP` statements before each SQL statement recorded, the recovered data and related MySQL logs will reflect the original times at which the transactions were executed.

7.6 MyISAM Table Maintenance and Crash Recovery

This section discusses how to use `myisamchk` to check or repair MyISAM tables (tables that have `.MYD` and `.MYI` files for storing data and indexes). For general `myisamchk` background, see [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#). Other table-repair information can be found at [Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”](#).

You can use `myisamchk` to check, repair, or optimize database tables. The following sections describe how to perform these operations and how to set up a table maintenance schedule. For information about using `myisamchk` to get information about your tables, see [Section 4.6.3.5, “Obtaining Table Information with myisamchk”](#).

Even though table repair with `myisamchk` is quite secure, it is always a good idea to make a backup *before* doing a repair or any maintenance operation that could make a lot of changes to a table.

`myisamchk` operations that affect indexes can cause `FULLTEXT` indexes to be rebuilt with full-text parameters that are incompatible with the values used by the MySQL server. To avoid this problem, follow the guidelines in [Section 4.6.3.1, “myisamchk General Options”](#).

`MyISAM` table maintenance can also be done using the SQL statements that perform operations similar to what `myisamchk` can do:

- To check `MyISAM` tables, use `CHECK TABLE`.
- To repair `MyISAM` tables, use `REPAIR TABLE`.
- To optimize `MyISAM` tables, use `OPTIMIZE TABLE`.
- To analyze `MyISAM` tables, use `ANALYZE TABLE`.

For additional information about these statements, see [Section 13.7.2, “Table Maintenance Statements”](#).

These statements can be used directly or by means of the `mysqlcheck` client program. One advantage of these statements over `myisamchk` is that the server does all the work. With `myisamchk`, you must make sure that the server does not use the tables at the same time so that there is no unwanted interaction between `myisamchk` and the server.

7.6.1 Using `myisamchk` for Crash Recovery

This section describes how to check for and deal with data corruption in MySQL databases. If your tables become corrupted frequently, you should try to find the reason why. See [Section B.5.4.2, “What to Do If MySQL Keeps Crashing”](#).

For an explanation of how `MyISAM` tables can become corrupted, see [Section 15.3.4, “MyISAM Table Problems”](#).

If you run `mysqld` with external locking disabled (which is the default), you cannot reliably use `myisamchk` to check a table when `mysqld` is using the same table. If you can be certain that no one will access the tables through `mysqld` while you run `myisamchk`, you only have to execute `mysqladmin flush-tables` before you start checking the tables. If you cannot guarantee this, you must stop `mysqld` while you check the tables. If you run `myisamchk` to check tables that `mysqld` is updating at the same time, you may get a warning that a table is corrupt even when it is not.

If the server is run with external locking enabled, you can use `myisamchk` to check tables at any time. In this case, if the server tries to update a table that `myisamchk` is using, the server will wait for `myisamchk` to finish before it continues.

If you use `myisamchk` to repair or optimize tables, you *must* always ensure that the `mysqld` server is not using the table (this also applies if external locking is disabled). If you do not stop `mysqld`, you should at least do a `mysqladmin flush-tables` before you run `myisamchk`. Your tables *may become corrupted* if the server and `myisamchk` access the tables simultaneously.

When performing crash recovery, it is important to understand that each `MyISAM` table `tbl_name` in a database corresponds to the three files in the database directory shown in the following table.

File	Purpose
<code>tbl_name.frm</code>	Definition (format) file
<code>tbl_name.MYD</code>	Data file
<code>tbl_name.MYI</code>	Index file

Each of these three file types is subject to corruption in various ways, but problems occur most often in data files and index files.

`myisamchk` works by creating a copy of the `.MYD` data file row by row. It ends the repair stage by removing the old `.MYD` file and renaming the new file to the original file name. If you use `--quick`, `myisamchk` does not create a temporary `.MYD` file, but instead assumes that the `.MYD` file is correct and generates only a new index file without touching the `.MYD` file. This is safe, because `myisamchk` automatically detects whether the `.MYD` file is corrupt and aborts the repair if it is. You can also specify the `--quick` option twice to `myisamchk`. In this case, `myisamchk` does not abort on some errors (such as duplicate-key errors) but instead tries to resolve them by modifying the `.MYD` file. Normally the use of two `--quick` options is useful only if you have too little free disk space to perform a normal repair. In this case, you should at least make a backup of the table before running `myisamchk`.

7.6.2 How to Check **MyISAM** Tables for Errors

To check a **MyISAM** table, use the following commands:

- `myisamchk tbl_name`

This finds 99.99% of all errors. What it cannot find is corruption that involves *only* the data file (which is very unusual). If you want to check a table, you should normally run `myisamchk` without options or with the `-s` (silent) option.

- `myisamchk -m tbl_name`

This finds 99.999% of all errors. It first checks all index entries for errors and then reads through all rows. It calculates a checksum for all key values in the rows and verifies that the checksum matches the checksum for the keys in the index tree.

- `myisamchk -e tbl_name`

This does a complete and thorough check of all data (`-e` means “extended check”). It does a check-read of every key for each row to verify that they indeed point to the correct row. This may take a long time for a large table that has many indexes. Normally, `myisamchk` stops after the first error it finds. If you want to obtain more information, you can add the `-v` (verbose) option. This causes `myisamchk` to keep going, up through a maximum of 20 errors.

- `myisamchk -e -i tbl_name`

This is like the previous command, but the `-i` option tells `myisamchk` to print additional statistical information.

In most cases, a simple `myisamchk` command with no arguments other than the table name is sufficient to check a table.

7.6.3 How to Repair **MyISAM** Tables

The discussion in this section describes how to use `myisamchk` on **MyISAM** tables (extensions `.MYI` and `.MYD`).

You can also use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair **MyISAM** tables. See [Section 13.7.2.2, “CHECK TABLE Syntax”](#), and [Section 13.7.2.5, “REPAIR TABLE Syntax”](#).

Symptoms of corrupted tables include queries that abort unexpectedly and observable errors such as these:

- `tbl_name.frm` is locked against change

- Can't find file `tbl_name.MYI` (Errcode: `nnn`)
- Unexpected end of file
- Record file is crashed
- Got error `nnn` from table handler

To get more information about the error, run `pererror nnn`, where `nnn` is the error number. The following example shows how to use `pererror` to find the meanings for the most common error numbers that indicate a problem with a table:

```
shell> pererror 126 127 132 134 135 136 141 144 145
MySQL error code 126 = Index file is crashed
MySQL error code 127 = Record-file is crashed
MySQL error code 132 = Old database file
MySQL error code 134 = Record was already deleted (or record file crashed)
MySQL error code 135 = No more room in record file
MySQL error code 136 = No more room in index file
MySQL error code 141 = Duplicate unique key or constraint on write or update
MySQL error code 144 = Table is crashed and last repair failed
MySQL error code 145 = Table was marked as crashed and should be repaired
```

Note that error 135 (no more room in record file) and error 136 (no more room in index file) are not errors that can be fixed by a simple repair. In this case, you must use `ALTER TABLE` to increase the `MAX_ROWS` and `AVG_ROW_LENGTH` table option values:

```
ALTER TABLE tbl_name MAX_ROWS=xxx AVG_ROW_LENGTH=yyy;
```

If you do not know the current table option values, use `SHOW CREATE TABLE`.

For the other errors, you must repair your tables. `myisamchk` can usually detect and fix most problems that occur.

The repair process involves up to four stages, described here. Before you begin, you should change location to the database directory and check the permissions of the table files. On Unix, make sure that they are readable by the user that `mysqld` runs as (and to you, because you need to access the files you are checking). If it turns out you need to modify files, they must also be writable by you.

This section is for the cases where a table check fails (such as those described in [Section 7.6.2, “How to Check MyISAM Tables for Errors”](#)), or you want to use the extended features that `myisamchk` provides.

The `myisamchk` options used for table maintenance with are described in [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#). `myisamchk` also has variables that you can set to control memory allocation that may improve performance. See [Section 4.6.3.6, “myisamchk Memory Usage”](#).

If you are going to repair a table from the command line, you must first stop the `mysqld` server. Note that when you do `mysqladmin shutdown` on a remote server, the `mysqld` server is still available for a while after `mysqladmin` returns, until all statement-processing has stopped and all index changes have been flushed to disk.

Stage 1: Checking your tables

Run `myisamchk *.MYI` or `myisamchk -e *.MYI` if you have more time. Use the `-s` (silent) option to suppress unnecessary information.

If the `mysqld` server is stopped, you should use the `--update-state` option to tell `myisamchk` to mark the table as “checked.”

You have to repair only those tables for which `myisamchk` announces an error. For such tables, proceed to Stage 2.

If you get unexpected errors when checking (such as `out of memory` errors), or if `myisamchk` crashes, go to Stage 3.

Stage 2: Easy safe repair

First, try `myisamchk -r -q tbl_name` (`-r -q` means “quick recovery mode”). This attempts to repair the index file without touching the data file. If the data file contains everything that it should and the delete links point at the correct locations within the data file, this should work, and the table is fixed. Start repairing the next table. Otherwise, use the following procedure:

1. Make a backup of the data file before continuing.
2. Use `myisamchk -r tbl_name` (`-r` means “recovery mode”). This removes incorrect rows and deleted rows from the data file and reconstructs the index file.
3. If the preceding step fails, use `myisamchk --safe-recover tbl_name`. Safe recovery mode uses an old recovery method that handles a few cases that regular recovery mode does not (but is slower).

Note

If you want a repair operation to go much faster, you should set the values of the `sort_buffer_size` and `key_buffer_size` variables each to about 25% of your available memory when running `myisamchk`.

If you get unexpected errors when repairing (such as `out of memory` errors), or if `myisamchk` crashes, go to Stage 3.

Stage 3: Difficult repair

You should reach this stage only if the first 16KB block in the index file is destroyed or contains incorrect information, or if the index file is missing. In this case, it is necessary to create a new index file. Do so as follows:

1. Move the data file to a safe place.
2. Use the table description file to create new (empty) data and index files:

```
shell> mysql db_name
mysql> SET autocommit=1;
mysql> TRUNCATE TABLE tbl_name;
mysql> quit
```

3. Copy the old data file back onto the newly created data file. (Do not just move the old file back onto the new file. You want to retain a copy in case something goes wrong.)

Important

If you are using replication, you should stop it prior to performing the above procedure, since it involves file system operations, and these are not logged by MySQL.

Go back to Stage 2. `myisamchk -r -q` should work. (This should not be an endless loop.)

You can also use the `REPAIR TABLE tbl_name USE_FRM` SQL statement, which performs the whole procedure automatically. There is also no possibility of unwanted interaction between a utility and the

server, because the server does all the work when you use `REPAIR TABLE`. See [Section 13.7.2.5, “REPAIR TABLE Syntax”](#).

Stage 4: Very difficult repair

You should reach this stage only if the `.frm` description file has also crashed. That should never happen, because the description file is not changed after the table is created:

1. Restore the description file from a backup and go back to Stage 3. You can also restore the index file and go back to Stage 2. In the latter case, you should start with `myisamchk -r`.
2. If you do not have a backup but know exactly how the table was created, create a copy of the table in another database. Remove the new data file, and then move the `.frm` description and `.MYI` index files from the other database to your crashed database. This gives you new description and index files, but leaves the `.MYD` data file alone. Go back to Stage 2 and attempt to reconstruct the index file.

7.6.4 MyISAM Table Optimization

To coalesce fragmented rows and eliminate wasted space that results from deleting or updating rows, run `myisamchk` in recovery mode:

```
shell> myisamchk -r tbl_name
```

You can optimize a table in the same way by using the `OPTIMIZE TABLE` SQL statement. `OPTIMIZE TABLE` does a table repair and a key analysis, and also sorts the index tree so that key lookups are faster. There is also no possibility of unwanted interaction between a utility and the server, because the server does all the work when you use `OPTIMIZE TABLE`. See [Section 13.7.2.4, “OPTIMIZE TABLE Syntax”](#).

`myisamchk` has a number of other options that you can use to improve the performance of a table:

- `--analyze` or `-a`: Perform key distribution analysis. This improves join performance by enabling the join optimizer to better choose the order in which to join the tables and which indexes it should use.
- `--sort-index` or `-S`: Sort the index blocks. This optimizes seeks and makes table scans that use indexes faster.
- `--sort-records=index_num` or `-R index_num`: Sort data rows according to a given index. This makes your data much more localized and may speed up range-based `SELECT` and `ORDER BY` operations that use this index.

For a full description of all available options, see [Section 4.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#).

7.6.5 Setting Up a MyISAM Table Maintenance Schedule

It is a good idea to perform table checks on a regular basis rather than waiting for problems to occur. One way to check and repair MyISAM tables is with the `CHECK TABLE` and `REPAIR TABLE` statements. See [Section 13.7.2, “Table Maintenance Statements”](#).

Another way to check tables is to use `myisamchk`. For maintenance purposes, you can use `myisamchk -s`. The `-s` option (short for `--silent`) causes `myisamchk` to run in silent mode, printing messages only when errors occur.

It is also a good idea to enable automatic MyISAM table checking. For example, whenever the machine has done a restart in the middle of an update, you usually need to check each table that could have been affected before it is used further. (These are “expected crashed tables.”) To cause the server to check

[MyISAM](#) tables automatically, start it with the `--myisam-recover-options` option. See [Section 5.1.3, “Server Command Options”](#).

You should also check your tables regularly during normal system operation. For example, you can run a [cron](#) job to check important tables once a week, using a line like this in a [crontab](#) file:

```
35 0 * * 0 /path/to/myisamchk --fast --silent /path/to/datadir/*/*.MYI
```

This prints out information about crashed tables so that you can examine and repair them as necessary.

To start with, execute `myisamchk -s` each night on all tables that have been updated during the last 24 hours. As you see that problems occur infrequently, you can back off the checking frequency to once a week or so.

Normally, MySQL tables need little maintenance. If you are performing many updates to [MyISAM](#) tables with dynamic-sized rows (tables with [VARCHAR](#), [BLOB](#), or [TEXT](#) columns) or have tables with many deleted rows you may want to defragment/reclaim space from the tables from time to time. You can do this by using [OPTIMIZE TABLE](#) on the tables in question. Alternatively, if you can stop the `mysqld` server for a while, change location into the data directory and use this command while the server is stopped:

```
shell> myisamchk -r -s --sort-index --myisam_sort_buffer_size=16M /*/*.MYI
```

Chapter 8 Optimization

8.5.4 Bulk Data Loading for <code>InnoDB</code> Tables	907
8.5.5 Optimizing <code>InnoDB</code> Queries	908
8.5.6 Optimizing <code>InnoDB</code> DDL Operations	909
8.5.7 Optimizing <code>InnoDB</code> Disk I/O	909
8.5.8 Optimizing <code>InnoDB</code> Configuration Variables	910
8.5.9 Optimizing <code>InnoDB</code> for Systems with Many Tables	911
8.6 Optimizing for <code>MyISAM</code> Tables	911
8.6.1 Optimizing <code>MyISAM</code> Queries	911
8.6.2 Bulk Data Loading for <code>MyISAM</code> Tables	913
8.6.3 Speed of <code>REPAIR TABLE</code> Statements	914
8.7 Optimizing for <code>MEMORY</code> Tables	916
8.8 Understanding the Query Execution Plan	916
8.8.1 Optimizing Queries with <code>EXPLAIN</code>	916
8.8.2 <code>EXPLAIN</code> Output Format	917
8.8.3 <code>EXPLAIN EXTENDED</code> Output Format	928
8.8.4 Estimating Query Performance	929
8.8.5 Controlling the Query Optimizer	929
8.9 Buffering and Caching	932
8.9.1 The <code>InnoDB</code> Buffer Pool	932
8.9.2 The <code>MyISAM</code> Key Cache	935
8.9.3 The MySQL Query Cache	939
8.10 Optimizing Locking Operations	945
8.10.1 Internal Locking Methods	946

8.10.2 Table Locking Issues	948
8.10.3 Concurrent Inserts	949
8.10.4 Metadata Locking	950
8.10.5 External Locking	951
8.11 Optimizing the MySQL Server	952
8.11.1 System Factors and Startup Parameter Tuning	952
8.11.2 Tuning Server Parameters	952
8.11.3 Optimizing Disk I/O	959
8.11.4 Optimizing Memory Use	963
8.11.5 Optimizing Network Use	967
8.11.6 The Thread Pool Plugin	969
8.12 Measuring Performance (Benchmarking)	975
8.12.1 Measuring the Speed of Expressions and Functions	975
8.12.2 The MySQL Benchmark Suite	975
8.12.3 Using Your Own Benchmarks	976
8.12.4 Measuring Performance with performance_schema	977
8.12.5 Examining Thread Information	977

This chapter explains how to optimize MySQL performance and provides examples. Optimization involves configuring, tuning, and measuring performance, at several levels. Depending on your job role (developer, DBA, or a combination of both), you might optimize at the level of individual SQL statements, entire applications, a single database server, or multiple networked database servers. Sometimes you can be proactive and plan in advance for performance, while other times you might troubleshoot a configuration or code issue after a problem occurs. Optimizing CPU and memory usage can also improve scalability, allowing the database to handle more load without slowing down.

8.1 Optimization Overview

Database performance depends on several factors at the database level, such as tables, queries, and configuration settings. These software constructs result in CPU and I/O operations at the hardware level, which you must minimize and make as efficient as possible. As you work on database performance, you start by learning the high-level rules and guidelines for the software side, and measuring performance using wall-clock time. As you become an expert, you learn more about what happens internally, and start measuring things such as CPU cycles and I/O operations.

Typical users aim to get the best database performance out of their existing software and hardware configurations. Advanced users look for opportunities to improve the MySQL software itself, or develop their own storage engines and hardware appliances to expand the MySQL ecosystem.

Optimizing at the Database Level

The most important factor in making a database application fast is its basic design:

- Are the tables structured properly? In particular, do the columns have the right data types, and does each table have the appropriate columns for the type of work? For example, applications that perform frequent updates often have many tables with few columns, while applications that analyze large amounts of data often have few tables with many columns.
