Notice that @x is 3 after the procedure executes, which shows that execution continued to the end of the procedure after the error occurred. If the DECLARE ... HANDLER statement had not been present, MySQL would have taken the default action (EXIT) after the second INSERT failed due to the PRIMARY KEY constraint, and SELECT @x would have returned 2.

To ignore a condition, declare a CONTINUE handler for it and associate it with an empty block. For example:

DECLARE CONTINUE HANDLER FOR SQLWARNING BEGIN END;

The scope of a block label does not include the code for handlers declared within the block. Therefore, the statement associated with a handler cannot use ITERATE or LEAVE to refer to labels for blocks that enclose the handler declaration. Consider the following example, where the REPEAT block has a label of retry:

CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 3;
  retry:
    REPEAT
      DECLARE CONTINUE HANDLER FOR SQLWARNING
      BEGIN
        BEGIN
          ITERATE retry;  # illegal
        END;
        IF i < 0 THEN
          LEAVE retry;  # legal
        END IF;
        SET i = i - 1;
      END;
    UNTIL FALSE END REPEAT;
END;

The retry label is in scope for the IF statement within the block. It is not in scope for the CONTINUE handler, so the reference there is invalid and results in an error:

ERROR 1308 (42000): LEAVE with no matching label: retry

To avoid references to outer labels in handlers, use one of these strategies:

• To leave the block, use an EXIT handler. If no block cleanup is required, the BEGIN ... END handler body can be empty:

DECLARE EXIT HANDLER FOR SQLWARNING BEGIN END;

Otherwise, put the cleanup statements in the handler body:
DECLARE EXIT HANDLER FOR SQLWARNING
BEGIN
  block cleanup statements
END;

• To continue execution, set a status variable in a CONTINUE handler that can be checked in the enclosing block to determine whether the handler was invoked. The following example uses the variable done for this purpose:

CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 3;
  DECLARE done INT DEFAULT FALSE;
  retry:
  REPEAT
    BEGIN
      DECLARE CONTINUE HANDLER FOR SQLWARNING
      BEGIN
        SET done = TRUE;
      END;
      IF done OR i < 0 THEN
        LEAVE retry;
      END IF;
      SET i = i - 1;
    END;
    UNTIL FALSE END REPEAT;
END;

13.6.7.3 RESIGNAL Syntax

RESIGNAL [condition_value]
  [SET signal_information_item
   [, signal_information_item] ...]

condition_value:
  SQLSTATE [VALUE] sqlstate_value
  | condition_name

signal_information_item:
  condition_information_item_name = simple_value_specification

condition_information_item_name:
  CLASS_ORIGIN
  | SUBCLASS_ORIGIN
  | MESSAGE_TEXT
  | MYSQL_ERRNO
  | CONSTRAINT_CATALOG
  | CONSTRAINT_SCHEMA
  | CONSTRAINT_NAME
  | CATALOG_NAME
  | SCHEMA_NAME
  | TABLE_NAME
  | COLUMN_NAME
  | CURSOR_NAME

condition_name, simple_value_specification:
  (see following discussion)

RESIGNAL passes on the error condition information that is available during execution of a condition handler within a compound statement inside a stored procedure or function, trigger, or event. RESIGNAL may change some or all information before passing it on. RESIGNAL is related to SIGNAL, but instead of originating a condition as SIGNAL does, RESIGNAL relays existing condition information, possibly after modifying it.
**RESIGNAL** makes it possible to both handle an error and return the error information. Otherwise, by executing an SQL statement within the handler, information that caused the handler's activation is destroyed. **RESIGNAL** also can make some procedures shorter if a given handler can handle part of a situation, then pass the condition “up the line” to another handler.

No special privileges are required to execute the **RESIGNAL** statement.

All forms of **RESIGNAL** require that the current context be a condition handler. Otherwise, **RESIGNAL** is illegal and a **RESIGNAL when handler not active** error occurs.

For **condition_value** and **signal_information_item**, the definitions and rules are the same for **RESIGNAL** as for **SIGNAL**. For example, the **condition_value** can be an **SQLSTATE** value, and the value can indicate errors, warnings, or “not found.” For additional information, see Section 13.6.7.4, “**SIGNAL Syntax**”.

The **RESIGNAL** statement takes **condition_value** and **SET** clauses, both of which are optional. This leads to several possible uses:

- **RESIGNAL** alone:

  ```
  RESIGNAL;
  ```

- **RESIGNAL** with new signal information:

  ```
  RESIGNAL SET signal_information_item [, signal_information_item] ...;
  ```

- **RESIGNAL** with a condition value and possibly new signal information:

  ```
  RESIGNAL condition_value [SET signal_information_item [, signal_information_item] ...];
  ```

These use cases all cause changes to the diagnostics and condition areas:

- A diagnostics area contains one or more condition areas.

- A condition area contains condition information items, such as the **SQLSTATE** value, **MYSQL_ERRNO**, or **MESSAGE_TEXT**.

The maximum number of condition areas in a diagnostics area is determined by the value of the **max_error_count** system variable.

**RESIGNAL** Alone

A simple **RESIGNAL** alone means “pass on the error with no change.” It restores the last diagnostics area and makes it the current diagnostics area. That is, it “pops” the diagnostics area stack.

Within a condition handler that catches a condition, one use for **RESIGNAL** alone is to perform some other actions, and then pass on without change the original condition information (the information that existed before entry into the handler).

Example:

```sql
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
```
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SET @error_count = @error_count + 1;
    IF @a = 0 THEN RESIGNAL; END IF;
  END;
  DROP TABLE xx;
END/
delimiter ;
SET @error_count = 0;
SET @a = 0;
CALL p();

Suppose that the DROP TABLE xx statement fails. The diagnostics area stack looks like this:

DA 1. ERROR 1051 (42S02): Unknown table 'xx'

Then execution enters the EXIT handler. It starts by pushing a diagnostics area to the top of the stack, which now looks like this:

DA 1. ERROR 1051 (42S02): Unknown table 'xx'
DA 2. ERROR 1051 (42S02): Unknown table 'xx'

Usually a procedure statement clears the first diagnostics area (also called the “current” diagnostics area). BEGIN is an exception, it does not clear, it does nothing. SET is not an exception, it clears, performs the operation, and produces a result of “success.” The diagnostics area stack now looks like this:

DA 1. ERROR 0000 (00000): Successful operation
DA 2. ERROR 1051 (42S02): Unknown table 'xx'

At this point, if @a = 0, RESIGNAL pops the diagnostics area stack, which now looks like this:

DA 1. ERROR 1051 (42S02): Unknown table 'xx'

And that is what the caller sees.

If @a is not 0, the handler simply ends, which means that there is no more use for the current diagnostics area (it has been "handled"), so it can be thrown away, causing the stacked diagnostics area to become the current diagnostics area again. The diagnostics area stack looks like this:

DA 1. ERROR 0000 (00000): Successful operation

The details make it look complex, but the end result is quite useful: Handlers can execute without destroying information about the condition that caused activation of the handler.

RESIGNAL with New Signal Information

RESIGNAL with a SET clause provides new signal information, so the statement means “pass on the error with changes”:

RESIGNAL SET signal_information_item [, signal_information_item] ...

As with RESIGNAL alone, the idea is to pop the diagnostics area stack so that the original information will go out. Unlike RESIGNAL alone, anything specified in the SET clause changes.

Example:
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SET @error_count = @error_count + 1;
    IF @a = 0 THEN RESIGNAL SET MYSQL_ERRNO = 5; END IF;
  END;
  DROP TABLE xx;
END;
delimiter ;
SET @error_count = 0;
SET @a = 0;
CALL p();

Remember from the previous discussion that RESIGNAL alone results in a diagnostics area stack like this:

DA 1. ERROR 1051 (42S02): Unknown table 'xx'

The RESIGNAL SET MYSQL_ERRNO = 5 statement results in this stack instead, which is what the caller sees:

DA 1. ERROR 5 (42S02): Unknown table 'xx'

In other words, it changes the error number, and nothing else.

The RESIGNAL statement can change any or all of the signal information items, making the first condition area of the diagnostics area look quite different.

**RESIGNAL with a Condition Value and Optional New Signal Information**

RESIGNAL with a condition value means “push a condition into the current diagnostics area.” If the SET clause is present, it also changes the error information.

RESIGNAL condition_value
  [SET signal_information_item [, signal_information_item] ...];

This form of RESIGNAL restores the last diagnostics area and makes it the current diagnostics area. That is, it “pops” the diagnostics area stack, which is the same as what a simple RESIGNAL alone would do. However, it also changes the diagnostics area depending on the condition value or signal information.

Example:

DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SET @error_count = @error_count + 1;
    IF @a = 0 THEN RESIGNAL SQLSTATE '45000' SET MYSQL_ERRNO=5; END IF;
  END;
  DROP TABLE xx;
END;
delimiter ;
SET @error_count = 0;
SET @a = 0;
SET @@max_error_count = 2;
CALL p();
SHOW ERRORS;

This is similar to the previous example, and the effects are the same, except that if RESIGNAL happens, the current condition area looks different at the end. (The reason the condition adds to rather than replaces the existing condition is the use of a condition value.)

The RESIGNAL statement includes a condition value (SQLSTATE '45000'), so it adds a new condition area, resulting in a diagnostics area stack that looks like this:

DA 1. (condition 2) ERROR 1051 (42S02): Unknown table 'xx'
   (condition 1) ERROR 5 (45000) Unknown table 'xx'

The result of CALL p() and SHOW ERRORS for this example is:

mysql> CALL p();
ERROR 5 (45000): Unknown table 'xx'
mysql> SHOW ERRORS;
+-------+------+----------------------------------+
| Level | Code | Message                          |
+-------+------+----------------------------------+
| Error | 1051 | Unknown table 'xx'               |
| Error |    5 | Unknown table 'xx'               |
+-------+------+----------------------------------+

RESIGNAL Requires Condition Handler Context

All forms of RESIGNAL require that the current context be a condition handler. Otherwise, RESIGNAL is illegal and a RESIGNAL when handler not active error occurs. For example:

mysql> CREATE PROCEDURE p () RESIGNAL;
Query OK, 0 rows affected (0.00 sec)

mysql> CALL p();
ERROR 1645 (0K000): RESIGNAL when handler not active

Here is a more difficult example:

delimiter //
CREATE FUNCTION f () RETURNS INT
BEGIN
   RESIGNAL;
   RETURN 5;
END;//
CREATE PROCEDURE p ()
BEGIN
   DECLARE EXIT HANDLER FOR SQLEXCEPTION SET @a=f();
   SIGNAL SQLSTATE '55555';
END;//
delimiter ;
CALL p();

RESIGNAL occurs within the stored function f(), which is invoked from within the EXIT handler. Thus, a handler is active at the time RESIGNAL executes, even though RESIGNAL is not defined inside the handler.

13.6.7.4 SIGNAL Syntax
**SIGNAL** <condition_value> [SET <signal_information_item>, <signal_information_item>] ...]

**condition_value:**
- SQLSTATE [VALUE] sqlstate_value
- condition_name

**signal_information_item:**
- condition_information_item_name = simple_value_specification

**condition_information_item_name:**
- CLASS_ORIGIN
- SUBCLASS_ORIGIN
- MESSAGE_TEXT
- MYSQL_ERRNO
- CONSTRAINT_CATALOG
- CONSTRAINT_SCHEMA
- CONSTRAINT_NAME
- CATALOG_NAME
- SCHEMA_NAME
- TABLE_NAME
- COLUMN_NAME
- CURSOR_NAME

**condition_name, simple_value_specification:**
(see following discussion)

**SIGNAL** is the way to "return" an error. **SIGNAL** provides error information to a handler, to an outer portion of the application, or to the client. Also, it provides control over the error's characteristics (error number, SQLSTATE value, message). Without **SIGNAL**, it is necessary to resort to workarounds such as deliberately referring to a nonexistent table to cause a routine to return an error.

No special privileges are required to execute the **SIGNAL** statement.

The **condition_value** in a **SIGNAL** statement indicates the error value to be returned. It can be an SQLSTATE value (a 5-character string literal) or a **condition_name** that refers to a named condition previously defined with **DECLARE ... CONDITION** (see Section 13.6.7.1, "**DECLARE ... CONDITION Syntax").

An SQLSTATE value can indicate errors, warnings, or "not found." The first two characters of the value indicate its error class, as discussed in **Signal Condition Information Items**. Some signal values cause statement termination; see Effect of Signals on Handlers, Cursors, and Statements.

The SQLSTATE value for a **SIGNAL** statement should not start with '00' because such values indicate success and are not valid for signaling an error. This is true whether the SQLSTATE value is specified directly in the **SIGNAL** statement or in a named condition referred to in the statement. If the value is invalid, a Bad SQLSTATE error occurs.

To signal a generic SQLSTATE value, use '45000', which means "unhandled user-defined exception."

The **SIGNAL** statement optionally includes a **SET** clause that contains multiple signal items, in a comma-separated list of **condition_information_item_name = simple_value_specification** assignments.

Each **condition_information_item_name** may be specified only once in the **SET** clause. Otherwise, a Duplicate condition information item error occurs.

Valid simple_value_specification designators can be specified using stored procedure or function parameters, stored program local variables declared with **DECLARE**, user-defined variables, system variables, or literals. A character literal may include a _charset introducer.
Condition Handling

For information about permissible condition information item values, see Signal Condition Information Items.

The following procedure signals an error or warning depending on the value of `pval`, its input parameter:

```sql
CREATE PROCEDURE p (pval INT)
BEGIN
  DECLARE specialty CONDITION FOR SQLSTATE '45000';
  IF pval = 0 THEN
    SIGNAL SQLSTATE '01000';
  ELSEIF pval = 1 THEN
    SIGNAL SQLSTATE '45000'
    SET MESSAGE_TEXT = 'An error occurred';
  ELSEIF pval = 2 THEN
    SIGNAL specialty
    SET MESSAGE_TEXT = 'An error occurred';
  ELSE
    SIGNAL SQLSTATE '01000'
    SET MESSAGE_TEXT = 'An error occurred', MYSQL_ERRNO = 1000;
    SIGNAL SQLSTATE '45000'
    SET MESSAGE_TEXT = 'An error occurred', MYSQL_ERRNO = 1001;
  END IF;
END;
```

If `pval` is 0, `p()` signals a warning because SQLSTATE values that begin with '01' are signals in the warning class. The warning does not terminate the procedure, and can be seen with `SHOW WARNINGS` after the procedure returns.

If `pval` is 1, `p()` signals an error and sets the MESSAGE_TEXT condition information item. The error terminates the procedure, and the text is returned with the error information.

If `pval` is 2, the same error is signaled, although the SQLSTATE value is specified using a named condition in this case.

If `pval` is anything else, `p()` first signals a warning and sets the message text and error number condition information items. This warning does not terminate the procedure, so execution continues and `p()` then signals an error. The error does terminate the procedure. The message text and error number set by the warning are replaced by the values set by the error, which are returned with the error information.

`SIGNAL` is typically used within stored programs, but it is a MySQL extension that it is permitted outside handler context. For example, if you invoke the `mysql` client program, you can enter any of these statements at the prompt:

```sql
mysql> SIGNAL SQLSTATE '77777';
mysql> CREATE TRIGGER t_bi BEFORE INSERT ON t
    -> FOR EACH ROW SIGNAL SQLSTATE '77777';
mysql> CREATE EVENT e ON SCHEDULE EVERY 1 SECOND
    -> DO SIGNAL SQLSTATE '77777';
```

`SIGNAL` executes according to the following rules:

If the `SIGNAL` statement indicates a particular SQLSTATE value, that value is used to signal the condition specified. Example:

```sql
CREATE PROCEDURE p (divisor INT)
BEGIN
  IF divisor = 0 THEN
    SIGNAL SQLSTATE '22012';
  END IF;
END;
```
If the `SIGNAL` statement uses a named condition, the condition must be declared in some scope that applies to the `SIGNAL` statement, and must be defined using an `SQLSTATE` value, not a MySQL error number. Example:

```sql
CREATE PROCEDURE p (divisor INT)
BEGIN
    DECLARE divide_by_zero CONDITION FOR SQLSTATE '22012';
    IF divisor = 0 THEN
        SIGNAL divide_by_zero;
    END IF;
END;
```

If the named condition does not exist in the scope of the `SIGNAL` statement, an **Undefined CONDITION** error occurs.

If `SIGNAL` refers to a named condition that is defined with a MySQL error number rather than an `SQLSTATE` value, a `SIGNAL/RESIGNAL` can only use a `CONDITION` defined with `SQLSTATE` error occurs. The following statements cause that error because the named condition is associated with a MySQL error number:

```sql
DECLARE no_such_table CONDITION FOR 1051;
SIGNAL no_such_table;
```

If a condition with a given name is declared multiple times in different scopes, the declaration with the most local scope applies. Consider the following procedure:

```sql
CREATE PROCEDURE p (divisor INT)
BEGIN
    DECLARE my_error CONDITION FOR SQLSTATE '45000';
    IF divisor = 0 THEN
        BEGIN
            DECLARE my_error CONDITION FOR SQLSTATE '22012';
            SIGNAL my_error;
        END;
    END IF;
    SIGNAL my_error;
END;
```

If `divisor` is 0, the first `SIGNAL` statement executes. The innermost `my_error` condition declaration applies, raising `SQLSTATE '22012'`.

If `divisor` is not 0, the second `SIGNAL` statement executes. The outermost `my_error` condition declaration applies, raising `SQLSTATE '45000'`.

Signals can be raised within exception handlers:

```sql
CREATE PROCEDURE p ()
BEGIN
    DECLARE EXIT HANDLER FOR SQLEXCEPTION
    BEGIN
        SIGNAL SQLSTATE VALUE '99999'
        SET MESSAGE_TEXT = 'An error occurred';
    END;
    DROP TABLE no_such_table;
END;
```
CALL p() reaches the DROP TABLE statement. There is no table named no_such_table, so the error handler is activated. The error handler destroys the original error ("no such table") and makes a new error with SQLSTATE '99999' and message An error occurred.

Signal Condition Information Items

The following table lists the names of diagnostics area condition information items that can be set in a SIGNAL (or RESIGNAL) statement. All items are standard SQL except MYSQL_ERRNO, which is a MySQL extension.

<table>
<thead>
<tr>
<th>Item Name</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLASS_ORIGIN</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>SUBCLASS_ORIGIN</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>CONSTRAINT_CATALOG</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>CONSTRAINT_SCHEMA</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>CONSTRAINT_NAME</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>CATALOG_NAME</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>CURSOR_NAME</td>
<td>VARCHAR(64)</td>
</tr>
<tr>
<td>MESSAGE_TEXT</td>
<td>VARCHAR(128)</td>
</tr>
<tr>
<td>MYSQL_ERRNO</td>
<td>SMALLINT UNSIGNED</td>
</tr>
</tbody>
</table>

The character set for character items is UTF-8.

It is illegal to assign NULL to a condition information item in a SIGNAL statement.

A SIGNAL statement always specifies an SQLSTATE value, either directly, or indirectly by referring to a named condition defined with an SQLSTATE value. The first two characters of an SQLSTATE value are its class, and the class determines the default value for the condition information items:

- **Class = '00' (success)**
  
  Illegal. SQLSTATE values that begin with '00' indicate success and are not valid for SIGNAL.

- **Class = '01' (warning)**

  MESSAGE_TEXT = 'Unhandled user-defined warning condition';
  MYSQL_ERRNO = ER_SIGNAL_WARN

- **Class = '02' (not found)**

  MESSAGE_TEXT = 'Unhandled user-defined not found condition';
  MYSQL_ERRNO = ER_SIGNAL_NOT_FOUND

- **Class > '02' (exception)**

  MESSAGE_TEXT = 'Unhandled user-defined exception condition';
  MYSQL_ERRNO = ER_SIGNAL_EXCEPTION

For legal classes, the other condition information items are set as follows:

CLASS_ORIGIN = SUBCLASS_ORIGIN = '|
CONSTRAINT_CATALOG = CONSTRAINT_SCHEMA = CONSTRAINT_NAME = '|
CATALOG_NAME = SCHEMA_NAME = TABLE_NAME = COLUMN_NAME = '
CURSOR_NAME = '|

1532
The error values that are accessible after `SIGNAL` executes are the `SQLSTATE` value raised by the `SIGNAL` statement and the `MESSAGE_TEXT` and `MYSQL_ERRNO` items. These values are available from the C API:

- **SQLSTATE value**: Call `mysql_sqlstate()`
- **MYSQL_ERRNO value**: Call `mysql_errno()`
- **MESSAGE_TEXT value**: Call `mysql_error()`

From SQL, the output from `SHOW WARNINGS` and `SHOW ERRORS` indicates the `MYSQL_ERRNO` and `MESSAGE_TEXT` values in the `Code` and `Message` columns.

Other condition information items can be set, but currently have no effect, in the sense that they are not accessible from error returns. For example, you can set `CLASS_ORIGIN` in a `SIGNAL` statement, but cannot see it after `SIGNAL` executes. In MySQL 5.6, condition information can be inspected with the `GET DIAGNOSTICS` statement.

**Effect of Signals on Handlers, Cursors, and Statements**

Signals have different effects on statement execution depending on the signal class. The class determines how severe an error is. MySQL ignores the value of the `sql_mode` system variable; in particular, strict SQL mode does not matter. MySQL also ignores `IGNORE`: The intent of `SIGNAL` is to raise a user-generated error explicitly, so a signal is never ignored.

In the following descriptions, “unhandled” means that no handler for the signaled `SQLSTATE` value has been defined with `DECLARE ... HANDLER`.

- **Class = '00' (success)**
  
  Illegal. `SQLSTATE` values that begin with '00' indicate success and are not valid for `SIGNAL`.

- **Class = '01' (warning)**
  
  The value of the `warning_count` system variable goes up. `SHOW WARNINGS` shows the signal. `SQLWARNING` handlers catch the signal. If the signal is unhandled in a function, statements do not end.

- **Class = '02' (not found)**
  
  `NOT FOUND` handlers catch the signal. There is no effect on cursors. If the signal is unhandled in a function, statements end.

- **Class > '02' (exception)**
  
  `SQLEXCEPTION` handlers catch the signal. If the signal is unhandled in a function, statements end.

- **Class = '40'**
  
  Treated as an ordinary exception.

Example:

```sql
mysql> delimiter //
mysql> CREATE FUNCTION f () RETURNS INT
    -> BEGIN
    -> SIGNAL SQLSTATE '01234';  -- signal a warning
    -> RETURN 5;
    -> END//
mysql> delimiter ;
mysql> CREATE TABLE t (s1 INT);
```
13.7 Database Administration Statements

13.7.1 Account Management Statements

MySQL account information is stored in the tables of the mysql database. This database and the access control system are discussed extensively in Chapter 5, MySQL Server Administration, which you should consult for additional details.

Important

Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features. To make sure that you can take advantage of any new capabilities, update your grant tables to have the current structure whenever you update to a new version of MySQL. See Section 4.4.7, "mysql_upgrade — Check and Upgrade MySQL Tables".

13.7.1.1 CREATE USER Syntax

CREATE USER user_specification [, user_specification] ...

user_specification:
  user
    [ 
      IDENTIFIED WITH auth_plugin [AS 'auth_string']
      IDENTIFIED BY [PASSWORD] 'password'
    ]

The CREATE USER statement creates new MySQL accounts. An error occurs for accounts that already exist. To use this statement, you must have the global CREATE USER privilege or the INSERT privilege for the mysql database. For each account, CREATE USER creates a new row in the mysql.user table with no privileges and (as of MySQL 5.5.7) assigns the account an authentication plugin. Depending on the syntax used, CREATE USER may also assign the account a password.

Each user_specification clause consists of an account name and information about how authentication occurs for clients that use the account. This part of CREATE USER syntax is shared with GRANT, so the description here applies to GRANT as well.

Each account name uses the format described in Section 6.2.3, "Specifying Account Names". For example:

CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'mypass';

If you specify only the user name part of the account name, a host name part of '%' is used.

The server assigns an authentication plugin and password to each account as follows, depending on whether the user specification clause includes IDENTIFIED WITH to specify a plugin or IDENTIFIED BY to specify a password:

Note

IDENTIFIED WITH is available as of MySQL 5.5.7. Before 5.5.7, authentication plugins are not used, so only the remarks about IDENTIFIED BY apply.
Account Management Statements

- With **IDENTIFIED WITH**, the server assigns the specified plugin and the account has no password.
- With **IDENTIFIED BY**, the server assigns no plugin and assigns the specified password.
- With neither **IDENTIFIED WITH** nor **IDENTIFIED BY**, the server assigns no plugin and the account has no password.

If the account has no password, the **Password** column in the account's mysql.user table row remains empty, which is insecure. To set the password, use **SET PASSWORD**. See Section 13.7.1.6, "SET PASSWORD Syntax".

If the server assigns no plugin to the account, the **plugin** column in the account's mysql.user table row remains empty.

For client connections that use a given account, the server invokes the authentication plugin assigned to the account and the client must provide credentials as required by the authentication method that the plugin implements. If the server cannot find the plugin, either at account-creation time or connect time, an error occurs.

If an account's mysql.user table row has a nonempty **plugin** column:

- The server authenticates client connection attempts using the named plugin.

- Changes to the account password using **SET PASSWORD** with **PASSWORD()** must be made with the **old_passwords** system variable set to the value required by the authentication plugin, so that **PASSWORD()** uses the appropriate password hashing method. If the plugin is **mysql_old_password**, the password can also be changed using **SET PASSWORD** with **OLD_PASSWORD()**, which uses pre-4.1 password hashing regardless of the value of **old_passwords**.

If an account's mysql.user table row has an empty **plugin** column:

- The server authenticates client connection attempts using the **mysql_native_password** or **mysql_old_password** authentication plugin, depending on the hash format of the password stored in the **Password** column.

- Changes to the account password using **SET PASSWORD** can be made with **PASSWORD()**, with **old_passwords** set to 0 or 1 for 4.1 or pre-4.1 password hashing, respectively, or with **OLD_PASSWORD()**, which uses pre-4.1 password hashing regardless of the value of **old_passwords**.

**CREATE USER** examples:

- To specify an authentication plugin for an account, use **IDENTIFIED WITH auth_plugin**. The plugin name can be a quoted string literal or an unquoted name. 'auth_string' is an optional quoted string literal to pass to the plugin. The plugin interprets the meaning of the string, so its format is plugin specific. Consult the documentation for a given plugin for information about the authentication string values it accepts, if any.

  ```sql
  CREATE USER 'jeffrey'@'localhost' IDENTIFIED WITH mysql_native_password;
  ```

  The server assigns the given authentication plugin to the account but no password. Clients must provide no password when they connect. However, an account with no password is insecure. To ensure that an account uses a specific authentication plugin and has a password with the corresponding hash format, specify the plugin explicitly with **IDENTIFIED WITH**, then use **SET PASSWORD** to set the password:

  ```sql
  CREATE USER 'jeffrey'@'localhost' IDENTIFIED WITH mysql_native_password;
  SET old_passwords = 0;
  ```
SET PASSWORD FOR 'jeffrey'@'localhost' = PASSWORD('mypass');

Changes to the account password using SET PASSWORD with PASSWORD() must be made with the old_passwords system variable set to the value required by the account's authentication plugin, so that PASSWORD() uses the appropriate password hashing method. Therefore, to use the mysql_old_password plugin instead, name that plugin in the CREATE USER statement and set old_passwords to 1 before using SET PASSWORD.

- To specify a password for an account at account-creation time, use IDENTIFIED BY with the literal plaintext password value:

```sql
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'mypass';
```

The server assigns the given password to the account but no authentication plugin. Clients must provide the password when they connect.

- To avoid specifying the plaintext password if you know its hash value (the value that PASSWORD() would return for the password), specify the hash value preceded by the keyword PASSWORD:

```sql
CREATE USER 'jeffrey'@'localhost'
IDENTIFIED BY PASSWORD '*90E462C37378CED12064BB3388827D2BA3A9B689';
```

The server assigns the given password to the account but no authentication plugin. Clients must provide the password when they connect.

- To enable the user to connect with no password, include no IDENTIFIED BY clause:

```sql
CREATE USER 'jeffrey'@'localhost';
```

The server assigns no authentication plugin or password to the account. Clients must provide no password when they connect. However, an account with no password is insecure. To avoid this, use SET PASSWORD to set the account password.

For additional information about setting passwords and authentication plugins, see Section 6.3.5, “Assigning Account Passwords”, and Section 6.3.6, “Pluggable Authentication”.

**Important**

CREATE USER may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about password logging in the server logs, see Section 6.1.2.3, “Passwords and Logging”. For similar information about client-side logging, see Section 4.5.1.3, “mysql Logging”.

**Important**

Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features. To make sure that you can take advantage of any new capabilities, update your grant tables to have the current structure whenever you update to a new version of MySQL. See Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”.

### 13.7.1.2 DROP USER Syntax

```sql
DROP USER user [, user] ...`

The `DROP USER` statement removes one or more MySQL accounts and their privileges. It removes privilege rows for the account from all grant tables. An error occurs for accounts that do not exist. To use this statement, you must have the global `CREATE USER` privilege or the `DELETE` privilege for the `mysql` database.

Each account name uses the format described in Section 6.2.3, “Specifying Account Names”. For example:

```
DROP USER 'jeffrey'@'localhost';
```

If you specify only the user name part of the account name, a host name part of `'%` is used.

**Important**

`DROP USER` does not automatically close any open user sessions. Rather, in the event that a user with an open session is dropped, the statement does not take effect until that user's session is closed. Once the session is closed, the user is dropped, and that user's next attempt to log in will fail. *This is by design.*

`DROP USER` does not automatically drop or invalidate databases or objects within them that the old user created. This includes stored programs or views for which the `DEFINER` attribute names the dropped user. Attempts to access such objects may produce an error if they execute in definer security context. (For information about security context, see Section 20.6, “Access Control for Stored Programs and Views”.)

### 13.7.1.3 `GRANT` Syntax

```
GRANT
  `priv_type` {[`column_list`]}
  [, `priv_type` {[`column_list`]}] ... 
ON [`object_type`] `priv_level`
TO `user_specification` [, `user_specification`] ... 
  [REQUIRE {NONE | `ssl_option` [[AND] `ssl_option`] ...}]
  [WITH `with_option` ...]
GRANT PROXY ON `user_specification`
  TO `user_specification` [, `user_specification`] ... 
  [WITH GRANT OPTION]

`object_type`:
  `TABLE` | `FUNCTION` | `PROCEDURE`

`priv_level`:
  `*`
  `*.*`
  `db_name.*`
  `db_name.tbl_name`
  `tbl_name`
  `db_name.routine_name`

`user_specification`:
  `user`
  [ `IDENTIFIED WITH `auth_plugin` [AS `auth_string'`]
    `IDENTIFIED BY [PASSWORD] `password'
  ]

`ssl_option`:
  `SSL`
  `X509`
  `CIPHER `cipher`
```
The `GRANT` statement grants privileges to MySQL user accounts. `GRANT` also serves to specify other account characteristics such as use of secure connections and limits on access to server resources. To use `GRANT`, you must have the `GRANT OPTION` privilege, and you must have the privileges that you are granting.

Normally, a database administrator first uses `CREATE USER` to create an account, then `GRANT` to define its privileges and characteristics. For example:

```sql
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'mypass';
GRANT ALL ON db1.* TO 'jeffrey'@'localhost';
GRANT SELECT ON db2.invoice TO 'jeffrey'@'localhost';
GRANT USAGE ON *.* TO 'jeffrey'@'localhost' WITH MAX_QUERIES_PER_HOUR 90;
```

However, if an account named in a `GRANT` statement does not already exist, `GRANT` may create it under the conditions described later in the discussion of the `NO_AUTO_CREATE_USER` SQL mode.

The `REVOKE` statement is related to `GRANT` and enables administrators to remove account privileges. See Section 13.7.1.5, "REVOKE Syntax".

When successfully executed from the `mysql` program, `GRANT` responds with `Query OK, 0 rows affected`. To determine what privileges result from the operation, use `SHOW GRANTS`. See Section 13.7.5.22, "SHOW GRANTS Syntax".

There are several aspects to the `GRANT` statement, described under the following topics in this section:

- **Privileges Supported by MySQL**
- **Global Privileges**
- **Database Privileges**
- **Table Privileges**
- **Column Privileges**
- **Stored Routine Privileges**
- **Proxy User Privileges**
- **Account Names and Passwords**
- **Other Account Characteristics**
- **MySQL and Standard SQL Versions of `GRANT`**

**Important**

Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features. To make sure that you can take advantage of any new capabilities, update your grant tables to have the current structure whenever
you update to a new version of MySQL. See Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”.

### Privileges Supported by MySQL

The following table summarizes the permissible `priv_type` privilege types that can be specified for the `GRANT` and `REVOKE` statements, and the levels at which each privilege can be granted. For additional information about these privileges, see Section 6.2.1, “Privileges Provided by MySQL”.

#### Table 13.1 Permissible Privileges for `GRANT` and `REVOKE`

<table>
<thead>
<tr>
<th>Privilege</th>
<th>Meaning and Grantable Levels</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ALL [PRIVILEGES]</strong></td>
<td>Grant all privileges at specified access level except <code>GRANT OPTION</code></td>
</tr>
<tr>
<td><strong>ALTER</strong></td>
<td>Enable use of <code>ALTER TABLE</code>. Levels: Global, database, table.</td>
</tr>
<tr>
<td><strong>ALTER ROUTINE</strong></td>
<td>Enable stored routines to be altered or dropped. Levels: Global, database, procedure.</td>
</tr>
<tr>
<td><strong>CREATE</strong></td>
<td>Enable database and table creation. Levels: Global, database, table.</td>
</tr>
<tr>
<td><strong>CREATE ROUTINE</strong></td>
<td>Enable stored routine creation. Levels: Global, database.</td>
</tr>
<tr>
<td><strong>CREATE TABLESPACE</strong></td>
<td>Enable tablespaces and log file groups to be created, altered, or dropped. Level: Global.</td>
</tr>
<tr>
<td><strong>CREATE TEMPORARY TABLES</strong></td>
<td>Enable use of <code>CREATE TEMPORARY TABLE</code>. Levels: Global, database.</td>
</tr>
<tr>
<td><strong>CREATE USER</strong></td>
<td>Enable use of <code>CREATE USER, DROP USER, RENAME USER, and REVOKE ALL PRIVILEGES</code>. Level: Global</td>
</tr>
<tr>
<td><strong>CREATE VIEW</strong></td>
<td>Enable views to be created or altered. Levels: Global, database, table.</td>
</tr>
<tr>
<td><strong>DELETE</strong></td>
<td>Enable use of <code>DELETE</code>. Level: Global, database, table.</td>
</tr>
<tr>
<td><strong>DROP</strong></td>
<td>Enable databases, tables, and views to be dropped. Levels: Global, database, table.</td>
</tr>
<tr>
<td><strong>EVENT</strong></td>
<td>Enable use of events for the Event Scheduler. Levels: Global, database.</td>
</tr>
<tr>
<td><strong>EXECUTE</strong></td>
<td>Enable the user to execute stored routines. Levels: Global, database, table.</td>
</tr>
<tr>
<td><strong>FILE</strong></td>
<td>Enable the user to cause the server to read or write files. Level: Global.</td>
</tr>
<tr>
<td><strong>GRANT OPTION</strong></td>
<td>Enable privileges to be granted to or removed from other accounts. Levels: Global, database, table, procedure, proxy.</td>
</tr>
<tr>
<td><strong>INDEX</strong></td>
<td>Enable indexes to be created or dropped. Levels: Global, database, table.</td>
</tr>
<tr>
<td><strong>INSERT</strong></td>
<td>Enable use of <code>INSERT</code>. Levels: Global, database, table, column.</td>
</tr>
<tr>
<td><strong>LOCK TABLES</strong></td>
<td>Enable use of <code>LOCK TABLES</code> on tables for which you have the <code>SELECT</code> privilege. Levels: Global, database.</td>
</tr>
<tr>
<td><strong>PROCESS</strong></td>
<td>Enable the user to see all processes with <code>SHOW PROCESSLIST</code>. Level: Global.</td>
</tr>
<tr>
<td><strong>PROXY</strong></td>
<td>Enable user proxying. Level: From user to user.</td>
</tr>
<tr>
<td><strong>REFERENCES</strong></td>
<td>Not implemented</td>
</tr>
<tr>
<td><strong>RELOAD</strong></td>
<td>Enable use of <code>FLUSH</code> operations. Level: Global.</td>
</tr>
<tr>
<td><strong>REPLICATION CLIENT</strong></td>
<td>Enable the user to ask where master or slave servers are. Level: Global.</td>
</tr>
<tr>
<td><strong>REPLICATION SLAVE</strong></td>
<td>Enable replication slaves to read binary log events from the master. Level: Global.</td>
</tr>
</tbody>
</table>
Account Management Statements

<table>
<thead>
<tr>
<th>Privilege</th>
<th>Meaning and Grantable Levels</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT</td>
<td>Enable use of SELECT. Levels: Global, database, table, column.</td>
</tr>
<tr>
<td>SHOW DATABASES</td>
<td>Enable SHOW DATABASES to show all databases. Level: Global.</td>
</tr>
<tr>
<td>SHOW VIEW</td>
<td>Enable use of SHOW CREATE VIEW. Levels: Global, database, table.</td>
</tr>
<tr>
<td>SHUTDOWN</td>
<td>Enable use of mysqladmin shutdown. Level: Global.</td>
</tr>
<tr>
<td>SUPER</td>
<td>Enable use of other administrative operations such as CHANGE MASTER TO, KILL, PURGE BINARY LOGS, SET GLOBAL, and mysqladmin debug command. Level: Global.</td>
</tr>
<tr>
<td>TRIGGER</td>
<td>Enable trigger operations. Levels: Global, database, table.</td>
</tr>
<tr>
<td>UPDATE</td>
<td>Enable use of UPDATE. Levels: Global, database, table.</td>
</tr>
<tr>
<td>USAGE</td>
<td>Synonym for &quot;no privileges&quot;</td>
</tr>
</tbody>
</table>

The PROXY privilege was added in MySQL 5.5.7.

A trigger is associated with a table, so to create or drop a trigger, you must have the TRIGGER privilege for the table, not the trigger.

In GRANT statements, the ALL [PRIVILEGES] or PROXY privilege must be named by itself and cannot be specified along with other privileges. ALL [PRIVILEGES] stands for all privileges available for the level at which privileges are to be granted except for the GRANT OPTION and PROXY privileges.

USAGE can be specified to create a user that has no privileges, or to specify the REQUIRE or WITH clauses for an account without changing its existing privileges.

MySQL account information is stored in the tables of the mysql database. This database and the access control system are discussed extensively in Section 6.2, “The MySQL Access Privilege System”, which you should consult for additional details.

If the grant tables hold privilege rows that contain mixed-case database or table names and the lower_case_table_names system variable is set to a nonzero value, REVOKE cannot be used to revoke these privileges. It will be necessary to manipulate the grant tables directly. (GRANT will not create such rows when lower_case_table_names is set, but such rows might have been created prior to setting that variable.)

Privileges can be granted at several levels, depending on the syntax used for the ON clause. For REVOKE, the same ON syntax specifies which privileges to take away. The examples shown here include no IDENTIFIED BY 'password' clause for brevity, but you should include one if the account does not already exist, to avoid creating an insecure account that has no password.

**Global Privileges**

Global privileges are administrative or apply to all databases on a given server. To assign global privileges, use ON *.* syntax:

```sql
GRANT ALL ON *.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON *.* TO 'someuser'@'somehost';
```

The CREATE TABLESPACE, CREATE USER, FILE, PROCESS, RELOAD, REPLICATION CLIENT, REPLICATION SLAVE, SHOW DATABASES, SHUTDOWN, and SUPER privileges are administrative and can only be granted globally.

Other privileges can be granted globally or at more specific levels.
MySQL stores global privileges in the `mysql.user` table.

**Database Privileges**

Database privileges apply to all objects in a given database. To assign database-level privileges, use `ON db_name.*` syntax:

```
GRANT ALL ON mydb.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON mydb.* TO 'someuser'@'somehost';
```

If you use `ON *` syntax (rather than `ON *.*`) and you have selected a default database, privileges are assigned at the database level for the default database. An error occurs if there is no default database.

The `CREATE`, `DROP`, `EVENT`, `GRANT OPTION`, and `LOCK TABLES` privileges can be specified at the database level. Table or routine privileges also can be specified at the database level, in which case they apply to all tables or routines in the database.

MySQL stores database privileges in the `mysql.db` table.

**Table Privileges**

Table privileges apply to all columns in a given table. To assign table-level privileges, use `ON db_name.tbl_name` syntax:

```
GRANT ALL ON mydb.mytbl TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON mydb.mytbl TO 'someuser'@'somehost';
```

If you specify `tbl_name` rather than `db_name.tbl_name`, the statement applies to `tbl_name` in the default database. An error occurs if there is no default database.

The permissible `priv_type` values at the table level are `ALTER`, `CREATE VIEW`, `CREATE`, `DELETE`, `DROP`, `GRANT OPTION`, `INDEX`, `INSERT`, `SELECT`, `SHOW VIEW`, `TRIGGER`, and `UPDATE`.

MySQL stores table privileges in the `mysql.tables_priv` table.

**Column Privileges**

Column privileges apply to single columns in a given table. Each privilege to be granted at the column level must be followed by the column or columns, enclosed within parentheses.

```
GRANT SELECT (col1), INSERT (col1, col2) ON mydb.mytbl TO 'someuser'@'somehost';
```

The permissible `priv_type` values for a column (that is, when you use a `column_list` clause) are `INSERT`, `SELECT`, and `UPDATE`.

MySQL stores column privileges in the `mysql.columns_priv` table.

**Stored Routine Privileges**

The `ALTER ROUTINE`, `CREATE ROUTINE`, `EXECUTE`, and `GRANT OPTION` privileges apply to stored routines (procedures and functions). They can be granted at the global and database levels. Except for `CREATE ROUTINE`, these privileges can be granted at the routine level for individual routines.

```
GRANT CREATE ROUTINE ON mydb.* TO 'someuser'@'somehost';
GRANT EXECUTE ON PROCEDURE mydb.myproc TO 'someuser'@'somehost';
```
The permissible \texttt{priv_type} values at the routine level are \texttt{ALTER ROUTINE}, \texttt{EXECUTE}, and \texttt{GRANT OPTION}. \texttt{CREATE ROUTINE} is not a routine-level privilege because you must have this privilege to create a routine in the first place.

MySQL stores routine-level privileges in the \texttt{mysql.procs_priv} table.

**Proxy User Privileges**

The \texttt{PROXY} privilege enables one user to be a proxy for another. The proxy user impersonates or takes the identity of the proxied user.

\begin{verbatim}
GRANT PROXY ON 'localuser'@'localhost' TO 'externaluser'@'somehost';
\end{verbatim}

When \texttt{PROXY} is granted, it must be the only privilege named in the \texttt{GRANT} statement, the \texttt{REQUIRE} clause cannot be given, and the only permitted \texttt{WITH} option is \texttt{WITH GRANT OPTION}.

Proxying requires that the proxy user authenticate through a plugin that returns the name of the proxied user to the server when the proxy user connects, and that the proxy user have the \texttt{PROXY} privilege for the proxied user. For details and examples, see Section 6.3.8, “Proxy Users”.

MySQL stores proxy privileges in the \texttt{mysql.proxies_priv} table.

For the global, database, table, and routine levels, \texttt{GRANT ALL} assigns only the privileges that exist at the level you are granting. For example, \texttt{GRANT ALL ON db_name.*} is a database-level statement, so it does not grant any global-only privileges such as \texttt{FILE}. Granting \texttt{ALL} does not assign the \texttt{PROXY} privilege.

The \texttt{object_type} clause, if present, should be specified as \texttt{TABLE}, \texttt{FUNCTION}, or \texttt{PROCEDURE} when the following object is a table, a stored function, or a stored procedure.

The privileges for a database, table, column, or routine are formed additively as the logical \texttt{OR} of the privileges at each of the privilege levels. For example, if a user has a global \texttt{SELECT} privilege, the privilege cannot be denied by an absence of the privilege at the database, table, or column level. Details of the privilege-checking procedure are presented in Section 6.2.5, “Access Control, Stage 2: Request Verification”.

MySQL enables you to grant privileges on databases or tables that do not exist. For tables, the privileges to be granted must include the \texttt{CREATE} privilege. This behavior is by design, and is intended to enable the database administrator to prepare user accounts and privileges for databases or tables that are to be created at a later time.

\begin{center}
\textbf{Important}
\end{center}

\begin{quote}
\textit{MySQL does not automatically revoke any privileges when you drop a database or table.} However, if you drop a routine, any routine-level privileges granted for that routine are revoked.
\end{quote}

**Account Names and Passwords**

The \texttt{user} value indicates the MySQL account to which the \texttt{GRANT} statement applies. To accommodate granting rights to users from arbitrary hosts, MySQL supports specifying the \texttt{user} value in the form \texttt{user-name@host-name}. If a \texttt{user-name} or \texttt{host-name} value is legal as an unquoted identifier, you need not quote it. However, quotation marks are necessary to specify a \texttt{user-name} string containing special characters (such as \texttt{-}), or a \texttt{host-name} string containing special characters or wildcard characters (such as \texttt{\%}); for example, \texttt{'test-user'@'%.com'}. Quote the user name and host name separately.
You can specify wildcards in the host name. For example, `user_name@'%.example.com'` applies to `user_name` for any host in the `example.com` domain, and `user_name@'192.168.1.1'` applies to `user_name` for any host in the 192.168.1 class C subnet.

The simple form `user_name` is a synonym for `user_name@'%'`.

*MMySQL does not support wildcards in user names.* To refer to an anonymous user, specify an account with an empty user name with the `GRANT` statement:

```sql
GRANT ALL ON test.* TO ''@'localhost' ...
```

In this case, any user who connects from the local host with the correct password for the anonymous user will be permitted access, with the privileges associated with the anonymous-user account.

For additional information about user name and host name values in account names, see Section 6.2.3, “Specifying Account Names”.

To specify quoted values, quote database, table, column, and routine names as identifiers. Quote user names and host names as identifiers or as strings. Quote passwords as strings. For string-quoting and identifier-quoting guidelines, see Section 9.1.1, “String Literals”, and Section 9.2, “Schema Object Names”.

The `"_"` and `"%"` wildcards are permitted when specifying database names in `GRANT` statements that grant privileges at the global or database levels. This means, for example, that if you want to use a `"_"` character as part of a database name, you should specify it as `"\\"` in the `GRANT` statement, to prevent the user from being able to access additional databases matching the wildcard pattern; for example, `GRANT ... ON `foo\_bar`.* TO ...`

**Warning**

If you permit anonymous users to connect to the MySQL server, you should also grant privileges to all local users as `user_name@localhost`. Otherwise, the anonymous user account for `localhost` in the `mysql.user` table (created during MySQL installation) is used when named users try to log in to the MySQL server from the local machine. For details, see Section 6.2.4, “Access Control, Stage 1: Connection Verification”.

To determine whether the preceding warning applies to you, execute the following query, which lists any anonymous users:

```sql
SELECT Host, User FROM mysql.user WHERE User='';
```

To avoid the problem just described, delete the local anonymous user account using this statement:

```sql
DROP USER ''@'localhost';
```

`GRANT` supports host names up to 60 characters long. Database, table, column, and routine names can be up to 64 characters. User names can be up to 16 characters.

**Warning**

*The permissible length for user names cannot be changed by altering the `mysql.user` table. Attempting to do so results in unpredictable behavior which may even make it impossible for users to log in to the MySQL server.* You should never alter any of the tables in the `mysql` database in any manner whatsoever except by means of the procedure described in Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”.
To indicate how the user should authenticate when connecting to the server, the `user_specification` clause may include `IDENTIFIED WITH` to specify an authentication plugin or `IDENTIFIED BY` to specify a password. Syntax of the user specification is the same as for the `CREATE USER` statement. For details, see Section 13.7.1.1, “CREATE USER Syntax”.

When `IDENTIFIED BY` is present and you have the global grant privilege (`GRANT OPTION`), the password becomes the new password for the account, even if the account exists and already has a password. Without `IDENTIFIED BY`, the account password remains unchanged.

If an account named in a `GRANT` statement does not exist, the action taken depends on the `NO_AUTO_CREATE_USER` SQL mode:

- If `NO_AUTO_CREATE_USER` is not enabled, `GRANT` creates the account. *This is very insecure* unless you specify a nonempty password using `IDENTIFIED BY`.

- If `NO_AUTO_CREATE_USER` is enabled, `GRANT` fails and does not create the account, unless you specify a nonempty password using `IDENTIFIED BY` or name an authentication plugin using `IDENTIFIED WITH`.

**Important**

`GRANT` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about password logging in the server logs, see Section 6.1.2.3, “Passwords and Logging”. For similar information about client-side logging, see Section 4.5.1.3, “mysql Logging”.

**Other Account Characteristics**

The `WITH` clause is used for several purposes:

- To enable a user to grant privileges to other users
- To specify resource limits for a user
- To specify whether and how a user must use secure connections to the server

The `WITH GRANT OPTION` clause gives the user the ability to give to other users any privileges the user has at the specified privilege level. You should be careful to whom you give the `GRANT OPTION` privilege because two users with different privileges may be able to combine privileges!

You cannot grant another user a privilege which you yourself do not have; the `GRANT OPTION` privilege enables you to assign only those privileges which you yourself possess.

Be aware that when you grant a user the `GRANT OPTION` privilege at a particular privilege level, any privileges the user possesses (or may be given in the future) at that level can also be granted by that user to other users. Suppose that you grant a user the `INSERT` privilege on a database. If you then grant the `SELECT` privilege on the database and specify `WITH GRANT OPTION`, that user can give to other users not only the `SELECT` privilege, but also `INSERT`. If you then grant the `UPDATE` privilege to the user on the database, the user can grant `INSERT`, `SELECT`, and `UPDATE`.

For a nonadministrative user, you should not grant the `ALTER` privilege globally or for the `mysql` database. If you do that, the user can try to subvert the privilege system by renaming tables!

For additional information about security risks associated with particular privileges, see Section 6.2.1, “Privileges Provided by MySQL”.

1544
Several **WITH** clause options specify limits on use of server resources by an account:

- **The** `MAX_QUERIES_PER_HOUR count`, `MAX_UPDATES_PER_HOUR count`, and `MAX_CONNECTIONS_PER_HOUR count` limits restrict the number of queries, updates, and connections to the server permitted to this account during any given one-hour period. (Queries for which results are served from the query cache do not count against the `MAX_QUERIES_PER_HOUR` limit.) If `count` is 0 (the default), this means that there is no limitation for the account.

- **The** `MAX_USER_CONNECTIONS count` limit restricts the maximum number of simultaneous connections to the server by the account. A nonzero `count` specifies the limit for the account explicitly. If `count` is 0 (the default), the server determines the number of simultaneous connections for the account from the global value of the `max_user_connections` system variable. If `max_user_connections` is also zero, there is no limit for the account.

To specify resource limits for an existing user without affecting existing privileges, use **GRANT USAGE** at the global level (**ON** `*.*`) and name the limits to be changed. For example:

```
GRANT USAGE ON *.* TO ... 
  WITH MAX_QUERIES_PER_HOUR 500 MAX_UPDATES_PER_HOUR 100;
```

Limits not specified retain their current values.

For more information on restricting access to server resources, see [Section 6.3.4, “Setting Account Resource Limits”](#).

MySQL can check X509 certificate attributes in addition to the usual authentication that is based on the user name and password. To specify SSL-related options for a MySQL account, use the **REQUIRE** clause of the **GRANT** statement. (For background information on the use of SSL with MySQL, see [Section 6.3.9, “Using SSL for Secure Connections”](#).)

There are a number of different possibilities for limiting connection types for a given account:

- **REQUIRE NONE** indicates that the account has no SSL or X509 requirements. This is the default if no SSL-related **REQUIRE** options are specified. Unencrypted connections are permitted if the user name and password are valid. However, encrypted connections can also be used, at the client's option, if the client has the proper certificate and key files. That is, the client need not specify any SSL command options, in which case the connection will be unencrypted. To use an encrypted connection, the client must specify either the **--ssl-ca** option, or all three of the **--ssl-ca**, **--ssl-key**, and **--ssl-cert** options.

- **The** **REQUIRE SSL** option tells the server to permit only SSL-encrypted connections for the account.

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
  IDENTIFIED BY 'goodsecret' REQUIRE SSL;
```

To connect, the client must specify the **--ssl-ca** option to authenticate the server certificate, and may additionally specify the **--ssl-key** and **--ssl-cert** options. If neither **--ssl-ca** option nor **--ssl-capath** option is specified, the client does not authenticate the server certificate.

- **REQUIRE X509** means that the client must have a valid certificate but that the exact certificate, issuer, and subject do not matter. The only requirement is that it should be possible to verify its signature with one of the CA certificates.

```
GRANT ALL PRIVILEGES ON test.* TO 'root'@'localhost'
```
IDENTIFIED BY 'goodsecret' REQUIRE X509;

To connect, the client must specify the --ssl-ca, --ssl-key, and --ssl-cert options. This is also true for ISSUER and SUBJECT because those REQUIRE options imply X509.

- **REQUIRE ISSUER 'issuer'** places the restriction on connection attempts that the client must present a valid X509 certificate issued by CA 'issuer'. If the client presents a certificate that is valid but has a different issuer, the server rejects the connection. Use of X509 certificates always implies encryption, so the SSL option is unnecessary in this case.

```sql
GRANT ALL PRIVILEGES ON test.* TO 'root' '@'localhost'
IDENTIFIED BY 'goodsecret'
REQUIRE ISSUER '/C=FI/ST=Some-State/L=Helsinki/
O=MySQL Finland AB/CN=Tonu Samuel/emailAddress=tonu@example.com';
```

The 'issuer' value should be entered as a single string.

**Note**

If MySQL is linked against a version of OpenSSL older than 0.9.6h, use Email rather than emailAddress in the 'issuer' value.

- **REQUIRE SUBJECT 'subject'** places the restriction on connection attempts that the client must present a valid X509 certificate containing the subject subject. If the client presents a certificate that is valid but has a different subject, the server rejects the connection.

```sql
GRANT ALL PRIVILEGES ON test.* TO 'root' '@'localhost'
IDENTIFIED BY 'goodsecret'
REQUIRE SUBJECT '/C=EE/ST=Some-State/L=Tallinn/
O=MySQL demo client certificate/
CN=Tonu Samuel/emailAddress=tonu@example.com';
```

The 'subject' value should be entered as a single string. MySQL does a simple string comparison of this value to the value in the certificate, so lettercase and component ordering must be given exactly as present in the certificate.

**Note**

Regarding emailAddress, see the note in the description of REQUIRE ISSUER.

- **REQUIRE CIPHER 'cipher'** is needed to ensure that ciphers and key lengths of sufficient strength are used. SSL itself can be weak if old algorithms using short encryption keys are used. Using this option, you can ask that a specific cipher method is used for a connection.

```sql
GRANT ALL PRIVILEGES ON test.* TO 'root' '@'localhost'
IDENTIFIED BY 'goodsecret'
REQUIRE CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

The SUBJECT, ISSUER, and CIPHER options can be combined in the REQUIRE clause like this:

```sql
GRANT ALL PRIVILEGES ON test.* TO 'root' '@'localhost'
IDENTIFIED BY 'goodsecret'
REQUIRE SUBJECT '/C=EE/ST=Some-State/L=Tallinn/
O=MySQL demo client certificate/
CN=Tonu Samuel/emailAddress=tonu@example.com'
AND ISSUER '/C=FI/ST=Some-State/L=Helsinki/
O=MySQL Finland AB/CN=Tonu Samuel/emailAddress=tonu@example.com'
```
The order of the options does not matter, but no option can be specified twice. The AND keyword is optional between REQUIRE options.

If you are using table, column, or routine privileges for even one user, the server examines table, column, and routine privileges for all users and this slows down MySQL a bit. Similarly, if you limit the number of queries, updates, or connections for any users, the server must monitor these values.

MySQL and Standard SQL Versions of `GRANT`

The biggest differences between the MySQL and standard SQL versions of `GRANT` are:

- MySQL associates privileges with the combination of a host name and user name and not with only a user name.
- Standard SQL does not have global or database-level privileges, nor does it support all the privilege types that MySQL supports.
- MySQL does not support the standard SQL UNDER privilege.
- Standard SQL privileges are structured in a hierarchical manner. If you remove a user, all privileges the user has been granted are revoked. This is also true in MySQL if you use DROP USER. See Section 13.7.1.2, “DROP USER Syntax”.
- In standard SQL, when you drop a table, all privileges for the table are revoked. In standard SQL, when you revoke a privilege, all privileges that were granted based on that privilege are also revoked. In MySQL, privileges can be dropped only with explicit DROP USER or REVOKE statements or by manipulating the MySQL grant tables directly.
- In MySQL, it is possible to have the INSERT privilege for only some of the columns in a table. In this case, you can still execute INSERT statements on the table, provided that you insert values only for those columns for which you have the INSERT privilege. The omitted columns are set to their implicit default values if strict SQL mode is not enabled. In strict mode, the statement is rejected if any of the omitted columns have no default value. (Standard SQL requires you to have the INSERT privilege on all columns.) Section 5.1.7, “Server SQL Modes”, discusses strict mode. Section 11.6, “Data Type Default Values”, discusses implicit default values.

13.7.1.4 `RENAME USER` Syntax

```
RENAME USER old_user TO new_user
 [, old_user TO new_user] ...
```

The `RENAME USER` statement renames existing MySQL accounts. An error occurs for old accounts that do not exist or new accounts that already exist. To use this statement, you must have the global CREATE USER privilege or the UPDATE privilege for the mysql database.

Each account name uses the format described in Section 6.2.3, “Specifying Account Names”. For example:

```
RENAME USER 'jeffrey'@'localhost' TO 'jeff'@'127.0.0.1';
```

If you specify only the user name part of the account name, a host name part of ‘%’ is used.

`RENAME USER` causes the privileges held by the old user to be those held by the new user. However, `RENAME USER` does not automatically drop or invalidate databases or objects within them that the old user created. This includes stored programs or views for which the DEFINER attribute names the old user.
Attempts to access such objects may produce an error if they execute in definer security context. (For information about security context, see Section 20.6, “Access Control for Stored Programs and Views”.)

The privilege changes take effect as indicated in Section 6.2.6, “When Privilege Changes Take Effect”.

### 13.7.1.5 REVOKE Syntax

```plaintext
REVOKE
  priv_type [(column_list)]
  [, priv_type [(column_list)]] ...
ON [object_type] priv_level
FROM user [, user] ...

REVOKE ALL PRIVILEGES, GRANT OPTION
FROM user [, user] ...

REVOKE PROXY ON user
  FROM user [, user] ...
```

The `REVOKE` statement enables system administrators to revoke privileges from MySQL accounts. Each account name uses the format described in Section 6.2.3, “Specifying Account Names”. For example:

```sql
REVOKE INSERT ON *.* FROM 'jeffrey'@'localhost';
```

If you specify only the user name part of the account name, a host name part of '%' is used.

For details on the levels at which privileges exist, the permissible `priv_type` and `priv_level` values, and the syntax for specifying users and passwords, see Section 13.7.1.3, “GRANT Syntax”.

To use the first `REVOKE` syntax, you must have the `GRANT OPTION` privilege, and you must have the privileges that you are revoking.

To revoke all privileges, use the second syntax, which drops all global, database, table, column, and routine privileges for the named user or users:

```sql
REVOKE ALL PRIVILEGES, GRANT OPTION FROM user [, user] ...
```

To use this `REVOKE` syntax, you must have the global `CREATE USER` privilege or the `UPDATE` privilege for the `mysql` database.

`REVOKE` removes privileges, but does not drop `mysql.user` table entries. To remove a user account entirely, use `DROP USER` (see Section 13.7.1.2, “DROP USER Syntax”) or `DELETE`.

If the grant tables hold privilege rows that contain mixed-case database or table names and the `lower_case_table_names` system variable is set to a nonzero value, `REVOKE` cannot be used to revoke these privileges. It will be necessary to manipulate the grant tables directly. (`GRANT` will not create such rows when `lower_case_table_names` is set, but such rows might have been created prior to setting the variable.)

When successfully executed from the `mysql` program, `REVOKE` responds with `Query OK, 0 rows affected`. To determine what privileges result from the operation, use `SHOW GRANTS`. See Section 13.7.5.22, “SHOW GRANTS Syntax”.

### 13.7.1.6 SET PASSWORD Syntax
The `SET PASSWORD` statement assigns a password to a MySQL user account:

- With no `FOR user` clause, this statement sets the password for the current user:

  ```sql
  SET PASSWORD = PASSWORD('cleartext password');
  ```

  Any client who connects to the server using a nonanonymous account can change the password for that account. To see which account the server authenticated you for, invoke the `CURRENT_USER()` function:

  ```sql
  SELECT CURRENT_USER();
  ```

- With a `FOR user` clause, this statement sets the password for the named account, which must exist:

  ```sql
  SET PASSWORD FOR 'jeffrey'@'localhost' = PASSWORD('cleartext password');
  ```

  In this case, you must have the `UPDATE` privilege for the `mysql` database.

When the `read_only` system variable is enabled, `SET PASSWORD` requires the `SUPER` privilege, in addition to any other required privileges.

If a `FOR user` clause is given, the account name uses the format described in Section 6.2.3, “Specifying Account Names”. The `user` value should be given as `'user_name'@'host_name'`, where `'user_name'` and `'host_name'` are exactly as listed in the `User` and `Host` columns of the account's `mysql.user` table row. (If you specify only a user name, a host name of `%` is used.) For example, to set the password for an account with `User` and `Host` column values of 'bob' and '%.example.org', write the statement like this:

```sql
SET PASSWORD FOR 'bob'@'%.example.org' = PASSWORD('cleartext password');
```

The password can be specified in these ways:

- Using the `PASSWORD()` function

  The function argument is the cleartext (unencrypted) password. `PASSWORD()` hashes the password and returns the encrypted password string.

  The `old_passwords` system variable value determines the hashing method used by `PASSWORD()`. It should be set to a value compatible with the hash format required by the account authentication plugin. For example, if the account uses the `mysql_native_password` authentication plugin, `old_passwords` should be 0 for `PASSWORD()` to produce a hash value in the correct format. For `mysql_old_password`, `old_passwords` should be 1.

- Using the `OLD_PASSWORD()` function:

  The function argument is the cleartext (unencrypted) password. `OLD_PASSWORD()` hashes the password using pre-4.1 hashing and returns the encrypted password string. This hashing method is appropriate only for accounts that use the `mysql_old_password` authentication plugin.

- Using an already encrypted password string
The password is specified as a string literal. It must represent the already encrypted password value, in the hash format required by the authentication method used for the account.

The following table shows the permitted values of `old_passwords`, the password hashing method for each value, and which authentication plugins use passwords hashed with each method.

<table>
<thead>
<tr>
<th>Value</th>
<th>Password Hashing Method</th>
<th>Associated Authentication Plugin</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 or OFF</td>
<td>MySQL 4.1 native hashing</td>
<td>mysql_native_password</td>
</tr>
<tr>
<td>1 or ON</td>
<td>Pre-4.1 (“old”) hashing</td>
<td>mysql_old_password</td>
</tr>
</tbody>
</table>

For more information about setting passwords, see Section 6.3.5, “Assigning Account Passwords”

**Important**

`SET PASSWORD` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about password logging in the server logs, see Section 6.1.2.3, “Passwords and Logging”. For similar information about client-side logging, see Section 4.5.1.3, “mysql Logging”.

**Caution**

If you are connecting to a MySQL 4.1 or later server using a pre-4.1 client program, do not change your password without first reading Section 6.1.2.4, “Password Hashing in MySQL”. The default password hashing format changed in MySQL 4.1, and if you change your password, it might be stored using a hashing format that pre-4.1 clients cannot generate, thus preventing you from connecting to the server afterward.

If you are using MySQL Replication, be aware that, currently, a password used by a replication slave as part of a `CHANGE MASTER TO` statement is effectively limited to 32 characters in length; if the password is longer, any excess characters are truncated. This is not due to any limit imposed by the MySQL Server generally, but rather is an issue specific to MySQL Replication. (For more information, see Bug #43439.)

### 13.7.2 Table Maintenance Statements

#### 13.7.2.1 `ANALYZE TABLE` Syntax

```
ANALYZE [NO_WRITE_TO_BINLOG | LOCAL] TABLE
    tbl_name [, tbl_name] ...
```

`ANALYZE TABLE` analyzes and stores the key distribution for a table. During the analysis, the table is locked with a read lock for InnoDB and MyISAM. This statement works with InnoDB, NDB, and MyISAM tables. For MyISAM tables, this statement is equivalent to using `myisamchk --analyze`.

For more information on how the analysis works within InnoDB, see Section 14.16.15, “Configuring Optimizer Statistics Parameters”. Also see Section 14.16.16, “Estimating `ANALYZE TABLE` Complexity for InnoDB Tables” and Section 14.9.7, “Limits on InnoDB Tables”.

MySQL uses the stored key distribution to decide the order in which tables should be joined when you perform a join on something other than a constant. In addition, key distributions can be used when deciding which indexes to use for a specific table within a query.

This statement requires `SELECT` and `INSERT` privileges for the table.
**ANALYZE TABLE** is supported for partitioned tables, and you can use **ALTER TABLE ... ANALYZE PARTITION** to analyze one or more partitions; for more information, see Section 13.1.7, "ALTER TABLE Syntax", and Section 19.3.3, "Maintenance of Partitions".

**ANALYZE TABLE** returns a result set with the following columns.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td>Always analyze</td>
</tr>
<tr>
<td>Msg_type</td>
<td>status, error, info, note, or warning</td>
</tr>
<tr>
<td>Msg_text</td>
<td>An informational message</td>
</tr>
</tbody>
</table>

You can check the stored key distribution with the **SHOW INDEX** statement. See Section 13.7.5.23, "SHOW INDEX Syntax".

If the table has not changed since the last **ANALYZE TABLE** statement, the table is not analyzed again.

By default, the server writes **ANALYZE TABLE** statements to the binary log so that they replicate to replication slaves. To suppress logging, specify the optional **NO_WRITE_TO_BINLOG** keyword or its alias **LOCAL**.

### 13.7.2.2 CHECK TABLE Syntax

**CHECK TABLE** checks a table or tables for errors. **CHECK TABLE** works for **InnoDB**, **MyISAM**, **ARCHIVE**, and **CSV** tables. For **MyISAM** tables, the key statistics are updated as well.

To check a table, you must have some privilege for it.

**CHECK TABLE** can also check views for problems, such as tables that are referenced in the view definition that no longer exist.

**CHECK TABLE** is supported for partitioned tables, and you can use **ALTER TABLE ... CHECK PARTITION** to check one or more partitions; for more information, see Section 13.1.7, "ALTER TABLE Syntax", and Section 19.3.3, "Maintenance of Partitions".

**Output**

**CHECK TABLE** returns a result set with the following columns.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td>Always check</td>
</tr>
<tr>
<td>Msg_type</td>
<td>status, error, info, note, or warning</td>
</tr>
<tr>
<td>Msg_text</td>
<td>An informational message</td>
</tr>
</tbody>
</table>

Note that the statement might produce many rows of information for each checked table. The last row has a **Msg_type** value of **status** and the **Msg_text** normally should be **OK**. If you don’t get **OK**, or **Table is**
already up to date you should normally run a repair of the table. See Section 7.6, “MyISAM Table Maintenance and Crash Recovery”. Table is already up to date means that the storage engine for the table indicated that there was no need to check the table.

Checking Version Compatibility

The FOR_UPGRADE option checks whether the named tables are compatible with the current version of MySQL. With FOR_UPGRADE, the server checks each table to determine whether there have been any incompatible changes in any of the table's data types or indexes since the table was created. If not, the check succeeds. Otherwise, if there is a possible incompatibility, the server runs a full check on the table (which might take some time). If the full check succeeds, the server marks the table's .frm file with the current MySQL version number. Marking the .frm file ensures that further checks for the table with the same version of the server will be fast.

Incompatibilities might occur because the storage format for a data type has changed or because its sort order has changed. Our aim is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases.

Currently, FOR_UPGRADE discovers these incompatibilities:

• The indexing order for end-space in TEXT columns for InnoDB and MyISAM tables changed between MySQL 4.1 and 5.0.

• The storage method of the new DECIMAL data type changed between MySQL 5.0.3 and 5.0.5.

• If your table was created by a different version of the MySQL server than the one you are currently running, FOR_UPGRADE indicates that the table has an .frm file with an incompatible version. In this case, the result set returned by CHECK TABLE contains a line with a Msg_type value of error and a Msg_text value of Table upgrade required. Please do "REPAIR TABLE `tbl_name`" to fix it!

• Changes are sometimes made to character sets or collations that require table indexes to be rebuilt. For details about these changes and when FOR_UPGRADE detects them, see Section 2.11.3, “Checking Whether Tables or Indexes Must Be Rebuilt”.

Checking Data Consistency

The other check options that can be given are shown in the following table. These options are passed to the storage engine, which may use them or not.

<table>
<thead>
<tr>
<th>Type</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUICK</td>
<td>Do not scan the rows to check for incorrect links. Applies to InnoDB and MyISAM tables and views.</td>
</tr>
<tr>
<td>FAST</td>
<td>Check only tables that have not been closed properly. Applies only to MyISAM tables and views; ignored for InnoDB.</td>
</tr>
<tr>
<td>CHANGED</td>
<td>Check only tables that have been changed since the last check or that have not been closed properly. Applies only to MyISAM tables and views; ignored for InnoDB.</td>
</tr>
<tr>
<td>MEDIUM</td>
<td>Scan rows to verify that deleted links are valid. This also calculates a key checksum for the rows and verifies this with a calculated checksum for the keys. Applies only to MyISAM tables and views; ignored for InnoDB.</td>
</tr>
<tr>
<td>EXTENDED</td>
<td>Do a full key lookup for all keys for each row. This ensures that the table is 100% consistent, but takes a long time. Applies only to MyISAM tables and views; ignored for InnoDB.</td>
</tr>
</tbody>
</table>
If none of the options QUICK, MEDIUM, or EXTENDED are specified, the default check type for dynamic-format MyISAM tables is MEDIUM. This has the same result as running myisamchk --medium-check tbl_name on the table. The default check type also is MEDIUM for static-format MyISAM tables, unless CHANGED or FAST is specified. In that case, the default is QUICK. The row scan is skipped for CHANGED and FAST because the rows are very seldom corrupted.

You can combine check options, as in the following example that does a quick check on the table to determine whether it was closed properly:

```sql
CHECK TABLE test_table FAST QUICK;
```

**Note**

In some cases, CHECK TABLE changes the table. This happens if the table is marked as “corrupted” or “not closed properly” but CHECK TABLE does not find any problems in the table. In this case, CHECK TABLE marks the table as okay.

If a table is corrupted, it is most likely that the problem is in the indexes and not in the data part. All of the preceding check types check the indexes thoroughly and should thus find most errors.

If you just want to check a table that you assume is okay, you should use no check options or the QUICK option. The latter should be used when you are in a hurry and can take the very small risk that QUICK does not find an error in the data file. (In most cases, under normal usage, MySQL should find any error in the data file. If this happens, the table is marked as “corrupted” and cannot be used until it is repaired.)

FAST and CHANGED are mostly intended to be used from a script (for example, to be executed from cron) if you want to check tables from time to time. In most cases, FAST is to be preferred over CHANGED. (The only case when it is not preferred is when you suspect that you have found a bug in the MyISAM code.)

EXTENDED is to be used only after you have run a normal check but still get strange errors from a table when MySQL tries to update a row or find a row by key. This is very unlikely if a normal check has succeeded.

Use of CHECK TABLE ... EXTENDED might influence the execution plan generated by the query optimizer.

Some problems reported by CHECK TABLE cannot be corrected automatically:

- **Found row where the auto_increment column has the value 0.**

  This means that you have a row in the table where the AUTO_INCREMENT index column contains the value 0. (It is possible to create a row where the AUTO_INCREMENT column is 0 by explicitly setting the column to 0 with an UPDATE statement.)

  This is not an error in itself, but could cause trouble if you decide to dump the table and restore it or do an ALTER TABLE on the table. In this case, the AUTO_INCREMENT column changes value according to the rules of AUTO_INCREMENT columns, which could cause problems such as a duplicate-key error.

  To get rid of the warning, simply execute an UPDATE statement to set the column to some value other than 0.

**InnoDB Tables**

The following notes apply to InnoDB tables:

- **If CHECK TABLE finds a problem for an InnoDB table, the server may shut down to prevent error propagation. Details of the error will be written to the error log.**
Table Maintenance Statements

- If `CHECK TABLE` encounters corruptions or errors in InnoDB tables or indexes, it reports an error. It does not shut down the server. Starting with MySQL 5.5, `CHECK TABLE` usually marks the index and sometimes marks the table as corrupted, preventing further use of the index or table.

- If `CHECK TABLE` finds the wrong number of entries in a secondary index, it will report an error but will not shut down the server or prevent access to the file.

- `CHECK TABLE` surveys the index page structure, then surveys each key entry. It does not validate the key pointer to a clustered record or follow the path for BLOB pointers.

- When an InnoDB table is stored in its own .ibd file in file-per-table mode, the first 3 pages of the .ibd contain header information rather than table or index data. The `CHECK TABLE` statement does not detect inconsistencies that only affect the header data. To verify the entire contents of an InnoDB .ibd file, use the `innochecksum` command.

- When running `CHECK TABLE` on large InnoDB tables, other threads may be blocked during `CHECK TABLE` execution. To avoid timeouts, the semaphore wait threshold (600 seconds) is extended by 2 hours (7200 seconds) for `CHECK TABLE` operations. If InnoDB detects semaphore waits of 240 seconds or more it starts printing InnoDB monitor output to the error log. If a lock request extends beyond the semaphore wait threshold, InnoDB will abort the process. To avoid the possibility of a semaphore wait timeout entirely, you can run `CHECK TABLE QUICK` instead of `CHECK TABLE`.

### 13.7.2.3 CHECKSUM TABLE Syntax

```
CHECKSUM TABLE tbl_name [, tbl_name] ... [ QUICK | EXTENDED ]
```

`CHECKSUM TABLE` reports a table checksum. This statement requires the `SELECT` privilege for the table.

With `QUICK`, the live table checksum is reported if it is available, or `NULL` otherwise. This is very fast. A live checksum is enabled by specifying the `CHECKSUM=1` table option when you create the table; currently, this is supported only for MyISAM tables. See Section 13.1.17, "CREATE TABLE Syntax".

With `EXTENDED`, the entire table is read row by row and the checksum is calculated. This can be very slow for large tables.

If neither `QUICK` nor `EXTENDED` is specified, MySQL returns a live checksum if the table storage engine supports it and scans the table otherwise.

For a nonexistent table, `CHECKSUM TABLE` returns `NULL` and generates a warning.

In MySQL 5.5, `CHECKSUM TABLE` returns 0 for partitioned tables unless you include the `EXTENDED` option. This issue is resolved in MySQL 5.6. (Bug #11933226, Bug #60681)

The checksum value depends on the table row format. If the row format changes, the checksum also changes. For example, the storage format for VARCHAR changed between MySQL 4.1 and 5.0, so if a 4.1 table is upgraded to MySQL 5.0, the checksum value may change.

<table>
<thead>
<tr>
<th>Important</th>
</tr>
</thead>
<tbody>
<tr>
<td>If the checksums for two tables are different, then it is almost certain that the tables are different in some way. However, because the hashing function used by <code>CHECKSUM TABLE</code> is not guaranteed to be collision-free, there is a slight chance that two tables which are not identical can produce the same checksum.</td>
</tr>
</tbody>
</table>

### 13.7.2.4 OPTIMIZE TABLE Syntax

```
OPTIMIZE TABLE tbl_name 
```
Table Maintenance Statements

OPTIMIZE [NO_WRITE_TO_BINLOG | LOCAL] TABLE
tbl_name [, tbl_name] ...

Reorganizes the physical storage of table data and associated index data, to reduce storage space and improve I/O efficiency when accessing the table. The exact changes made to each table depend on the storage engine used by that table.

Use **OPTIMIZE TABLE** in these cases, depending on the type of table:

- After doing substantial insert, update, or delete operations on an **InnoDB** table that has its own .ibd file because it was created with the **innodb_file_per_table** option enabled. The table and indexes are reorganized, and disk space can be reclaimed for use by the operating system.

- After deleting a large part of a **MyISAM** or **ARCHIVE** table, or making many changes to a **MyISAM** or **ARCHIVE** table with variable-length rows (tables that have VARCHAR, VARBINARY, BLOB, or TEXT columns). Deleted rows are maintained in a linked list and subsequent INSERT operations reuse old row positions. You can use **OPTIMIZE TABLE** to reclaim the unused space and to defragment the data file. After extensive changes to a table, this statement may also improve performance of statements that use the table, sometimes significantly.

This statement requires **SELECT** and **INSERT** privileges for the table.

**OPTIMIZE TABLE** is also supported for partitioned tables. For information about using this statement with partitioned tables and table partitions, see Section 19.3.3, “Maintenance of Partitions”.

**OPTIMIZE TABLE** works for **InnoDB**, **MyISAM**, and **ARCHIVE** tables. **OPTIMIZE TABLE** is also supported for dynamic columns of in-memory **NDB** tables. It does not work for **Disk Data** tables. The performance of **OPTIMIZE** on Cluster tables can be tuned by adjusting the value of the **ndb_optimization_delay** system variable, which controls the number of milliseconds to wait between processing batches of rows by **OPTIMIZE TABLE**. For more information, see Section 18.1.6.11, “Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x”.

For MySQL Cluster tables, **OPTIMIZE TABLE** can be interrupted by (for example) killing the SQL thread performing the **OPTIMIZE** operation.

By default, **OPTIMIZE TABLE** does not work for tables created using any other storage engine and returns a result indicating this lack of support. You can make **OPTIMIZE TABLE** work for other storage engines by starting **mysql** with the **--skip-new** option. In this case, **OPTIMIZE TABLE** is just mapped to **ALTER TABLE**.

**InnoDB Details**

For **InnoDB** tables, **OPTIMIZE TABLE** is mapped to **ALTER TABLE**, which rebuilds the table to update index statistics and free unused space in the clustered index. This is displayed in the output of **OPTIMIZE TABLE** when you run it on an **InnoDB** table, as shown here:

```
mysql> OPTIMIZE TABLE foo;
+----------+----------+----------+-------------------------------------------------------------------+
| Table    | Op       | Msg_type | Msg_text                                                          |
+----------+----------+----------+-------------------------------------------------------------------+
| test.foo | optimize | note     | Table does not support optimize, doing recreate + analyze instead |
| test.foo | optimize | status   | OK                                                                |
+----------+----------+----------+-------------------------------------------------------------------+
```

This operation does not use fast index creation. Secondary indexes are not created as efficiently because keys are inserted in the order they appeared in the primary key. See Section 14.14.6, “Limitations of Fast Index Creation”.

1555
Table Maintenance Statements

**InnoDB** stores data using a page-allocation method and does not suffer from fragmentation in the same way that legacy storage engines (such as **MyISAM**) will. When considering whether or not to run optimize, consider the workload of transactions that your server will process:

- Some level of fragmentation is expected. **InnoDB** only fills pages 93% full, to leave room for updates without having to split pages.

- Delete operations might leave gaps that leave pages less filled than desired, which could make it worthwhile to optimize the table.

- Updates to rows usually rewrite the data within the same page, depending on the data type and row format, when sufficient space is available. See Section 14.10.5, “How Compression Works for InnoDB Tables” and Section 14.12.1, “Overview of InnoDB Row Storage”.

- High-concurrency workloads might leave gaps in indexes over time, as **InnoDB** retains multiple versions of the same data due through its MVCC mechanism. See Section 14.5.12, “InnoDB Multi-Versioning”.

**MyISAM** Details

For **MyISAM** tables, **OPTIMIZE TABLE** works as follows:

1. If the table has deleted or split rows, repair the table.
2. If the index pages are not sorted, sort them.
3. If the table’s statistics are not up to date (and the repair could not be accomplished by sorting the index), update them.

**Other Considerations**

**OPTIMIZE TABLE** returns a result set with the following columns.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td>Always optimize</td>
</tr>
<tr>
<td>Msg_type</td>
<td>status, error, info, note, or warning</td>
</tr>
<tr>
<td>Msg_text</td>
<td>An informational message</td>
</tr>
</tbody>
</table>

Note that MySQL locks the table during the time **OPTIMIZE TABLE** is running.

By default, the server writes **OPTIMIZE TABLE** statements to the binary log so that they replicate to replication slaves. To suppress logging, specify the optional **NO_WRITE_TO_BINLOG** keyword or its alias **LOCAL**.

**OPTIMIZE TABLE** does not sort R-tree indexes, such as spatial indexes on **POINT** columns. (Bug #23578)

As of MySQL 5.5.6, **OPTIMIZE TABLE** table catches and throws any errors that occur while copying table statistics from the old file to the newly created file. For example, if the user ID of the owner of the **.frm**, **.MYD**, or **.MYI** file is different from the user ID of the **mysqld** process, **OPTIMIZE TABLE** generates a "cannot change ownership of the file" error unless **mysqld** is started by the root user.

**13.7.2.5 REPAIR TABLE Syntax**

```
REPAIR [NO_WRITE_TO_BINLOG | LOCAL] TABLE
    tbl_name [, tbl_name] ...
```
The REPAIR TABLE statement might produce many rows of information for each repaired table. The last row has a `Msg_type` value of status and `Msg_text` normally should be `OK`. If you do not get `OK` for a MyISAM table, you should try repairing it with `myisamchk --safe-recover`. (REPAIR TABLE does not implement all the options of `myisamchk`.) With `myisamchk --safe-recover`, you can also use options that REPAIR TABLE does not support, such as `--max-record-length`.

If you use the `QUICK` option, REPAIR TABLE tries to repair only the index file, and not the data file. This type of repair is like that done by `myisamchk --recover --quick`.

If you use the `EXTENDED` option, MySQL creates the index row by row instead of creating one index at a time with sorting. This type of repair is like that done by `myisamchk --safe-recover`. 

---

**Warning**

If the server crashes during a REPAIR TABLE operation, it is essential after restarting it that you immediately execute another REPAIR TABLE statement for the table before performing any other operations on it. In the worst case, you might have a new clean index file without information about the data file, and then the next operation you perform could overwrite the data file. This is an unlikely but possible scenario that underscores the value of making a backup first.

---

**Caution**

It is best to make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors. See Chapter 7, *Backup and Recovery*.

---

REPAIR TABLE returns a result set with the following columns.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>The table name</td>
</tr>
<tr>
<td>Op</td>
<td>Always repair</td>
</tr>
<tr>
<td>Msg_type</td>
<td>status, error, info, note, or warning</td>
</tr>
<tr>
<td>Msg_text</td>
<td>An informational message</td>
</tr>
</tbody>
</table>
The `USE_FRM` option is available for use if the `.MYI` index file is missing or if its header is corrupted. This option tells MySQL not to trust the information in the `.MYI` file header and to re-create it using information from the `.frm` file. This kind of repair cannot be done with `myisamchk`.

**Note**

Use the `USE_FRM` option only if you cannot use regular `REPAIR` modes! Telling the server to ignore the `.MYI` file makes important table metadata stored in the `.MYI` file unavailable to the repair process, which can have deleterious consequences:

- The current `AUTO_INCREMENT` value is lost.
- The link to deleted records in the table is lost, which means that free space for deleted records will remain unoccupied thereafter.
- The `.MYI` header indicates whether the table is compressed. If the server ignores this information, it cannot tell that a table is compressed and repair can cause change or loss of table contents. This means that `USE_FRM` should not be used with compressed tables. That should not be necessary, anyway: Compressed tables are read only, so they should not become corrupt.

**Caution**

If you use `USE_FRM` for a table that was created by a different version of the MySQL server than the one you are currently running, `REPAIR TABLE` will not attempt to repair the table. In this case, the result set returned by `REPAIR TABLE` contains a line with a `Msg_type` value of `error` and a `Msg_text` value of `Failed repairing incompatible .FRM file`.

If `USE_FRM` is not used, `REPAIR TABLE` checks the table to see whether an upgrade is required. If so, it performs the upgrade, following the same rules as `CHECK TABLE ... FOR UPGRADE`. See Section 13.7.2.2, "CHECK TABLE Syntax", for more information. `REPAIR TABLE` without `USE_FRM` upgrades the `.frm` file to the current version.

By default, the server writes `REPAIR TABLE` statements to the binary log so that they replicate to replication slaves. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

**Important**

In the event that a table on the master becomes corrupted and you run `REPAIR TABLE` on it, any resulting changes to the original table are not propagated to slaves.

You may be able to increase `REPAIR TABLE` performance by setting certain system variables. See Section 8.6.3, "Speed of `REPAIR TABLE` Statements".

As of MySQL 5.5.6, `REPAIR TABLE` table catches and throws any errors that occur while copying table statistics from the old corrupted file to the newly created file. For example, if the user ID of the owner of the `.frm`, `.MYD`, or `.MYI` file is different from the user ID of the `mysqld` process, `REPAIR TABLE` generates a "cannot change ownership of the file" error unless `mysqld` is started by the root user.

### 13.7.3 Plugin and User-Defined Function Statements

#### 13.7.3.1 `CREATE FUNCTION` Syntax for User-Defined Functions
A user-defined function (UDF) is a way to extend MySQL with a new function that works like a native (built-in) MySQL function such as `ABS()` or `CONCAT()`.

`function_name` is the name that should be used in SQL statements to invoke the function. The `RETURNS` clause indicates the type of the function’s return value. `DECIMAL` is a legal value after `RETURNS`, but currently `DECIMAL` functions return string values and should be written like `STRING` functions.

`shared_library_name` is the basename of the shared object file that contains the code that implements the function. The file must be located in the plugin directory. This directory is given by the value of the `plugin_dir` system variable. For more information, see Section 24.3.2.5, “Compiling and Installing User-Defined Functions”.

To create a function, you must have the `INSERT` privilege for the `mysql` database. This is necessary because `CREATE FUNCTION` adds a row to the `mysql.func` system table that records the function’s name, type, and shared library name. If you do not have this table, you should run the `mysql_upgrade` command to create it. See Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”.

An active function is one that has been loaded with `CREATE FUNCTION` and not removed with `DROP FUNCTION`. All active functions are reloaded each time the server starts, unless you start `mysqld` with the `--skip-grant-tables` option. In this case, UDF initialization is skipped and UDFs are unavailable.

For instructions on writing user-defined functions, see Section 24.3.2, “Adding a New User-Defined Function”. For the UDF mechanism to work, functions must be written in C or C++ (or another language that can use C calling conventions), your operating system must support dynamic loading and you must have compiled `mysqld` dynamically (not statically).

An `AGGREGATE` function works exactly like a native MySQL aggregate (summary) function such as `SUM` or `COUNT()`. For `AGGREGATE` to work, your `mysql.func` table must contain a `type` column. If your `mysql.func` table does not have this column, you should run the `mysql_upgrade` program to create it (see Section 4.4.7, “mysql_upgrade — Check and Upgrade MySQL Tables”).

Note

To upgrade the shared library associated with a UDF, issue a `DROP FUNCTION` statement, upgrade the shared library, and then issue a `CREATE FUNCTION` statement. If you upgrade the shared library first and then use `DROP FUNCTION`, the server may crash.

### 13.7.3.2 DROP FUNCTION Syntax

```
DROP FUNCTION function_name
```

This statement drops the user-defined function (UDF) named `function_name`.

To drop a function, you must have the `DELETE` privilege for the `mysql` database. This is because `DROP FUNCTION` removes a row from the `mysql.func` system table that records the function’s name, type, and shared library name.

Note

To upgrade the shared library associated with a UDF, issue a `DROP FUNCTION` statement, upgrade the shared library, and then issue a `CREATE FUNCTION`.
DROP FUNCTION is also used to drop stored functions (see Section 13.1.26, "DROP PROEDURE and DROP FUNCTION Syntax").

13.7.3 INSTALL PLUGIN Syntax

```
INSTALL PLUGIN plugin_name SONAME 'shared_library_name'
```

This statement installs a server plugin. It requires the INSERT privilege for the mysql.plugin table.

`plugin_name` is the name of the plugin as defined in the plugin descriptor structure contained in the library file (see Section 24.2.4.2, "Plugin Data Structures"). Plugin names are not case sensitive. For maximal compatibility, plugin names should be limited to ASCII letters, digits, and underscore because they are used in C source files, shell command lines, M4 and Bourne shell scripts, and SQL environments.

`shared_library_name` is the name of the shared library that contains the plugin code. The name includes the file name extension (for example, libmyplugin.so, libmyplugin.dll, or libmyplugin.dylib).

The shared library must be located in the plugin directory (the directory named by the plugin_dir system variable). The library must be in the plugin directory itself, not in a subdirectory. By default, plugin_dir is the plugin directory under the directory named by the pkglibdir configuration variable, but it can be changed by setting the value of plugin_dir at server startup. For example, set its value in a my.cnf file:

```
[mysqld]
plugin_dir=/path/to/plugin/directory
```

If the value of plugin_dir is a relative path name, it is taken to be relative to the MySQL base directory (the value of the basedir system variable).

INSTALL PLUGIN loads and initializes the plugin code to make the plugin available for use. A plugin is initialized by executing its initialization function, which handles any setup that the plugin must perform before it can be used. When the server shuts down, it executes the deinitialization function for each plugin that is loaded so that the plugin has a chance to perform any final cleanup.

INSTALL PLUGIN also registers the plugin by adding a line that indicates the plugin name and library file name to the mysql.plugin table. At server startup, the server loads and initializes any plugin that is listed in the mysql.plugin table. This means that a plugin is installed with INSTALL PLUGIN only once, not every time the server starts. Plugin loading at startup does not occur if the server is started with the --skip-grant-tables option.

A plugin library can contain multiple plugins. For each of them to be installed, use a separate INSTALL PLUGIN statement. Each statement names a different plugin, but all of them specify the same library name.

INSTALL PLUGIN causes the server to read option (my.cnf) files just as during server startup. This enables the plugin to pick up any relevant options from those files. It is possible to add plugin options to an option file even before loading a plugin (if the loose prefix is used). It is also possible to uninstall a plugin, edit my.cnf, and install the plugin again. Restarting the plugin this way enables it to the new option values without a server restart.

For options that control individual plugin loading at server startup, see Section 5.1.8.1, “Installing and Uninstalling Plugins”. If you need to load plugins for a single server startup when the --skip-grant-
tables option is given (which tells the server not to read system tables), use the --plugin-load option. See Section 5.1.3, “Server Command Options”.

To remove a plugin, use the UNINSTALL PLUGIN statement.

For additional information about plugin loading, see Section 5.1.8.1, “Installing and Uninstalling Plugins”.

To see what plugins are installed, use the SHOW PLUGINS statement or query the INFORMATION_SCHEMA.PLUGINS table.

If you recompile a plugin library and need to reinstall it, you can use either of the following methods:

- Use UNINSTALL PLUGIN to uninstall all plugins in the library, install the new plugin library file in the plugin directory, and then use INSTALL PLUGIN to install all plugins in the library. This procedure has the advantage that it can be used without stopping the server. However, if the plugin library contains many plugins, you must issue many INSTALL PLUGIN and UNINSTALL PLUGIN statements.

- Stop the server, install the new plugin library file in the plugin directory, and restart the server.

### 13.7.3.4 UNINSTALL PLUGIN Syntax

```
UNINSTALL PLUGIN plugin_name
```

This statement removes an installed server plugin. It requires the DELETE privilege for the mysql.plugin table.

`plugin_name` must be the name of some plugin that is listed in the mysql.plugin table. The server executes the plugin’s deinitialization function and removes the row for the plugin from the mysql.plugin table, so that subsequent server restarts will not load and initialize the plugin. UNINSTALL PLUGIN does not remove the plugin’s shared library file.

You cannot uninstall a plugin if any table that uses it is open.

Plugin removal has implications for the use of associated tables. For example, if a full-text parser plugin is associated with a FULLTEXT index on the table, uninstalling the plugin makes the table unusable. Any attempt to access the table results in an error. The table cannot even be opened, so you cannot drop an index for which the plugin is used. This means that uninstalling a plugin is something to do with care unless you do not care about the table contents. If you are uninstalling a plugin with no intention of reinstalling it later and you care about the table contents, you should dump the table with mysqldump and remove the WITH PARSER clause from the dumped CREATE TABLE statement so that you can reload the table later. If you do not care about the table, DROP TABLE can be used even if any plugins associated with the table are missing.

For additional information about plugin loading, see Section 5.1.8.1, “Installing and Uninstalling Plugins”.

### 13.7.4 SET Syntax

```
SET variable_assignment [, variable_assignment] ...
```

```
variable_assignment:
  user_var_name = expr
  | [GLOBAL | SESSION] system_var_name = expr
  | [@@global. | @@session. | @@] system_var_name = expr
```

The SET statement assigns values to different types of variables that affect the operation of the server or your client. Older versions of MySQL employed SET OPTION, but this syntax is deprecated in favor of SET without OPTION.
This section describes use of `SET` for assigning values to variables. The `SET` statement can be used to assign values to these types of variables:

- System variables. See Section 5.1.4, “Server System Variables”. System variables also can be set at server startup, as described in Section 5.1.5, “Using System Variables”.

- User-defined variables. See Section 9.4, “User-Defined Variables”.

- Stored procedure and function parameters, and stored program local variables. See Section 13.6.4, “Variables in Stored Programs”.

Some variants of `SET` syntax are used in other contexts:

- `SET CHARACTER SET` and `SET NAMES` assign values to character set and collation variables associated with the connection to the server. `SET ONE_SHOT` is used for replication. These variants are described later in this section.

- `SET PASSWORD` assigns account passwords. See Section 13.7.1.6, “SET PASSWORD Syntax”.

- `SET TRANSACTION ISOLATION LEVEL` sets the isolation level for transaction processing. See Section 13.3.6, “SET TRANSACTION Syntax”.

The following discussion shows the different `SET` syntaxes that you can use to set variables. The examples use the `=` assignment operator, but you can also use the `:=` assignment operator for this purpose.

A user variable is written as `@var_name` and can be set as follows:

```
SET @var_name = expr;
```

Many system variables are dynamic and can be changed while the server runs by using the `SET` statement. For a list, see Section 5.1.5.2, “Dynamic System Variables”. To change a system variable with `SET`, refer to it as `var_name`, optionally preceded by a modifier:

- To indicate explicitly that a variable is a global variable, precede its name by `GLOBAL` or `@@global..`. The `SUPER` privilege is required to set global variables.

- To indicate explicitly that a variable is a session variable, precede its name by `SESSION`, `@@session..`, or `@@`. Setting a session variable requires no special privilege, but a client can change only its own session variables, not those of any other client.

- `LOCAL` and `@@local..` are synonyms for `SESSION` and `@@session..`.

- If no modifier is present, `SET` changes the session variable.

A `SET` statement can contain multiple variable assignments, separated by commas. For example, the statement can assign values to a user-defined variable and a system variable. If you set several system variables, the most recent `GLOBAL` or `SESSION` modifier in the statement is used for following variables that have no modifier specified.

Examples:

```
SET sort_buffer_size=10000;
SET @local.sort_buffer_size=10000;
SET GLOBAL sort_buffer_size=1000000, SESSION sort_buffer_size=1000000;
SET @@sort_buffer_size=1000000;
SET @@global.sort_buffer_size=1000000, @local.sort_buffer_size=1000000;
```
The `@@var_name` syntax for system variables is supported for compatibility with some other database systems.

If you change a session system variable, the value remains in effect until your session ends or until you change the variable to a different value. The change is not visible to other clients.

If you change a global system variable, the value is remembered and used for new connections until the server restarts. (To make a global system variable setting permanent, you should set it in an option file.) The change is visible to any client that accesses that global variable. However, the change affects the corresponding session variable only for clients that connect after the change. The global variable change does not affect the session variable for any client that is currently connected (not even that of the client that issues the `SET GLOBAL` statement).

To prevent incorrect usage, MySQL produces an error if you use `SET GLOBAL` with a variable that can only be used with `SET SESSION` or if you do not specify `GLOBAL` (or `@@global.`) when setting a global variable.

To set a `SESSION` variable to the `GLOBAL` value or a `GLOBAL` value to the compiled-in MySQL default value, use the `DEFAULT` keyword. For example, the following two statements are identical in setting the session value of `max_join_size` to the global value:

```sql
SET max_join_size=DEFAULT;
SET @@session.max_join_size=@@global.max_join_size;
```

Not all system variables can be set to `DEFAULT`. In such cases, use of `DEFAULT` results in an error.

It is not permitted to assign the value `DEFAULT` to user-defined variables, and not supported for stored procedure or function parameters or stored program local variables. This results in a syntax error for user-defined variables, and the results are undefined for parameters or local variables.

You can refer to the values of specific global or session system variables in expressions by using one of the `@@`-modifiers. For example, you can retrieve values in a `SELECT` statement like this:

```sql
SELECT @@global.sql_mode, @@session.sql_mode, @@sql_mode;
```

When you refer to a system variable in an expression as `@@var_name` (that is, when you do not specify `@@global.` or `@@session.`), MySQL returns the session value if it exists and the global value otherwise. (This differs from `SET @@var_name = value`, which always refers to the session value.)

**Note**

Some variables displayed by `SHOW VARIABLES` may not be available using `SELECT @@var_name` syntax; an `Unknown system variable` occurs. As a workaround in such cases, you can use `SHOW VARIABLES LIKE 'var_name'`.

Suffixes for specifying a value multiplier can be used when setting a variable at server startup, but not to set the value with `SET` at runtime. On the other hand, with `SET` you can assign a variable's value using an expression, which is not true when you set a variable at server startup. For example, the first of the following lines is legal at server startup, but the second is not:

```shell
shell> mysql --max_allowed_packet=16M
shell> mysql --max_allowed_packet=16*1024*1024
```

Conversely, the second of the following lines is legal at runtime, but the first is not:
To display system variables names and values, use the `SHOW VARIABLES` statement. (See Section 13.7.5.40, “SHOW VARIABLES Syntax”.)

The following list describes `SET` options that have nonstandard syntax (that is, options that are not set with `name = value` syntax).

- **CHARACTER SET `{charset_name | DEFAULT}`**

  This maps all strings from and to the client with the given mapping. You can add new mappings by editing `sql/convert.cc` in the MySQL source distribution. `SET CHARACTER SET` sets three session system variables: `character_set_client` and `character_set_results` are set to the given character set, and `character_set_connection` to the value of `character_set_database`. See Section 10.1.4, “Connection Character Sets and Collations”.

  The default mapping can be restored by using the value `DEFAULT`. The default depends on the server configuration.

  `ucs2`, `utf16`, and `utf32` cannot be used as a client character set, which means that they do not work for `SET CHARACTER SET`.

- **NAMES `{charset_name [COLLATE 'collation_name'] | DEFAULT}`**

  `SET NAMES` sets the three session system variables `character_set_client`, `character_set_connection`, and `character_set_results` to the given character set. Setting `character_set_connection` to `charset_name` also sets `collation_connection` to the default collation for `charset_name`. The optional `COLLATE` clause may be used to specify a collation explicitly. See Section 10.1.4, “Connection Character Sets and Collations”.

  The default mapping can be restored by using a value of `DEFAULT`. The default depends on the server configuration.

  `ucs2`, `utf16`, and `utf32` cannot be used as a client character set, which means that they do not work for `SET NAMES`.

- **ONE_SHOT**

  This option is a modifier, not a variable. It is only for internal use for replication: `mysqlbinlog` uses `SET ONE_SHOT` to modify temporarily the values of character set, collation, and time zone variables to reflect at rollover forward what they were originally. `ONE_SHOT` is for internal use only and is deprecated for MySQL 5.0 and up.

  `ONE_SHOT` is intended for use only with the permitted set of variables. It changes the variables as requested, but only for the next non-`SET` statement. After that, the server resets all character set, collation, and time zone-related system variables to their previous values. Example:

  ```
  mysql> SET ONE_SHOT character_set_connection = latin5;
  mysql> SET ONE_SHOT collation_connection = latin5_turkish_ci;
  mysql> SHOW VARIABLES LIKE '%_connection';
  +--------------------------+-------------------+
  | Variable_name            | Value             |
  +--------------------------+-------------------+--------------------------+-------------------+
  | character_set_connection | latin5            |
### SHOW Syntax

SHOW has many forms that provide information about databases, tables, columns, or status information about the server. This section describes those following:

- **SHOW AUTHORS**
- **SHOW (BINARY | MASTER) LOGS**
- **SHOW BINLOG EVENTS [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]**
- **SHOW CHARACTER SET [like_or_where]**
- **SHOW COLLATION [like_or_where]**
- **SHOW [FULL] COLUMNS FROM tbl_name [FROM db_name] [like_or_where]**
- **SHOW CONTRIBUTORS**
- **SHOW CREATE DATABASE db_name**
- **SHOW CREATE EVENT event_name**
- **SHOW CREATE FUNCTION func_name**
- **SHOW CREATE PROCEDURE proc_name**
- **SHOW CREATE TABLE tbl_name**
- **SHOW CREATE TRIGGER trigger_name**
- **SHOW CREATE VIEW view_name**
- **SHOW DATABASES [like_or_where]**
- **SHOW ENGINE engine_name (STATUS | MUTEX)**
- **SHOW [STORAGE] ENGINES**
- **SHOW ERRORS [LIMIT [offset,] row_count]**
- **SHOW EVENTS**
- **SHOW FUNCTION CODE func_name**
- **SHOW FUNCTION STATUS [like_or_where]**
- **SHOW GRANTS FOR user**
- **SHOW INDEX FROM tbl_name [FROM db_name]**
- **SHOW MASTER STATUS**
- **SHOW OPEN TABLES [FROM db_name] [like_or_where]**
- **SHOW PLUGINS**
- **SHOW PROCEDURE CODE proc_name**
- **SHOW PROCEDURE STATUS [like_or_where]**
- **SHOW PRIVILEGES**
- **SHOW [FULL] PROCESSLIST**
- **SHOW PROFILE [types] [FOR QUERY n] [OFFSET n] [LIMIT n]**
- **SHOW PROFILES**
- **SHOW SLAVE HOSTS**
- **SHOW SLAVE STATUS**
- **SHOW [GLOBAL | SESSION] STATUS [like_or_where]**
- **SHOW TABLE STATUS [FROM db_name] [like_or_where]**
- **SHOW [FULL] TABLES [FROM db_name] [like_or_where]**
- **SHOW [GLOBAL | SESSION] VARIABLES [like_or_where]**
- **SHOW WARNINGS [LIMIT [offset,] row_count]**

If the syntax for a given SHOW statement includes a LIKE 'pattern' part, 'pattern' is a string that can contain the SQL "%" and "_" wildcard characters. The pattern is useful for restricting statement output to matching values.
Several `SHOW` statements also accept a `WHERE` clause that provides more flexibility in specifying which rows to display. See Section 21.31, “Extensions to `SHOW` Statements”.

Many MySQL APIs (such as PHP) enable you to treat the result returned from a `SHOW` statement as you would a result set from a `SELECT`; see Chapter 23, Connectors and APIs, or your API documentation for more information. In addition, you can work in SQL with results from queries on tables in the `INFORMATION_SCHEMA` database, which you cannot easily do with results from `SHOW` statements. See Chapter 21, `INFORMATION_SCHEMA` Tables.

### 13.7.5.1 `SHOW AUTHORS` Syntax

```sql
SHOW AUTHORS
```

The `SHOW AUTHORS` statement displays information about the people who work on MySQL. For each author, it displays `Name`, `Location`, and `Comment` values.

This statement is deprecated as of MySQL 5.5.29 and is removed in MySQL 5.6.

### 13.7.5.2 `SHOW BINARY LOGS` Syntax

```sql
SHOW BINARY LOGS
SHOW MASTER LOGS
```

Lists the binary log files on the server. This statement is used as part of the procedure described in Section 13.4.1.1, “PURGE BINARY LOGS Syntax”, that shows how to determine which logs can be purged.

```
mysql> SHOW BINARY LOGS;
+---------------+-----------+
| Log_name      | File_size |
+---------------+-----------+
| binlog.000015 | 724935    |
| binlog.000016 | 733481    |
+---------------+-----------+
```

`SHOW MASTER LOGS` is equivalent to `SHOW BINARY LOGS`.

In MySQL 5.5.24 and earlier, the `SUPER` privilege was required to use this statement. Starting with MySQL 5.5.25, a user with the `REPLICATION CLIENT` privilege may also execute this statement.

### 13.7.5.3 `SHOW BINLOG EVENTS` Syntax

```sql
SHOW BINLOG EVENTS [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
```

Shows the events in the binary log. If you do not specify `'log_name'`, the first binary log is displayed.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See Section 13.2.9, “SELECT Syntax”.

<table>
<thead>
<tr>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Issuing a <code>SHOW BINLOG EVENTS</code> with no <code>LIMIT</code> clause could start a very time- and resource-consuming process because the server returns to the client the complete contents of the binary log (which includes all statements executed by the server that modify data). As an alternative to <code>SHOW BINLOG EVENTS</code>, use the...</td>
</tr>
</tbody>
</table>
**SHOW Syntax**

`mysqlbinlog` utility to save the binary log to a text file for later examination and analysis. See Section 4.6.7, "mysqlbinlog — Utility for Processing Binary Log Files".

**Note**

Some events relating to the setting of user and system variables are not included in the output from `SHOW BINLOG EVENTS`. To get complete coverage of events within a binary log, use `mysqlbinlog`.

**Note**

`SHOW BINLOG EVENTS` does not work with relay log files. You can use `SHOW RELAYLOG EVENTS` for this purpose.

### 13.7.5.4 SHOW CHARACTER SET Syntax

```
SHOW CHARACTER SET
[LIKE 'pattern' | WHERE expr]
```

The `SHOW CHARACTER SET` statement shows all available character sets. The `LIKE` clause, if present, indicates which character set names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 21.31, "Extensions to SHOW Statements". For example:

```
mysql> SHOW CHARACTER SET LIKE 'latin%';
+------------+-----------------------------+-------------------+--------+
| Charset    | Description                 | Default collation | Maxlen |
+------------+-----------------------------+-------------------+--------+
| latin1     | cp1252 West European        | latin1_swedish_ci |      1 |
| latin2     | ISO 8859-2 Central European | latin2_general_ci |      1 |
| latin5     | ISO 8859-9 Turkish          | latin5_turkish_ci |      1 |
| latin7     | ISO 8859-13 Baltic          | latin7_general_ci |      1 |
+------------+-----------------------------+-------------------+--------+
```

The `Maxlen` column shows the maximum number of bytes required to store one character.

The `filename` character set is for internal use only; consequently, `SHOW CHARACTER SET` does not display it.

### 13.7.5.5 SHOW COLLATION Syntax

```
SHOW COLLATION
[LIKE 'pattern' | WHERE expr]
```

This statement lists collations supported by the server. By default, the output from `SHOW COLLATION` includes all available collations. The `LIKE` clause, if present, indicates which collation names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 21.31, "Extensions to SHOW Statements". For example:

```
mysql> SHOW COLLATION LIKE 'latin1%';
+-------------------+---------+----+---------+----------+---------+
| Collation          | Charset | Id | Default | Compiled | Sortlen |
+-------------------+---------+----+---------+----------+---------+
| latin1_german1_ci | latin1  |  5 |         |          |       0 |
| latin1_swedish_ci | latin1  |  8 | Yes     | Yes      |       0 |
| latin1_danish_ci  | latin1  | 15 |         |          |       0 |
+-------------------+---------+----+---------+----------+---------+
```
SHOW Syntax

| latin1_german2_ci | latin1 | 31 | Yes | 2 |
| latin1_bin | latin1 | 47 | Yes | 0 |
| latin1_general_ci | latin1 | 48 | Yes | 0 |
| latin1_general_cs | latin1 | 49 | Yes | 0 |
| latin1_spanish_ci | latin1 | 94 | Yes | 0 |
| | | | | |

The **Collation** and **Charset** columns indicate the names of the collation and the character set with which it is associated. **Id** is the collation ID. **Default** indicates whether the collation is the default for its character set. **Compiled** indicates whether the character set is compiled into the server. **Sortlen** is related to the amount of memory required to sort strings expressed in the character set.

To see the default collation for each character set, use the following statement. **Default** is a reserved word, so to use it as an identifier, it must be quoted as such:

```sql
mysql> SHOW COLLATION WHERE `Default` = 'Yes';
+---------------------+----------+----+---------+----------+---------+
| Collation           | Charset  | Id | Default | Compiled | Sortlen |
+---------------------+----------+----+---------+----------+---------+
| big5_chinese_ci     | big5     |  1 | Yes     | Yes      |       1 |
| dec8_swedish_ci     | dec8     |  3 | Yes     | Yes      |       1 |
| cp850_general_ci    | cp850    |  4 | Yes     | Yes      |       1 |
| hp8_english_ci      | hp8      |  6 | Yes     | Yes      |       1 |
| koi8r_general_ci    | koi8r    |  7 | Yes     | Yes      |       1 |
| latin1_swedish_ci   | latin1   |  8 | Yes     | Yes      |       1 |
+---------------------+----------+----+---------+----------+---------+
```

**13.7.5.6 SHOW COLUMNS Syntax**

SHOW [FULL] COLUMNS {FROM | IN} tbl_name [{FROM | IN} db_name] [LIKE 'pattern' | WHERE expr]

**SHOW COLUMNS** displays information about the columns in a given table. It also works for views. The **LIKE** clause, if present, indicates which column names to match. The **WHERE** clause can be given to select rows using more general conditions, as discussed in **Section 21.31, "Extensions to SHOW Statements"**.

**SHOW COLUMNS** displays information only for those columns for which you have some privilege.

```sql
mysql> SHOW COLUMNS FROM City;
+------------+----------+------+-----+---------+----------------+
| Field      | Type     | Null | Key | Default | Extra          |
|------------+----------+------+-----+---------+----------------+
| Id         | int(11)  | NO   | PRI | NULL    | auto_increment |
| Name       | char(35) | NO   |     |         |                |
| Country    | char(3)  | NO   | UNI |         |                |
| District   | char(20) | YES  | MUL |         |                |
| Population | int(11)  | NO   |     | 0       |                |
+------------+----------+------+-----+---------+----------------+
5 rows in set (0.00 sec)
```

If the data types differ from what you expect them to be based on a **CREATE TABLE** statement, note that MySQL sometimes changes data types when you create or alter a table. The conditions under which this occurs are described in **Section 13.1.17.3, “Silent Column Specification Changes”**.

The **FULL** keyword causes the output to include the column collation and comments, as well as the privileges you have for each column.

You can use **db_name.tbl_name** as an alternative to the **tbl_name FROM db_name** syntax. In other words, these two statements are equivalent:
SHOW Columns displays the following values for each table column:

Field indicates the column name.

Type indicates the column data type.

Collation indicates the collation for nonbinary string columns, or NULL for other columns. This value is displayed only if you use the FULL keyword.

The Null field contains YES if NULL values can be stored in the column, NO if not.

The Key field indicates whether the column is indexed:

- If Key is empty, the column either is not indexed or is indexed only as a secondary column in a multiple-column, nonunique index.
- If Key is PRI, the column is a PRIMARY KEY or is one of the columns in a multiple-column PRIMARY KEY.
- If Key is UNI, the column is the first column of a UNIQUE index. (A UNIQUE index permits multiple NULL values, but you can tell whether the column permits NULL by checking the Null field.)
- If Key is MUL, the column is the first column of a nonunique index in which multiple occurrences of a given value are permitted within the column.

If more than one of the Key values applies to a given column of a table, Key displays the one with the highest priority, in the order PRI, UNI, MUL.

A UNIQUE index may be displayed as PRI if it cannot contain NULL values and there is no PRIMARY KEY in the table. A UNIQUE index may display as MUL if several columns form a composite UNIQUE index; although the combination of the columns is unique, each column can still hold multiple occurrences of a given value.

The Default field indicates the default value that is assigned to the column. This is NULL if the column has an explicit default of NULL, or if the column definition has no DEFAULT clause.

The Extra field contains any additional information that is available about a given column. The value is nonempty in these cases: auto_increment for columns that have the AUTO_INCREMENT attribute; on update CURRENT_TIMESTAMP for TIMESTAMP columns that have the ON UPDATE CURRENT_TIMESTAMP attribute.

Privileges indicates the privileges you have for the column. This value is displayed only if you use the FULL keyword.

Comment indicates any comment the column has. This value is displayed only if you use the FULL keyword.

SHOW FIELDS is a synonym for SHOW COLUMNS. You can also list a table's columns with the mysqlshow db_name tbl_name command.

The DESCRIPTOR statement provides information similar to SHOW COLUMNS. See Section 13.8.1, "DESCRIBE Syntax".
SHOW Syntax

The SHOW CREATE TABLE, SHOW TABLE STATUS, and SHOW INDEX statements also provide information about tables. See Section 13.7.5, “SHOW Syntax”.

13.7.5.7 SHOW CONTRIBUTORS Syntax

SHOW CONTRIBUTORS

The SHOW CONTRIBUTORS statement displays information about the people who contribute to MySQL source or to causes that we support. For each contributor, it displays Name, Location, and Comment values.

This statement is deprecated as of MySQL 5.5.29 and is removed in MySQL 5.6.

13.7.5.8 SHOW CREATE DATABASE Syntax

SHOW CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name

Shows the CREATE DATABASE statement that creates the named database. If the SHOW statement includes an IF NOT EXISTS clause, the output too includes such a clause. SHOW CREATE SCHEMA is a synonym for SHOW CREATE DATABASE.

mysql> SHOW CREATE DATABASE test\G
*************************** 1. row ***************************
  Database: test
  Create Database: CREATE DATABASE `test`
  /*!40100 DEFAULT CHARACTER SET latin1 */

mysql> SHOW CREATE SCHEMA test\G
*************************** 1. row ***************************
  Database: test
  Create Database: CREATE DATABASE `test`
  /*!40100 DEFAULT CHARACTER SET latin1 */

SHOW CREATE DATABASE quotes table and column names according to the value of the sql_quote_show_create option. See Section 5.1.4, “Server System Variables”.

13.7.5.9 SHOW CREATE EVENT Syntax

SHOW CREATE EVENT event_name

This statement displays the CREATE EVENT statement needed to re-create a given event. It requires the EVENT privilege for the database from which the event is to be shown. For example (using the same event e_daily defined and then altered in Section 13.7.5.19, “SHOW EVENTS Syntax”):

mysql> SHOW CREATE EVENT test.e_daily\G
*************************** 1. row ***************************
  Event: e_daily
  sql_mode:              
  time_zone: SYSTEM
  Create Event: CREATE EVENT `e_daily`
    ON SCHEDULE EVERY 1 DAY
    STARTS CURRENT_TIMESTAMP + INTERVAL 6 HOUR
    ON COMPLETION NOT PRESERVE
    ENABLE
    COMMENT 'Saves total number of sessions then clears the table each day'
SHOW Syntax

```sql
DO BEGIN
  INSERT INTO site_activity.totals (time, total)
  SELECT CURRENT_TIMESTAMP, COUNT(*)
  FROM site_activity.sessions;
  DELETE FROM site_activity.sessions;
END
```

`character_set_client` is the session value of the `character_set_client` system variable when the event was created. `collation_connection` is the session value of the `collation_connection` system variable when the event was created. `Database Collation` is the collation of the database with which the event is associated.

Note that the output reflects the current status of the event (ENABLE) rather than the status with which it was created.

### 13.7.5.10 SHOW CREATE FUNCTION Syntax

```sql
SHOW CREATE FUNCTION func_name
```

This statement is similar to `SHOW CREATE PROCEDURE` but for stored functions. See Section 13.7.5.11, "SHOW CREATE PROCEDURE Syntax".

### 13.7.5.11 SHOW CREATE PROCEDURE Syntax

```sql
SHOW CREATE PROCEDURE proc_name
```

This statement is a MySQL extension. It returns the exact string that can be used to re-create the named stored procedure. A similar statement, `SHOW CREATE FUNCTION`, displays information about stored functions (see Section 13.7.5.10, "SHOW CREATE FUNCTION Syntax").

To use either statement, you must be the owner of the routine or have `SELECT` access to the `mysql.proc` table. If you do not have privileges for the routine itself, the value displayed for the Create Procedure or Create Function field will be NULL.

```sql
mysql> SHOW CREATE PROCEDURE test.simpleproc
+----------------------------------------------------------+
|              Procedure: simpleproc                       |
|              sql_mode: simpleproc                         |
| Create Procedure: CREATE PROCEDURE `simpleproc`(OUT param1 INT)
|              BEGIN
|              SELECT COUNT(*) INTO param1 FROM t;
|              END
| character_set_client: latin1                            |
| collation_connection: latin1_swedish_ci                  |
| Database Collation: latin1_swedish_ci                    |
+----------------------------------------------------------+

mysql> SHOW CREATE FUNCTION test.hello
+----------------------------------------------------------+
|              Function: hello                              |
|              sql_mode: hello                              |
| Create Function: CREATE FUNCTION `hello`(s CHAR(20))     |
|              RETURNS CHAR(50)
|              RETURN CONCAT('Hello, ',s,'!')              |
| character_set_client: latin1                            |
| collation_connection: latin1_swedish_ci                  |
| Database Collation: latin1_swedish_ci                    |
+----------------------------------------------------------+
```
SHOW Syntax

**character_set_client** is the session value of the *character_set_client* system variable when the routine was created. **collation_connection** is the session value of the *collation_connection* system variable when the routine was created. **Database Collation** is the collation of the database with which the routine is associated.

### 13.7.5.12 SHOW CREATE TABLE Syntax

**SHOW CREATE TABLE** *tbl_name*

Shows the **CREATE TABLE** statement that creates the named table. To use this statement, you must have some privilege for the table. This statement also works with views.

```
mysql> SHOW CREATE TABLE t\G
*************************** 1. row ***************************
Table: t
Create Table: CREATE TABLE t {
  id INT(11) default NULL auto_increment,
  s char(60) default NULL,
} PRIMARY KEY (id)
) ENGINE=MyISAM
```

**SHOW CREATE TABLE** quotes table and column names according to the value of the `sql_quote_show_create` option. See Section 5.1.4, “Server System Variables”.

### 13.7.5.13 SHOW CREATE TRIGGER Syntax

**SHOW CREATE TRIGGER** *trigger_name*

This statement shows the **CREATE TRIGGER** statement that creates the named trigger.

```
mysql> SHOW CREATE TRIGGER ins_sum\G
*************************** 1. row ***************************
Trigger: ins_sum
sql_mode:
SQL Original Statement: CREATE DEFINER=`bob`@`localhost` TRIGGER ins_sum
  BEFORE INSERT ON account
  FOR EACH ROW SET @sum = @sum + NEW.amount
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci
```

**SHOW CREATE TRIGGER** output has the following columns:

- **Trigger**: The trigger name.
- **sql_mode**: The SQL mode in effect when the trigger executes.
- **SQL Original Statement**: The **CREATE TRIGGER** statement that defines the trigger.
- **character_set_client**: The session value of the *character_set_client* system variable when the trigger was created.
- **collation_connection**: The session value of the *collation_connection* system variable when the trigger was created.
- **Database Collation**: The collation of the database with which the trigger is associated.
You can also obtain information about trigger objects from INFORMATION_SCHEMA, which contains a TRIGGERS table. See Section 21.25, “The INFORMATION_SCHEMA TRIGGERS Table”.

### 13.7.5.14 SHOW CREATE VIEW Syntax

SHOW CREATE VIEW view_name

This statement shows the CREATE VIEW statement that creates the named view.

```sql
mysql> SHOW CREATE VIEW v\G
*************************** 1. row ***************************
View: v
Create View: CREATE ALGORITHM=UNDEFINED
DEFINER=`bob`@`localhost` SQL SECURITY DEFINER VIEW
`v` AS select 1 AS `a`,2 AS `b`
character_set_client: latin1
collation_connection: latin1_swedish_ci
```

character_set_client is the session value of the character_set_client system variable when the view was created. collation_connection is the session value of the collation_connection system variable when the view was created.

Use of SHOW CREATE VIEW requires the SHOW VIEW privilege and the SELECT privilege for the view in question.

You can also obtain information about view objects from INFORMATION_SCHEMA, which contains a VIEWS table. See Section 21.27, “The INFORMATION_SCHEMA VIEWS Table”.

MySQL lets you use different sql_mode settings to tell the server the type of SQL syntax to support. For example, you might use the ANSI SQL mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (||), in your queries. If you then create a view that concatenates items, you might worry that changing the sql_mode setting to a value different from ANSI could cause the view to become invalid. But this is not the case. No matter how you write out a view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a CONCAT() function:

```sql
mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as col1;
Query OK, 0 rows affected (0.01 sec)

mysql> SHOW CREATE VIEW test.v\G
*************************** 1. row ***************************
View: v
Create View: CREATE VIEW "v" AS select concat('a','b') AS "col1"
... 1 row in set (0.00 sec)
```

The advantage of storing a view definition in canonical form is that changes made later to the value of sql_mode will not affect the results from the view. However an additional consequence is that comments prior to SELECT are stripped from the definition by the server.

### 13.7.5.15 SHOW DATABASES Syntax

SHOW DATABASES;
SHOW Syntax

SHOW {DATABASES | SCHEMAS} [LIKE 'pattern' | WHERE expr]

SHOW DATABASES lists the databases on the MySQL server host. SHOW SCHEMAS is a synonym for SHOW DATABASES. The LIKE clause, if present, indicates which database names to match. The WHERE clause can be given to select rows using more general conditions, as discussed in Section 21.31, “Extensions to SHOW Statements”.

You see only those databases for which you have some kind of privilege, unless you have the global SHOW DATABASES privilege. You can also get this list using the mysqlshow command.

If the server was started with the --skip-show-database option, you cannot use this statement at all unless you have the SHOW DATABASES privilege.

MySQL implements databases as directories in the data directory, so this statement simply lists directories in that location. However, the output may include names of directories that do not correspond to actual databases.

13.7.5.16 SHOW ENGINE Syntax

SHOW ENGINE engine_name {STATUS | MUTE}

SHOW ENGINE displays operational information about a storage engine. It requires the PROCESS privilege. The statement has these variants:

SHOW ENGINE INNODB STATUS
SHOW ENGINE INNODB MUTEX
SHOW ENGINE {NDB | NDBCLUSTER} STATUS
SHOW ENGINE PERFORMANCE_SCHEMA STATUS

SHOW ENGINE INNODB STATUS displays extensive information from the standard InnoDB Monitor about the state of the InnoDB storage engine. For information about the standard monitor and other InnoDB Monitors that provide information about InnoDB processing, see Section 14.18, “InnoDB Monitors”.

SHOW ENGINE INNODB MUTEX displays InnoDB mutex and rw-lock statistics. Statement output has the following columns:

• Type
  Always InnoDB.

• Name
  The source file where the mutex is implemented, and the line number in the file where the mutex is created. The line number is specific to your version of MySQL.

• Status
  The mutex status. This field displays several values if UNIV_DEBUG was defined at MySQL compilation time (for example, in include/univ.i in the InnoDB part of the MySQL source tree). If UNIV_DEBUG was not defined, the statement displays only the os_waits value. In the latter case (without UNIV_DEBUG), the information on which the output is based is insufficient to distinguish regular mutexes and mutexes that protect rw-locks (which permit multiple readers or a single writer). Consequently, the output may appear to contain multiple rows for the same mutex.

• count indicates how many times the mutex was requested.
• **spin_waits** indicates how many times the spinlock had to run.

• **spin_rounds** indicates the number of spinlock rounds. (spin_rounds divided by spin_waits provides the average round count.)

• **os_waits** indicates the number of operating system waits. This occurs when the spinlock did not work (the mutex was not locked during the spinlock and it was necessary to yield to the operating system and wait).

• **os_yields** indicates the number of times a thread trying to lock a mutex gave up its timeslice and yielded to the operating system (on the presumption that permitting other threads to run will free the mutex so that it can be locked).

• **os_wait_times** indicates the amount of time (in ms) spent in operating system waits. In MySQL 5.5 timing is disabled and this value is always 0.

As of MySQL 5.5, **SHOW ENGINE INNODB MUTEX** skips the mutexes and rw-locks of buffer pool blocks, as the amount of output can be overwhelming on systems with a large buffer pool. (There is one mutex and one rw-lock in each 16K buffer pool block, and there are 65,536 blocks per gigabyte.) **SHOW ENGINE INNODB MUTEX** also does not list any mutexes or rw-locks that have never been waited on (os_waits=0). Thus, **SHOW ENGINE INNODB MUTEX** only displays information about mutexes and rw-locks outside of the buffer pool that have caused at least one OS-level wait.

**SHOW ENGINE INNODB MUTEX** information can be used to diagnose system problems. For example, large values of spin_waits and spin_rounds may indicate scalability problems.

Use **SHOW ENGINE PERFORMANCE_SCHEMA STATUS** to inspect the internal operation of the Performance Schema code:

```sql
mysql> SHOW ENGINE PERFORMANCE_SCHEMA STATUS\GV
...
*************************** 3. row ***************************
  Type: performance_schema
  Name: events_waits_history.row_size
  Status: 76
*************************** 4. row ***************************
  Type: performance_schema
  Name: events_waits_history.row_count
  Status: 10000
*************************** 5. row ***************************
  Type: performance_schema
  Name: events_waits_history.memory
  Status: 760000
...
*************************** 57. row ***************************
  Type: performance_schema
  Name: performance_schema.memory
  Status: 26459600
...
```

This statement is intended to help the DBA understand the effects that different Performance Schema options have on memory requirements.

**Name** values consist of two parts, which name an internal buffer and a buffer attribute, respectively. Interpret buffer names as follows:

• An internal buffer that is not exposed as a table is named within parentheses. Examples: 
SHOW Syntax

- An internal buffer that is exposed as a table in the performance_schema database is named after the table, without parentheses. Examples: events_waits_history.row_size, mutex_instances.row_count.

Buffer attributes have these meanings:

- row_size is the size of the internal record used by the implementation, such as the size of a row in a table. row_size values cannot be changed.

- row_count is the number of internal records, such as the number of rows in a table. row_count values can be changed using Performance Schema configuration options.

- For a table, tbl_name.memory is the product of row_size and row_count. For the Performance Schema as a whole, performance_schema.memory is the sum of all the memory used (the sum of all other memory values).

In some cases, there is a direct relationship between a Performance Schema configuration parameter and a SHOW ENGINE value. For example, events_waits_history_long.row_count corresponds to performance_schema_events_waits_history_long_size. In other cases, the relationship is more complex. For example, events_waits_history.row_count corresponds to performance_schema_events_waits_history_size (the number of rows per thread) multiplied by performance_schema_max_thread_instances (the number of threads).

If the server has the NDBCLUSTER storage engine enabled, SHOW ENGINE NDB STATUS displays cluster status information such as the number of connected data nodes, the cluster connectstring, and cluster binlog epochs, as well as counts of various Cluster API objects created by the MySQL Server when connected to the cluster. Sample output from this statement is shown here:

```sql
mysql> SHOW ENGINE NDB STATUS;
+------------+-----------------------+--------------------------------------------------+
| Type       | Name                  | Status                                           |
+------------+-----------------------+--------------------------------------------------+
| ndbcluster | connection            | cluster_node_id=7, connected_host=192.168.0.103, number_of_data_nodes=4, number_of_ready_data_nodes=3, connect_count=0 |
| ndbcluster | NdbTransaction        | created=6, free=0, sizeof=212                    |
| ndbcluster | NdbOperation          | created=8, free=8, sizeof=660                    |
| ndbcluster | NdbIndexScanOperation | created=1, free=1, sizeof=744                    |
| ndbcluster | NdbIndexOperation     | created=0, free=0, sizeof=664                    |
| ndbcluster | NdbRecAttr            | created=1285, free=1285, sizeof=60               |
| ndbcluster | NdbApiSignal          | created=16, free=16, sizeof=136                  |
| ndbcluster | NdbLabel              | created=0, free=0, sizeof=196                    |
| ndbcluster | NdbBranch             | created=0, free=0, sizeof=24                     |
| ndbcluster | NdbSubroutine         | created=0, free=0, sizeof=68                     |
| ndbcluster | NdbCall               | created=0, free=0, sizeof=16                     |
| ndbcluster | NdbBlob               | created=1, free=1, sizeof=264                    |
| ndbcluster | NdbReceiver           | created=4, free=0, sizeof=68                     |
| ndbcluster | binlog                | latest_epoch=155467, latest_trans_epoch=148126, last_activity=0, latest_received_binlog_epoch=0, latest_handled_binlog_epoch=0, latest_applied_binlog_epoch=0     |
+------------+-----------------------+--------------------------------------------------+
```

The rows with connection and binlog in the Name column were added to the output of this statement in MySQL 5.1. The Status column in each of these rows provides information about the MySQL server's connection to the cluster and about the cluster binary log's status, respectively. The Status information is in the form of comma-delimited set of name/value pairs.
SHOW Syntax

The connection row’s Status column contains the name/value pairs described in the following table.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>cluster_node_id</td>
<td>The node ID of the MySQL server in the cluster</td>
</tr>
<tr>
<td>connected_host</td>
<td>The host name or IP address of the cluster management server to which the MySQL server is connected</td>
</tr>
<tr>
<td>connected_port</td>
<td>The port used by the MySQL server to connect to the management server (connected_host)</td>
</tr>
<tr>
<td>number_of_data_nodes</td>
<td>The number of data nodes configured for the cluster (that is, the number of [ndbd] sections in the cluster config.ini file)</td>
</tr>
<tr>
<td>number_of_ready_data_nodes</td>
<td>The number of data nodes in the cluster that are actually running</td>
</tr>
<tr>
<td>connect_count</td>
<td>The number of times this mysqld has connected or reconnected to cluster data nodes</td>
</tr>
</tbody>
</table>

The binlog row’s Status column contains information relating to MySQL Cluster Replication. The name/value pairs it contains are described in the following table.

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>latest_epoch</td>
<td>The most recent epoch most recently run on this MySQL server (that is, the sequence number of the most recent transaction run on the server)</td>
</tr>
<tr>
<td>latest_trans_epoch</td>
<td>The most recent epoch processed by the cluster’s data nodes</td>
</tr>
<tr>
<td>latest_received_binlog_epoch</td>
<td>The most recent epoch received by the binlog thread</td>
</tr>
<tr>
<td>latest_handled_binlog_epoch</td>
<td>The most recent epoch processed by the binlog thread (for writing to the binlog)</td>
</tr>
<tr>
<td>latest_applied_binlog_epoch</td>
<td>The most recent epoch actually written to the binlog</td>
</tr>
</tbody>
</table>

See Section 18.6, "MySQL Cluster Replication", for more information.

The remaining rows from the output of SHOW ENGINE NDB STATUS which are most likely to prove useful in monitoring the cluster are listed here by Name:

- **NdbTransaction**: The number and size of NdbTransaction objects that have been created. An NdbTransaction is created each time a table schema operation (such as CREATE TABLE or ALTER TABLE) is performed on an NDB table.

- **NdbOperation**: The number and size of NdbOperation objects that have been created.

- **NdbIndexScanOperation**: The number and size of NdbIndexScanOperation objects that have been created.

- **NdbIndexOperation**: The number and size of NdbIndexOperation objects that have been created.

- **NdbRecAttr**: The number and size of NdbRecAttr objects that have been created. In general, one of these is created each time a data manipulation statement is performed by an SQL node.

- **NdbBlob**: The number and size of NdbBlob objects that have been created. An NdbBlob is created for each new operation involving a BLOB column in an NDB table.
SHOW Syntax

- **NdbReceiver**: The number and size of any NdbReceiver object that have been created. The number in the created column is the same as the number of data nodes in the cluster to which the MySQL server has connected.

**Note**

SHOW ENGINE NDB STATUS returns an empty result if no operations involving NDB tables have been performed during the current session by the MySQL client accessing the SQL node on which this statement is run.

### 13.7.5.17 SHOW ENGINES Syntax

SHOW [STORAGE] ENGINES

**SHOW ENGINES** displays status information about the server’s storage engines. This is particularly useful for checking whether a storage engine is supported, or to see what the default engine is. This information can also be obtained from the INFORMATION_SCHEMA ENGINES table. See Section 21.6, “The INFORMATION_SCHEMA ENGINES Table”.

```
mysql> SHOW ENGINES\G
*************************** 1. row ***************************
Engine: MEMORY
   Support: YES
     Comment: Hash based, stored in memory, useful for temporary tables
Transactions: NO
   XA: NO
   Savepoints: NO
*************************** 2. row ***************************
Engine: MyISAM
   Support: YES
     Comment: MyISAM storage engine
Transactions: NO
   XA: NO
   Savepoints: NO
*************************** 3. row ***************************
Engine: InnoDB
   Support: DEFAULT
     Comment: Supports transactions, row-level locking, and foreign keys
Transactions: YES
   XA: YES
   Savepoints: YES
*************************** 4. row ***************************
Engine: EXAMPLE
   Support: YES
     Comment: Example storage engine
Transactions: NO
   XA: NO
   Savepoints: NO
*************************** 5. row ***************************
Engine: ARCHIVE
   Support: YES
     Comment: Archive storage engine
Transactions: NO
   XA: NO
   Savepoints: NO
*************************** 6. row ***************************
Engine: CSV
   Support: YES
     Comment: CSV storage engine
Transactions: NO
   XA: NO
   Savepoints: NO
```
The output from `SHOW ENGINES` may vary according to the MySQL version used and other factors. The values shown in the `Support` column indicate the server's level of support for the storage engine, as shown in the following table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>YES</td>
<td>The engine is supported and is active</td>
</tr>
<tr>
<td>DEFAULT</td>
<td>Like YES, plus this is the default engine</td>
</tr>
<tr>
<td>NO</td>
<td>The engine is not supported</td>
</tr>
<tr>
<td>DISABLED</td>
<td>The engine is supported but has been disabled</td>
</tr>
</tbody>
</table>

A value of NO means that the server was compiled without support for the engine, so it cannot be enabled at runtime.

A value of DISABLED occurs either because the server was started with an option that disables the engine, or because not all options required to enable it were given. In the latter case, the error log file should contain a reason indicating why the option is disabled. See Section 5.2.2, “The Error Log”.

You might also see DISABLED for a storage engine if the server was compiled to support it, but was started with a --skip-engine_name option. For the NDBCLUSTER storage engine, DISABLED means the server was compiled with support for MySQL Cluster, but was not started with the --ndbcluster option.

All MySQL servers support MyISAM tables, because MyISAM is the default storage engine. It is not possible to disable MyISAM.

The `Transactions`, `XA`, and `Savepoints` columns indicate whether the storage engine supports transactions, XA transactions, and savepoints, respectively.

### 13.7.5.18 SHOW ERRORS Syntax

```
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW COUNT(*) ERRORS
```

`SHOW ERRORS` is a diagnostic statement that is similar to `SHOW WARNINGS`, except that it displays information only for errors, rather than for errors, warnings, and notes.
The `LIMIT` clause has the same syntax as for the `SELECT` statement. See Section 13.2.9, "SELECT Syntax".

The `SHOW COUNT(*) ERRORS` statement displays the number of errors. You can also retrieve this number from the `error_count` variable:

```sql
SHOW COUNT(*) ERRORS;
SELECT @@error_count;
```

`SHOW ERRORS` and `error_count` apply only to errors, not warnings or notes. In other respects, they are similar to `SHOW WARNINGS` and `warning_count`. In particular, `SHOW ERRORS` cannot display information for more than `max_error_count` messages, and `error_count` can exceed the value of `max_error_count` if the number of errors exceeds `max_error_count`.

For more information, see Section 13.7.5.41, "SHOW WARNINGS Syntax".

### 13.7.5.19 SHOW EVENTS Syntax

```sql
SHOW EVENTS {[FROM | IN] schema_name} 
[LIKE 'pattern' | WHERE expr]
```

This statement displays information about Event Manager events. It requires the `EVENT` privilege for the database from which the events are to be shown.

In its simplest form, `SHOW EVENTS` lists all of the events in the current schema:

```sql
mysql> SELECT CURRENT_USER(), SCHEMA();
+----------------+----------+
| CURRENT_USER() | SCHEMA()  |
+----------------+----------+
| jon@ghidora    | myschema |
+----------------+----------+
1 row in set (0.00 sec)
```

```sql
mysql> SHOW EVENTS\G
**************************** 1. row ***************************
Db: myschema
Name: e_daily
Definer: jon@ghidora
Time zone: SYSTEM
Type: RECURRING
Execute at: NULL
Interval value: 10
Interval field: SECOND
Starts: 2006-02-09 10:41:23
Ends: NULL
Status: ENABLED
Originator: 0
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci
```

To see events for a specific schema, use the `FROM` clause. For example, to see events for the `test` schema, use the following statement:

```sql
SHOW EVENTS FROM test;
```

The `LIKE` clause, if present, indicates which event names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 21.31, "Extensions to SHOW Statements".
SHOW EVENTS output has the following columns:

- **Db**: The schema (database) on which the event is defined.
- **Name**: The name of the event.
- **Time zone**: The event time zone, which is the time zone used for scheduling the event and that is in effect within the event as it executes. The default value is **SYSTEM**.
- **Definer**: The account of the user who created the event, in 'user_name'@'host_name' format.
- **Type**: The event repetition type, either **ONE TIME** (transient) or **RECURRING** (repeating).
- **Execute At**: The date and time when a transient event is set to execute. Shown as a **DATETIME** value.
  
  For a recurring event, the value of this column is always **NULL**.
- **Interval Value**: For a recurring event, the number of intervals to wait between event executions.
  
  For a transient event, the value of this column is always **NULL**.
- **Interval Field**: The time units used for the interval which a recurring event waits before repeating.
  
  For a transient event, the value of this column is always **NULL**.
- **Starts**: The start date and time for a recurring event. This is displayed as a **DATETIME** value, and is **NULL** if no start date and time are defined for the event.
  
  For a transient event, this column is always **NULL**.
- **Ends**: The end date and time for a recurring event. This is displayed as a **DATETIME** value, and defaults to **NULL** if no end date and time is defined for the event.
  
  For a transient event, this column is always **NULL**.
- **Status**: The event status. One of **ENABLED**, **DISABLED**, or **SLAVESIDE_DISABLED**.
  
  **SLAVESIDE_DISABLED** indicates that the creation of the event occurred on another MySQL server acting as a replication master and replicated to the current MySQL server which is acting as a slave, but the event is not presently being executed on the slave.
- **Originator**: The server ID of the MySQL server on which the event was created. Defaults to 0.
- **character_set_client** is the session value of the **character_set_client** system variable when the routine was created. **collation_connection** is the session value of the **collation_connection** system variable when the routine was created. **Database Collation** is the collation of the database with which the routine is associated.

For more information about **SLAVE_DISABLED** and the **Originator** column, see Section 17.4.1.11, “Replication of Invoked Features”.

The event action statement is not shown in the output of **SHOW EVENTS**. Use **SHOW CREATE EVENT** or the **INFORMATION_SCHEMA.EVENTS** table.

Times displayed by **SHOW EVENTS** are given in the event time zone, as discussed in Section 20.4.4, “Event Metadata”.

The columns in the output of **SHOW EVENTS** are similar to, but not identical to the columns in the **INFORMATION_SCHEMA.EVENTS** table. See Section 21.7, “The INFORMATION_SCHEMA EVENTS Table”.
13.7.5.20 **SHOW FUNCTION CODE Syntax**

```
SHOW FUNCTION CODE func_name
```

This statement is similar to **SHOW PROCEDURE CODE** but for stored functions. See Section 13.7.5.28, “**SHOW PROCEDURE CODE Syntax**”.

13.7.5.21 **SHOW FUNCTION STATUS Syntax**

```
SHOW FUNCTION STATUS
[LIKE 'pattern' | WHERE expr]
```

This statement is similar to **SHOW PROCEDURE STATUS** but for stored functions. See Section 13.7.5.29, “**SHOW PROCEDURE STATUS Syntax**”.

13.7.5.22 **SHOW GRANTS Syntax**

```
SHOW GRANTS [FOR user]
```

This statement lists the **GRANT** statement or statements that must be issued to duplicate the privileges that are granted to a MySQL user account. The account is named using the same format as for the **GRANT** statement; for example, "jeffrey'@'localhost'. If you specify only the user name part of the account name, a host name part of '%' is used. For additional information about specifying account names, see Section 13.7.1.3, "**GRANT Syntax**".

```
mysql> SHOW GRANTS FOR 'root'@'localhost';
+---------------------------------------------------------------------------------------+
| Grants for root@localhost                                                               |
| +---------------------------------------------------------------------+--------------------------|
| | GRANT ALL PRIVILEGES ON *.* TO 'root'@'localhost' WITH GRANT OPTION |                          |
+---------------------------------------------------------------------------------------+
```

To list the privileges granted to the account that you are using to connect to the server, you can use any of the following statements:

```
SHOW GRANTS;
SHOW GRANTS FOR CURRENT_USER;
SHOW GRANTS FOR CURRENT_USER();
```

If **SHOW GRANTS FOR CURRENT_USER** (or any of the equivalent syntaxes) is used in **DEFINER** context, such as within a stored procedure that is defined with **SQL SECURITY DEFINER**), the grants displayed are those of the definer and not the invoker.

**SHOW GRANTS** displays only the privileges granted explicitly to the named account. Other privileges might be available to the account, but they are not displayed. For example, if an anonymous account exists, the named account might be able to use its privileges, but **SHOW GRANTS** will not display them.

**SHOW GRANTS** requires the **SELECT** privilege for the **mysql** database, except to see the privileges for the current user.

13.7.5.23 **SHOW INDEX Syntax**

```
SHOW {INDEX | INDEXES | KEYS}
```

1582
SHOW Syntax

SHOW INDEX returns table index information. The format resembles that of the SQLStatistics call in ODBC. This statement requires some privilege for any column in the table.

SHOW INDEX returns the following fields:

- **Table**
  The name of the table.

- **Non_unique**
  0 if the index cannot contain duplicates, 1 if it can.

- **Key_name**
  The name of the index. If the index is the primary key, the name is always PRIMARY.

- **Seq_in_index**
  The column sequence number in the index, starting with 1.

- **Column_name**
  The column name.

- **Collation**
  How the column is sorted in the index. In MySQL, this can have values "A" (Ascending) or NULL (Not sorted).

- **Cardinality**
  An estimate of the number of unique values in the index. This is updated by running ANALYZE TABLE or myisamchk -a. Cardinality is counted based on statistics stored as integers, so the value is not necessarily exact even for small tables. The higher the cardinality, the greater the chance that MySQL uses the index when doing joins.

- **Sub_part**
  The number of indexed characters if the column is only partly indexed, NULL if the entire column is indexed.

- **Packed**
  Indicates how the key is packed. NULL if it is not.

- **Null**
  Contains YES if the column may contain NULL values and '' if not.

- **Index_type**
  The index method used (BTREE, FULLTEXT, HASH, RTREE).

- **Comment**
Information about the index not described in its own column, such as disabled if the index is disabled.

- **Index_comment**

Any comment provided for the index with a COMMENT attribute when the index was created.

You can use `db_name.tbl_name` as an alternative to the `tbl_name FROM db_name` syntax. These two statements are equivalent:

```
SHOW INDEX FROM mytable FROM mydb;
SHOW INDEX FROM mydb.mytable;
```

The WHERE clause can be given to select rows using more general conditions, as discussed in [Section 21.31, "Extensions to SHOW Statements"](#).

You can also list a table's indexes with the `mysqlshow -k db_name tbl_name` command.

### 13.7.24 SHOW MASTER STATUS Syntax

```
SHOW MASTER STATUS
```

This statement provides status information about the binary log files of the master. It requires either the SUPER or REPLICATION CLIENT privilege.

Example:

```
mysql> SHOW MASTER STATUS;
+---------------+----------+--------------+------------------+
| File          | Position | Binlog_Do_DB | Binlog_Ignore_DB |
+---------------+----------+--------------+------------------+
| mysql-bin.003 | 73       | test         | manual,mysql     |
+---------------+----------+--------------+------------------+
```

### 13.7.25 SHOW OPEN TABLES Syntax

```
SHOW OPEN TABLES {{FROM | IN} db_name} [LIKE 'pattern' | WHERE expr]
```

SHOW OPEN TABLES lists the non-TEMPORARY tables that are currently open in the table cache. See [Section 8.4.3.1, “How MySQL Opens and Closes Tables”](#). The FROM clause, if present, restricts the tables shown to those present in the `db_name` database. The LIKE clause, if present, indicates which table names to match. The WHERE clause can be given to select rows using more general conditions, as discussed in [Section 21.31, “Extensions to SHOW Statements”](#).

SHOW OPEN TABLES output has the following columns:

- **Database**

  The database containing the table.

- **Table**

  The table name.

- **In_use**
The number of table locks or lock requests there are for the table. For example, if one client acquires a lock for a table using `LOCK TABLE t1 WRITE`, `In_use` will be 1. If another client issues `LOCK TABLE t1 WRITE` while the table remains locked, the client will block waiting for the lock, but the lock request causes `In_use` to be 2. If the count is zero, the table is open but not currently being used. `In_use` is also increased by the `HANDLER ... OPEN` statement and decreased by `HANDLER ... CLOSE`.

- **Name_locked**

Whether the table name is locked. Name locking is used for operations such as dropping or renaming tables.

If you have no privileges for a table, it does not show up in the output from `SHOW OPEN TABLES`.

**13.7.5.26 SHOW PLUGINS Syntax**

SHOW PLUGINS displays information about server plugins. Plugin information is also available in the `INFORMATION_SCHEMA.PLUGINS` table. See Section 21.13, "The INFORMATION_SCHEMA PLUGINS Table".

Example of `SHOW PLUGINS` output:

```
mysql> SHOW PLUGINS
*************************** 1. row ***************************
  Name: binlog
  Status: ACTIVE
  Type: STORAGE ENGINE
  Library: NULL
  License: GPL
*************************** 2. row ***************************
  Name: CSV
  Status: ACTIVE
  Type: STORAGE ENGINE
  Library: NULL
  License: GPL
*************************** 3. row ***************************
  Name: MEMORY
  Status: ACTIVE
  Type: STORAGE ENGINE
  Library: NULL
  License: GPL
*************************** 4. row ***************************
  Name: MyISAM
  Status: ACTIVE
  Type: STORAGE ENGINE
  Library: NULL
  License: GPL
...
```

`SHOW PLUGINS` output has the following columns:

- **Name**: The name used to refer to the plugin in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`.

- **Status**: The plugin status, one of `ACTIVE`, `INACTIVE`, `DISABLED`, or `DELETED`.

- **Type**: The type of plugin, such as `STORAGE ENGINE`, `INFORMATION_SCHEMA`, or `AUTHENTICATION`.
• **Library**: The name of the plugin shared object file. This is the name used to refer to the plugin file in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`. This file is located in the directory named by the `plugin_dir` system variable. If the library name is `NULL`, the plugin is compiled in and cannot be uninstalled with `UNINSTALL PLUGIN`.

• **License**: How the plugin is licensed; for example, `GPL`.

For plugins installed with `INSTALL PLUGIN`, the `Name` and `Library` values are also registered in the `mysql.plugin` table.

For information about plugin data structures that form the basis of the information displayed by `SHOW PLUGINS`, see Section 24.2, “The MySQL Plugin API”.

### 13.7.5.27 **SHOW PRIVILEGES** Syntax

```
SHOW PRIVILEGES
SHOW PRIVILEGES
```

`SHOW PRIVILEGES` shows the list of system privileges that the MySQL server supports. The exact list of privileges depends on the version of your server.

```
mysql> SHOW PRIVILEGES\G
*************************** 1. row ***************************
  Privilege: Alter
   Context: Tables
     Comment: To alter the table
*************************** 2. row ***************************
  Privilege: Alter routine
   Context: Functions,Procedures
     Comment: To alter or drop stored functions/procedures
*************************** 3. row ***************************
  Privilege: Create
   Context: Databases,Tables,Indexes
     Comment: To create new databases and tables
*************************** 4. row ***************************
  Privilege: Create routine
   Context: Databases
     Comment: To use CREATE FUNCTION/PROCEDURE
*************************** 5. row ***************************
  Privilege: Create temporary tables
   Context: Databases
     Comment: To use CREATE TEMPORARY TABLE
...
```

Privileges belonging to a specific user are displayed by the `SHOW GRANTS` statement. See Section 13.7.5.22, “`SHOW GRANTS` Syntax”, for more information.

### 13.7.5.28 **SHOW PROCEDURE CODE** Syntax

```
SHOW PROCEDURE CODE proc_name

SHOW PROCEDURE CODE proc_name
```

This statement is a MySQL extension that is available only for servers that have been built with debugging support. It displays a representation of the internal implementation of the named stored procedure. A similar statement, `SHOW FUNCTION CODE`, displays information about stored functions (see Section 13.7.5.20, “`SHOW FUNCTION CODE` Syntax”).

To use either statement, you must be the owner of the routine or have `SELECT` access to the `mysql.proc` table.
If the named routine is available, each statement produces a result set. Each row in the result set corresponds to one “instruction” in the routine. The first column is `Pos`, which is an ordinal number beginning with 0. The second column is `Instruction`, which contains an SQL statement (usually changed from the original source), or a directive which has meaning only to the stored-routine handler.

```sql
mysql> DELIMITER //
mysql> CREATE PROCEDURE p1 ()
    
    -> BEGIN
    -> DECLARE fanta INT DEFAULT 55;
    -> DROP TABLE t2;
    -> LOOP
    -> INSERT INTO t3 VALUES (fanta);
    -> END LOOP;
    -> END //
Query OK, 0 rows affected (0.00 sec)
mysql> SHOW PROCEDURE CODE p1//
+-----+----------------------------------------+
<table>
<thead>
<tr>
<th>Pos</th>
<th>Instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>set fanta@0 55</td>
</tr>
<tr>
<td>1</td>
<td>stmt 9 &quot;DROP TABLE t2&quot;</td>
</tr>
<tr>
<td>2</td>
<td>stmt 5 &quot;INSERT INTO t3 VALUES (fanta)&quot;</td>
</tr>
<tr>
<td>3</td>
<td>jump 2</td>
</tr>
</tbody>
</table>
+-----+----------------------------------------+
4 rows in set (0.00 sec)
```

In this example, the nonexecutable `BEGIN` and `END` statements have disappeared, and for the `DECLARE variable_name` statement, only the executable part appears (the part where the default is assigned). For each statement that is taken from source, there is a code word `stmt` followed by a type (9 means `DROP`, 5 means `INSERT`, and so on). The final row contains an instruction `jump 2`, meaning `GOTO instruction #2`.

### 13.7.5.29 `SHOW PROCEDURE STATUS` Syntax

```sql
SHOW PROCEDURE STATUS
    [LIKE 'pattern' | WHERE expr]
```

This statement is a MySQL extension. It returns characteristics of a stored procedure, such as the database, name, type, creator, creation and modification dates, and character set information. A similar statement, `SHOW FUNCTION STATUS`, displays information about stored functions (see Section 13.7.5.21, “SHOW FUNCTION STATUS Syntax”).

The `LIKE` clause, if present, indicates which procedure or function names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 21.31, “Extensions to `SHOW Statements`”.

```sql
mysql> SHOW PROCEDURE STATUS LIKE 'sp1'
```

```
/*----------------------------- 1. row -----------------------------*/
Db: test
Name: sp1
Type: PROCEDURE
Definer: testuser@localhost
Modified: 2004-08-03 15:29:37
Created: 2004-08-03 15:29:37
Security_type: DEFINER
Comment: character_set_client: latin1
collation_connection: latin1_swedish_ci
```
SHOW Syntax

character_set_client is the session value of the character_set_client system variable when the routine was created. collation_connection is the session value of the collation_connection system variable when the routine was created. Database Collation is the collation of the database with which the routine is associated.

You can also get information about stored routines from the Routines table in INFORMATION_SCHEMA. See Section 21.17, “The INFORMATION_SCHEMA ROUTINES Table”.

13.7.5.30 SHOW PROCESSLIST Syntax

SHOW [FULL] PROCESSLIST

SHOW PROCESSLIST shows you which threads are running. You can also get this information from the INFORMATION_SCHEMA PROCESSLIST table or the mysqladmin processlist command. If you have the PROCESS privilege, you can see all threads. Otherwise, you can see only your own threads (that is, threads associated with the MySQL account that you are using). If you do not use the FULL keyword, only the first 100 characters of each statement are shown in the Info field.

This statement is very useful if you get the “too many connections” error message and want to find out what is going on. MySQL reserves one extra connection to be used by accounts that have the SUPER privilege, to ensure that administrators should always be able to connect and check the system (assuming that you are not giving this privilege to all your users).

Threads can be killed with the KILL statement. See Section 13.7.6.4, “KILL Syntax”.

Here is an example of SHOW PROCESSLIST output:

mysql> SHOW FULL PROCESSLIST\G
*************************** 1. row ***************************
Id: 1
User: system user
Host: 
db: NULL
Command: Connect
Time: 1030455
State: Waiting for master to send event
Info: NULL
*************************** 2. row ***************************
Id: 2
User: system user
Host: 
db: NULL
Command: Connect
Time: 1004
State: Has read all relay log; waiting for the slave I/O thread to update it
Info: NULL
*************************** 3. row ***************************
Id: 3112
User: replikator
Host: artemis:2204
db: NULL
Command: Binlog Dump
Time: 2144
State: Has sent all binlog to slave; waiting for binlog to be updated
Info: NULL
*************************** 4. row ***************************
Id: 3113
The columns produced by `SHOW PROCESSLIST` have the following meanings:

- **Id**
  The connection identifier.

- **User**
  The MySQL user who issued the statement. If this is a **system user**, it refers to a nonclient thread spawned by the server to handle tasks internally. This could be the I/O or SQL thread used on replication slaves or a delayed-row handler. **unauthenticated user** refers to a thread that has become associated with a client connection but for which authentication of the client user has not yet been done. **event_scheduler** refers to the thread that monitors scheduled events. For **system user**, there is no host specified in the **Host** column.

- **Host**
  The host name of the client issuing the statement (except for **system user** where there is no host). `SHOW PROCESSLIST` reports the host name for TCP/IP connections in `host_name:client_port` format to make it easier to determine which client is doing what.

- **db**
  The default database, if one is selected, otherwise **NULL**.

- **Command**
  The type of command the thread is executing. For descriptions for thread commands, see **Section 8.12.5, “Examining Thread Information”**. The value of this column corresponds to the **COM_xxx** commands of the client/server protocol and **Com_xxx** status variables. See **Section 5.1.6, “Server Status Variables”**.

- **Time**
  The time in seconds that the thread has been in its current state. For a slave SQL thread, the value is the number of seconds between the timestamp of the last replicated event and the real time of the slave machine. See **Section 17.2.1, “Replication Implementation Details”**.

- **State**
  An action, event, or state that indicates what the thread is doing. Descriptions for **State** values can be found at **Section 8.12.5, “Examining Thread Information”**.
Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

For the `SHOW PROCESSLIST` statement, the value of `State` is `NULL`.

- `Info`

  The statement the thread is executing, or `NULL` if it is not executing any statement. The statement might be the one sent to the server, or an innermost statement if the statement executes other statements. For example, if a `CALL` statement executes a stored procedure that is executing a `SELECT` statement, the `Info` value shows the `SELECT` statement.

### 13.7.5.31 SHOW PROFILE Syntax

```
SHOW PROFILE [type [, type] ... ]
  [FOR QUERY n]
  [LIMIT row_count [OFFSET offset]]
```

type:
  ALL
  | BLOCK IO
  | CONTEXT SWITCHES
  | CPU
  | IPC
  | MEMORY
  | PAGE FAULTS
  | SOURCE
  | SWAPS

The `SHOW PROFILE` and `SHOW PROFILES` statements display profiling information that indicates resource usage for statements executed during the course of the current session.

Profiling is controlled by the `profiling` session variable, which has a default value of 0 (`OFF`). Profiling is enabled by setting `profiling` to 1 or `ON`:

```
mysql> SET profiling = 1;
```

`SHOW PROFILES` displays a list of the most recent statements sent to the server. The size of the list is controlled by the `profiling_history_size` session variable, which has a default value of 15. The maximum value is 100. Setting the value to 0 has the practical effect of disabling profiling.

All statements are profiled except `SHOW PROFILE` and `SHOW PROFILES`, so you will find neither of those statements in the profile list. Malformed statements are profiled. For example, `SHOW PROFILING` is an illegal statement, and a syntax error occurs if you try to execute it, but it will show up in the profiling list.

`SHOW PROFILE` displays detailed information about a single statement. Without the `FOR QUERY n` clause, the output pertains to the most recently executed statement. If `FOR QUERY n` is included, `SHOW PROFILE` displays information for statement `n`. The values of `n` correspond to the `Query_ID` values displayed by `SHOW PROFILES`.

The `LIMIT row_count` clause may be given to limit the output to `row_count` rows. If `LIMIT` is given, `OFFSET offset` may be added to begin the output `offset` rows into the full set of rows.

By default, `SHOW PROFILE` displays `Status` and `Duration` columns. The `Status` values are like the `State` values displayed by `SHOW PROCESSLIST`, although there might be some minor differences in interpretation for the two statements for some status values (see Section 8.12.5, "Examining Thread Information").
Optional type values may be specified to display specific additional types of information:

- **ALL** displays all information
- **BLOCK IO** displays counts for block input and output operations
- **CONTEXT SWITCHES** displays counts for voluntary and involuntary context switches
- **CPU** displays user and system CPU usage times
- **IPC** displays counts for messages sent and received
- **MEMORY** is not currently implemented
- **PAGE FAULTS** displays counts for major and minor page faults
- **SOURCE** displays the names of functions from the source code, together with the name and line number of the file in which the function occurs
- **SWAPS** displays swap counts

Profiling is enabled per session. When a session ends, its profiling information is lost.

```sql
mysql> SELECT @@profiling;
+-------------+
| @@profiling |
+-------------+
| 0           |
+-------------+
1 row in set (0.00 sec)

mysql> SET profiling = 1;
Query OK, 0 rows affected (0.00 sec)

mysql> DROP TABLE IF EXISTS t1;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> CREATE TABLE t1 (id INT);
Query OK, 0 rows affected (0.01 sec)

mysql> SHOW PROFILES;
+----------+----------+--------------------------+
<table>
<thead>
<tr>
<th>Query_ID</th>
<th>Duration</th>
<th>Query</th>

7 rows in set (0.00 sec)

Note
Profiling is only partially functional on some architectures. For values that depend on the getrusage() system call, NULL is returned on systems such as Windows that do not support the call. In addition, profiling is per process and not per thread. This means that activity on threads within the server other than your own may affect the timing information that you see.

You can also get profiling information from the PROFILING table in INFORMATION_SCHEMA. See Section 21.15, “The INFORMATION_SCHEMA PROFILING Table”. For example, the following queries produce the same result:

SHOW PROFILE FOR QUERY 2;

SELECT STATE, FORMAT(DURATION, 6) AS DURATION
FROM INFORMATION_SCHEMA.PROFILING
WHERE QUERY_ID = 2 ORDER BY SEQ;

13.7.5.32 SHOW PROFILES Syntax

SHOW PROFILES

The SHOW PROFILES statement, together with SHOW PROFILE, displays profiling information that indicates resource usage for statements executed during the course of the current session. For more information, see Section 13.7.5.31, “SHOW PROFILE Syntax”.

13.7.5.33 SHOW RELAYLOG EVENTS Syntax

SHOW RELAYLOG EVENTS

SHOW RELAYLOG EVENTS
   [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]

Shows the events in the relay log of a replication slave. If you do not specify 'log_name', the first relay log is displayed. This statement has no effect on the master.
The **LIMIT** clause has the same syntax as for the **SELECT** statement. See Section 13.2.9, “**SELECT Syntax**”.

**Note**
Issuing a **SHOW RELAYLOG EVENTS** with no **LIMIT** clause could start a very time- and resource-consuming process because the server returns to the client the complete contents of the relay log (including all statements modifying data that have been received by the slave).

**Note**
Some events relating to the setting of user and system variables are not included in the output from **SHOW RELAYLOG EVENTS**. To get complete coverage of events within a relay log, use **mysqlbinlog**.

### 13.7.5.34 **SHOW SLAVE HOSTS** Syntax

**SHOW SLAVE HOSTS**

Displays a list of replication slaves currently registered with the master. (Before MySQL 5.5.3, only slaves started with the **--report-host=host_name** option are visible in this list.)

**SHOW SLAVE HOSTS** should be executed on a server that acts as a replication master. The statement displays information about servers that are or have been connected as replication slaves, with each row of the result corresponding to one slave server, as shown here:

```
mysql> SHOW SLAVE HOSTS;
+------------+-----------+------+-----------+
| Server_id  | Host      | Port | Master_id |
+------------+-----------+------+-----------+
| 192168010  | iconnect2 | 3306 | 192168011 |
| 1921680101 | athena    | 3306 | 192168011 |
+------------+-----------+------+-----------+
```

- **Server_id**: The unique server ID of the slave server, as configured in the slave server's option file, or on the command line with **--server-id=value** [1974].
- **Host**: The host name of the slave server, as configured in the slave server's option file, or on the command line with **--report-host=host_name**. Note that this can differ from the machine name as configured in the operating system.
- **Port**: The port on the master to which the slave server is listening.

In MySQL 5.5.23 and later, a zero in this column means that the slave port (**--report-port**) was not set. Prior to MySQL 5.5.23, 3306 was used as the default in such cases (Bug #13333431).

- **Master_id**: The unique server ID of the master server that the slave server is replicating from. This is the server ID of the server on which **SHOW SLAVE HOSTS** is executed, so this same value is listed for each row in the result.

Some MySQL versions report another variable, **Rpl_recovery_rank**. This variable was never used, and was removed in MySQL 5.5.3. (Bug #13963)

### 13.7.5.35 **SHOW SLAVE STATUS** Syntax

- **Server_id**: The unique server ID of the slave server, as configured in the slave server's option file, or on the command line with **--server-id=value** [1974].
- **Host**: The host name of the slave server, as configured in the slave server's option file, or on the command line with **--report-host=host_name**. Note that this can differ from the machine name as configured in the operating system.
- **Port**: The port on the master to which the slave server is listening.

In MySQL 5.5.23 and later, a zero in this column means that the slave port (**--report-port**) was not set. Prior to MySQL 5.5.23, 3306 was used as the default in such cases (Bug #13333431).

- **Master_id**: The unique server ID of the master server that the slave server is replicating from. This is the server ID of the server on which **SHOW SLAVE HOSTS** is executed, so this same value is listed for each row in the result.

Some MySQL versions report another variable, **Rpl_recovery_rank**. This variable was never used, and was removed in MySQL 5.5.3. (Bug #13963)
SHOW SLAVE STATUS

This statement provides status information on essential parameters of the slave threads. It requires either the `SUPER` or `REPLICATION CLIENT` privilege.

If you issue this statement using the `mysql` client, you can use a `\G` statement terminator rather than a semicolon to obtain a more readable vertical layout:

```sql
mysql> SHOW SLAVE STATUS\G
*************************** 1. row ***************************
    Slave_IO_State: Waiting for master to send event
    Master_Host: localhost
    Master_User: root
    Master_Port: 3306
    Connect_Retry: 3
    Master_Log_File: gbichot-bin.005
    Read_Master_Log_Pos: 79
    Relay_Log_File: gbichot-relay-bin.005
    Relay_Log_Pos: 548
    Relay_Master_Log_File: gbichot-bin.005
    Slave_IO_Running: Yes
    Slave_SQL_Running: Yes
    Replicate_Do_DB: 
    Replicate_Ignore_DB: 
    Replicate_Do_Table: 
    Replicate_Ignore_Table: 
    Replicate_Wild_Do_Table: 
    Replicate_Wild_Ignore_Table: 
    Last_Errno: 0
    Last_Error: 
    Skip_Counter: 0
    Exec_Master_Log_Pos: 79
    Relay_Log_Space: 552
    Until_Condition: None
    Until_Log_File: 
    Until_Log_Pos: 0
    Master_SSL_Allowed: No
    Master_SSL_CA_File: 
    Master_SSL_CA_Path: 
    Master_SSL_Cert: 
    Master_SSL_Cipher: 
    Master_SSL_Key: 
    Seconds_Behind_Master: 8
    Master_SSL_Verify_Server_Cert: No
    Last_IO_Errno: 0
    Last_IO_Error: 
    Last_SQL_Errno: 0
    Last_SQL_Error: 
    Replicate_Ignore_Server_Ids: 0
    Master_Server_Id: 1
```

The following list describes the fields returned by `SHOW SLAVE STATUS`. For additional information about interpreting their meanings, see Section 8.12.5.6, “Replication Slave I/O Thread States”.

- **Slave_IO_State**
  
  A copy of the `State` field of the `SHOW PROCESSLIST` output for the slave I/O thread. This tells you what the thread is doing: trying to connect to the master, waiting for events from the master, reconnecting to the master, and so on. For a listing of possible states, see Section 8.12.5.6, “Replication Slave I/O Thread States”.

- **Master_Host**
SHOW Syntax

The master host that the slave is connected to.

- **Master_User**
  The user name of the account used to connect to the master.

- **Master_Port**
  The port used to connect to the master.

- **Connect_Retry**
  The number of seconds between connect retries (default 60). This can be set with the `CHANGE MASTER TO` statement.

- **Master_Log_File**
  The name of the master binary log file from which the I/O thread is currently reading.

- **Read_Master_Log_Pos**
  The position in the current master binary log file up to which the I/O thread has read.

- **Relay_Log_File**
  The name of the relay log file from which the SQL thread is currently reading and executing.

- **Relay_Log_Pos**
  The position in the current relay log file up to which the SQL thread has read and executed.

- **Relay_Master_Log_File**
  The name of the master binary log file containing the most recent event executed by the SQL thread.

- **Slave_IO_Running**
  Whether the I/O thread is started and has connected successfully to the master. Internally, the state of this thread is represented by one of the following three values:

  - **MYSQL_SLAVE_NOT_RUN.** The slave I/O thread is not running. For this state, `Slave_IO_Running` is **No**.

  - **MYSQL_SLAVE_RUN_NOT_CONNECT.** The slave I/O thread is running, but is not connected to a replication master. For this state, `Slave_IO_Running` depends on the server version as shown in the following table.

    | MySQL Version | Slave_IO_Running |
    |---------------|-------------------|
    | 4.1 (4.1.13 and earlier); 5.0 (5.0.11 and earlier) | Yes |
    | 4.1 (4.1.14 and later); 5.0 (5.0.12 and later) | No |
    | 5.1 (5.1.45 and earlier) | No |
    | 5.1 (5.1.46 and later); 5.5 | Connecting |

  - **MYSQL_SLAVE_RUN_CONNECT.** The slave I/O thread is running, and is connected to a replication master. For this state, `Slave_IO_Running` is **Yes**.
The value of the `Slave_running` system status variable corresponds with this value.

- **Slave_SQL_Running**
  Whether the SQL thread is started.

- **Replicate_Do_DB, Replicate_Ignore_DB**
  The lists of databases that were specified with the `--replicate-do-db` and `--replicate-ignore-db` options, if any.

- **Replicate_Do_Table, Replicate_Ignore_Table, Replicate_Wild_Do_Table, Replicate_Wild_Ignore_Table**
  The lists of tables that were specified with the `--replicate-do-table`, `--replicate-ignore-table`, `--replicate-wild-do-table`, and `--replicate-wild-ignore-table` options, if any.

- **Last_Errno, Last_Error**
  These columns are aliases for `Last_SQL_Errno` and `Last_SQL_Error`.
  Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

  **Note**
  When the slave SQL thread receives an error, it reports the error first, then stops the SQL thread. This means that there is a small window of time during which `SHOW SLAVE STATUS` shows a nonzero value for `Last_SQL_Errno` even though `Slave_SQL_Running` still displays `Yes`.

- **Skip_Counter**
  The current value of the `sql_slave_skip_counter` system variable. See Section 13.4.2.4, “SET GLOBAL sql_slave_skip_counter Syntax”.

- **Exec_Master_Log_Pos**
  The position in the current master binary log file to which the SQL thread has read and executed, marking the start of the next transaction or event to be processed. You can use this value with the `CHANGE MASTER TO` statement's `MASTER_LOG_POS` option when starting a new slave from an existing slave, so that the new slave reads from this point. The coordinates given by `(Relay_Master_Log_File, Exec_Master_Log_Pos)` in the master's binary log correspond to the coordinates given by `(Relay_Log_File, Relay_Log_Pos)` in the relay log.

- **Relay_Log_Space**
  The total combined size of all existing relay log files.

- **Until_Condition, Until_Log_File, Until_Log_Pos**
  The values specified in the `UNTIL` clause of the `START SLAVE` statement. `Until_Condition` has these values:
  - **None** if no `UNTIL` clause was specified
  - **Master** if the slave is reading until a given position in the master's binary log
• **Relay** if the slave is reading until a given position in its relay log

*Until_Log_File* and *Until_Log_Pos* indicate the log file name and position that define the coordinates at which the SQL thread stops executing.

• **Master_SSL_Allowed, Master_SSL_CA_File, Master_SSL_CA_Path, Master_SSL_Cert, Master_SSL_Cipher, Master_SSL_Key, Master_SSL_Verify_Server_Cert**

These fields show the SSL parameters used by the slave to connect to the master, if any.

**Master_SSL_Allowed** has these values:

• **Yes** if an SSL connection to the master is permitted

• **No** if an SSL connection to the master is not permitted

• **Ignored** if an SSL connection is permitted but the slave server does not have SSL support enabled

The values of the other SSL-related fields correspond to the values of the **MASTER_SSL_CA, MASTER_SSL_CAPATH, MASTER_SSL_CERT, MASTER_SSL_CIPHER, MASTER_SSL_KEY, and MASTER_SSL_VERIFY_SERVER_CERT** options to the **CHANGE MASTER TO** statement. See **Section 13.4.2.1, “CHANGE MASTER TO Syntax”**.

• **Seconds_Behind_Master**

This field is an indication of how “late” the slave is:

• When the slave is actively processing updates, this field shows the difference between the current timestamp on the slave and the original timestamp logged on the master for the most event currently being processed on the slave.

• When no event is currently being processed on the slave, this value is 0.

In essence, this field measures the time difference in seconds between the slave SQL thread and the slave I/O thread. If the network connection between master and slave is fast, the slave I/O thread is very close to the master, so this field is a good approximation of how late the slave SQL thread is compared to the master. If the network is slow, this is not a good approximation; the slave SQL thread may quite often be caught up with the slow-reading slave I/O thread, so *Seconds_Behind_Master* often shows a value of 0, even if the I/O thread is late compared to the master. In other words, **this column is useful only for fast networks**.

This time difference computation works even if the master and slave do not have identical clock times, provided that the difference, computed when the slave I/O thread starts, remains constant from then on. Any changes—including NTP updates—can lead to clock skews that can make calculation of *Seconds_Behind_Master* less reliable.

This field is **NULL** (undefined or unknown) if the slave SQL thread is not running, or if the slave I/O thread is not running or is not connected to the master. For example, if the slave I/O thread is running but is not connected to the master and is sleeping for the number of seconds given by the **CHANGE MASTER TO** statement or **--master-connect-retry** option (default 60) before reconnecting, the value is **NULL**. This is because the slave cannot know what the master is doing, and so cannot say reliably how late it is.

The value of **Seconds_Behind_Master** is based on the timestamps stored in events, which are preserved through replication. This means that if a master M1 is itself a slave of M0, any event from M1’s binary log that originates from M0’s binary log has M0’s timestamp for that event. This enables MySQL
show syntax

to replicate TIMESTAMP successfully. However, the problem for Seconds_Behind_Master is that if M1 also receives direct updates from clients, the Seconds_Behind_Master value randomly fluctuates because sometimes the last event from M1 originates from M0 and sometimes is the result of a direct update on M1.

- Last_IO_Errno, Last_IO_Error

The error number and error message of the most recent error that caused the I/O thread to stop. An error number of 0 and message of the empty string mean "no error." If the Last_IO_Error value is not empty, the error values also appear in the slave's error log.

Prior to MySQL 5.5, Last_IO_Error and Last_IO_Errno were not set in the event that replication failed due to exceeding max_allowed_packet (Bug #42914).

Issuing RESET MASTER or RESET SLAVE resets the values shown in these columns.

- Last_SQL_Errno, Last_SQL_Error

The error number and error message of the most recent error that caused the SQL thread to stop. An error number of 0 and message of the empty string mean "no error." If the Last_SQL_Error value is not empty, the error values also appear in the slave's error log.

Example:

```
Last_SQL_Errno: 1051
Last_SQL_Error: error 'Unknown table 'z'' on query 'drop table z'
```

The message indicates that the table z existed on the master and was dropped there, but it did not exist on the slave, so DROP TABLE failed on the slave. (This might occur, for example, if you forget to copy the table to the slave when setting up replication.)

Issuing RESET MASTER or RESET SLAVE resets the values shown in these columns.

- Replicate_Ignore_Server_Ids

Beginning with MySQL 5.5, you can tell a slave to ignore events from 0 or more masters using the IGNORE_SERVER_IDS option of the CHANGE MASTER TO statement. This is normally of interest only when using a circular or other multi-master replication setup.

The message shown for Replicate_Ignore_Server_Ids consists of a space-delimited list of one or more numbers, the first value indicating the number of servers to be ignored; if not 0 (the default), this server-count value is followed by the actual server IDs. For example, if a CHANGE MASTER TO statement containing the IGNORE_SERVER_IDS = (2,6,9) option has been issued to tell a slave to ignore masters having the server ID 2, 6, or 9, that information appears as shown here:

```
Replicate_Ignore_Server_Ids: 3 2 6 9
```

Replicate_Ignore_Server_Ids filtering is performed by the I/O thread, rather than by the SQL thread, which means that events which are filtered out are not written to the relay log. This differs from the filtering actions taken by server options such --replicate-do-table, which apply to the SQL thread.

- Master_Server_Id

The server_id value from the master.
13.7.5.36 **SHOW STATUS** Syntax

SHOW [GLOBAL | SESSION] STATUS
    [LIKE 'pattern' | WHERE expr]

**SHOW STATUS** provides server status information. This information also can be obtained using the `mysqladmin extended-status` command. The **LIKE** clause, if present, indicates which variable names to match. The **WHERE** clause can be given to select rows using more general conditions, as discussed in Section 21.31, “Extensions to SHOW Statements”. This statement does not require any privilege. It requires only the ability to connect to the server.

Partial output is shown here. The list of names and values may be different for your server. The meaning of each variable is given in Section 5.1.6, “Server Status Variables”.

```
mysql> SHOW STATUS;
+--------------------------+------------+
| Variable_name            | Value      |
+--------------------------+------------+
| Aborted_clients          | 0          |
| Aborted_connects         | 0          |
| Bytes_received           | 155372598  |
| Bytes_sent               | 1176560426 |
| Connections              | 30023      |
| Created_tmp_disk_tables  | 0          |
| Created_tmp_tables       | 8340       |
| Created_tmp_files        | 60         |
| ...                      |            |
| Open_tables              | 1          |
| Open_files               | 2          |
| Open_streams             | 0          |
| Opened_tables            | 44600      |
| Questions                | 2026873    |
| ...                      |            |
| Table_locks_immediate    | 1920382    |
| Table_locks_waited       | 0          |
| Threads_cached           | 0          |
| Threads_created          | 30022      |
| Threads_connected        | 1          |
| Threads_running          | 1          |
| Uptime                   | 80380      |
+--------------------------+------------+
```

With a **LIKE** clause, the statement displays only rows for those variables with names that match the pattern:

```
mysql> SHOW STATUS LIKE 'Key%';
+--------------------------+----------+
| Variable_name            | Value    |
+--------------------------+----------+
| Key_blocks_used          | 14955    |
| Key_read_requests        | 96894827 |
| Key_reads                | 162040   |
| Key_write_requests       | 7589728  |
| Key_writes               | 3813196  |
+--------------------------+----------+
```

With the **GLOBAL** modifier, **SHOW STATUS** displays the status values for all connections to MySQL. With **SESSION**, it displays the status values for the current connection. If no modifier is present, the default is **SESSION**. **LOCAL** is a synonym for **SESSION**.
Some status variables have only a global value. For these, you get the same value for both \texttt{GLOBAL} and \texttt{SESSION}. The scope for each status variable is listed at Section 5.1.6, “Server Status Variables”.

Each invocation of the \texttt{SHOW\ STATUS} statement uses an internal temporary table and increments the global \texttt{Created_tmp_tables} value.

### 13.7.5.37 \texttt{SHOW\ TABLE\ STATUS} Syntax

\begin{verbatim}
SHOW TABLE STATUS \{\{FROM | IN\} db_name\} \\
    \{LIKE 'pattern' | WHERE expr\}
\end{verbatim}

\texttt{SHOW TABLE STATUS} works like \texttt{SHOW TABLES}, but provides a lot of information about each non-\texttt{TEMPORARY} table. You can also get this list using the \texttt{mysqlshow --status db_name} command. The \texttt{LIKE} clause, if present, indicates which table names to match. The \texttt{WHERE} clause can be given to select rows using more general conditions, as discussed in Section 21.31, “Extensions to \texttt{SHOW} Statements”.

This statement also displays information about views.

\texttt{SHOW TABLE STATUS} output has the following columns:

- **Name**
  
  The name of the table.

- **Engine**
  
  The storage engine for the table. See Chapter 15, \textit{Alternative Storage Engines}.

- **Version**
  
  The version number of the table’s \texttt{.frm} file.

- **Row_format**
  
  The row-storage format (\texttt{Fixed, Dynamic, Compressed, Redundant, Compact}). For \texttt{MyISAM} tables, \texttt{Dynamic} corresponds to what \texttt{myisamchk -dvv} reports as \texttt{Packed}. The format of \texttt{InnoDB} tables is reported as \texttt{Redundant} or \texttt{Compact}. For the \texttt{Barracuda} file format of the \texttt{InnoDB Plugin}, the format may be \texttt{Compressed} or \texttt{Dynamic}.

- **Rows**
  
  The number of rows. Some storage engines, such as \texttt{MyISAM}, store the exact count. For other storage engines, such as \texttt{InnoDB}, this value is an approximation, and may vary from the actual value by as much as 40 to 50%. In such cases, use \texttt{SELECT COUNT(*)} to obtain an accurate count.

  The \texttt{Rows} value is \texttt{NULL} for tables in the \texttt{INFORMATION_SCHEMA} database.

- **Avg_row_length**
  
  The average row length.

- **Data_length**
  
  The length of the data file.

- **Max_data_length**
  
  The maximum data length.
SHOW Syntax

The maximum length of the data file. This is the total number of bytes of data that can be stored in the table, given the data pointer size used.

- **Index_length**

  The length of the index file.

- **Data_free**

  The number of allocated but unused bytes.

  This information is also shown for InnoDB tables (previously, it was in the Comment value). InnoDB tables report the free space of the tablespace to which the table belongs. For a table located in the shared tablespace, this is the free space of the shared tablespace. If you are using multiple tablespaces and the table has its own tablespace, the free space is for only that table. Free space means the number of completely free 1MB extents minus a safety margin. Even if free space displays as 0, it may be possible to insert rows as long as new extents need not be allocated.

  For partitioned tables, this value is only an estimate and may not be absolutely correct. A more accurate method of obtaining this information in such cases is to query the INFORMATION_SCHEMA.PARTITIONS table, as shown in this example:

  ```sql
  SELECT SUM(DATA_FREE)
  FROM INFORMATION_SCHEMA.PARTITIONS
  WHERE TABLE_SCHEMA = 'mydb'
  AND TABLE_NAME = 'mytable';
  ```

  For more information, see Section 21.12, “The INFORMATION_SCHEMA PARTITIONS Table”.

- **Auto_increment**

  The next AUTO_INCREMENT value.

- **Create_time**

  When the table was created.

- **Update_time**

  When the data file was last updated. For some storage engines, this value is NULL. For example, InnoDB stores multiple tables in its system tablespace and the data file timestamp does not apply. Even with file-per-table mode with each InnoDB table in a separate .ibd file, change buffering can delay the write to the data file, so the file modification time is different from the time of the last insert, update, or delete. For MyISAM, the data file timestamp is used; however, on Windows the timestamp is not updated by updates so the value is inaccurate.

- **Check_time**

  When the table was last checked. Not all storage engines update this time, in which case the value is always NULL.

- **Collation**

  The table’s character set and collation.

- **Checksum**
SHOW Syntax

The live checksum value (if any).

- **Create_options**
  Extra options used with `CREATE TABLE`. The original options supplied when `CREATE TABLE` is called are retained and the options reported here may differ from the active table settings and options.

- **Comment**
  The comment used when creating the table (or information as to why MySQL could not access the table information).

For MEMORY tables, the `Data_length`, `Max_data_length`, and `Index_length` values approximate the actual amount of allocated memory. The allocation algorithm reserves memory in large amounts to reduce the number of allocation operations.

For NDBCLUSTER tables, the output of this statement shows appropriate values for the `Avg_row_length` and `Data_length` columns, with the exception that BLOB columns are not taken into account.

For views, all the fields displayed by `SHOW TABLE STATUS` are NULL except that `Name` indicates the view name and `Comment` says `view`.

### 13.7.5.38 SHOW TABLES Syntax

```
SHOW [FULL] TABLES [{FROM | IN} db_name]
   [LIKE 'pattern' | WHERE expr]
```

`SHOW TABLES` lists the non-TEMPORARY tables in a given database. You can also get this list using the `mysqlshow db_name` command. The `LIKE` clause, if present, indicates which table names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 21.31, “Extensions to SHOW Statements”.

Matching performed by the `LIKE` clause is dependent on the setting of the `lower_case_table_names` system variable.

This statement also lists any views in the database. The `FULL` modifier is supported such that `SHOW FULL TABLES` displays a second output column. Values for the second column are `BASE TABLE` for a table and `VIEW` for a view.

If you have no privileges for a base table or view, it does not show up in the output from `SHOW TABLES` or `mysqlshow db_name`.

### 13.7.5.39 SHOW TRIGGERS Syntax

```
SHOW TRIGGERS [{FROM | IN} db_name]
   [LIKE 'pattern' | WHERE expr]
```

`SHOW TRIGGERS` lists the triggers currently defined for tables in a database (the default database unless a `FROM` clause is given). This statement returns results only for databases and tables for which you have the TRIGGER privilege. The `LIKE` clause, if present, indicates which table names to match (not trigger names) and causes the statement to display triggers for those tables. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Section 21.31, “Extensions to SHOW Statements”.

For the trigger `ins_sum` as defined in Section 20.3, “Using Triggers”, the output of this statement is as shown here:
SHOW Syntax

MySQL> SHOW TRIGGERS LIKE 'acc%'
*************************** 1. row ***************************
    Trigger: ins_sum    
      Event: INSERT    
        Table: account    
    Statement: SET @sum = @sum + NEW.amount    
    Timing: BEFORE    
    Created: NULL    
    sql_mode:    
      Definer: myname@localhost    
   character_set_client: latin1    
  collation_connection: latin1_swedish_ci    
Database Collation: latin1_swedish_ci

SHOW TRIGGERS output has the following columns:

- **Trigger**: The trigger name.
- **Event**: The type of operation that causes trigger activation. The value is 'INSERT', 'UPDATE', or 'DELETE'.
- **Table**: The table for which the trigger is defined.
- **Statement**: The trigger body; that is, the statement executed when the trigger activates.
- **Timing**: Whether the trigger activates before or after the triggering event. The value is 'BEFORE' or 'AFTER'.
- **Created**: Currently, the value of this column is always NULL.
- **sql_mode**: The SQL mode in effect when the trigger executes.
- **Definer**: The account of the user who created the trigger, in 'user_name'@'host_name' format.
- **character_set_client**: The session value of the character_set_client system variable when the trigger was created.
- **collation_connection**: The session value of the collation_connection system variable when the trigger was created.
- **Database Collation**: The collation of the database with which the trigger is associated.

You can also obtain information about trigger objects from INFORMATION_SCHEMA, which contains a TRIGGERS table. See Section 21.25, “The INFORMATION_SCHEMA TRIGGERS Table”.

13.7.5.40 SHOW VARIABLES Syntax

SHOW [GLOBAL | SESSION] VARIABLES
    [LIKE 'pattern' | WHERE expr]

SHOW VARIABLES shows the values of MySQL system variables. This information also can be obtained using the mysqladmin variables command. The LIKE clause, if present, indicates which variable names to match. The WHERE clause can be given to select rows using more general conditions, as discussed in Section 21.31, “Extensions to SHOW Statements”. This statement does not require any privilege. It requires only the ability to connect to the server.

With the GLOBAL modifier, SHOW VARIABLES displays the values that are used for new connections to MySQL. As of MySQL 5.5.3, if a variable has no global value, no value is displayed. Before 5.5.3, the session value is displayed. With SESSION, SHOW VARIABLES displays the values that are in effect for the current connection. If no modifier is present, the default is SESSION. LOCAL is a synonym for SESSION.
SHOW VARIABLES is subject to a version-dependent display-width limit. For variables with very long values that are not completely displayed, use SELECT as a workaround. For example:

```
SELECT @@GLOBAL.innodb_data_file_path;
```

If the default system variable values are unsuitable, you can set them using command options when mysqld starts, and most can be changed at runtime with the SET statement. See Section 5.1.5, “Using System Variables”, and Section 13.7.4, “SET Syntax”.

Partial output is shown here. The list of names and values may be different for your server. Section 5.1.4, “Server System Variables”, describes the meaning of each variable, and Section 8.11.2, “Tuning Server Parameters”, provides information about tuning them.

```
mysql> SHOW VARIABLES;
+-----------------------------------------+---------------------------+
| Variable_name                           | Value                     |
+-----------------------------------------+---------------------------+
| auto_increment_increment                | 1                         |
| auto_increment_offset                   | 1                         |
| autocommit                              | ON                        |
| automatic_sp_privileges                 | ON                        |
| back_log                                | 50                        |
| basedir                                 | /home/jon/bin/mysql-5.5   |
| big_tables                              | OFF                       |
| binlog_cache_size                       | 32768                     |
| binlog_direct_non_transactional_updates | OFF                       |
| binlog_format                           | STATEMENT                 |
| binlog_stmt_cache_size                  | 32768                     |
| bulk_insert_buffer_size                 | 8388608                   |
| max_allowed_packet                      | 1048576                   |
| max_binlog_cache_size                   | 18446744073709547520      |
| max_binlog_size                         | 1073741824                |
| max_binlog_stmt_cache_size              | 18446744073709547520      |
| max_connect_errors                      | 10                        |
| max_connections                         | 151                       |
| max_delayed_threads                     | 20                        |
| max_error_count                         | 64                        |
| max_heap_table_size                     | 16777216                  |
| max_insert_delayed_threads              | 20                        |
| max_join_size                           | 18446744073709551615      |
| thread_handling                         | one-thread-per-connection |
| thread_stack                            | 262144                    |
| time_format                             | %H:%i:%s                  |
| time_zone                               | SYSTEM                    |
| timed_mutexes                           | OFF                       |
| timestamp                               | 1316689732                |
| tmpdir                                  | /tmp                      |
| transaction_alloc_block_size            | 8192                      |
| transaction_prealloc_size               | 4096                      |
| tx_isolation                            | REPEATABLE-READ           |
| unique_checks                           | ON                        |
| updatable_views_with_limit              | YES                       |
| version                                 | 5.5.17-log                |
| version_comment                         | Source distribution       |
| version_compile_machine                 | x86_64                    |
| version_compile_os                      | Linux                     |
| wait_timeout                            | 28800                     |
| warning_count                           | 0                         |
+-----------------------------------------+---------------------------+
```
SHOW Syntax

With a `LIKE` clause, the statement displays only rows for those variables with names that match the pattern. To obtain the row for a specific variable, use a `LIKE` clause as shown:

```sql
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the “%” wildcard character in a `LIKE` clause:

```sql
SHOW VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because “_” is a wildcard that matches any single character, you should escape it as “\_” to match it literally. In practice, this is rarely necessary.

13.7.5.41 SHOW WARNINGS Syntax

```sql
SHOW WARNINGS [LIMIT [offset,] row_count]
SHOW COUNT(*) WARNINGS
```

`SHOW WARNINGS` is a diagnostic statement that displays information about the conditions (errors, warnings, and notes) resulting from executing a statement in the current session. Warnings are generated for DML statements such as `INSERT`, `UPDATE`, and `LOAD DATA INFILE` as well as DDL statements such as `CREATE TABLE` and `ALTER TABLE`.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See Section 13.2.9, “SELECT Syntax”.

`SHOW WARNINGS` is also used following `EXPLAIN EXTENDED`, to display the extra information generated by `EXPLAIN` when the `EXTENDED` keyword is used. See Section 8.8.3, “EXPLAIN EXTENDED Output Format”.

`SHOW WARNINGS` displays information about the conditions resulting from the most recent statement in the current session that generated messages. It shows nothing if the most recent statement used a table and generated no messages. (That is, statements that use a table but generate no messages clear the message list.) Statements that do not use tables and do not generate messages have no effect on the message list.

The `SHOW COUNT(*) WARNINGS` diagnostic statement displays the total number of errors, warnings, and notes. You can also retrieve this number from the `warning_count` system variable:

```sql
SHOW COUNT(*) WARNINGS;
SELECT @@warning_count;
```

A related diagnostic statement, `SHOW ERRORS`, shows only error conditions (it excludes warnings and notes), and `SHOW COUNT(*) ERRORS` statement displays the total number of errors. See Section 13.7.5.18, “SHOW ERRORS Syntax”.

Here is a simple example that shows data-conversion warnings for `INSERT`:

```sql
mysql> CREATE TABLE t1 (a TINYINT NOT NULL, b CHAR(4));
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO t1 VALUES(10,'mysql'), (NULL,'test'), (300,'xyz');
Query OK, 3 rows affected, 3 warnings (0.00 sec)
```
SHOW Syntax

```sql
SHOW WARNINGS;
```

```
*************************** 1. row ***************************
  Level: Warning
  Code: 1265
  Message: Data truncated for column 'b' at row 1

*************************** 2. row ***************************
  Level: Warning
  Code: 1048
  Message: Column 'a' cannot be null

*************************** 3. row ***************************
  Level: Warning
  Code: 1264
  Message: Out of range value for column 'a' at row 3
```

3 rows in set (0.00 sec)

The `max_error_count` system variable controls the maximum number of error, warning, and note messages for which the server stores information, and thus the number of messages that `SHOW WARNINGS` displays. To change the number of messages the server can store, change the value of `max_error_count`. The default is 64.

`max_error_count` controls only how many messages are stored, not how many are counted. The value of `warning_count` is not limited by `max_error_count`, even if the number of messages generated exceeds `max_error_count`. The following example demonstrates this. The `ALTER TABLE` statement produces three warning messages (strict SQL mode is disabled for the example to prevent an error from occurring after a single conversion issue). Only one message is stored and displayed because `max_error_count` has been set to 1, but all three are counted (as shown by the value of `warning_count`):

```
mysql> SET max_error_count=1, sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> ALTER TABLE t1 MODIFY b CHAR;
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 3

mysql> SELECT @@warning_count;
+-----------------+
| @@warning_count |
+-----------------+
|               3 |
+-----------------+
```

To disable message storage, set `max_error_count` to 0. In this case, `warning_count` still indicates how many warnings occurred, but messages are not stored and cannot be displayed.
The `sql_notes` system variable controls whether note messages increment `warning_count` and whether the server stores them. By default, `sql_notes` is 1, but if set to 0, notes do not increment `warning_count` and the server does not store them:

```sql
mysql> SET sql_notes = 1;
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected, 1 warning (0.00 sec)
mysql> SHOW WARNINGS;
+-------+------+-------------------------------+
| Level | Code | Message                       |
+-------+------+-------------------------------+
| Note  | 1051 | Unknown table 'no_such_table' |
+-------+------+-------------------------------+
1 row in set (0.00 sec)

mysql> SET sql_notes = 0;
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected (0.00 sec)
mysql> SHOW WARNINGS;
Empty set (0.00 sec)
```

The MySQL server sends to each client a count indicating the total number of errors, warnings, and notes resulting from the most recent statement executed by that client. From the C API, this value can be obtained by calling `mysql_warning_count()`. See Section 23.8.7.72, "mysql_warning_count()".

### 13.7.6 Other Administrative Statements

#### 13.7.6.1 BINLOG Syntax

```
BINLOG 'str'
```

`BINLOG` is an internal-use statement. It is generated by the `mysqlbinlog` program as the printable representation of certain events in binary log files. (See Section 4.6.7, "mysqlbinlog — Utility for Processing Binary Log Files"). The `str` value is a base 64-encoded string that the server decodes to determine the data change indicated by the corresponding event. This statement requires the `SUPER` privilege.

#### 13.7.6.2 CACHE INDEX Syntax

```
CACHE INDEX
tbl_index_list [, tbl_index_list] ...
[PARTITION (partition_list | ALL)]
IN key_cache_name

tbl_index_list:
  tbl_name ([INDEX|KEY] (index_name[, index_name] ...))

partition_list:
  partition_name[, partition_name][, ...]
```

The `CACHE INDEX` statement assigns table indexes to a specific key cache. It is used only for MyISAM tables. After the indexes have been assigned, they can be preloaded into the cache if desired with `LOAD INDEX INTO CACHE`.

The following statement assigns indexes from the tables `t1`, `t2`, and `t3` to the key cache named `hot_cache`:

```sql
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
```
The syntax of **CACHE INDEX** enables you to specify that only particular indexes from a table should be assigned to the cache. The current implementation assigns all the table's indexes to the cache, so there is no reason to specify anything other than the table name.

The key cache referred to in a **CACHE INDEX** statement can be created by setting its size with a parameter setting statement or in the server parameter settings. For example:

```
mysql> SET GLOBAL keycache1.key_buffer_size=128*1024;
```

Key cache parameters can be accessed as members of a structured system variable. See Section 5.1.5.1, “Structured System Variables”.

A key cache must exist before you can assign indexes to it:

```
mysql> CACHE INDEX t1 IN non_existent_cache;
ERROR 1284 (HY000): Unknown key cache 'non_existent_cache'
```

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it become assigned to the default key cache again.

Index assignment affects the server globally: If one client assigns an index to a given cache, this cache is used for all queries involving the index, no matter which client issues the queries.

In MySQL 5.5, this statement is also supported for partitioned **MyISAM** tables. You can assign one or more indexes for one, several, or all partitions to a given key cache. For example, you can do the following:

```
CREATE TABLE pt (c1 INT, c2 VARCHAR(50), INDEX i(c1))
  PARTITION BY HASH(c1)
  PARTITIONS 4;
SET GLOBAL kc_fast.key_buffer_size = 128 * 1024;
SET GLOBAL kc_slow.key_buffer_size = 128 * 1024;
CACHE INDEX pt PARTITION (p0) IN kc_fast;
CACHE INDEX pt PARTITION (p1, p3) IN kc_slow;
```

The previous set of statements performs the following actions:

- Creates a partitioned table with 4 partitions; these partitions are automatically named **p0**, ..., **p3**; this table has an index named **i** on column **c1**.
- Creates 2 key caches named **kc_fast** and **kc_slow**
- Assigns the index for partition **p0** to the **kc_fast** key cache and the index for partitions **p1** and **p3** to the **kc_slow** key cache; the index for the remaining partition (**p2**) uses the server's default key cache.

If you wish instead to assign the indexes for all partitions in table **pt** to a single key cache named **kc_all**, you can use either one of the following 2 statements:

```
CACHE INDEX pt PARTITION (ALL) IN kc_all;
```
Other Administrative Statements

```
CACHE INDEX pt IN kc_all;
```

The two statements just shown are equivalent, and issuing either one of them has exactly the same effect. In other words, if you wish to assign indexes for all partitions of a partitioned table to the same key cache, then the `PARTITION (ALL)` clause is optional.

When assigning indexes for multiple partitions to a key cache, the partitions do not have to be contiguous, and you are not required to list their names in any particular order. Indexes for any partitions that are not explicitly assigned to a key cache automatically use the server’s default key cache.

As of MySQL 5.5, index preloading is also supported for partitioned MyISAM tables. For more information, see Section 13.7.5.6.5, "LOAD INDEX INTO CACHE Syntax".

### 13.7.6.3 FLUSH Syntax

```
FLUSH [NO_WRITE_TO_BINLOG | LOCAL]
    flush_option [, flush_option] ...
```

The `FLUSH` statement has several variant forms that clear or reload various internal caches, flush tables, or acquire locks. To execute `FLUSH`, you must have the `RELOAD` privilege. Specific flush options might require additional privileges, as described later.

By default, the server writes `FLUSH` statements to the binary log so that they replicate to replication slaves. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

**Note**

`FLUSH LOGS,FLUSH MASTER,FLUSH SLAVE, and FLUSH TABLES WITH READ LOCK (with or without a table list) are not written to the binary log in any case because they would cause problems if replicated to a slave.`

Sending a `SIGHUP` signal to the server causes several flush operations to occur that are similar to various forms of the `FLUSH` statement. See Section 5.1.11, “Server Response to Signals”.

The `FLUSH` statement causes an implicit commit. See Section 13.3.3, “Statements That Cause an Implicit Commit”.

The `RESET` statement is similar to `FLUSH`. See Section 13.7.6.6, “RESET Syntax”, for information about using the `RESET` statement with replication.

`flush_option` can be any of the following items.

- **DES_KEY_FILE**

  Reloads the DES keys from the file that was specified with the `--des-key-file` option at server startup time.

- **HOSTS**

  Empties the host cache. You should flush the host cache if some of your hosts change IP address or if the error message `Host 'host_name' is blocked` occurs. (See Section B.5.2.6, “Host 'host_name' is blocked".) When more than `max_connect_errors` errors occur successively for a given host while connecting to the MySQL server, MySQL assumes that something is wrong and blocks the host from further connection requests. Flushing the host cache enables further connection attempts from the host. The default value of `max_connect_errors` is 10. To avoid this error message, start the server with `max_connect_errors` set to a large value.
• [log_type] LOGS

With no log_type option, FLUSH LOGS closes and reopens all log files. If binary logging is enabled, the sequence number of the binary log file is incremented by one relative to the previous file.

Prior to MySQL 5.5.7, if you flush the logs using FLUSH LOGS and mysqld is writing the error log to a file (for example, if it was started with the --log-error option), log file renaming may occur, as described in Section 5.2.2, "The Error Log".

With a log_type option, only the specified log type is flushed. These log_type options are permitted:

• BINARY closes and reopens the binary log files.
• ENGINE closes and reopens any flushable logs for installed storage engines. Currently, this causes InnoDB to flush its logs to disk.
• ERROR closes and reopens the error log file.
• GENERAL closes and reopens the general query log file.
• RELAY closes and reopens the relay log files.
• SLOW closes and reopens the slow query log file.

The log_type options were added in MySQL 5.5.3.

• MASTER

Deletes all binary logs, resets the binary log index file and creates a new binary log. FLUSH MASTER is deprecated in favor of RESET MASTER. FLUSH MASTER is still accepted in MySQL 5.5 for backward compatibility, but is removed in MySQL 5.6. See Section 13.4.1.2, "RESET MASTER Syntax".

• PRIVILEGES

Reloads the privileges from the grant tables in the mysql database.

The server caches information in memory as a result of GRANT, CREATE USER, CREATE SERVER, and INSTALL PLUGIN statements. This memory is not released by the corresponding REVOKE, DROP USER, DROP SERVER, and UNINSTALL PLUGIN statements, so for a server that executes many instances of the statements that cause caching, there will be an increase in memory use. This cached memory can be freed with FLUSH PRIVILEGES.

• QUERY CACHE

Defragment the query cache to better utilize its memory. FLUSH QUERY CACHE does not remove any queries from the cache, unlike FLUSH TABLES or RESET QUERY CACHE.

• SLAVE

Resets all replication slave parameters, including relay log files and replication position in the master's binary logs. FLUSH SLAVE is deprecated in favor of RESET SLAVE. FLUSH SLAVE is still accepted in MySQL 5.5 for backward compatibility, but is removed in MySQL 5.6. See Section 13.4.2.3, "RESET SLAVE Syntax".

• STATUS

This option adds the current thread's session status variable values to the global values and resets the session values to zero. Some global variables may be reset to zero as well. It also resets the counters
for key caches (default and named) to zero and sets `Max_used_connections` to the current number of open connections. This is something you should use only when debugging a query. See Section 1.7, “How to Report Bugs or Problems”.

- **TABLES**

  `FLUSH TABLES` flushes tables, and, depending on the variant used, acquires locks. The permitted syntax is discussed later in this section.

- **USER_RESOURCES**

  Resets all per-hour user resources to zero. This enables clients that have reached their hourly connection, query, or update limits to resume activity immediately. `FLUSH USER_RESOURCES` does not apply to the limit on maximum simultaneous connections. See Section 6.3.4, “Setting Account Resource Limits”.

The `mysqladmin` utility provides a command-line interface to some flush operations, using commands such as `flush-hosts, flush-logs, flush-privileges, flush-status, and flush-tables`. See Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”.

**Note**

It is not possible to issue `FLUSH` statements within stored functions or triggers. However, you may use `FLUSH` in stored procedures, so long as these are not called from stored functions or triggers. See Section D.1, “Restrictions on Stored Programs”.

**FLUSH TABLES Syntax**

`FLUSH TABLES` has several forms, described following. As of MySQL 5.5.3, if any variant of the `TABLES` option is used in a `FLUSH` statement, it must be the only option used. `FLUSH TABLE` is a synonym for `FLUSH TABLES`, except that `TABLE` does not work with the `WITH READ LOCK` variants prior to MySQL 5.5.3.

- **FLUSH TABLES**

  Closes all open tables, forces all tables in use to be closed, and flushes the query cache. `FLUSH TABLES` also removes all query results from the query cache, like the `RESET QUERY CACHE` statement.

  As of MySQL 5.5.3, `FLUSH TABLES` is not permitted when there is an active `LOCK TABLES ... READ`. To flush and lock tables, use `FLUSH TABLES tbl_name ... WITH READ LOCK` instead.

- **FLUSH TABLES tbl_name [, tbl_name] ...**

  With a list of one or more comma-separated table names, this statement is like `FLUSH TABLES` with no names except that the server flushes only the named tables. No error occurs if a named table does not exist.

- **FLUSH TABLES WITH READ LOCK**

  Closes all open tables and locks all tables for all databases with a global read lock. This is a very convenient way to get backups if you have a file system such as Veritas or ZFS that can take snapshots in time. Use `UNLOCK TABLES` to release the lock.

  `FLUSH TABLES WITH READ LOCK` acquires a global read lock and not table locks, so it is not subject to the same behavior as `LOCK TABLES` and `UNLOCK TABLES` with respect to table locking and implicit commits.
Other Administrative Statements

- **UNLOCK TABLES** implicitly commits any active transaction only if any tables currently have been locked with **LOCK TABLES**. The commit does not occur for **UNLOCK TABLES** following **FLUSH TABLES WITH READ LOCK** because the latter statement does not acquire table locks.

- Beginning a transaction causes table locks acquired with **LOCK TABLES** to be released, as though you had executed **UNLOCK TABLES**. Beginning a transaction does not release a global read lock acquired with **FLUSH TABLES WITH READ LOCK**.

**FLUSH TABLES WITH READ LOCK** does not prevent the server from inserting rows into the log tables (see Section 5.2.1, “Selecting General Query and Slow Query Log Output Destinations”).

- **FLUSH TABLES tbl_name [, tbl_name] ... WITH READ LOCK**

  This statement flushes and acquires read locks for the named tables. The statement first acquires exclusive metadata locks for the tables, so it waits for transactions that have those tables open to complete. Then the statement flushes the tables from the table cache, reopens the tables, acquires table locks (like **LOCK TABLES ... READ**), and downgrades the metadata locks from exclusive to shared. After the statement acquires locks and downgrades the metadata locks, other sessions can read but not modify the tables.

  Because this statement acquires table locks, you must have the **LOCK TABLES** privilege for each table, in addition to the **RELOAD** privilege that is required to use any **FLUSH** statement.

  This statement applies only to existing base tables. If a name refers to a base table, that table is used. If it refers to a **TEMPORARY** table, it is ignored. If a name applies to a view, an **ER_WRONG_OBJECT** error occurs. Otherwise, an **ER_NO_SUCH_TABLE** error occurs.

  Use **UNLOCK TABLES** to release the locks, **LOCK TABLES** to release the locks and acquire other locks, or **START TRANSACTION** to release the locks and begin a new transaction.

  This variant of **FLUSH** enables tables to be flushed and locked in a single operation. It provides a workaround for the restriction as of MySQL 5.5.3 that **FLUSH TABLES** is not permitted when there is an active **LOCK TABLES ... READ**.

  This statement does not perform an implicit **UNLOCK TABLES**, so an error results if you use the statement while there is any active **LOCK TABLES** or use it a second time without first releasing the locks acquired.

  If a flushed table was opened with **HANDLER**, the handler is implicitly flushed and loses its position.

  This variant of **FLUSH** is available as of MySQL 5.5.3.

### 13.7.6.4 **KILL** Syntax

```plaintext
KILL [CONNECTION | QUERY] thread_id
```

Each connection to `mysql` runs in a separate thread. You can see which threads are running with the **SHOW PROCESSLIST** statement and kill a thread with the **KILL thread_id** statement.

**KILL** permits an optional **CONNECTION** or **QUERY** modifier:

- **KILL CONNECTION** is the same as **KILL** with no modifier: It terminates the connection associated with the given **thread_id**.

- **KILL QUERY** terminates the statement that the connection is currently executing, but leaves the connection itself intact.
If you have the **PROCESS** privilege, you can see all threads. If you have the **SUPER** privilege, you can kill all threads and statements. Otherwise, you can see and kill only your own threads and statements.

You can also use the `mysqladmin processlist` and `mysqladmin kill` commands to examine and kill threads.

---

**Note**

You cannot use `KILL` with the Embedded MySQL Server library because the embedded server merely runs inside the threads of the host application. It does not create any connection threads of its own.

When you use `KILL`, a thread-specific kill flag is set for the thread. In most cases, it might take some time for the thread to die because the kill flag is checked only at specific intervals:

- In `SELECT`, `ORDER BY` and `GROUP BY` loops, the flag is checked after reading a block of rows. If the kill flag is set, the statement is aborted.
- During `ALTER TABLE`, the kill flag is checked before each block of rows are read from the original table. If the kill flag was set, the statement is aborted and the temporary table is deleted.
- During `UPDATE` or `DELETE` operations, the kill flag is checked after each block read and after each updated or deleted row. If the kill flag is set, the statement is aborted. Note that if you are not using transactions, the changes are not rolled back.
- `GET_LOCK()` aborts and returns `NULL`.
- An `INSERT DELAYED` thread quickly flushes (inserts) all rows it has in memory and then terminates.
- If the thread is in the table lock handler (state: `Locked`), the table lock is quickly aborted.
- If the thread is waiting for free disk space in a write call, the write is aborted with a “disk full” error message.

**Warning**

Killing a `REPAIR TABLE` or `OPTIMIZE TABLE` operation on a **MyISAM** table results in a table that is corrupted and unusable. Any reads or writes to such a table fail until you optimize or repair it again (without interruption).

### 13.7.6.5 `LOAD INDEX INTO CACHE` Syntax

```sql
LOAD INDEX INTO CACHE
   tbl_index_list [, tbl_index_list] ...,

tbl_index_list:
   tbl_name
      [PARTITION (partition_list | ALL)]
      [[INDEX|KEY] (index_name[, index_name] ...)]
      [IGNORE LEAVES]

partition_list:
   partition_name[, partition_name][, ...]
```

The `LOAD INDEX INTO CACHE` statement preloads a table index into the key cache to which it has been assigned by an explicit `CACHE INDEX` statement, or into the default key cache otherwise.

**LOAD INDEX INTO CACHE** is used only for **MyISAM** tables. In MySQL 5.5, it is also supported for partitioned **MyISAM** tables; in addition, indexes on partitioned tables can be preloaded for one, several, or all partitions.
The `IGNORE LEAVES` modifier causes only blocks for the nonleaf nodes of the index to be preloaded. `IGNORE LEAVES` is also supported for partitioned `MyISAM` tables.

The following statement preloads nodes (index blocks) of indexes for the tables `t1` and `t2`:

```
mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
```

<table>
<thead>
<tr>
<th>Table</th>
<th>Op</th>
<th>Msg_type</th>
<th>Msg_text</th>
</tr>
</thead>
<tbody>
<tr>
<td>test.t1</td>
<td>preload_keys</td>
<td>status</td>
<td>OK</td>
</tr>
<tr>
<td>test.t2</td>
<td>preload_keys</td>
<td>status</td>
<td>OK</td>
</tr>
</tbody>
</table>

This statement preloads all index blocks from `t1`. It preloads only blocks for the nonleaf nodes from `t2`.

The syntax of `LOAD INDEX INTO CACHE` enables you to specify that only particular indexes from a table should be preloaded. The current implementation preloads all the table's indexes into the cache, so there is no reason to specify anything other than the table name.

In MySQL 5.5, it is possible to preload indexes on specific partitions of partitioned `MyISAM` tables. For example, of the following 2 statements, the first preloads indexes for partition `p0` of a partitioned table `pt`, while the second preloads the indexes for partitions `p1` and `p3` of the same table:

```
LOAD INDEX INTO CACHE pt PARTITION (p0);
LOAD INDEX INTO CACHE pt PARTITION (p1, p3);
```

To preload the indexes for all partitions in table `pt`, you can use either one of the following 2 statements:

```
LOAD INDEX INTO CACHE pt PARTITION (ALL);
LOAD INDEX INTO CACHE pt;
```

The two statements just shown are equivalent, and issuing either one of them has exactly the same effect. In other words, if you wish to preload indexes for all partitions of a partitioned table, then the `PARTITION (ALL)` clause is optional.

When preloading indexes for multiple partitions, the partitions do not have to be contiguous, and you are not required to list their names in any particular order.

`LOAD INDEX INTO CACHE ... IGNORE LEAVES` fails unless all indexes in a table have the same block size. You can determine index block sizes for a table by using `myisamchk -dv` and checking the `Blocksize` column.

### 13.7.6.6 `RESET` Syntax

```
RESET reset_option [, reset_option] ...
```

The `RESET` statement is used to clear the state of various server operations. You must have the `RELOAD` privilege to execute `RESET`.

`RESET` acts as a stronger version of the `FLUSH` statement. See Section 13.7.6.3, "FLUSH Syntax".

The `RESET` statement causes an implicit commit. See Section 13.3.3, "Statements That Cause an Implicit Commit".

`reset_option` can be any of the following:
• **MASTER**

   Deletes all binary logs listed in the index file, resets the binary log index file to be empty, and creates a new binary log file.

• **QUERY CACHE**

   Removes all query results from the query cache.

• **SLAVE**

   Makes the slave forget its replication position in the master binary logs. Also resets the relay log by deleting any existing relay log files and beginning a new one.

**13.8 MySQL Utility Statements**

**13.8.1 DESCRIBE Syntax**

The `DESCRIBE` and `EXPLAIN` statements are synonyms, used either to obtain information about table structure or query execution plans. For more information, see Section 13.7.5.6, "SHOW COLUMNS Syntax", and Section 13.8.2, "EXPLAIN Syntax".

**13.8.2 EXPLAIN Syntax**

```
{EXPLAIN | DESCRIBE | DESC} [col_name | wild]
```

```
{EXPLAIN | DESCRIBE | DESC} [explain_type] SELECT select_options
```

`explain_type`: (EXTENDED | PARTITIONS)

The `DESCRIBE` and `EXPLAIN` statements are synonyms. In practice, the `DESCRIBE` keyword is more often used to obtain information about table structure, whereas `EXPLAIN` is used to obtain a query execution plan (that is, an explanation of how MySQL would execute a query). The following discussion uses the `DESCRIBE` and `EXPLAIN` keywords in accordance with those uses, but the MySQL parser treats them as completely synonymous.

**Obtaining Table Structure Information**

`DESCRIBE` provides information about the columns in a table:

```
mysql> DESCRIBE City;
+------------+----------+------+-----+---------+----------------+
| Field      | Type     | Null | Key | Default | Extra          |
+------------+----------+------+-----+---------+----------------+
| Id         | int(11)  | NO   | PRI | NULL    | auto_increment |
| Name       | char(35) | NO   |     |         |                |
| Country    | char(3)  | NO   | UNI |         |                |
| District   | char(20) | YES  | MUL |         |                |
| Population | int(11)  | NO   |     | 0       |                |
+------------+----------+------+-----+---------+----------------+
```

`DESCRIBE` is a shortcut for `SHOW COLUMNS`. These statements also display information for views. The description for `SHOW COLUMNS` provides more information about the output columns. See Section 13.7.5.6, "SHOW COLUMNS Syntax".
By default, `DESCRIBE` displays information about all columns in the table. `col_name`, if given, is the name of a column in the table. In this case, the statement displays information only for the named column. `wild`, if given, is a pattern string. It can contain the SQL “%” and “_” wildcard characters. In this case, the statement displays output only for the columns with names matching the string. There is no need to enclose the string within quotation marks unless it contains spaces or other special characters.

The `DESCRIBE` statement is provided for compatibility with Oracle.

The `SHOW CREATE TABLE`, `SHOW TABLE STATUS`, and `SHOW INDEX` statements also provide information about tables. See Section 13.7.5, "SHOW Syntax".

### Obtaining Execution Plan Information

The `EXPLAIN` statement provides information about how MySQL executes statements:

- When you precede a `SELECT` statement with the keyword `EXPLAIN`, MySQL displays information from the optimizer about the statement execution plan. That is, MySQL explains how it would process the statement, including information about how tables are joined and in which order. For information about using `EXPLAIN` to obtain execution plan information, see Section 8.8.2, "EXPLAIN Output Format".

- `EXPLAIN EXTENDED` can be used to obtain additional execution plan information. See Section 8.8.3, "EXPLAIN EXTENDED Output Format".

- `EXPLAIN PARTITIONS` is useful for examining queries involving partitioned tables. See Section 19.3.4, "Obtaining Information About Partitions".

With the help of `EXPLAIN`, you can see where you should add indexes to tables so that the statement executes faster by using indexes to find rows. You can also use `EXPLAIN` to check whether the optimizer joins the tables in an optimal order. To give a hint to the optimizer to use a join order corresponding to the order in which the tables are named in a `SELECT` statement, begin the statement with `SELECT STRAIGHT_JOIN` rather than just `SELECT` (See Section 13.2.9, "SELECT Syntax").

If you have a problem with indexes not being used when you believe that they should be, run `ANALYZE TABLE` to update table statistics, such as cardinality of keys, that can affect the choices the optimizer makes. See Section 13.7.2.1, "ANALYZE TABLE Syntax".

#### 13.8.3 HELP Syntax

```
HELP 'search_string'
```

The `HELP` statement returns online information from the MySQL Reference manual. Its proper operation requires that the help tables in the `mysql` database be initialized with help topic information (see Section 5.1.10, “Server-Side Help”).

The `HELP` statement searches the help tables for the given search string and displays the result of the search. The search string is not case sensitive.

The search string can contain the wildcard characters “%” and “_”. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator. For example, `HELP 'rep%'` returns a list of topics that begin with `rep`.

The `HELP` statement understands several types of search strings:

- At the most general level, use `contents` to retrieve a list of the top-level help categories:

```
HELP 'contents'
```
• For a list of topics in a given help category, such as Data Types, use the category name:

```
HELP 'data types'
```

• For help on a specific help topic, such as the ASCII() function or the CREATE TABLE statement, use the associated keyword or keywords:

```
HELP 'ascii'
HELP 'create table'
```

In other words, the search string matches a category, many topics, or a single topic. You cannot necessarily tell in advance whether a given search string will return a list of items or the help information for a single help topic. However, you can tell what kind of response HELP returned by examining the number of rows and columns in the result set.

The following descriptions indicate the forms that the result set can take. Output for the example statements is shown using the familiar “tabular” or “vertical” format that you see when using the `mysql` client, but note that `mysql` itself reformats HELP result sets in a different way.

• Empty result set

   No match could be found for the search string.

• Result set containing a single row with three columns

   This means that the search string yielded a hit for the help topic. The result has three columns:

   • `name`: The topic name.
   • `description`: Descriptive help text for the topic.
   • `example`: Usage example or examples. This column might be blank.

   Example: HELP 'replace'

   Yields:

<table>
<thead>
<tr>
<th>name</th>
<th>description</th>
<th>example</th>
</tr>
</thead>
<tbody>
<tr>
<td>REPLACE</td>
<td>Syntax:</td>
<td>REPLACE(str,from_str,to_str)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Returns the string str with all occurrences of the string from_str replaced by the string to_str. REPLACE() performs a case-sensitive match when searching for from_str.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>example: mysql&gt; SELECT REPLACE('www.mysql.com', 'w', 'Ww');</td>
</tr>
<tr>
<td></td>
<td></td>
<td>-&gt; 'WwWwWw.mysql.com'</td>
</tr>
</tbody>
</table>

• Result set containing multiple rows with two columns

   This means that the search string matched many help topics. The result set indicates the help topic names:

   • `name`: The help topic name.

   • `is_it_category`: Y if the name represents a help category, N if it does not. If it does not, the name value when specified as the argument to the HELP statement should yield a single-row result set containing a description for the named item.
Example: `HELP 'status'

Yields:

<table>
<thead>
<tr>
<th>name</th>
<th>is_it_category</th>
</tr>
</thead>
<tbody>
<tr>
<td>SHOW</td>
<td>N</td>
</tr>
<tr>
<td>SHOW ENGINE</td>
<td>N</td>
</tr>
<tr>
<td>SHOW MASTER STATUS</td>
<td>N</td>
</tr>
<tr>
<td>SHOW PROCEDURE STATUS</td>
<td>N</td>
</tr>
<tr>
<td>SHOW SLAVE STATUS</td>
<td>N</td>
</tr>
<tr>
<td>SHOW STATUS</td>
<td>N</td>
</tr>
<tr>
<td>SHOW TABLE STATUS</td>
<td>N</td>
</tr>
</tbody>
</table>

• Result set containing multiple rows with three columns

This means the search string matches a category. The result set contains category entries:

• `source_category_name`: The help category name.

• `name`: The category or topic name

• `is_it_category`: Y if the name represents a help category, N if it does not. If it does not, the `name` value when specified as the argument to the `HELP` statement should yield a single-row result set containing a description for the named item.

Example: `HELP 'functions'

Yields:

<table>
<thead>
<tr>
<th>source_category_name</th>
<th>name</th>
<th>is_it_category</th>
</tr>
</thead>
<tbody>
<tr>
<td>Functions</td>
<td>CREATE FUNCTION</td>
<td>N</td>
</tr>
<tr>
<td>Functions</td>
<td>DROP FUNCTION</td>
<td>N</td>
</tr>
<tr>
<td>Functions</td>
<td>Bit Functions</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Comparison operators</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Control flow functions</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Date and Time Functions</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Encryption Functions</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Information Functions</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Logical operators</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Miscellaneous Functions</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>Numeric Functions</td>
<td>Y</td>
</tr>
<tr>
<td>Functions</td>
<td>String Functions</td>
<td>Y</td>
</tr>
</tbody>
</table>

13.8.4 **USE Syntax**

**USE db_name**

The `USE db_name` statement tells MySQL to use the `db_name` database as the default (current) database for subsequent statements. The database remains the default until the end of the session or another `USE` statement is issued:

**USE db1;**
SELECT COUNT(*) FROM mytable;  # selects from db1.mytable
USE db2;
SELECT COUNT(*) FROM mytable;  # selects from db2.mytable

Making a particular database the default by means of the `USE` statement does not preclude you from accessing tables in other databases. The following example accesses the `author` table from the `db1` database and the `editor` table from the `db2` database:

```
USE db1;
SELECT author_name,editor_name FROM author,db2.editor
  WHERE author.editor_id = db2.editor.editor_id;
```

**14.1 Introduction to InnoDB 1.1**

InnoDB 1.1 combines the familiar reliability and performance of the InnoDB storage engine, with new performance and usability enhancements. InnoDB 1.1 includes all the features that were part of the InnoDB Plugin for MySQL 5.1, plus new features specific to MySQL 5.5 and higher.

Beginning with MySQL version 5.5, InnoDB is the default storage engine, rather than MyISAM. As of MySQL 5.5, issuing the `CREATE TABLE` statement without an `ENGINE=` clause creates an InnoDB table.

**Key Advantages of InnoDB**

Key advantages of InnoDB tables include:

- Its DML operations follow the ACID model, with transactions featuring commit, rollback, and crash-recovery capabilities to protect user data.

- Row-level locking and Oracle-style consistent reads increase multi-user concurrency and performance.

- InnoDB tables arrange your data on disk to optimize queries based on primary keys. Each InnoDB table has a primary key index called the clustered index that organizes the data to minimize I/O for primary key lookups.

- To maintain data integrity, InnoDB also supports FOREIGN KEY constraints. Inserts, updates, and deletes are all checked to ensure they do not result in inconsistencies across different tables.

- You can freely mix InnoDB tables with tables from other MySQL storage engines, even within the same statement. For example, you can use a `join` operation to combine data from InnoDB and MEMORY tables in a single query.

- InnoDB has been designed for maximum performance when processing large data volumes. Its CPU efficiency is probably not matched by any other disk-based relational database engine.

To determine whether your server supports InnoDB use the `SHOW ENGINES` statement. See Section 13.7.5.17, "SHOW ENGINES Syntax".

**InnoDB Storage Engine Features**

The InnoDB storage engine maintains its own buffer pool for caching data and indexes in main memory. When the `innodb_file_per_table` setting is enabled, each new InnoDB table and its associated indexes are stored in a separate file. When the `innodb_file_per_table` option is disabled, InnoDB stores all its tables and indexes in the single system tablespace, which may consist of several files (or raw
InnoDB tables can handle large quantities of data, even on operating systems where file size is limited to 2GB.

InnoDB Enhancements and New Features

The InnoDB storage engine in MySQL 5.5 releases includes a number of performance improvements that in MySQL 5.1 were only available by installing the InnoDB Plugin. This latest InnoDB (now known as InnoDB 1.1) offers new features, improved performance and scalability, enhanced reliability and new capabilities for flexibility and ease of use. Among the top features are Fast Index Creation, table and index compression, file format management, new INFORMATION_SCHEMA tables, capacity tuning, multiple background I/O threads, multiple buffer pools, and group commit. For more information about these features, see Section 14.1.1, “Features of the InnoDB Storage Engine”.

For additional information about InnoDB enhancements and new features in MySQL 5.5, also refer to:

- Section 1.4, “What Is New in MySQL 5.5”, which provides an overview of the features added in MySQL 5.5.
- The Release Notes, which provide information about changes in each version.

Additional Resources

- For InnoDB-related terms and definitions, see MySQL Glossary.
- InnoDB is published under the same GNU GPL License Version 2 (of June 1991) as MySQL. For more information on MySQL licensing, see http://www.mysql.com/company/legal/licensing/.

14.1.1 Features of the InnoDB Storage Engine

InnoDB in MySQL 5.5 contains several important new features:

- Fast index creation: add or drop indexes without copying the data
- Data compression: shrink tables, to significantly reduce storage and I/O
- New row format: fully off-page storage of long BLOB, TEXT, and VARCHAR columns
- File format management: protects upward and downward compatibility
- INFORMATION_SCHEMA tables: information about compression and locking
- Performance and scalability enhancements:
  - Section 14.16.3, “InnoDB Mutex and Read/Write Lock Implementation”
  - Section 14.16.4, “Configuring the Memory Allocator for InnoDB”
  - Section 14.16.5, “Configuring InnoDB Change Buffering”
  - Section 14.5.13.5, “Adaptive Hash Indexes”
  - Section 14.16.6, “Configuring Thread Concurrency for InnoDB”
  - Section 14.16.2.1, “Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)”
  - Section 14.16.7, “Configuring the Number of Background InnoDB I/O Threads”
• Asynchronous I/O is supported on Linux systems. For additional information, see `innodb_use_native_aio`.

• Section 14.16.8, “Group Commit”

• Section 14.16.9, “Configuring the InnoDB Master Thread I/O Rate”

• Section 14.16.2.2, “Configuring the Rate of InnoDB Buffer Pool Flushing”

• Section 14.16.10, “Using the PAUSE Instruction in InnoDB Spin Loops”

• Section 14.16.11, “Configuring Spin Lock Polling”

• Section 14.16.2.3, “Making the Buffer Pool Scan Resistant”

• Improvements to crash recovery performance, as described in Section 8.5.8, “Optimizing InnoDB Configuration Variables”.

• Section 14.16.12, “InnoDB Integration with MySQL Performance Schema”

• Section 14.16.2.4, “Using Multiple Buffer Pool Instances”

• Section 14.16.13, “Better Scalability with Multiple Rollback Segments”

• Section 14.16.14, “Configuring InnoDB Purge Scheduling”

• Section 14.15.1.3, “Parameters with New Defaults”

• Other changes for flexibility, ease of use and reliability:

  • The Barracuda File Format. See Section 14.11, “InnoDB File-Format Management”.

  • As of MySQL 5.5, `innodb_file_per_table`, `innodb_stats_on_metadata`, `innodb_lock_wait_timeout`, and `innodb_adaptive_hash_index` can be set at runtime using the `SET` statement.

  • Section 14.13.5, “Reclaiming Disk Space with TRUNCATE TABLE”

  • InnoDB Strict Mode. For usage information, refer to the `innodb_strict_mode` parameter documentation.

  • Section 14.16.15, “Configuring Optimizer Statistics Parameters”

  • More compact output for `SHOW ENGINE INNODB MUTEX`. For more information see, Section 13.7.5.16, “SHOW ENGINE Syntax”.

  • `SHOW ENGINE INNODB STATUS` output displays counter information for the `Innodb_buffer_pool_readAhead` and `Innodb_buffer_pool_readAheadEvicted` global status variables, which can help you fine-tune the `innodb_random_readAhead` setting and evaluate the effectiveness of the read-ahead algorithm.

**Upward and Downward Compatibility**

Note that the ability to use data compression and the new row format require the use of a new InnoDB file format called Barracuda. The previous file format, used by the built-in InnoDB in MySQL 5.1 and earlier, is now called Antelope and does not support these features, but does support the other features introduced with the InnoDB storage engine.
The InnoDB storage engine is upward compatible from standard InnoDB as built in to, and distributed with, MySQL. Existing databases can be used with the InnoDB Storage Engine for MySQL. The new parameter `innodb_file_format` can help protect upward and downward compatibility between InnoDB versions and database files, allowing users to enable or disable use of new features that can only be used with certain versions of InnoDB.

InnoDB since version 5.0.21 has a safety feature that prevents it from opening tables that are in an unknown format. However, the system tablespace may contain references to new-format tables that confuse the built-in InnoDB in MySQL 5.1 and earlier. These references are cleared in a slow shutdown.

With previous versions of InnoDB, no error would be returned until you try to access a table that is in a format “too new” for the software. To provide early feedback, InnoDB 1.1 checks the system tablespace before startup to ensure that the file format used in the database is supported by the storage engine. See Section 14.11.2.1, “Compatibility Check When InnoDB Is Started” for the details.

### 14.1.2 InnoDB as the Default MySQL Storage Engine

MySQL has a well-earned reputation for being easy-to-use and delivering performance and scalability. In previous versions of MySQL, MyISAM was the default storage engine. In our experience, most users never changed the default settings. With MySQL 5.5, InnoDB becomes the default storage engine. Again, we expect most users will not change the default settings. But, because of InnoDB, the default settings deliver the benefits users expect from their RDBMS: ACID Transactions, Referential Integrity, and Crash Recovery. Let’s explore how using InnoDB tables improves your life as a MySQL user, DBA, or developer.

### Trends in Storage Engine Usage

In the first years of MySQL growth, early web-based applications didn’t push the limits of concurrency and availability. In recent years, hard drive and memory capacity and the performance/price ratio have all gone through the roof. Users pushing the performance boundaries of MySQL care a lot about reliability and crash recovery. MySQL databases are big, busy, robust, distributed, and important.

InnoDB addresses these top user priorities. The trend of storage engine usage has shifted in favor of the more scalable InnoDB. Thus MySQL 5.5 is the logical transition release to make InnoDB the default storage engine.

### Consequences of InnoDB as Default MySQL Storage Engine

Starting from MySQL 5.5.5, the default storage engine for new tables is InnoDB. This change applies to newly created tables that don’t specify a storage engine with a clause such as `ENGINE=MyISAM`. Given this change of default behavior, MySQL 5.5 might be a logical point to evaluate whether your tables that do use MyISAM could benefit from switching to InnoDB.

The `mysql` and `information_schema` databases, that implement some of the MySQL internals, still use MyISAM. In particular, you cannot switch the grant tables to use InnoDB.

### Benefits of InnoDB Tables

If you use MyISAM tables but aren’t tied to them for technical reasons, you’ll find many things more convenient when you use InnoDB tables in MySQL 5.5:

- If your server crashes because of a hardware or software issue, regardless of what was happening in the database at the time, you don’t need to do anything special after restarting the database. InnoDB crash recovery automatically finalizes any changes that were committed before the time of the crash, and undoes any changes that were in process but not committed. Just restart and continue where you left off. This process is now much faster than in MySQL 5.1 and earlier.
InnoDB as the Default MySQL Storage Engine

- The InnoDB buffer pool caches table and index data as the data is accessed. Frequently used data is processed directly from memory. This cache applies to so many types of information, and speeds up processing so much, that dedicated database servers assign up to 80% of their physical memory to the InnoDB buffer pool.

- If you split up related data into different tables, you can set up foreign keys that enforce referential integrity. Update or delete data, and the related data in other tables is updated or deleted automatically. Try to insert data into a secondary table without corresponding data in the primary table, and the bad data gets kicked out automatically.

- If data becomes corrupted on disk or in memory, a checksum mechanism alerts you to the bogus data before you use it.

- When you design your database with appropriate primary key columns for each table, operations involving those columns are automatically optimized. It is very fast to reference the primary key columns in WHERE clauses, ORDER BY clauses, GROUP BY clauses, and join operations.

- Inserts, updates, deletes are optimized by an automatic mechanism called change buffering. InnoDB not only allows concurrent read and write access to the same table, it caches changed data to streamline disk I/O.

- Performance benefits are not limited to giant tables with long-running queries. When the same rows are accessed over and over from a table, a feature called the Adaptive Hash Index takes over to make these lookups even faster, as if they came out of a hash table.

Best Practices for InnoDB Tables

If you have been using InnoDB for a long time, you already know about features like transactions and foreign keys. If not, read about them throughout this chapter. To make a long story short:

- Specify a primary key for every table using the most frequently queried column or columns, or an auto-increment value if there is no obvious primary key.

- Embrace the idea of joins, where data is pulled from multiple tables based on identical ID values from those tables. For fast join performance, define foreign keys on the join columns, and declare those columns with the same data type in each table. The foreign keys also propagate deletes or updates to all affected tables, and prevent insertion of data in a child table if the corresponding IDs are not present in the parent table.

- Turn off autocommit. Committing hundreds of times a second puts a cap on performance (limited by the write speed of your storage device).

- Group sets of related DML operations into transactions, by bracketing them with START TRANSACTION and COMMIT statements. While you don't want to commit too often, you also don't want to issue huge batches of INSERT, UPDATE, or DELETE statements that run for hours without committing.

- Stop using LOCK TABLE statements. InnoDB can handle multiple sessions all reading and writing to the same table at once, without sacrificing reliability or high performance. To get exclusive write access to a set of rows, use the SELECT ... FOR UPDATE syntax to lock just the rows you intend to update.

- Enable the innodb_file_per_table option to put the data and indexes for individual tables into separate files, instead of in a single giant system tablespace. This setting is required to use some of the other features, such as table compression and fast truncation.

- Evaluate whether your data and access patterns benefit from the new InnoDB table compression feature (ROW_FORMAT=COMPRESSED) on the CREATE TABLE statement. You can compress InnoDB tables without sacrificing read/write capability.
InnoDB as the Default MySQL Storage Engine

- Run your server with the option `--sql_mode=NO_ENGINE_SUBSTITUTION` to prevent tables being created with a different storage engine if there is an issue with the one specified in the `ENGINE=` clause of `CREATE TABLE`.

Recent Improvements for InnoDB Tables (from the Plugin Era)

- You can compress tables and associated indexes.
- You can create and drop indexes with much less performance or availability impact than before.
- Truncating a table is very fast, and can free up disk space for the operating system to reuse, rather than freeing up space within the system tablespace that only InnoDB could reuse.
- The storage layout for table data is more efficient for BLOBs and long text fields.
- You can monitor the internal workings of the storage engine by querying `INFORMATION_SCHEMA` tables.
- You can monitor the performance details of the storage engine by querying `performance_schema` tables.
- There are many performance improvements. In particular, crash recovery, the automatic process that makes all data consistent when the database is restarted, is fast and reliable (much faster than long-time InnoDB users are used to). The bigger the database, the more dramatic the speedup.

Most new performance features are automatic, or at most require setting a value for a configuration option. For details, see Section 14.16, “InnoDB Performance”. For InnoDB-specific tuning techniques you can apply in your application code, see Section 8.5, “Optimizing for InnoDB Tables”. Advanced users can review Section 14.15, “InnoDB Startup Options and System Variables”.

Testing and Benchmarking with InnoDB as Default Storage Engine

Even before completing your upgrade to MySQL 5.5, you can preview whether your database server or application works correctly with InnoDB as the default storage engine. To set up InnoDB as the default storage engine with an earlier MySQL release, either specify on the command line `--default-storage-engine=InnoDB`, or add to your `my.cnf` file `default-storage-engine=innodb` in the `[mysqld]` section, then restart the server.

Since changing the default storage engine only affects new tables as they are created, run all your application installation and setup steps to confirm that everything installs properly. Then exercise all the application features to make sure all the data loading, editing, and querying features work. If a table relies on some MyISAM-specific feature, you’ll receive an error; add the `ENGINE=MyISAM` clause to the `CREATE TABLE` statement to avoid the error (for example, tables that rely on full-text search must be MyISAM tables rather than InnoDB ones).

If you did not make a deliberate decision about the storage engine, and you just want to preview how certain tables work when they're created under InnoDB, issue the command `ALTER TABLE table_name ENGINE=InnoDB;` for each table. Or, to run test queries and other statements without disturbing the original table, make a copy like so:

```
CREATE TABLE InnoDB_Table (...) ENGINE=InnoDB AS SELECT * FROM MyISAM_Table;
```

Since there are so many performance enhancements in the InnoDB that is part of MySQL 5.5, to get a true idea of the performance with a full application under a realistic workload, install the real MySQL 5.5 and run benchmarks.
Checking InnoDB Availability

Test the full application lifecycle, from installation, through heavy usage, and server restart. Kill the server process while the database is busy to simulate a power failure, and verify that the data is recovered successfully when you restart the server.

Test any replication configurations, especially if you use different MySQL versions and options on the master and the slaves.

Verifying that InnoDB is the Default Storage Engine

To know what the status of InnoDB is, whether you’re doing what-if testing with an older MySQL or comprehensive testing with MySQL 5.5:

• Issue the command `SHOW VARIABLES LIKE 'have_innodb';` to confirm that InnoDB is available at all. If the result is NO, you have a mysqld binary that was compiled without InnoDB support and you need to get a different one. If the result is DISABLED, go back through your startup options and configuration file and get rid of any `skip-innodb` option.

• Issue the command `SHOW ENGINES;` to see all the different MySQL storage engines. Look for DEFAULT in the InnoDB line.

14.1.3 Checking InnoDB Availability

To determine whether your server supports InnoDB, use the `SHOW ENGINES` statement. (Now that InnoDB is the default MySQL storage engine, only very specialized environments might not support it.)

14.1.4 Turning Off InnoDB

Oracle recommends InnoDB as the preferred storage engine for typical database applications, from single-user wikis and blogs running on a local system, to high-end applications pushing the limits of performance. As of MySQL 5.5, InnoDB is the default storage engine for new tables.

If you do not want to use InnoDB tables:

• Start the server with the `--innodb=OFF` or `--skip-innodb` option to disable the InnoDB storage engine.

• Because the default storage engine is InnoDB, the server will not start unless you also use `--default-storage-engine` to set the default to some other engine.

• To prevent the server from crashing when the InnoDB-related information_schema tables are queried, also disable the plugins associated with those tables. Specify in the `[mysqld]` section of the MySQL configuration file:

```
loose-innodb-trx=0
loose-innodb-locks=0
loose-innodb-lock-waits=0
loose-innodb-cmp=0
loose-innodb-cmp-per-index=0
loose-innodb-cmp-per-index-reset=0
loose-innodb-cmp-reset=0
loose-innodb-cmpmem=0
loose-innodb-cmpmem-reset=0
loose-innodb-buffer-page=0
loose-innodb-buffer-page-lru=0
loose-innodb-buffer-pool-stats=0
```

14.1.5 Obtaining and Installing the InnoDB Storage Engine
Starting with MySQL 5.4.2, you do not need to do anything special to get or install the most up-to-date InnoDB storage engine. From that version forward, the InnoDB storage engine in the server is what was formerly known as the InnoDB Plugin. Earlier versions of MySQL required some extra build and configuration steps to get the Plugin-specific features such as fast index creation and table compression.

14.1.6 Viewing the InnoDB Storage Engine Version Number

Up to MySQL version 5.5.30, InnoDB storage engine releases are numbered with version numbers independent of MySQL releases. Starting with MySQL 5.5.30, the use of independent version numbering for the InnoDB storage engine is discontinued in favor of MySQL server version numbering.

The following information describes the InnoDB storage engine independent version numbering scheme and how to view the version number for the InnoDB storage engine.

The initial release of the InnoDB storage engine is version 1.0, and it is designed to work with MySQL 5.1. Version 1.1 of the InnoDB storage engine is for MySQL 5.5 and up.

- The first component of the InnoDB storage engine version number designates a major release level.
- The second component corresponds to the MySQL release. The digit 0 corresponds to MySQL 5.1. The digit 1 corresponds to MySQL 5.5.
- The third component indicates the specific release of the InnoDB storage engine (at a given major release level and for a specific MySQL release); only bug fixes and minor functional changes are introduced at this level.

Once you have installed the InnoDB storage engine, you can check its version number in three ways:

- In the error log, it is printed during startup.
- SELECT * FROM information_schema.plugins;
- SELECT @@innodb_version;

The InnoDB storage engine writes its version number to the error log, which can be helpful in diagnosis of errors:

091105 12:28:06 InnoDB Plugin 1.0.5 started; log sequence number 46509

Note that the PLUGIN_VERSION column in the table INFORMATION_SCHEMA.PLUGINS does not display the third component of the version number, only the first and second components, as in 1.0.

14.1.7 Compatibility Considerations for Downgrade and Backup

Because InnoDB 1.1 supports the “Barracuda” file format, with new on-disk data structures within both the database and log files, pay special attention to file format compatibility with respect to the following scenarios:

- Downgrading from MySQL 5.5 to the MySQL 5.1 or earlier (without the InnoDB Plugin enabled), or otherwise using earlier versions of MySQL with database files created by MySQL 5.5 and higher.
- Using mysqldump.
- Using MySQL replication.
**InnoDB Storage Engine Change History**

- Using MySQL Enterprise Backup or InnoDB Hot Backup.

**WARNING:** Once you create any tables with the Barracuda file format, take care to avoid crashes and corruptions when using those files with an earlier version of MySQL. It is *strongly* recommended that you use a "slow shutdown" (SET GLOBAL innodb_fast_shutdown=0) when stopping the MySQL server before downgrading to MySQL 5.1 or earlier. This ensures that the log files and other system information do not cause consistency issues or startup problems when using a prior version of MySQL.

**WARNING:** If you dump a database containing compressed tables with `mysqldump`, the dump file may contain `CREATE TABLE` statements that attempt to create compressed tables, or those using `ROW_FORMAT=DYNAMIC` in the new database. Therefore, be sure the new database is running the InnoDB storage engine, with the proper settings for `innodb_file_format` and `innodb_file_per_table`, if you want to have the tables re-created as they exist in the original database. Typically, when the `mysqldump` file is loaded, MySQL and InnoDB ignore `CREATE TABLE` options they do not recognize, and the table(s) are created in a format used by the running server.

**WARNING:** If you use MySQL replication, ensure all slaves are configured with the InnoDB storage engine, with the same settings for `innodb_file_format` and `innodb_file_per_table`. If you do not do so, and you create tables that require the new Barracuda file format, replication errors may occur. If a slave MySQL server is running an older version of MySQL, it ignores the `CREATE TABLE` options to create a compressed table or one with `ROW_FORMAT=DYNAMIC`, and creates the table uncompressed, with `ROW_FORMAT=COMPACT`.

**WARNING:** Version 3.0 of InnoDB Hot Backup does not support the new Barracuda file format. Using InnoDB Hot Backup Version 3 to backup databases in this format causes unpredictable behavior. MySQL Enterprise Backup, the successor product to InnoDB Hot Backup, does support tables with the Barracuda file format. You can also back up such databases with `mysqldump`.

### 14.1.8 InnoDB Storage Engine Change History

#### 14.1.8.1 Changes in InnoDB Storage Engine 1.x

Since InnoDB 1.1 is tightly integrated with MySQL 5.5, for changes after the initial InnoDB 1.1 release, see the MySQL 5.5 Release Notes.

#### 14.1.8.2 Changes in InnoDB Storage Engine 1.1 (April 13, 2010)

For an overview of the changes, see [this introduction article for MySQL 5.5 with InnoDB 1.1](#). The following is a condensed version of the change log.

Fix for Bug #52580: Crash in ha_innobase::open on executing INSERT with concurrent ALTER TABLE.

Change in MySQL Bug #51557 releases the mutex LOCK_open before ha_innobase::open(), causing racing condition for index translation table creation. Fix it by adding dict_sys mutex for the operation.

Add support for multiple buffer pools.

Fix Bug #26590: MySQL does not allow more than 1023 open transactions. Create additional rollback segments on startup. Reduce the upper limit of total rollback segments from 256 to 128. This is because we can't use the sign bit. It has not caused problems in the past because we only created one segment. InnoDB has always had the capability to use the additional rollback segments, therefore this patch is backward compatible. The only requirement to maintain backward compatibility has been to ensure that the additional segments are created after the double write buffer. This is to avoid breaking assumptions in the existing code.

Implement Performance Schema in InnoDB. Objects in four different modules in InnoDB have been performance instrumented, these modules are: mutexes, rwlocks, file I/O, and threads. We mostly
preserved the existing APIs, but APIs would point to instrumented function wrappers if performance schema is defined. There are 4 different defines that control the instrumentation of each module. The feature is off by default, and will be compiled in with a special build option, and require a configure option to turn it on when the server boots.

Implement the buf_pool_watch for DeleteBuffering in the page hash table. This serves two purposes. It allows multiple watches to be set at the same time (by multiple purge threads) and it removes a race condition when the read of a block completes about the time the buffer pool watch is being set.

Introduce a new mutex to protect flush_list. Redesign mtr_commit() in a way that log_sys mutex is not held while all mtr_memos are popped and is released just after the modified blocks are inserted into the flush_list. This should reduce contention on log_sys mutex.

Implement the global variable `innodb_change_buffering`, with the following values:

- **none**: buffer nothing
- **inserts**: buffer inserts (like InnoDB so far)
- **deletes**: buffer delete-marks
- **changes**: buffer inserts and delete-marks
- **purges**: buffer delete-marks and deletes
- **all**: buffer all operations (insert, delete-mark, delete)

The default is **all**. All values except **none** and **inserts** will make InnoDB write new-format records to the insert buffer, even for inserts.

Provide support for native AIO on Linux.

### 14.1.8.3 Changes in InnoDB Plugin 1.0.x

The InnoDB 1.0.x releases that accompany MySQL 5.1 have their own change history. Changes up to InnoDB 1.0.8 are listed at [http://dev.mysql.com/doc/innodb-plugin/1.0/en/innodb-changes.html](http://dev.mysql.com/doc/innodb-plugin/1.0/en/innodb-changes.html). Changes from InnoDB 1.0.9 and up are incorporated in the MySQL 5.1 Release Notes.

### 14.1.9 Third-Party Software Contributions

Oracle acknowledges that certain Third Party and Open Source software has been used to develop or is incorporated in the InnoDB storage engine. This appendix includes required third-party license information.

#### 14.1.9.1 Performance Patches from Google

Oracle gratefully acknowledges the following contributions from Google, Inc. to improve InnoDB performance:

- Replacing InnoDB's use of Pthreads mutexes with calls to GCC atomic builtins, as discussed in [Section 14.16.3, “InnoDB Mutex and Read/Write Lock Implementation”](#). This change means that InnoDB mutex and rw-lock operations take less CPU time, and improves throughput on those platforms where the atomic operations are available.

- Controlling master thread I/O rate, as discussed in [Section 14.16.9, “Configuring the InnoDB Master Thread I/O Rate”](#). The master thread in InnoDB is a thread that performs various tasks in the background. Historically, InnoDB has used a hard coded value as the total I/O capacity of the server. With this change, user can control the number of I/O operations that can be performed per second based on their own workload.
Third-Party Software Contributions

Changes from the Google contributions were incorporated in the following source code files: `btr0cur.c`, `btr0sea.c`, `buf0buf.c`, `buf0buf.ic`, `ha_innodb.cc`, `log0log.c`, `log0log.h`, `os0sync.h`, `row0sel.c`, `srv0srv.c`, `srv0srv.h`, `srv0start.c`, `sync0arr.c`, `sync0rw.c`, `sync0rw.h`, `sync0rw.ic`, `sync0sync.c`, `sync0sync.h`, `sync0sync.ic`, and `univ.i`.

These contributions are incorporated subject to the conditions contained in the file `COPYING.Google`, which are reproduced here.

---

14.1.9.2 Multiple Background I/O Threads Patch from Percona

Oracle gratefully acknowledges the contribution of Percona, Inc. to improve InnoDB performance by implementing configurable background threads, as discussed in Section 14.16.7, “Configuring the Number of Background InnoDB I/O Threads”. InnoDB uses background threads to service various types of I/O requests. The change provides another way to make InnoDB more scalable on high end systems.

Changes from the Percona, Inc. contribution were incorporated in the following source code files: `ha_innodb.cc`, `os0file.c`, `os0file.h`, `srv0srv.c`, `srv0srv.h`, and `srv0start.c`.

This contribution is incorporated subject to the conditions contained in the file `COPYING.Percona`, which are reproduced here.

14.1.9.3 Performance Patches from Sun Microsystems

Oracle gratefully acknowledges the following contributions from Sun Microsystems, Inc. to improve InnoDB performance:

- Introducing the PAUSE instruction inside spin loops, as discussed in Section 14.16.10, “Using the PAUSE Instruction in InnoDB Spin Loops”. This change increases performance in high concurrency, CPU-bound workloads.

- Enabling inlining of functions and prefetch with Sun Studio.

Changes from the Sun Microsystems, Inc. contribution were incorporated in the following source code files: `univ.i`, `ut0ut.c`, and `ut0ut.h`.

This contribution is incorporated subject to the conditions contained in the file `COPYING.Sun_Microsystems`, which are reproduced here.
14.2 Installing the InnoDB Storage Engine

When you use the InnoDB storage engine 1.1 and above, with MySQL 5.5 and above, you do not need to do anything special to install: everything comes configured as part of the MySQL source and binary distributions. This is a change from earlier releases of the InnoDB Plugin, where you were required to match up MySQL and InnoDB version numbers and update your build and configuration processes.

The InnoDB storage engine is included in the MySQL distribution, starting from MySQL 5.1.38. From MySQL 5.1.46 and up, this is the only download location for the InnoDB storage engine; it is not available from the InnoDB web site.

If you used any scripts or configuration files with the earlier InnoDB storage engine from the InnoDB web site, be aware that the filename of the shared library as supplied by MySQL is `ha_innodb_plugin.so` or `ha_innodb_plugin.dll`, as opposed to `ha_innodb.so` or `ha_innodb.dll` in the older Plugin downloaded from the InnoDB web site. You might need to change the applicable file names in your startup or configuration scripts.

Because the InnoDB storage engine has now replaced the built-in InnoDB, you no longer need to specify options like `--ignore-built-in-innodb` and `--plugin-load` during startup.

To take best advantage of current InnoDB features, we recommend specifying the following options in your configuration file:

```ini
innodb_file_per_table=1
innodb_file_format=barracuda
innodb_strict_mode=1
```

For information about these features, see Section 14.15, “InnoDB Startup Options and System Variables”, Section 14.11, “InnoDB File-Format Management”, and `innodb_strict_mode`. You might need to continue to use the previous values for these parameters in some replication and similar configurations involving both new and older versions of MySQL.

14.3 Upgrading the InnoDB Storage Engine

Prior to MySQL 5.5, some upgrade scenarios involved upgrading the separate instance of InnoDB known as the InnoDB Plugin. In MySQL 5.5 and higher, the features of the InnoDB Plugin have been folded back into built-in InnoDB, so the upgrade procedure for InnoDB is the same as the one for the MySQL server. For details, see Section 2.11.1, “Upgrading MySQL”.

14.4 Downgrading the InnoDB Storage Engine

14.4.1 Overview

Prior to MySQL 5.5, some downgrade scenarios involved switching the separate instance of InnoDB known as the InnoDB Plugin back to the built-in InnoDB storage engine. In MySQL 5.5 and higher, the features of the InnoDB Plugin have been folded back into built-in InnoDB, so the downgrade procedure for InnoDB is the same as the one for the MySQL server. For details, see Section 2.11.2, “Downgrading MySQL”.

14.5 InnoDB Concepts and Architecture

The information in this section provides background to help you get the most performance and functionality from using InnoDB tables. It is intended for:

- Anyone switching to MySQL from another database system, to explain what things might seem familiar and which might be all-new.
MySQL and the ACID Model

- Anyone moving from MyISAM tables to InnoDB, now that InnoDB is the default MySQL storage engine.
- Anyone considering their application architecture or software stack, to understand the design considerations, performance characteristics, and scalability of InnoDB tables at a detailed level.

In this section, you will learn:

- How InnoDB closely adheres to ACID principles.
- How InnoDB implements transactions, and how the inner workings of transactions compare with other database systems you might be familiar with.
- How InnoDB implements row-level locking to allow queries and DML statements to read and write the same table simultaneously.
- How multi-version concurrency control (MVCC) keeps transactions from viewing or modifying each others' data before the appropriate time.
- The physical layout of InnoDB-related objects on disk, such as tables, indexes, tablespaces, undo logs, and the redo log.

14.5.1 MySQL and the ACID Model

The ACID model is a set of database design principles that emphasize aspects of reliability that are important for business data and mission-critical applications. MySQL includes components such as the InnoDB storage engine that adhere closely to the ACID model, so that data is not corrupted and results are not distorted by exceptional conditions such as software crashes and hardware malfunctions. When you rely on ACID-compliant features, you do not need to reinvent the wheel of consistency checking and crash recovery mechanisms. In cases where you have additional software safeguards, ultra-reliable hardware, or an application that can tolerate a small amount of data loss or inconsistency, you can adjust MySQL settings to trade some of the ACID reliability for greater performance or throughput.

The following sections discuss how MySQL features, in particular the InnoDB storage engine, interact with the categories of the ACID model:

- A: atomicity.
- C: consistency.
- I: isolation.
- D: durability.

Atomicity

The atomicity aspect of the ACID model mainly involves InnoDB transactions. Related MySQL features include:

- Autocommit setting.
- COMMIT statement.
- ROLLBACK statement.
- Operational data from the INFORMATION_SCHEMA tables.

Consistency

The consistency aspect of the ACID model mainly involves internal InnoDB processing to protect data from crashes. Related MySQL features include:
The InnoDB Transaction Model and Locking

- InnoDB doublewrite buffer.
- InnoDB crash recovery.

**Isolation**

The isolation aspect of the ACID model mainly involves InnoDB transactions, in particular the isolation level that applies to each transaction. Related MySQL features include:

- Autocommit setting.
- SET ISOLATION LEVEL statement.
- The low-level details of InnoDB locking. During performance tuning, you see these details through INFORMATION_SCHEMA tables.

**Durability**

The durability aspect of the ACID model involves MySQL software features interacting with your particular hardware configuration. Because of the many possibilities depending on the capabilities of your CPU, network, and storage devices, this aspect is the most complicated to provide concrete guidelines for. (And those guidelines might take the form of buy “new hardware”.) Related MySQL features include:

- InnoDB doublewrite buffer, turned on and off by the innodb_doublewrite configuration option.
- Configuration option innodb_flush_log_at_trx_commit.
- Configuration option sync_binlog.
- Configuration option innodb_file_per_table.
- Write buffer in a storage device, such as a disk drive, SSD, or RAID array.
- Battery-backed cache in a storage device.
- The operating system used to run MySQL, in particular its support for the fsync() system call.
- Uninterruptible power supply (UPS) protecting the electrical power to all computer servers and storage devices that run MySQL servers and store MySQL data.
- Your backup strategy, such as frequency and types of backups, and backup retention periods.
- For distributed or hosted data applications, the particular characteristics of the data centers where the hardware for the MySQL servers is located, and network connections between the data centers.

**14.5.2 The InnoDB Transaction Model and Locking**

To implement a large-scale, busy, or highly reliable database application, to port substantial code from a different database system, or to push MySQL performance to the limits of the laws of physics, you must understand the notions of transactions and locking as they relate to the InnoDB storage engine.

In the InnoDB transaction model, the goal is to combine the best properties of a multi-versioning database with traditional two-phase locking. InnoDB does locking on the row level and runs queries as nonlocking consistent reads by default, in the style of Oracle. The lock information in InnoDB is stored so space-efficiently that lock escalation is not needed: Typically, several users are permitted to lock every row in InnoDB tables, or any random subset of the rows, without causing InnoDB memory exhaustion.
InnoDB Lock Modes

In InnoDB, all user activity occurs inside a transaction. If autocommit mode is enabled, each SQL statement forms a single transaction on its own. By default, MySQL starts the session for each new connection with autocommit enabled, so MySQL does a commit after each SQL statement if that statement did not return an error. If a statement returns an error, the commit or rollback behavior depends on the error. See Section 14.21.4, “InnoDB Error Handling”.

A session that has autocommit enabled can perform a multiple-statement transaction by starting it with an explicit START TRANSACTION or BEGIN statement and ending it with a COMMIT or ROLLBACK statement. See Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”.

If autocommit mode is disabled within a session with SET autocommit = 0, the session always has a transaction open. A COMMIT or ROLLBACK statement ends the current transaction and a new one starts.

A COMMIT means that the changes made in the current transaction are made permanent and become visible to other sessions. A ROLLBACK statement, on the other hand, cancels all modifications made by the current transaction. Both COMMIT and ROLLBACK release all InnoDB locks that were set during the current transaction.

In terms of the SQL:1992 transaction isolation levels, the default InnoDB level is REPEATABLE READ. InnoDB offers all four transaction isolation levels described by the SQL standard: READ UNCOMMITTED, READ COMMITTED, REPEATABLE READ, and SERIALIZABLE.

A user can change the isolation level for a single session or for all subsequent connections with the SET TRANSACTION statement. To set the server's default isolation level for all connections, use the --transaction-isolation option on the command line or in an option file. For detailed information about isolation levels and level-setting syntax, see Section 13.3.6, “SET TRANSACTION Syntax”.

In row-level locking, InnoDB normally uses next-key locking. That means that besides index records, InnoDB can also lock the gap preceding an index record to block insertions by other sessions where the indexed values would be inserted in that gap within the tree data structure. A next-key lock refers to a lock that locks an index record and the gap before it. A gap lock refers to a lock that locks only the gap before some index record.

For more information about row-level locking, and the circumstances under which gap locking is disabled, see Section 14.5.6, “InnoDB Record, Gap, and Next-Key Locks”.

14.5.3 InnoDB Lock Modes

InnoDB implements standard row-level locking where there are two types of locks, shared (s) locks and exclusive (x) locks. For information about record, gap, and next-key lock types, see Section 14.5.6, “InnoDB Record, Gap, and Next-Key Locks”.

• A shared (s) lock permits the transaction that holds the lock to read a row.

• An exclusive (x) lock permits the transaction that holds the lock to update or delete a row.

If transaction T1 holds a shared (s) lock on row r, then requests from some distinct transaction T2 for a lock on row r are handled as follows:

• A request by T2 for an s lock can be granted immediately. As a result, both T1 and T2 hold an s lock on r.

• A request by T2 for an x lock cannot be granted immediately.

If a transaction T1 holds an exclusive (x) lock on row r, a request from some distinct transaction T2 for a lock of either type on r cannot be granted immediately. Instead, transaction T2 has to wait for transaction T1 to release its lock on row r.
Intention Locks

Additionally, InnoDB supports *multiple granularity locking* which permits coexistence of record locks and locks on entire tables. To make locking at multiple granularity levels practical, additional types of locks called *intention locks* are used. Intention locks are table locks in InnoDB that indicate which type of lock (shared or exclusive) a transaction will require later for a row in that table. There are two types of intention locks used in InnoDB (assume that transaction T has requested a lock of the indicated type on table t):

- **Intention shared (IS):** Transaction T intends to set S locks on individual rows in table t.
- **Intention exclusive (IX):** Transaction T intends to set X locks on those rows.

For example, `SELECT ... LOCK IN SHARE MODE` sets an IS lock and `SELECT ... FOR UPDATE` sets an IX lock.

The intention locking protocol is as follows:

- Before a transaction can acquire an S lock on a row in table t, it must first acquire an IS or stronger lock on t.
- Before a transaction can acquire an X lock on a row, it must first acquire an IX lock on t.

These rules can be conveniently summarized by means of the following *lock type compatibility matrix*.

<table>
<thead>
<tr>
<th></th>
<th>X</th>
<th>IX</th>
<th>S</th>
<th>IS</th>
</tr>
</thead>
<tbody>
<tr>
<td>X</td>
<td>Conflict</td>
<td>Conflict</td>
<td>Conflict</td>
<td>Conflict</td>
</tr>
<tr>
<td>IX</td>
<td>Conflict</td>
<td>Compatible</td>
<td>Conflict</td>
<td>Compatible</td>
</tr>
<tr>
<td>S</td>
<td>Conflict</td>
<td>Conflict</td>
<td>Compatible</td>
<td>Compatible</td>
</tr>
<tr>
<td>IS</td>
<td>Conflict</td>
<td>Compatible</td>
<td>Compatible</td>
<td>Compatible</td>
</tr>
</tbody>
</table>

A lock is granted to a requesting transaction if it is compatible with existing locks, but not if it conflicts with existing locks. A transaction waits until the conflicting existing lock is released. If a lock request conflicts with an existing lock and cannot be granted because it would cause deadlock, an error occurs.

Thus, intention locks do not block anything except full table requests (for example, `LOCK TABLES ... WRITE`). The main purpose of IX and IS locks is to show that someone is locking a row, or going to lock a row in the table.

**Deadlock Example**

The following example illustrates how an error can occur when a lock request would cause a deadlock. The example involves two clients, A and B.

First, client A creates a table containing one row, and then begins a transaction. Within the transaction, A obtains an S lock on the row by selecting it in share mode:

```
mysql> CREATE TABLE t (i INT) ENGINE = InnoDB;
Query OK, 0 rows affected (1.07 sec)

mysql> INSERT INTO t (i) VALUES(1);
Query OK, 1 row affected (0.09 sec)

mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM t WHERE i = 1 LOCK IN SHARE MODE;
```
Next, client B begins a transaction and attempts to delete the row from the table:

```
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)
mysql> DELETE FROM t WHERE i = 1;
```

The delete operation requires an \textit{X} lock. The lock cannot be granted because it is incompatible with the \textit{S} lock that client A holds, so the request goes on the queue of lock requests for the row and client B blocks.

Finally, client A also attempts to delete the row from the table:

```
mysql> DELETE FROM t WHERE i = 1;
ERROR 1213 (40001): Deadlock found when trying to get lock; try restarting transaction
```

Deadlock occurs here because client A needs an \textit{X} lock to delete the row. However, that lock request cannot be granted because client B already has a request for an \textit{X} lock and is waiting for client A to release its \textit{S} lock. Nor can the \textit{S} lock held by A be upgraded to an \textit{X} lock because of the prior request by B for an \textit{X} lock. As a result, InnoDB generates an error for one of the clients and releases its locks. The client returns this error:

```
ERROR 1213 (40001): Deadlock found when trying to get lock; try restarting transaction
```

At that point, the lock request for the other client can be granted and it deletes the row from the table.

\textbf{Note}

If the \textit{LATEST DETECTED DEADLOCK} section of InnoDB Monitor output includes a message stating, “\textit{TOO DEEP OR LONG SEARCH IN THE LOCK TABLE WAITS-FOR GRAPH, WE WILL ROLL BACK FOLLOWING TRANSACTION},” this indicates that the number of transactions on the wait-for list has reached a limit of 200, which is defined by \texttt{LOCK\_MAX\_DEPTH\_IN\_DEADLOCK\_CHECK}. A wait-for list that exceeds 200 transactions is treated as a deadlock and the transaction attempting to check the wait-for list is rolled back.

The same error may also occur if the locking thread must look at more than 1,000,000 locks owned by the transactions on the wait-for list. The limit of 1,000,000 locks is defined by \texttt{LOCK\_MAX\_N\_STEPS\_IN\_DEADLOCK\_CHECK}.

### 14.5.4 Consistent Nonlocking Reads

A \textit{consistent read} means that InnoDB uses multi-versioning to present to a query a snapshot of the database at a point in time. The query sees the changes made by transactions that committed before that point of time, and no changes made by later or uncommitted transactions. The exception to this rule is that the query sees the changes made by earlier statements within the same transaction. This exception causes the following anomaly: If you update some rows in a table, a \texttt{SELECT} sees the latest version of the updated rows, but it might also see older versions of any rows. If other sessions simultaneously update the same table, the anomaly means that you might see the table in a state that never existed in the database.
If the transaction isolation level is **REPEATABLE READ** (the default level), all consistent reads within the same transaction read the snapshot established by the first such read in that transaction. You can get a fresher snapshot for your queries by committing the current transaction and after that issuing new queries.

With **READ COMMITTED** isolation level, each consistent read within a transaction sets and reads its own fresh snapshot.

Consistent read is the default mode in which InnoDB processes **SELECT** statements in **READ COMMITTED** and **REPEATABLE READ** isolation levels. A consistent read does not set any locks on the tables it accesses, and therefore other sessions are free to modify those tables at the same time a consistent read is being performed on the table.

Suppose that you are running in the default **REPEATABLE READ** isolation level. When you issue a consistent read (that is, an ordinary **SELECT** statement), InnoDB gives your transaction a timepoint according to which your query sees the database. If another transaction deletes a row and commits after your timepoint was assigned, you do not see the row as having been deleted. Inserts and updates are treated similarly.

### Note

The snapshot of the database state applies to **SELECT** statements within a transaction, not necessarily to **DML** statements. If you insert or modify some rows and then commit that transaction, a **DELETE** or **UPDATE** statement issued from another concurrent **REPEATABLE READ** transaction could affect those just-committed rows, even though the session could not query them. If a transaction does update or delete rows committed by a different transaction, those changes do become visible to the current transaction. For example, you might encounter a situation like the following:

```sql
SELECT COUNT(c1) FROM t1 WHERE c1 = 'xyz'; -- Returns 0: no rows match.
DELETE FROM t1 WHERE c1 = 'xyz'; -- Deletes several rows recently committed by other transactions.
SELECT COUNT(c2) FROM t1 WHERE c2 = 'abc'; -- Returns 0: no rows match.
UPDATE t1 SET c2 = 'cba' WHERE c2 = 'abc'; -- Affects 10 rows: another txn just committed.
SELECT COUNT(c2) FROM t1 WHERE c2 = 'cba'; -- Returns 10: this txn can now see the rows it just updated.
```

You can advance your timepoint by committing your transaction and then doing another **SELECT** or **START TRANSACTION WITH CONSISTENT SNAPSHOT**.

This is called **multi-versioned concurrency control**.

In the following example, session A sees the row inserted by B only when B has committed the insert and A has committed as well, so that the timepoint is advanced past the commit of B.
Locking Reads (SELECT ... FOR UPDATE and SELECT ... LOCK IN SHARE MODE)

COMMIT;
SELECT * FROM t;
---------------------
|    1    |    2    |
---------------------
1 row in set

If you want to see the “freshest” state of the database, use either the READ COMMITTED isolation level or a locking read:

SELECT * FROM t LOCK IN SHARE MODE;

With READ COMMITTED isolation level, each consistent read within a transaction sets and reads its own fresh snapshot. With LOCK IN SHARE MODE, a locking read occurs instead: A SELECT blocks until the transaction containing the freshest rows ends (see Section 14.5.5, “Locking Reads (SELECT ... FOR UPDATE and SELECT ... LOCK IN SHARE MODE)”).

Consistent read does not work over certain DDL statements:

- Consistent read does not work over DROP TABLE, because MySQL cannot use a table that has been dropped and InnoDB destroys the table.
- Consistent read does not work over ALTER TABLE, because that statement makes a temporary copy of the original table and deletes the original table when the temporary copy is built. When you reissue a consistent read within a transaction, rows in the new table are not visible because those rows did not exist when the transaction's snapshot was taken.

The type of read varies for selects in clauses like INSERT INTO ... SELECT, UPDATE ... (SELECT), and CREATE TABLE ... SELECT that do not specify FOR UPDATE or LOCK IN SHARE MODE:

- By default, InnoDB uses stronger locks and the SELECT part acts like READ COMMITTED, where each consistent read, even within the same transaction, sets and reads its own fresh snapshot.
- To use a consistent read in such cases, enable the innodb_locks_unsafe_for_binlog option and set the isolation level of the transaction to READ UNCOMMITTED, READ COMMITTED, or REPEATABLE READ (that is, anything other than SERIALizable). In this case, no locks are set on rows read from the selected table.

14.5.5 Locking Reads (SELECT ... FOR UPDATE and SELECT ... LOCK IN SHARE MODE)

If you query data and then insert or update related data within the same transaction, the regular SELECT statement does not give enough protection. Other transactions can update or delete the same rows you just queried. InnoDB supports two types of locking reads that offer extra safety:

- SELECT ... LOCK IN SHARE MODE sets a shared mode lock on any rows that are read. Other sessions can read the rows, but cannot modify them until your transaction commits. If any of these rows were changed by another transaction that has not yet committed, your query waits until that transaction ends and then uses the latest values.
- For index records the search encounters, SELECT ... FOR UPDATE locks the rows and any associated index entries, the same as if you issued an UPDATE statement for those rows. Other transactions are blocked from updating those rows, from doing SELECT ... LOCK IN SHARE MODE, or from reading the data in certain transaction isolation levels. Consistent reads ignore any locks set on the records that exist in the read view. (Old versions of a record cannot be locked; they are reconstructed by applying undo logs on an in-memory copy of the record.)
Locking Reads (SELECT ... FOR UPDATE and SELECT ... LOCK IN SHARE MODE)

These clauses are primarily useful when dealing with tree-structured or graph-structured data, either in a single table or split across multiple tables. You traverse edges or tree branches from one place to another, while reserving the right to come back and change any of these “pointer” values.

All locks set by LOCK IN SHARE MODE and FOR UPDATE queries are released when the transaction is committed or rolled back.

Note

Locking of rows for update using SELECT FOR UPDATE only applies when autocommit is disabled (either by beginning transaction with START TRANSACTION or by setting autocommit to 0. If autocommit is enabled, the rows matching the specification are not locked.

Usage Examples

Suppose that you want to insert a new row into a table child, and make sure that the child row has a parent row in table parent. Your application code can ensure referential integrity throughout this sequence of operations.

First, use a consistent read to query the table PARENT and verify that the parent row exists. Can you safely insert the child row to table CHILD? No, because some other session could delete the parent row in the moment between your SELECT and your INSERT, without you being aware of it.

To avoid this potential issue, perform the SELECT using LOCK IN SHARE MODE:

```
SELECT * FROM parent WHERE NAME = 'Jones' LOCK IN SHARE MODE;
```

After the LOCK IN SHARE MODE query returns the parent 'Jones', you can safely add the child record to the CHILD table and commit the transaction. Any transaction that tries to read or write to the applicable row in the PARENT table waits until you are finished, that is, the data in all tables is in a consistent state.

For another example, consider an integer counter field in a table CHILD_CODES, used to assign a unique identifier to each child added to table CHILD. Do not use either consistent read or a shared mode read to read the present value of the counter, because two users of the database could see the same value for the counter, and a duplicate-key error occurs if two transactions attempt to add rows with the same identifier to the CHILD table.

Here, LOCK IN SHARE MODE is not a good solution because if two users read the counter at the same time, at least one of them ends up in deadlock when it attempts to update the counter.

To implement reading and incrementing the counter, first perform a locking read of the counter using FOR UPDATE, and then increment the counter. For example:

```
SELECT counter_field FROM child_codes FOR UPDATE;
UPDATE child_codes SET counter_field = counter_field + 1;
```

A SELECT ... FOR UPDATE reads the latest available data, setting exclusive locks on each row it reads. Thus, it sets the same locks a searched SQL UPDATE would set on the rows.

The preceding description is merely an example of how SELECT ... FOR UPDATE works. In MySQL, the specific task of generating a unique identifier actually can be accomplished using only a single access to the table:
UPDATE child_codes SET counter_field = LAST_INSERT_ID(counter_field + 1);
SELECT LAST_INSERT_ID();

The SELECT statement merely retrieves the identifier information (specific to the current connection). It does not access any table.

### 14.5.6 InnoDB Record, Gap, and Next-Key Locks

InnoDB has several types of record-level locks including record locks, gap locks, and next-key locks. For information about shared locks, exclusive locks, and intention locks, see Section 14.5.3, "InnoDB Lock Modes".

- **Record lock**: This is a lock on an index record.
- **Gap lock**: This is a lock on a gap between index records, or a lock on the gap before the first or after the last index record.
- **Next-key lock**: This is a combination of a record lock on the index record and a gap lock on the gap before the index record.

#### Record Locks

Record locks always lock index records, even if a table is defined with no indexes. For such cases, InnoDB creates a hidden clustered index and uses this index for record locking. See Section 14.5.13.2, "Clustered and Secondary Indexes".

#### Next-key Locks

By default, InnoDB operates in REPEATABLE READ transaction isolation level and with the innodb_locks_unsafe_for_binlog system variable disabled. In this case, InnoDB uses next-key locks for searches and index scans, which prevents phantom rows (see Section 14.5.7, “Avoiding the Phantom Problem Using Next-Key Locking”).

Next-key locking combines index-row locking with gap locking. InnoDB performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. In addition, a next-key lock on an index record also affects the “gap” before that index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record \( R \) in an index, another session cannot insert a new index record in the gap immediately before \( R \) in the index order.

Suppose that an index contains the values 10, 11, 13, and 20. The possible next-key locks for this index cover the following intervals, where ( or ) denote exclusion of the interval endpoint and [ or ] denote inclusion of the endpoint:

- \( (-\infty, 10] \)
- \( (10, 11) \)
- \( (11, 13] \)
- \( (13, 20] \)
- \( (20, +\infty) \)

For the last interval, the next-key lock locks the gap above the largest value in the index and the “supremum” pseudo-record having a value higher than any value actually in the index. The supremum is not a real index record, so, in effect, this next-key lock locks only the gap following the largest index value.
Gap Locks

The next-key locking example in the previous section shows that a gap might span a single index value, multiple index values, or even be empty.

Gap locking is not needed for statements that lock rows using a unique index to search for a unique row. (This does not include the case that the search condition includes only some columns of a multiple-column unique index; in that case, gap locking does occur.) For example, if the `id` column has a unique index, the following statement uses only an index-record lock for the row having `id` value 100 and it does not matter whether other sessions insert rows in the preceding gap:

```
SELECT * FROM child WHERE id = 100;
```

If `id` is not indexed or has a nonunique index, the statement does lock the preceding gap.

A type of gap lock called an insertion intention gap lock is set by `INSERT` operations prior to row insertion. This lock signals the intent to insert in such a way that multiple transactions inserting into the same index gap need not wait for each other if they are not inserting at the same position within the gap. Suppose that there are index records with values of 4 and 7. Separate transactions that attempt to insert values of 5 and 6 each lock the gap between 4 and 7 with insert intention locks prior to obtaining the exclusive lock on the inserted row, but do not block each other because the rows are nonconflicting. For more information about intention locks, see Section 14.5.3, "InnoDB Lock Modes".

It is also worth noting here that conflicting locks can be held on a gap by different transactions. For example, transaction A can hold a shared gap lock (gap S-lock) on a gap while transaction B holds an exclusive gap lock (gap X-lock) on the same gap. The reason conflicting gap locks are allowed is that if a record is purged from an index, the gap locks held on the record by different transactions must be merged.

Gap locks in InnoDB are "purely inhibitive", which means they only stop other transactions from inserting to the gap. Thus, a gap X-lock has the same effect as a gap S-lock.

Disabling Gap Locking

Gap locking can be disabled explicitly. This occurs if you change the transaction isolation level to `READ COMMITTED` or enable the `innodb_locks_unsafe_for_binlog` system variable. Under these circumstances, gap locking is disabled for searches and index scans and is used only for foreign-key constraint checking and duplicate-key checking.

There are also other effects of using the `READ COMMITTED` isolation level or enabling `innodb_locks_unsafe_for_binlog`: Record locks for nonmatching rows are released after MySQL has evaluated the `WHERE` condition. For `UPDATE` statements, InnoDB does a "semi-consistent" read, such that it returns the latest committed version to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`.

14.5.7 Avoiding the Phantom Problem Using Next-Key Locking

The so-called `phantom` problem occurs within a transaction when the same query produces different sets of rows at different times. For example, if a `SELECT` is executed twice, but returns a row the second time that was not returned the first time, the row is a "phantom" row.

Suppose that there is an index on the `id` column of the `child` table and that you want to read and lock all rows from the table having an identifier value larger than 100, with the intention of updating some column in the selected rows later:

```
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```
The query scans the index starting from the first record where `id` is bigger than 100. Let the table contain rows having `id` values of 90 and 102. If the locks set on the index records in the scanned range do not lock out inserts made in the gaps (in this case, the gap between 90 and 102), another session can insert a new row into the table with an `id` of 101. If you were to execute the same `SELECT` within the same transaction, you would see a new row with an `id` of 101 (a “phantom”) in the result set returned by the query. If we regard a set of rows as a data item, the new phantom child would violate the isolation principle of transactions that a transaction should be able to run so that the data it has read does not change during the transaction.

To prevent phantoms, InnoDB uses an algorithm called *next-key locking* that combines index-row locking with gap locking. InnoDB performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. In addition, a next-key lock on an index record also affects the “gap” before that index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record \( R \) in an index, another session cannot insert a new index record in the gap immediately before \( R \) in the index order.

When InnoDB scans an index, it can also lock the gap after the last record in the index. Just that happens in the preceding example: To prevent any insert into the table where `id` would be bigger than 100, the locks set by InnoDB include a lock on the gap following `id` value 102.

You can use next-key locking to implement a uniqueness check in your application: If you read your data in share mode and do not see a duplicate for a row you are going to insert, then you can safely insert your row and know that the next-key lock set on the successor of your row during the read prevents anyone meanwhile inserting a duplicate for your row. Thus, the next-key locking enables you to “lock” the nonexistence of something in your table.

Gap locking can be disabled as discussed in Section 14.5.6, “InnoDB Record, Gap, and Next-Key Locks”. This may cause phantom problems because other sessions can insert new rows into the gaps when gap locking is disabled.

### 14.5.8 Locks Set by Different SQL Statements in InnoDB

A locking read, an `UPDATE`, or a `DELETE` generally set record locks on every index record that is scanned in the processing of the SQL statement. It does not matter whether there are `WHERE` conditions in the statement that would exclude the row. InnoDB does not remember the exact `WHERE` condition, but only knows which index ranges were scanned. The locks are normally next-key locks that also block inserts into the “gap” immediately before the record. However, gap locking can be disabled explicitly, which causes next-key locking not to be used. For more information, see Section 14.5.6, “InnoDB Record, Gap, and Next-Key Locks”. The transaction isolation level also can affect which locks are set; see Section 13.3.6, “SET TRANSACTION Syntax”.

If a secondary index is used in a search and index record locks to be set are exclusive, InnoDB also retrieves the corresponding clustered index records and sets locks on them.

Differences between shared and exclusive locks are described in Section 14.5.3, “InnoDB Lock Modes”.

If you have no indexes suitable for your statement and MySQL must scan the entire table to process the statement, every row of the table becomes locked, which in turn blocks all inserts by other users to the table. It is important to create good indexes so that your queries do not unnecessarily scan many rows.

For `SELECT ... FOR UPDATE` or `SELECT ... LOCK IN SHARE MODE`, locks are acquired for scanned rows, and expected to be released for rows that do not qualify for inclusion in the result set (for example, if they do not meet the criteria given in the `WHERE` clause). However, in some cases, rows might not be unlocked immediately because the relationship between a result row and its original source is lost during query execution. For example, in a `UNION`, scanned (and locked) rows from a table might be inserted
into a temporary table before evaluation whether they qualify for the result set. In this circumstance, the relationship of the rows in the temporary table to the rows in the original table is lost and the latter rows are not unlocked until the end of query execution.

**InnoDB** sets specific types of locks as follows.

- **SELECT ... FROM** is a consistent read, reading a snapshot of the database and setting no locks unless the transaction isolation level is set to **SERIALIZABLE**. For **SERIALIZABLE** level, the search sets shared next-key locks on the index records it encounters.

- **SELECT ... FROM ... LOCK IN SHARE MODE** sets shared next-key locks on all index records the search encounters.

- For index records the search encounters, **SELECT ... FROM ... FOR UPDATE** blocks other sessions from doing **SELECT ... FROM ... LOCK IN SHARE MODE** or from reading in certain transaction isolation levels. Consistent reads will ignore any locks set on the records that exist in the read view.

- **UPDATE ... WHERE ...** sets an exclusive next-key lock on every record the search encounters.

- **DELETE FROM ... WHERE ...** sets an exclusive next-key lock on every record the search encounters.

- **INSERT** sets an exclusive lock on the inserted row. This lock is an index-record lock, not a next-key lock (that is, there is no gap lock) and does not prevent other sessions from inserting into the gap before the inserted row.

Prior to inserting the row, a type of gap lock called an insertion intention gap lock is set. This lock signals the intent to insert in such a way that multiple transactions inserting into the same index gap need not wait for each other if they are not inserting at the same position within the gap. Suppose that there are index records with values of 4 and 7. Separate transactions that attempt to insert values of 5 and 6 each lock the gap between 4 and 7 with insert intention locks prior to obtaining the exclusive lock on the inserted row, but do not block each other because the rows are nonconflicting.

If a duplicate-key error occurs, a shared lock on the duplicate index record is set. This use of a shared lock can result in deadlock should there be multiple sessions trying to insert the same row if another session already has an exclusive lock. This can occur if another session deletes the row. Suppose that an **InnoDB** table `t1` has the following structure:

```
CREATE TABLE t1 (i INT, PRIMARY KEY (i)) ENGINE = InnoDB;
```

Now suppose that three sessions perform the following operations in order:

**Session 1:**

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

**Session 2:**

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

**Session 3:**

```
START TRANSACTION;
```
INSERT INTO t1 VALUES(1);

Session 1:

ROLLBACK;

The first operation by session 1 acquires an exclusive lock for the row. The operations by sessions 2 and 3 both result in a duplicate-key error and they both request a shared lock for the row. When session 1 rolls back, it releases its exclusive lock on the row and the queued shared lock requests for sessions 2 and 3 are granted. At this point, sessions 2 and 3 deadlock: Neither can acquire an exclusive lock for the row because of the shared lock held by the other.

A similar situation occurs if the table already contains a row with key value 1 and three sessions perform the following operations in order:

Session 1:

START TRANSACTION;
DELETE FROM t1 WHERE i = 1;

Session 2:

START TRANSACTION;
INSERT INTO t1 VALUES(1);

Session 3:

START TRANSACTION;
INSERT INTO t1 VALUES(1);

Session 1:

COMMIT;

The first operation by session 1 acquires an exclusive lock for the row. The operations by sessions 2 and 3 both result in a duplicate-key error and they both request a shared lock for the row. When session 1 commits, it releases its exclusive lock on the row and the queued shared lock requests for sessions 2 and 3 are granted. At this point, sessions 2 and 3 deadlock: Neither can acquire an exclusive lock for the row because of the shared lock held by the other.

• **INSERT ... ON DUPLICATE KEY UPDATE** differs from a simple **INSERT** in that an exclusive next-key lock rather than a shared lock is placed on the row to be updated when a duplicate-key error occurs.

• **REPLACE** is done like an **INSERT** if there is no collision on a unique key. Otherwise, an exclusive next-key lock is placed on the row to be replaced.

• **INSERT INTO T SELECT ... FROM S WHERE ...** sets an exclusive index record without a gap lock on each row inserted into T. If the transaction isolation level is **READ COMMITTED** or **innodb_locks_unsafe_for_binlog** is enabled, and the transaction isolation level is not **SERIALIZABLE**, InnoDB does the search on S as a consistent read (no locks). Otherwise, InnoDB sets shared next-key locks on rows from S. InnoDB has to set locks in the latter case: In roll-forward recovery from a backup, every SQL statement must be executed in exactly the same way it was done originally.

**CREATE TABLE ... SELECT ...** performs the **SELECT** with shared next-key locks or as a consistent read, as for **INSERT ... SELECT**.
When a `SELECT` is used in the constructs `REPLACE INTO t SELECT ... FROM s WHERE ...` or `UPDATE t ... WHERE col IN (SELECT ... FROM s ...)`, InnoDB sets shared next-key locks on rows from table `s`.

- While initializing a previously specified `AUTO_INCREMENT` column on a table, InnoDB sets an exclusive lock on the end of the index associated with the `AUTO_INCREMENT` column. In accessing the auto-increment counter, InnoDB uses a specific `AUTO-INC` table lock mode where the lock lasts only to the end of the current SQL statement, not to the end of the entire transaction. Other sessions cannot insert into the table while the `AUTO-INC` table lock is held; see Section 14.5.2, “The InnoDB Transaction Model and Locking”.

InnoDB fetches the value of a previously initialized `AUTO_INCREMENT` column without setting any locks.

- If a `FOREIGN KEY` constraint is defined on a table, any insert, update, or delete that requires the constraint condition to be checked sets shared record-level locks on the records that it looks at to check the constraint. InnoDB also sets these locks in the case where the constraint fails.

- `LOCK TABLES` sets table locks, but it is the higher MySQL layer above the InnoDB layer that sets these locks. InnoDB is aware of table locks if `innodb_table_locks = 1` (the default) and `autocommit = 0`, and the MySQL layer above InnoDB knows about row-level locks. Otherwise, InnoDB’s automatic deadlock detection cannot detect deadlocks where such table locks are involved. Also, because in this case the higher MySQL layer does not know about row-level locks, it is possible to get a table lock on a table where another session currently has row-level locks. However, this does not endanger transaction integrity, as discussed in Section 14.5.10, “Deadlock Detection and Rollback”. See also Section 14.9.7, “Limits on InnoDB Tables”.

### 14.5.9 Implicit Transaction Commit and Rollback

By default, MySQL starts the session for each new connection with autocommit mode enabled, so MySQL does a commit after each SQL statement if that statement did not return an error. If a statement returns an error, the commit or rollback behavior depends on the error. See Section 14.21.4, “InnoDB Error Handling”.

If a session that has autocommit disabled ends without explicitly committing the final transaction, MySQL rolls back that transaction.

Some statements implicitly end a transaction, as if you had done a `COMMIT` before executing the statement. For details, see Section 13.3.3, “Statements That Cause an Implicit Commit”.

### 14.5.10 Deadlock Detection and Rollback

InnoDB automatically detects transaction deadlocks and rolls back a transaction or transactions to break the deadlock. InnoDB tries to pick small transactions to roll back, where the size of a transaction is determined by the number of rows inserted, updated, or deleted.

InnoDB is aware of table locks if `innodb_table_locks = 1` (the default) and `autocommit = 0`, and the MySQL layer above it knows about row-level locks. Otherwise, InnoDB cannot detect deadlocks where a table lock set by a MySQL `LOCK TABLES` statement or a lock set by a storage engine other than InnoDB is involved. Resolve these situations by setting the value of the `innodb_lock_wait_timeout` system variable.

When InnoDB performs a complete rollback of a transaction, all locks set by the transaction are released. However, if just a single SQL statement is rolled back as a result of an error, some of the locks set by the
statement may be preserved. This happens because InnoDB stores row locks in a format such that it cannot know afterward which lock was set by which statement.

If a SELECT calls a stored function in a transaction, and a statement within the function fails, that statement rolls back. Furthermore, if ROLLBACK is executed after that, the entire transaction rolls back.

For techniques to organize database operations to avoid deadlocks, see Section 14.5.11, “How to Cope with Deadlocks”.

14.5.11 How to Cope with Deadlocks

This section builds on the conceptual information about deadlocks in Section 14.5.10, “Deadlock Detection and Rollback”. It explains how to organize database operations to minimize deadlocks and the subsequent error handling required in applications.

Deadlocks are a classic problem in transactional databases, but they are not dangerous unless they are so frequent that you cannot run certain transactions at all. Normally, you must write your applications so that they are always prepared to re-issue a transaction if it gets rolled back because of a deadlock.

InnoDB uses automatic row-level locking. You can get deadlocks even in the case of transactions that just insert or delete a single row. That is because these operations are not really “atomic”; they automatically set locks on the (possibly several) index records of the row inserted or deleted.

You can cope with deadlocks and reduce the likelihood of their occurrence with the following techniques:

• At any time, issue the SHOW ENGINE INNODB STATUS command to determine the cause of the most recent deadlock. That can help you to tune your application to avoid deadlocks.

• If frequent deadlock warnings cause concern, collect more extensive debugging information by restarting the server with the innodb_print_all_deadlocks configuration option enabled. Information about each deadlock, not just the latest one, is recorded in the MySQL error log. Remove this option and restart the server again once the debugging is finished.

• Always be prepared to re-issue a transaction if it fails due to deadlock. Deadlocks are not dangerous. Just try again.

• Commit your transactions immediately after making a set of related changes. Small transactions are less prone to collision. In particular, do not leave an interactive mysql session open for a long time with an uncommitted transaction.

• If you use locking reads (SELECT ... FOR UPDATE or SELECT ... LOCK IN SHARE MODE), try using a lower isolation level such as READ COMMITTED.

• When modifying multiple tables within a transaction, or different sets of rows in the same table, do those operations in a consistent order each time. Then transactions form well-defined queues and do not deadlock. For example, organize database operations into functions within your application, or call stored routines, rather than coding multiple similar sequences of INSERT, UPDATE, and DELETE statements in different places.

• Add well-chosen indexes to your tables. Then your queries need to scan fewer index records and consequently set fewer locks. Use EXPLAIN SELECT to determine which indexes the MySQL server regards as the most appropriate for your queries.

• Use less locking. If you can afford to permit a SELECT to return data from an old snapshot, do not add the clause FOR UPDATE or LOCK IN SHARE MODE to it. Using the READ COMMITTED isolation level is good here, because each consistent read within the same transaction reads from its own fresh snapshot.
• If nothing else helps, serialize your transactions with table-level locks. The correct way to use `LOCK TABLES` with transactional tables, such as InnoDB tables, is to begin a transaction with `SET autocommit = 0` (not `START TRANSACTION`) followed by `LOCK TABLES`, and to not call `UNLOCK TABLES` until you commit the transaction explicitly. For example, if you need to write to table t1 and read from table t2, you can do this:

```sql
SET autocommit=0;
LOCK TABLES t1 WRITE, t2 READ, ...;
... do something with tables t1 and t2 here ...
COMMIT;
UNLOCK TABLES;
```

Table-level locks prevent concurrent updates to the table, avoiding deadlocks at the expense of less responsiveness for a busy system.

• Another way to serialize transactions is to create an auxiliary "semaphore" table that contains just a single row. Have each transaction update that row before accessing other tables. In that way, all transactions happen in a serial fashion. Note that the InnoDB instant deadlock detection algorithm also works in this case, because the serializing lock is a row-level lock. With MySQL table-level locks, the timeout method must be used to resolve deadlocks.

14.5.12 InnoDB Multi-Versioning

InnoDB is a multi-versioned storage engine: it keeps information about old versions of changed rows, to support transactional features such as concurrency and rollback. This information is stored in the tablespace in a data structure called a rollback segment (after an analogous data structure in Oracle). InnoDB uses the information in the rollback segment to perform the undo operations needed in a transaction rollback. It also uses the information to build earlier versions of a row for a consistent read.

Internal Details of Multi-Versioning

Internally, InnoDB adds three fields to each row stored in the database. A 6-byte `DB_TRX_ID` field indicates the transaction identifier for the last transaction that inserted or updated the row. Also, a deletion is treated internally as an update where a special bit in the row is set to mark it as deleted. Each row also contains a 7-byte `DB_ROLL_PTR` field called the roll pointer. The roll pointer points to an undo log record written to the rollback segment. If the row was updated, the undo log record contains the information necessary to rebuild the content of the row before it was updated. A 6-byte `DB_ROW_ID` field contains a row ID that increases monotonically as new rows are inserted. If InnoDB generates a clustered index automatically, the index contains row ID values. Otherwise, the `DB_ROW_ID` column does not appear in any index.

Undo logs in the rollback segment are divided into insert and update undo logs. Insert undo logs are needed only in transaction rollback and can be discarded as soon as the transaction commits. Update undo logs are used also in consistent reads, but they can be discarded only after there is no transaction present for which InnoDB has assigned a snapshot that in a consistent read could need the information in the update undo log to build an earlier version of a database row.

Guidelines for Managing Rollback Segments

Commit your transactions regularly, including those transactions that issue only consistent reads. Otherwise, InnoDB cannot discard data from the update undo logs, and the rollback segment may grow too big, filling up your tablespace.

The physical size of an undo log record in the rollback segment is typically smaller than the corresponding inserted or updated row. You can use this information to calculate the space needed for your rollback segment.
In the InnoDB multi-versioning scheme, a row is not physically removed from the database immediately when you delete it with an SQL statement. InnoDB only physically removes the corresponding row and its index records when it discards the update undo log record written for the deletion. This removal operation is called a purge, and it is quite fast, usually taking the same order of time as the SQL statement that did the deletion.

If you insert and delete rows in smallish batches at about the same rate in the table, the purge thread can start to lag behind and the table can grow bigger and bigger because of all the “dead” rows, making everything disk-bound and very slow. In such a case, throttle new row operations, and allocate more resources to the purge thread by tuning the innodb_max_purge_lag system variable. See Section 14.15, “InnoDB Startup Options and System Variables” for more information.

14.5.13 InnoDB Table and Index Structures

14.5.13.1 Role of the .frm File for InnoDB Tables

MySQL stores its data dictionary information for tables in .frm files in database directories. Unlike other MySQL storage engines, InnoDB also encodes information about the table in its own internal data dictionary inside the tablespace. When MySQL drops a table or a database, it deletes one or more .frm files as well as the corresponding entries inside the InnoDB data dictionary. You cannot move InnoDB tables between databases simply by moving the .frm files.

14.5.13.2 Clustered and Secondary Indexes

Every InnoDB table has a special index called the clustered index where the data for the rows is stored. Typically, the clustered index is synonymous with the primary key. To get the best performance from queries, inserts, and other database operations, you must understand how InnoDB uses the clustered index to optimize the most common lookup and DML operations for each table.

- When you define a PRIMARY KEY on your table, InnoDB uses it as the clustered index. Define a primary key for each table that you create. If there is no logical unique and non-null column or set of columns, add a new auto-increment column, whose values are filled in automatically.

- If you do not define a PRIMARY KEY for your table, MySQL locates the first UNIQUE index where all the key columns are NOT NULL and InnoDB uses it as the clustered index.

- If the table has no PRIMARY KEY or suitable UNIQUE index, InnoDB internally generates a hidden clustered index on a synthetic column containing row ID values. The rows are ordered by the ID that InnoDB assigns to the rows in such a table. The row ID is a 6-byte field that increases monotonically as new rows are inserted. Thus, the rows ordered by the row ID are physically in insertion order.

How the Clustered Index Speeds Up Queries

Accessing a row through the clustered index is fast because the index search leads directly to the page with all the row data. If a table is large, the clustered index architecture often saves a disk I/O operation when compared to storage organizations that store row data using a different page from the index record. (For example, MyISAM uses one file for data rows and another for index records.)

How Secondary Indexes Relate to the Clustered Index

All indexes other than the clustered index are known as secondary indexes. In InnoDB, each record in a secondary index contains the primary key columns for the row, as well as the columns specified for the secondary index. InnoDB uses this primary key value to search for the row in the clustered index.

If the primary key is long, the secondary indexes use more space, so it is advantageous to have a short primary key.
14.5.13.3 Physical Structure of an InnoDB Index

All InnoDB indexes are B-trees where the index records are stored in the leaf pages of the tree. The default size of an index page is 16KB. When new records are inserted, InnoDB tries to leave 1/16 of the page free for future insertions and updates of the index records.

If index records are inserted in a sequential order (ascending or descending), the resulting index pages are about 15/16 full. If records are inserted in a random order, the pages are from 1/2 to 15/16 full. If the fill factor of an index page drops below 1/2, InnoDB tries to contract the index tree to free the page.

Note

Changing the page size is not a supported operation and there is no guarantee that InnoDB will function normally with a page size other than 16KB. Problems compiling or running InnoDB may occur. In particular, ROW_FORMAT=COMPRESSED in the Barracuda file format assumes that the page size is at most 16KB and uses 14-bit pointers.

A MySQL instance using a particular InnoDB page size cannot use data files or log files from an instance that uses a different page size.

14.5.13.4 Insert Buffering

Database applications often insert new rows in the ascending order of the primary key. In this case, due to the layout of the clustered index in the same order as the primary key, insertions into an InnoDB table do not require random reads from a disk.

On the other hand, secondary indexes are usually nonunique, and insertions into secondary indexes happen in a relatively random order. In the same way, deletes and updates can affect data pages that are not adjacent in secondary indexes. This would cause a lot of random disk I/O operations without a special mechanism used in InnoDB.

When an index record is inserted, marked for deletion, or deleted from a nonunique secondary index, InnoDB checks whether the secondary index page is in the buffer pool. If that is the case, InnoDB applies the change directly to the index page. If the index page is not found in the buffer pool, InnoDB records the change in a special structure known as the insert buffer. The insert buffer is kept small so that it fits entirely in the buffer pool, and changes can be applied very quickly. This process is known as change buffering. (Formerly, it applied only to inserts and was called insert buffering. The data structure is still called the insert buffer.)

Disk I/O for Flushing the Insert Buffer

Periodically, the insert buffer is merged into the secondary index trees in the database. Often, it is possible to merge several changes into the same page of the index tree, saving disk I/O operations. It has been measured that the insert buffer can speed up insertions into a table up to 15 times.

The insert buffer merging may continue to happen after the transaction has been committed. In fact, it may continue to happen after a server shutdown and restart (see Section 14.21.2, “Starting InnoDB on a Corrupted Database”).

Insert buffer merging may take many hours when many secondary indexes must be updated and many rows have been inserted. During this time, disk I/O will be increased, which can cause significant slowdown on disk-bound queries. Another significant background I/O operation is the purge thread (see Section 14.5.12, “InnoDB Multi-Versioning”).
14.5.13.5 Adaptive Hash Indexes

The feature known as the adaptive hash index (AHI) lets InnoDB perform more like an in-memory database on systems with appropriate combinations of workload and ample memory for the buffer pool, without sacrificing any transactional features or reliability. This feature is enabled by the `innodb_adaptive_hash_index` option, or turned off by the `--skip-innodb_adaptive_hash_index` at server startup.

Based on the observed pattern of searches, MySQL builds a hash index using a prefix of the index key. The prefix of the key can be any length, and it may be that only some of the values in the B-tree appear in the hash index. Hash indexes are built on demand for those pages of the index that are often accessed.

If a table fits almost entirely in main memory, a hash index can speed up queries by enabling direct lookup of any element, turning the index value into a sort of pointer. InnoDB has a mechanism that monitors index searches. If InnoDB notices that queries could benefit from building a hash index, it does so automatically.

With some workloads, the speedup from hash index lookups greatly outweighs the extra work to monitor index lookups and maintain the hash index structure. Sometimes, the read/write lock that guards access to the adaptive hash index can become a source of contention under heavy workloads, such as multiple concurrent joins. Queries with LIKE operators and % wildcards also tend not to benefit from the AHI. For workloads where the adaptive hash index is not needed, turning it off reduces unnecessary performance overhead. Because it is difficult to predict in advance whether this feature is appropriate for a particular system, consider running benchmarks with it both enabled and disabled, using a realistic workload.

The hash index is always built based on an existing B-tree index on the table. InnoDB can build a hash index on a prefix of any length of the key defined for the B-tree, depending on the pattern of searches that InnoDB observes for the B-tree index. A hash index can be partial, covering only those pages of the index that are often accessed.

You can monitor the use of the adaptive hash index and the contention for its use in the SEMAPHORES section of the output of the `SHOW ENGINE INNODB STATUS` command. If you see many threads waiting on an RW-latch created in `btr0sea.c`, then it might be useful to disable adaptive hash indexing.

For more information about the performance characteristics of hash indexes, see Section 8.3.8, “Comparison of B-Tree and Hash Indexes”.

14.5.13.6 Physical Row Structure

The physical row structure for an InnoDB table depends on the row format specified when the table was created. InnoDB uses the COMPACT format by default, but the REDUNDANT format is available to retain compatibility with older versions of MySQL. To check the row format of an InnoDB table, use `SHOW TABLE STATUS`.

The compact row format decreases row storage space by about 20% at the cost of increasing CPU use for some operations. If your workload is a typical one that is limited by cache hit rates and disk speed, compact format is likely to be faster. If the workload is a rare case that is limited by CPU speed, compact format might be slower.

Rows in InnoDB tables that use REDUNDANT row format have the following characteristics:

- Each index record contains a 6-byte header. The header is used to link together consecutive records, and also in row-level locking.

- Records in the clustered index contain fields for all user-defined columns. In addition, there is a 6-byte transaction ID field and a 7-byte roll pointer field.
• If no primary key was defined for a table, each clustered index record also contains a 6-byte row ID field.

• Each secondary index record also contains all the primary key fields defined for the clustered index key that are not in the secondary index.

• A record contains a pointer to each field of the record. If the total length of the fields in a record is less than 128 bytes, the pointer is one byte; otherwise, two bytes. The array of these pointers is called the record directory. The area where these pointers point is called the data part of the record.

• Internally, InnoDB stores fixed-length character columns such as `CHAR(10)` in a fixed-length format. InnoDB does not truncate trailing spaces from `VARCHAR` columns.

• An SQL `NULL` value reserves one or two bytes in the record directory. Besides that, an SQL `NULL` value reserves zero bytes in the data part of the record if stored in a variable length column. In a fixed-length column, it reserves the fixed length of the column in the data part of the record. Reserving the fixed space for `NULL` values enables an update of the column from `NULL` to a non-`NULL` value to be done in place without causing fragmentation of the index page.

Rows in InnoDB tables that use `COMPACT` row format have the following characteristics:

• Each index record contains a 5-byte header that may be preceded by a variable-length header. The header is used to link together consecutive records, and also in row-level locking.

• The variable-length part of the record header contains a bit vector for indicating `NULL` columns. If the number of columns in the index that can be `NULL` is $N$, the bit vector occupies $\text{CEILING}(N/8)$ bytes. (For example, if there are anywhere from 9 to 15 columns that can be `NULL`, the bit vector uses two bytes.) Columns that are `NULL` do not occupy space other than the bit in this vector. The variable-length part of the header also contains the lengths of variable-length columns. Each length takes one or two bytes, depending on the maximum length of the column. If all columns in the index are `NOT NULL` and have a fixed length, the record header has no variable-length part.

• For each non-`NULL` variable-length field, the record header contains the length of the column in one or two bytes. Two bytes will only be needed if part of the column is stored externally in overflow pages or the maximum length exceeds 255 bytes and the actual length exceeds 127 bytes. For an externally stored column, the 2-byte length indicates the length of the internally stored part plus the 20-byte pointer to the externally stored part. The internal part is 768 bytes, so the length is 768+20. The 20-byte pointer stores the true length of the column.

• The record header is followed by the data contents of the non-`NULL` columns.

• Records in the clustered index contain fields for all user-defined columns. In addition, there is a 6-byte transaction ID field and a 7-byte roll pointer field.

• If no primary key was defined for a table, each clustered index record also contains a 6-byte row ID field.

• Each secondary index record also contains all the primary key fields defined for the clustered index key that are not in the secondary index. If any of these primary key fields are variable length, the record header for each secondary index will have a variable-length part to record their lengths, even if the secondary index is defined on fixed-length columns.

• Internally, InnoDB stores fixed-length, fixed-width character columns such as `CHAR(10)` in a fixed-length format. InnoDB does not truncate trailing spaces from `VARCHAR` columns.

• Internally, InnoDB attempts to store UTF-8 `CHAR(N)` columns in $N$ bytes by trimming trailing spaces. (With `REDUNDANT` row format, such columns occupy $3 \times N$ bytes.) Reserving the minimum space $N$ in many cases enables column updates to be done in place without causing fragmentation of the index page.
14.6 InnoDB Configuration

The first decisions to make about InnoDB configuration involve how to lay out InnoDB data files, and how much memory to allocate for the InnoDB storage engine. You record these choices either by recording them in a configuration file that MySQL reads at startup, or by specifying them as command-line options in a startup script. The full list of options, descriptions, and allowed parameter values is at Section 14.15, “InnoDB Startup Options and System Variables”.

Overview of InnoDB Tablespace and Log Files

Two important disk-based resources managed by the InnoDB storage engine are its tablespace data files and its log files. If you specify no InnoDB configuration options, MySQL creates an auto-extending data file, slightly larger than 10MB, named ibdata1 and two log files named ib_logfile0 and ib_logfile1 in the MySQL data directory. Their size is given by the size of the innodb_log_file_size system variable. To get good performance, explicitly provide InnoDB parameters as discussed in the following examples. Naturally, edit the settings to suit your hardware and requirements.

The examples shown here are representative. See Section 14.15, “InnoDB Startup Options and System Variables” for additional information about InnoDB-related configuration parameters.

Considerations for Storage Devices

In some cases, database performance improves if the data is not all placed on the same physical disk. Putting log files on a different disk from data is very often beneficial for performance. The example illustrates how to do this. It places the two data files on different disks and places the log files on the third disk. InnoDB fills the tablespace beginning with the first data file. You can also use raw disk partitions (raw devices) as InnoDB data files, which may speed up I/O. See Section 14.8.5, “Using Raw Disk Partitions for the Shared Tablespace”.

Caution

InnoDB is a transaction-safe (ACID compliant) storage engine for MySQL that has commit, rollback, and crash-recovery capabilities to protect user data. However, it cannot do so if the underlying operating system or hardware does not work as advertised. Many operating systems or disk subsystems may delay or reorder write operations to improve performance. On some operating systems, the very fsync() system call that should wait until all unwritten data for a file has been flushed might actually return before the data has been flushed to stable storage. Because of this, an operating system crash or a power outage may destroy recently committed data, or in the worst case, even corrupt the database because of write operations having been reordered. If data integrity is important to you, perform some “pull-the-plug” tests before using anything in production. On Mac OS X 10.3 and up, InnoDB uses a special fcntl() file flush method. Under Linux, it is advisable to disable the write-back cache.

On ATA/SATA disk drives, a command such `hdparm -W0 /dev/hda` may work to disable the write-back cache. Beware that some drives or disk controllers may be unable to disable the write-back cache.

Caution
If reliability is a consideration for your data, do not configure InnoDB to use data files or log files on NFS volumes. Potential problems vary according to OS and version of NFS, and include such issues as lack of protection from conflicting writes, and limitations on maximum file sizes.

## Specifying the Location and Size for InnoDB Tablespace Files

To set up the InnoDB tablespace files, use the `innodb_data_file_path` option in the `[mysqld]` section of the `my.cnf` option file. On Windows, you can use `my.ini` instead. The value of `innodb_data_file_path` should be a list of one or more data file specifications. If you name more than one data file, separate them by semicolon (";") characters:

```
innodb_data_file_path=datafile_spec1;datafile_spec2;
```

For example, the following setting explicitly creates a minimally sized system tablespace:

```
[mysqld]
innodb_data_file_path=ibdata1:12M:autoextend
```

This setting configures a single data file, slightly larger than 10MB, named `ibdata1` that is auto-extending. No location for the file is given, so by default, InnoDB creates it in the MySQL data directory.

Sizes are specified using K, M, or G suffix letters to indicate units of KB, MB, or GB.

A tablespace containing a fixed-size 50MB data file named `ibdata1` and a 50MB auto-extending file named `ibdata2` in the data directory can be configured like this:

```
[mysqld]
innodb_data_file_path=ibdata1:50M;ibdata2:50M:autoextend
```

The full syntax for a data file specification includes the file name, its size, and several optional attributes:

```
file_name:file_size[:autoextend[:max:max_file_size]]
```

The `autoextend` and `max` attributes can be used only for the last data file in the `innodb_data_file_path` line.

If you specify the `autoextend` option for the last data file, InnoDB extends the data file if it runs out of free space in the tablespace. The increment is 8MB at a time by default. To modify the increment, change the `innodb_autoextend_increment` system variable.

If the disk becomes full, you might want to add another data file on another disk. For tablespace reconfiguration instructions, see Section 14.8.4, “Changing the Number or Size of InnoDB Log Files and Resizing the InnoDB Tablespace”.

InnoDB is not aware of the file system maximum file size, so be cautious on file systems where the maximum file size is a small value such as 2GB. To specify a maximum size for an auto-extending data file, use the `max` attribute following the `autoextend` attribute. Use the `max` attribute only in cases where constraining disk usage is of critical importance, because exceeding the maximum size causes a fatal error, possibly including a crash. The following configuration permits `ibdata1` to grow up to a limit of 500MB:
Specifying InnoDB Configuration Options

**innodb_data_file_path=ibdata1:12M:autoextend:max:500M**

**InnoDB** creates tablespace files in the MySQL data directory by default. To specify a location explicitly, use the `innodb_data_home_dir` option. For example, to use two files named `ibdata1` and `ibdata2` but create them in the `/ibdata` directory, configure **InnoDB** like this:

```plaintext
[mysqld]
innotifb_data_home_dir = /ibdata
innodb_data_file_path=ibdata1:50M;ibdata2:50M:autoextend
```

**Note**

**InnoDB** does not create directories, so make sure that the `/ibdata` directory exists before you start the server. This is also true of any log file directories that you configure. Use the Unix or DOS `mkdir` command to create any necessary directories.

Make sure that the MySQL server has the proper access rights to create files in the data directory. More generally, the server must have access rights in any directory where it needs to create data files or log files.

**InnoDB** forms the directory path for each data file by textually concatenating the value of `innodb_data_home_dir` to the data file name, adding a path name separator (slash or backslash) between values if necessary. If the `innodb_data_home_dir` option is not specified in `my.cnf` at all, the default value is the “dot” directory `./`, which means the MySQL data directory. (The MySQL server changes its current working directory to its data directory when it begins executing.)

If you specify `innodb_data_home_dir` as an empty string, you can specify absolute paths for the data files listed in the `innodb_data_file_path` value. The following example is equivalent to the preceding one:

```plaintext
[mysqld]
innotifb_data_home_dir =
innotifb_data_file_path=/ibdata/ibdata1:50M;/ibdata/ibdata2:50M:autoextend
```

### Specifying InnoDB Configuration Options

**Sample my.cnf file for small systems.** Suppose that you have a computer with 512MB RAM and one hard disk. The following example shows possible configuration parameters in `my.cnf` or `my.ini` for **InnoDB**, including the `autoextend` attribute. The example suits most users, both on Unix and Windows, who do not want to distribute **InnoDB** data files and log files onto several disks. It creates an auto-extending data file `ibdata1` and two **InnoDB** log files `ib_logfile0` and `ib_logfile1` in the MySQL data directory.

```plaintext
[mysqld]
# You can write your other MySQL server options here
# ...
# Data files must be able to hold your data and indexes.
# Make sure that you have enough free disk space.
innotifb_data_file_path = ibdata1:12M:autoextend
#
# Set buffer pool size to 50-80% of your computer's memory
innodb_buffer_pool_size=256M
innodb_additional_mem_pool_size=20M
#
# Set the log file size to about 25% of the buffer pool size
innodb_log_file_size=64M
```
Setting Up the InnoDB System Tablespace

When you create an InnoDB system tablespace for the first time, it is best that you start the MySQL server from the command prompt. InnoDB then prints the information about the database creation to the screen, so you can see what is happening. For example, on Windows, if mysqld is located in C:\Program Files\MySQL\MySQL Server 5.5\bin, you can start it like this:

C:\> "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysqld" --console

If you do not send server output to the screen, check the server’s error log to see what InnoDB prints during the startup process.

For an example of what the information displayed by InnoDB should look like, see Section 14.8.1, “Creating the InnoDB Tablespace”.

Editing the MySQL Configuration File

You can place InnoDB options in the [mysqld] group of any option file that your server reads when it starts. The locations for option files are described in Section 4.2.6, “Using Option Files”.

If you installed MySQL on Windows using the installation and configuration wizards, the option file will be the my.ini file located in your MySQL installation directory. See Section 2.3.3, “Installing MySQL on Microsoft Windows Using MySQL Installer”.

If your PC uses a boot loader where the C: drive is not the boot drive, your only option is to use the my.ini file in your Windows directory (typically C:\WINDOWS). You can use the SET command at the command prompt in a console window to print the value of WINDIR:

C:\> SET WINDIR
windir=C:\WINDOWS

To make sure that mysqld reads options only from a specific file, use the --defaults-file option as the first option on the command line when starting the server:

mysqld --defaults-file=your_path_to_my_cnf

Sample my.cnf file for large systems. Suppose that you have a Linux computer with 2GB RAM and three 60GB hard disks at directory paths /, /dr2 and /dr3. The following example shows possible configuration parameters in my.cnf for InnoDB.

```
[mysqld]
# You can write your other MySQL server options here
  ...
  innodb_data_home_dir =
  # Data files must be able to hold your data and indexes
```
Determining the Maximum Memory Allocation for InnoDB

Warning

On 32-bit GNU/Linux x86, be careful not to set memory usage too high. glibc may permit the process heap to grow over thread stacks, which crashes your server. It is a risk if the value of the following expression is close to or exceeds 2GB:

```
innodb_buffer_pool_size
+ key_buffer_size
+ max_connections*(sort_buffer_size+read_buffer_size+binlog_cache_size)
+ max_connections*2MB
```

Each thread uses a stack (often 2MB, but only 256KB in MySQL binaries provided by Oracle Corporation.) and in the worst case also uses `sort_buffer_size` + `read_buffer_size` additional memory.

Tuning other `mysqld` server parameters. The following values are typical and suit most users:

```
[mysqld]
skip-external-locking
max_connections=200
read_buffer_size=1M
sort_buffer_size=1M
#
# Set key_buffer to 5 - 50% of your RAM depending on how much
# you use MyISAM tables, but keep key_buffer_size + InnoDB
# buffer pool size < 80% of your RAM
key_buffer_size=value
```

On Linux, if the kernel is enabled for large page support, InnoDB can use large pages to allocate memory for its buffer pool and additional memory pool. See Section 8.11.4.2, “Enabling Large Page Support”.

Turning Off InnoDB

Oracle recommends InnoDB as the preferred storage engine for typical database applications, from single-user wikis and blogs running on a local system, to high-end applications pushing the limits of performance. In MySQL 5.5, InnoDB is the default storage engine for new tables.

If you do not want to use InnoDB tables, start the server with the `--innodb=OFF` or `--skip-innodb` option to disable the InnoDB storage engine. In this case, because the default storage engine is InnoDB, the server will not start unless you also use `--default-storage-engine` to set the default to some other engine.
14.7 **InnoDB Administration**

Administration tasks related to **InnoDB** mainly involve these aspects:

- Managing the data files that represent the system tablespace, **InnoDB** tables, and their associated indexes. You can change the way these files are laid out and divided, which affects both performance and the features available for specific tables.

- Managing the redo log files that are used for crash recovery. You can specify the size of these files.

- Making sure that **InnoDB** is used for the tables where it is intended, rather than a different storage engine.

- General administrative tasks related to performance. You might consult with application developers during the application design phase, monitor performance on an ongoing basis to ensure the system settings are working well, and diagnose and help fix performance and capacity issues that arise suddenly.

Since **InnoDB** tables are now the default for MySQL, much of the associated administration material is now in the main “Administration” chapter, Chapter 5, *MySQL Server Administration*.

14.8 **InnoDB** Tablespace Management

14.8.1 Creating the **InnoDB** Tablespace

Suppose that you have installed MySQL and have edited your option file so that it contains the necessary **InnoDB** configuration parameters. Before starting MySQL, verify that the directories you have specified for **InnoDB** data files and log files exist and that the MySQL server has access rights to those directories. **InnoDB** does not create directories, only files. Check also that you have enough disk space for the data and log files.

It is best to run the MySQL server **mysqld** from the command prompt when you first start the server with **InnoDB** enabled, not from **mysqld_safe** or as a Windows service. When you run from a command prompt you see what **mysqld** prints and what is happening. On Unix, just invoke **mysqld**. On Windows, start **mysqld** with the **--console** option to direct the output to the console window.

When you start the MySQL server after initially configuring **InnoDB** in your option file, **InnoDB** creates your data files and log files, and prints something like this:

```
InnoDB: The first specified datafile /home/heikki/data/ibdata1 did not exist:
InnoDB: a new database to be created!
InnoDB: Setting file /home/heikki/data/ibdata1 size to 134217728
InnoDB: Database physically writes the file full: wait...
InnoDB: datafile /home/heikki/data/ibdata2 did not exist:
new to be created
InnoDB: Setting file /home/heikki/data/ibdata2 size to 262144000
InnoDB: Database physically writes the file full: wait...
InnoDB: Log file /home/heikki/data/logs/ib_logfile0 did not exist:
new to be created
InnoDB: Setting log file /home/heikki/data/logs/ib_logfile0 size to 5242880
InnoDB: Log file /home/heikki/data/logs/ib_logfile1 did not exist:
new to be created
InnoDB: Setting log file /home/heikki/data/logs/ib_logfile1 size to 5242880
InnoDB: Doublewrite buffer not found: creating new
```
InnoDB File-Per-Table Mode

At this point InnoDB has initialized its tablespace and log files. You can connect to the MySQL server with the usual MySQL client programs like mysql. When you shut down the MySQL server with mysqladmin shutdown, the output is like this:

```
010321 18:33:34  mysqld: Normal shutdown
010321 18:33:34  mysqld: Shutdown Complete
InnoDB: Starting shutdown...
InnoDB: Shutdown completed
```

You can look at the data file and log directories and you see the files created there. When MySQL is started again, the data files and log files have been created already, so the output is much briefer:

```
InnoDB: Started
mysqld: ready for connections
```

If you add the innodb_file_per_table option to my.cnf, InnoDB stores each table in its own .ibd file, in the same MySQL database directory where the .frm file is created. See Section 14.8.2, “InnoDB File-Per-Table Mode”.

### 14.8.2 InnoDB File-Per-Table Mode

By default, all InnoDB tables and indexes are stored in the system tablespace. As an alternative, you can store each InnoDB table and its indexes in its own file. This feature is called “file-per-table mode” because each table that is created when this setting is in effect has its own .ibd file. Each such .ibd file represents a separate tablespace. This mode is controlled by the innodb_file_per_table configuration option.

#### Advantages of File-Per-Table Mode

- You can reclaim operating system disk space when truncating or dropping a table. For tables created when file-per-table mode is turned off, truncating or dropping the tables creates free space internally in the ibdata files but the free space can only be used for new InnoDB data.
- The TRUNCATE TABLE operation is faster when run on individual .ibd files.
- You can store specific tables on separate storage devices, for I/O optimization, space management, or backup purposes.
- You can run OPTIMIZE TABLE to compact or recreate a table space. When you run an OPTIMIZE TABLE, InnoDB will create a new .ibd file with a temporary name, using only the space required to store actual data. When the optimization is complete, InnoDB removes the old .ibd file and replaces it with the new .ibd file. If the previous .ibd file had grown significantly but actual data only accounted for a portion of its size, running OPTIMIZE TABLE allows you to reclaim the unused space.
- You can move individual InnoDB tables rather than entire databases.
- Tables created when innodb_file_per_table is enabled can use the Barracuda file format. The Barracuda file format enables features such as compressed and dynamic row formats. Tables created when innodb_file_per_table is off cannot use these features. To take advantage of these features for an existing table, you can turn on the file-per-table setting and run ALTER TABLE...
InnoDB File-Per-Table Mode

ENGINE=INNODB on the existing table. Before converting tables, refer to Section 14.9.4, “Converting Tables from MyISAM to InnoDB”.

• You can enable more efficient storage for tables with large BLOB or text columns using the dynamic row format.

• Using innodb_file_per_table may improve chances for a successful recovery and save time if a corruption occurs, a server cannot be restarted, or backup and binary logs are unavailable.

• You can back up or restore a single table quickly, without interrupting the use of other InnoDB tables, using the MySQL Enterprise Backup product. See Backing Up and Restoring a Single .ibd File for the procedure and restrictions.

• File-per-table mode allows you to excluded tables from a backup. This is beneficial if you have tables that require backup less frequently or on a different schedule.

• File-per-table mode is convenient for per-table status reporting when copying or backing up tables.

• File-per-table mode allows you to monitor table size at a file system level, without accessing MySQL.

• Common Linux file systems do not permit concurrent writes to a single file when innodb_flush_method is set to O_DIRECT. As a result, there are possible performance improvements when using innodb_file_per_table in conjunction with innodb_flush_method.

• If innodb_file_per_table is disabled, there is one shared tablespace (the system tablespace) for tables, the data dictionary, and undo logs. This single tablespace has a 64TB size limit. If innodb_file_per_table is enabled, each table has its own tablespace, each with a 64TB size limit. See Section D.10.3, “Limits on Table Size” for related information.

Potential Disadvantages of File-Per-Table Mode

• With innodb_file_per_table, each table may have unused table space, which can only be utilized by rows of the same table. This could lead to more rather than less wasted table space if not properly managed.

• fsync operations must run on each open table rather than on a single file. Because there is a separate fsync operation for each file, write operations on multiple tables cannot be combined into a single I/O operation. This may require InnoDB to perform a higher total number of fsync operations.

• mysqld must keep 1 open file handle per table, which may impact performance if you have numerous tables.

• More file descriptors are used.

• If backward compatibility with MySQL 5.1 is a concern, be aware that enabling innodb_file_per_table means that an ALTER TABLE operation will move an InnoDB table from the system tablespace to an individual .ibd file in cases where ALTER TABLE recreates the table (ALTER OFFLINE).

For example, when restructuring the clustered index for an InnoDB table, the table is re-created using the current settings for innodb_file_per_table. This behavior does not apply when adding or dropping InnoDB secondary indexes. When a secondary index is created without rebuilding the table, the index is stored in the same file as the table data, regardless of the current innodb_file_per_table setting.

• If many tables are growing there is potential for more fragmentation which can impede DROP TABLE and table scan performance. However, when fragmentation is managed, having files in their own tablespace can improve performance.
InnoDB File-Per-Table Mode

- The buffer pool is scanned when dropping a per-table tablespace, which can take several seconds for buffer pools that are tens of gigabytes in size. The scan is performed with a broad internal lock, which may delay other operations. Tables in the shared tablespace are not affected.

- The `innodb_autoextend_increment` variable, which defines increment size (in MB) for extending the size of an auto-extending shared tablespace file when it becomes full, does not apply to file-per-table tablespace files. File-per-table tablespace files are auto-extending regardless of the value of `innodb_autoextend_increment`. The initial extensions are by small amounts, after which extensions occur in increments of 4MB.

Enabling and Disabling Multiple Tablespaces

To enable multiple tablespaces, start the server with the `--innodb_file_per_table` option. For example, add a line to the `[mysqld]` section of `my.cnf`:

```
[mysqld]
innodb_file_per_table
```

With multiple tablespaces enabled, InnoDB stores each newly created table in its own `tbl_name.ibd` file in the appropriate database directory. Unlike the MyISAM storage engine, with its separate `tbl_name.MYD` and `tbl_name.MYI` files for indexes and data, InnoDB stores the data and the indexes together in a single `.ibd` file. The `tbl_name.frm` file is still created as usual.

If you remove the `innodb_file_per_table` line from `my.cnf` and restart the server, InnoDB creates any new tables inside the shared tablespace files.

You can always access both tables in the system tablespace and tables in their own tablespaces, regardless of the file-per-table setting. To move a table from the system tablespace to its own tablespace, or vice versa, you can change the `innodb_file_per_table` setting and issue the command:

```
-- Move table from system tablespace to its own tablespace.
SET GLOBAL innodb_file_per_table=1;
ALTER TABLE `table_name` ENGINE=InnoDB;

-- Move table from its own tablespace to system tablespace.
SET GLOBAL innodb_file_per_table=0;
ALTER TABLE `table_name` ENGINE=InnoDB;
```

Note

InnoDB always needs the shared tablespace because it puts its internal data dictionary and undo logs there. The `.ibd` files are not sufficient for InnoDB to operate.

When a table is moved out of the system tablespace into its own `.ibd` file, the data files that make up the system tablespace remain the same size. The space formerly occupied by the table can be reused for new InnoDB data, but is not reclaimed for use by the operating system. When moving large InnoDB tables out of the system tablespace, where disk space is limited, you might prefer to turn on `innodb_file_per_table` and then recreate the entire instance using the `mysqldump` command.

Portability Considerations for `.ibd` Files

You cannot freely move `.ibd` files between database directories as you can with MyISAM table files. The table definition stored in the InnoDB shared tablespace includes the database name. The transaction IDs and log sequence numbers stored in the tablespace files also differ between databases.
To move an `.ibd` file and the associated table from one database to another, use a `RENAME TABLE` statement:

```
RENAME TABLE db1.tbl_name TO db2.tbl_name;
```

If you have a “clean” backup of an `.ibd` file, you can restore it to the MySQL installation from which it originated as follows:

1. The table must not have been dropped or truncated since you copied the `.ibd` file, because doing so changes the table ID stored inside the tablespace.

2. Issue this `ALTER TABLE` statement to delete the current `.ibd` file:

```
ALTER TABLE tbl_name DISCARD TABLESPACE;
```

3. Copy the backup `.ibd` file to the proper database directory.

4. Issue this `ALTER TABLE` statement to tell InnoDB to use the new `.ibd` file for the table:

```
ALTER TABLE tbl_name IMPORT TABLESPACE;
```

In this context, a “clean” `.ibd` file backup is one for which the following requirements are satisfied:

- There are no uncommitted modifications by transactions in the `.ibd` file.
- There are no unmerged insert buffer entries in the `.ibd` file.
- Purge has removed all delete-marked index records from the `.ibd` file.
- `mysqld` has flushed all modified pages of the `.ibd` file from the buffer pool to the file.

You can make a clean backup `.ibd` file using the following method:

1. Stop all activity from the `mysqld` server and commit all transactions.

2. Wait until `SHOW ENGINE INNODB STATUS` shows that there are no active transactions in the database, and the main thread status of InnoDB is `Waiting for server activity`. Then you can make a copy of the `.ibd` file.

Another method for making a clean copy of an `.ibd` file is to use the MySQL Enterprise Backup product:

1. Use MySQL Enterprise Backup to back up the InnoDB installation.

2. Start a second `mysqld` server on the backup and let it clean up the `.ibd` files in the backup.

### 14.8.3 Enabling and Disabling File-Per-Table Mode

To make file-per-table mode the default for a MySQL server, start the server with the `--innodb_file_per_table` command-line option, or add this line to the `[mysqld]` section of `my.cnf`:

```
[mysqld]
inno$db_file_per_table
```

You can also issue the command while the server is running:

```
SET GLOBAL innodb_file_per_table=1;
```
With file-per-table mode enabled, InnoDB stores each newly created table in its own `tbl_name.ibd` file in the appropriate database directory. Unlike the MyISAM storage engine, with its separate `tbl_name.MYD` and `tbl_name.MYI` files for indexes and data, InnoDB stores the data and the indexes together in a single `.ibd` file. The `tbl_name.frm` file is still created as usual.

If you remove `innodb_file_per_table` from your startup options and restart the server, or turn it off with the `SET GLOBAL` command, InnoDB creates any new tables inside the system tablespace.

You can always read and write any InnoDB tables, regardless of the file-per-table setting.

To move a table from the system tablespace to its own tablespace, or vice versa, change the `innodb_file_per_table` setting and rebuild the table:

```
-- Move table from system tablespace to its own tablespace.
SET GLOBAL innodb_file_per_table=1;
ALTER TABLE table_name ENGINE=InnoDB;
-- Move table from its own tablespace to system tablespace.
SET GLOBAL innodb_file_per_table=0;
ALTER TABLE table_name ENGINE=InnoDB;
```

**Note**

InnoDB always needs the system tablespace because it puts its internal data dictionary and undo logs there. The `.ibd` files are not sufficient for InnoDB to operate.

When a table is moved out of the system tablespace into its own `.ibd` file, the data files that make up the system tablespace remain the same size. The space formerly occupied by the table can be reused for new InnoDB data, but is not reclaimed for use by the operating system. When moving large InnoDB tables out of the system tablespace, where disk space is limited, you might prefer to turn on `innodb_file_per_table` and then recreate the entire instance using the `mysqldump` command.

### 14.8.4 Changing the Number or Size of InnoDB Log Files and Resizing the InnoDB Tablespace

This section describes how to change the number or size of InnoDB redo log files and how to increase or decrease InnoDB system tablespace size.

#### Changing the Number or Size of InnoDB Log Files

To change the number or the size of your InnoDB redo log files, perform the following steps:

1. If `innodb_fast_shutdown` is set to 2, set `innodb_fast_shutdown` to 1:

   ```sql
   mysql> SET GLOBAL innodb_fast_shutdown = 1;
   ```

2. After ensuring that `innodb_fast_shutdown` is not set to 2, stop the MySQL server and make sure that it shuts down without errors (to ensure that there is no information for outstanding transactions in the log).

3. Copy the old log files into a safe place in case something went wrong during the shutdown and you need them to recover the tablespace.
Changing the Number or Size of InnoDB Log Files and Resizing the InnoDB Tablespace

4. Delete the old log files from the log file directory.
5. Edit my.cnf to change the log file configuration.
6. Start the MySQL server again. mysql sees that no InnoDB log files exist at startup and creates new ones.

Increasing the Size of the InnoDB Tablespace

The easiest way to increase the size of the InnoDB system tablespace is to configure it from the beginning to be auto-extending. Specify the autoextend attribute for the last data file in the tablesapce definition. Then InnoDB increases the size of that file automatically in 8MB increments when it runs out of space. The increment size can be changed by setting the value of the innodb_autoextend_increment system variable, which is measured in megabytes.

You can expand the system tablespace by a defined amount by adding another data file:

1. Shut down the MySQL server.
2. If the previous last data file is defined with the keyword autoextend, change its definition to use a fixed size, based on how large it has actually grown. Check the size of the data file, round it down to the closest multiple of 1024 × 1024 bytes (= 1MB), and specify this rounded size explicitly in innodb_data_file_path.
3. Add a new data file to the end of innodb_data_file_path, optionally making that file auto-extending. Only the last data file in the innodb_data_file_path can be specified as auto-extending.
4. Start the MySQL server again.

For example, this tablespace has just one auto-extending data file ibdata1:

```
innodb_data_home_dir =
innodb_data_file_path = /ibdata/ibdata1:10M:autoextend
```

Suppose that this data file, over time, has grown to 988MB. Here is the configuration line after modifying the original data file to use a fixed size and adding a new auto-extending data file:

```
innodb_data_home_dir =
innodb_data_file_path = /ibdata/ibdata1:988M;/disk2/ibdata2:50M:autoextend
```

When you add a new data file to the system tablespace configuration, make sure that the filename does not refer to an existing file. InnoDB creates and initializes the file when you restart the server.

Decreasing the Size of the InnoDB Tablespace

Currently, you cannot remove a data file from the system tablespace. To decrease the system tablespace size, use this procedure:

1. Use mysqldump to dump all your InnoDB tables.
2. Stop the server.
3. Remove all the existing tablesapce files, including the ibdata and ib_log files. If you want to keep a backup copy of the information, then copy all the ib* files to another location before the removing the files in your MySQL installation.
4. Remove any .frm files for InnoDB tables.
5. Configure a new tablespace.
6. Restart the server.
7. Import the dump files.

14.8.5 Using Raw Disk Partitions for the Shared Tablespace

You can use raw disk partitions as data files in the InnoDB system tablespace. This technique enables nonbuffered I/O on Windows and on some Linux and Unix systems without file system overhead. Perform tests with and without raw partitions to verify whether this change actually improves performance on your system.

When you use a raw disk partition, ensure that the user ID that runs the MySQL server has read and write privileges for that partition. For example, if you run the server as the mysql user, the partition must be readable and writeable by mysql. If you run the server with the --memlock option, the server must be run as root, so the partition must be readable and writeable by root.

The procedures described below involve option file modification. For additional information, see Section 4.2.6, “Using Option Files”.

Allocating a Raw Disk Partition on Linux and Unix Systems

1. When you create a new data file, specify the keyword newraw immediately after the data file size for the innodb_data_file_path option. The partition must be at least as large as the size that you specify. Note that 1MB in InnoDB is 1024 × 1024 bytes, whereas 1MB in disk specifications usually means 1,000,000 bytes.

   ```
   [mysqld]
   innodb_data_home_dir=
   innodb_data_file_path=/dev/hdd1:3Gnewraw;/dev/hdd2:2Gnewraw
   ```

2. Restart the server. InnoDB notices the newraw keyword and initializes the new partition. However, do not create or change any InnoDB tables yet. Otherwise, when you next restart the server, InnoDB reinitializes the partition and your changes are lost. (As a safety measure InnoDB prevents users from modifying data when any partition with newraw is specified.)

3. After InnoDB has initialized the new partition, stop the server, change newraw in the data file specification to raw:

   ```
   [mysqld]
   innodb_data_home_dir=
   innodb_data_file_path=/dev/hdd1:3Graw;/dev/hdd2:2Graw
   ```

4. Restart the server. InnoDB now permits changes to be made.

Allocating a Raw Disk Partition on Windows

On Windows systems, the same steps and accompanying guidelines described for Linux and Unix systems apply except that the innodb_data_file_path setting differs slightly on Windows.

1. When you create a new data file, specify the keyword newraw immediately after the data file size for the innodb_data_file_path option:

   ```
   [mysqld]
   innodb_data_home_dir=
   ```
InnoDB Table Management

```sql
innodb_data_file_path=/./D::10Gnewraw
```

The `././` corresponds to the Windows syntax of `\\\` for accessing physical drives. In the example above, `D:` is the drive letter of the partition.

2. Restart the server. InnoDB notices the `newraw` keyword and initializes the new partition.

3. After InnoDB has initialized the new partition, stop the server, change `newraw` in the data file specification to `raw`:

```ini
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=/./D::10Graw
```

4. Restart the server. InnoDB now permits changes to be made.

## 14.9 InnoDB Table Management

### 14.9.1 Creating InnoDB Tables

To create an InnoDB table, specify an `ENGINE=InnoDB` option in the `CREATE TABLE` statement:

```sql
CREATE TABLE t1 (a INT, b CHAR (20), PRIMARY KEY (a)) ENGINE=InnoDB;
```

Depending on the `innodb_file_per_table` setting, InnoDB creates each table and associated primary key index either in the system tablespace, or in a separate tablespace (represented by a `.ibd` file). MySQL creates the `t1.frm` file in the `test` directory under the MySQL database directory. Internally, InnoDB adds an entry for the table to its own data dictionary. The entry includes the database name. For example, if `test` is the database in which the `t1` table is created, the entry is for `'test/t1'`. This means you can create a table of the same name `t1` in some other database, and the table names do not collide inside InnoDB.

To see the properties of these tables, issue a `SHOW TABLE STATUS` statement:

```sql
SHOW TABLE STATUS FROM test LIKE 't%'
```

In the status output, you see the `row format` property of these first tables is `Compact`. Although that setting is fine for basic experimentation, to take advantage of the most powerful InnoDB performance features, you will quickly graduate to using other row formats such as `Dynamic` and `Compressed`. Using those values requires a little bit of setup first:

```sql
set global innodb_file_per_table=1;
set global innodb_file_format=barracuda;
CREATE TABLE t3 (a INT, b CHAR (20), PRIMARY KEY (a)) row_format=dynamic;
CREATE TABLE t4 (a INT, b CHAR (20), PRIMARY KEY (a)) row_format=compressed;
```

Always set up a primary key for each InnoDB table, specifying the column or columns that:

- Are referenced by the most important queries.
- Are never left blank.
- Never have duplicate values.
- Rarely if ever change value once inserted.
For example, in a table containing information about people, you would not create a primary key on (firstname, lastname) because more than one person can have the same name, some people have blank last names, and sometimes people change their names. With so many constraints, often there is not an obvious set of columns to use as a primary key, so you create a new column with a numeric ID to serve as all or part of the primary key. You can declare an auto-increment column so that ascending values are filled in automatically as rows are inserted:

```sql
-- The value of ID can act like a pointer between related items in different tables.
CREATE TABLE t5 (id INT AUTO_INCREMENT, b CHAR (20), PRIMARY KEY (id));
-- The primary key can consist of more than one column. Any autoinc column must come first.
CREATE TABLE t6 (id INT AUTO_INCREMENT, a INT, b CHAR (20), PRIMARY KEY (id,a));
```

Although the table works correctly without you defining a primary key, the primary key is involved with many aspects of performance and is a crucial design aspect for any large or frequently used table. Make a habit of always specifying one in the `CREATE TABLE` statement. (If you create the table, load data, and then do `ALTER TABLE` to add a primary key later, that operation is much slower than defining the primary key when creating the table.)

### 14.9.2 Moving or Copying InnoDB Tables to Another Machine

This section describes techniques for moving or copying some or all InnoDB tables to a different server. For example, you might move an entire MySQL instance to a larger, faster server; you might clone an entire MySQL instance to a new replication slave server; you might copy individual tables to another server to develop and test an application, or to a data warehouse server to produce reports.

Techniques for moving or copying InnoDB tables include:

- Copying Data Files (Cold Backup Method)
- Export and Import (mysqldump)

#### Using Lowercase Names for Cross-Platform Moving or Copying

On Windows, InnoDB always stores database and table names internally in lowercase. To move databases in a binary format from Unix to Windows or from Windows to Unix, create all databases and tables using lowercase names. A convenient way to accomplish this is to add the following line to the `[mysqld]` section of your `my.cnf` or `my.ini` file before creating any databases or tables:

```ini
[mysqld]
lower_case_table_names=1
```

#### Copying Data Files (Cold Backup Method)

You can move an InnoDB database simply by copying all the relevant files listed under "Cold Backups" in Section 14.19, "InnoDB Backup and Recovery".

Like MyISAM data files, InnoDB data and log files are binary-compatible on all platforms having the same floating-point number format. If the floating-point formats differ but you have not used `FLOAT` or `DOUBLE` data types in your tables, then the procedure is the same: simply copy the relevant files.

#### Export and Import (mysqldump)

You can use `mysqldump` to dump your tables on one machine and then import the dump files on the other machine. Using this method, it does not matter whether the formats differ or if your tables contain floating-point data.
Grouping DML Operations with Transactions

One way to increase the performance of this method is to switch off autocommit mode when importing data, assuming that the tablespace has enough space for the big rollback segment that the import transactions generate. Do the commit only after importing a whole table or a segment of a table.

14.9.3 Grouping DML Operations with Transactions

By default, connection to the MySQL server begins with autocommit mode enabled, which automatically commits every SQL statement as you execute it. This mode of operation might be unfamiliar if you have experience with other database systems, where it is standard practice to issue a sequence of DML statements and commit them or roll them back all together.

To use multiple-statement transactions, switch autocommit off with the SQL statement SET autocommit = 0 and end each transaction with COMMIT or ROLLBACK as appropriate. To leave autocommit on, begin each transaction with START TRANSACTION and end it with COMMIT or ROLLBACK. The following example shows two transactions. The first is committed; the second is rolled back.

```
shell> mysql test
mysql> CREATE TABLE customer (a INT, b CHAR (20), INDEX (a))
    
    -> ENGINE=InnoDB;
Query OK, 0 rows affected (0.00 sec)
mysql> -- Do a transaction with autocommit turned on.
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO customer VALUES (10, 'Heikki');
Query OK, 1 row affected (0.00 sec)
mysql> COMMIT;
Query OK, 0 rows affected (0.00 sec)
mysql> -- Do another transaction with autocommit turned off.
mysql> SET autocommit=0;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO customer VALUES (15, 'John');
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO customer VALUES (20, 'Paul');
Query OK, 1 row affected (0.00 sec)
mysql> DELETE FROM customer WHERE b = 'Heikki';
Query OK, 1 row affected (0.00 sec)
mysql> -- Now we undo those last 2 inserts and the delete.
mysql> ROLLBACK;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT * FROM customer;

+----+-------+
| a  | b     |
+----+-------+
| 10 | Heikki|
+----+-------+
1 row in set (0.00 sec)
```

Transactions in Client-Side Languages

In APIs such as PHP, Perl DBI, JDBC, ODBC, or the standard C call interface of MySQL, you can send transaction control statements such as COMMIT to the MySQL server as strings just like any other SQL statements such as SELECT or INSERT. Some APIs also offer separate special transaction commit and rollback functions or methods.

14.9.4 Converting Tables from MyISAM to InnoDB

If you have existing tables, and applications that use them, that you want to convert to InnoDB for better reliability and scalability, use the following guidelines and tips. This section assumes most such tables were originally MyISAM, which was formerly the default.
Converting Tables from MyISAM to InnoDB

Reduce Memory Usage for MyISAM, Increase Memory Usage for InnoDB

As you transition away from MyISAM tables, lower the value of the key_buffer_size configuration option to free memory no longer needed for caching results. Increase the value of the innodb_buffer_pool_size configuration option, which performs a similar role of allocating cache memory for InnoDB tables. The InnoDB buffer pool caches both table data and index data, so it does double duty in speeding up lookups for queries and keeping query results in memory for reuse.

- Allocate as much memory to this option as you can afford, often up to 80% of physical memory on the server.
- If the operating system runs short of memory for other processes and begins to swap, reduce the innodb_buffer_pool_size value. Swapping is such an expensive operation that it drastically reduces the benefit of the cache memory.
- If the innodb_buffer_pool_size value is several gigabytes or higher, consider increasing the values of innodb_buffer_pool_instances. Doing so helps on busy servers where many connections are reading data into the cache at the same time.
- On a busy server, run benchmarks with the Query Cache turned off. The InnoDB buffer pool provides similar benefits, so the Query Cache might be tying up memory unnecessarily.

Watch Out for Too-Long Or Too-Short Transactions

Because MyISAM tables do not support transactions, you might not have paid much attention to the autocommit configuration option and the COMMIT and ROLLBACK statements. These keywords are important to allow multiple sessions to read and write InnoDB tables concurrently, providing substantial scalability benefits in write-heavy workloads.

While a transaction is open, the system keeps a snapshot of the data as seen at the beginning of the transaction, which can cause substantial overhead if the system inserts, updates, and deletes millions of rows while a stray transaction keeps running. Thus, take care to avoid transactions that run for too long:

- If you are using a mysql session for interactive experiments, always COMMIT (to finalize the changes) or ROLLBACK (to undo the changes) when finished. Close down interactive sessions rather than leaving them open for long periods, to avoid keeping transactions open for long periods by accident.
- Make sure that any error handlers in your application also ROLLBACK incomplete changes or COMMIT completed changes.
- ROLLBACK is a relatively expensive operation, because INSERT, UPDATE, and DELETE operations are written to InnoDB tables prior to the COMMIT, with the expectation that most changes will be committed successfully and rollbacks will be rare. When experimenting with large volumes of data, avoid making changes to large numbers of rows and then rolling back those changes.
- When loading large volumes of data with a sequence of INSERT statements, periodically COMMIT the results to avoid having transactions that last for hours. In typical load operations for data warehousing, if something goes wrong, you TRUNCATE TABLE and start over from the beginning rather than doing a ROLLBACK.

The preceding tips save memory and disk space that can be wasted during too-long transactions. When transactions are shorter than they should be, the problem is excessive I/O. With each COMMIT, MySQL makes sure each change is safely recorded to disk, which involves some I/O.

- For most operations on InnoDB tables, you should use the setting autocommit=0. From an efficiency perspective, this avoids unnecessary I/O when you issue large numbers of consecutive INSERT,
Converting Tables from MyISAM to InnoDB

UPDATE, or DELETE statements. From a safety perspective, this allows you to issue a ROLLBACK statement to recover lost or garbled data if you make a mistake on the mysql command line, or in an exception handler in your application.

The time when autocommit=1 is suitable for InnoDB tables is when running a sequence of queries for generating reports or analyzing statistics. In this situation, there is no I/O penalty related to COMMIT or ROLLBACK, and InnoDB can automatically optimize the read-only workload.

If you make a series of related changes, finalize all those changes at once with a single COMMIT at the end. For example, if you insert related pieces of information into several tables, do a single COMMIT after making all the changes. Or if you run many consecutive INSERT statements, do a single COMMIT after all the data is loaded; if you are doing millions of INSERT statements, perhaps split up the huge transaction by issuing a COMMIT every ten thousand or hundred thousand records, so the transaction does not grow too large.

Remember that even a SELECT statement opens a transaction, so after running some report or debugging queries in an interactive mysql session, either issue a COMMIT or close the mysql session.

Don’t Worry Too Much About Deadlocks

You might see warning messages referring to “deadlocks” in the MySQL error log, or the output of SHOW ENGINE INNODB STATUS. Despite the scary-sounding name, a deadlock is not a serious issue for InnoDB tables, and often does not require any corrective action. When two transactions start modifying multiple tables, accessing the tables in a different order, they can reach a state where each transaction is waiting for the other and neither can proceed. MySQL immediately detects this condition and cancels (rolls back) the “smaller” transaction, allowing the other to proceed.

Your applications do need error-handling logic to restart a transaction that is forcibly cancelled like this. When you re-issue the same SQL statements as before, the original timing issue no longer applies: either the other transaction has already finished and yours can proceed, or the other transaction is still in progress and your transaction waits until it finishes.

If deadlock warnings occur constantly, you might review the application code to reorder the SQL operations in a consistent way, or to shorten the transactions.

Plan the Storage Layout

To get the best performance from InnoDB tables, you can adjust a number of parameters related to storage layout.

When you convert MyISAM tables that are large, frequently accessed, and hold vital data, investigate and consider the innodb_file_per_table and innodb_file_format configuration options, and the ROW_FORMAT and KEY_BLOCK_SIZE clauses of the CREATE TABLE statement.

During your initial experiments, the most important setting is innodb_file_per_table. Enabling this option before creating new InnoDB tables ensures that the InnoDB system tablespace files do not allocate disk space permanently for all the InnoDB data. With innodb_file_per_table enabled, DROP TABLE and TRUNCATE TABLE free disk space as you would expect.

Converting an Existing Table

To convert a non-InnoDB table to use InnoDB use ALTER TABLE:

```
ALTER TABLE table_name ENGINE=InnoDB;
```
Converting Tables from MyISAM to InnoDB

Important
Do not convert MySQL system tables in the mysql database (such as user or host) to the InnoDB type. This is an unsupported operation. The system tables must always be of the MyISAM type.

Cloning the Structure of a Table

You might make an InnoDB table that is a clone of a MyISAM table, rather than doing the ALTER TABLE conversion, to test the old and new table side-by-side before switching.

Create an empty InnoDB table with identical column and index definitions. Use `show create table table_name\G` to see the full CREATE TABLE statement to use. Change the ENGINE clause to `ENGINE=INNODB`.

Transferring Existing Data

To transfer a large volume of data into an empty InnoDB table created as shown in the previous section, insert the rows with `INSERT INTO innodb_table SELECT * FROM myisam_table ORDER BY primary_key_columns`.

You can also create the indexes for the InnoDB table after inserting the data. Historically, creating new secondary indexes was a slow operation for InnoDB, but now you can create the indexes after the data is loaded with relatively little overhead from the index creation step.

If you have UNIQUE constraints on secondary keys, you can speed up a table import by turning off the uniqueness checks temporarily during the import operation:

```sql
SET unique_checks=0;
... import operation ... SET unique_checks=1;
```

For big tables, this saves disk I/O because InnoDB can use its insert buffer to write secondary index records as a batch. Be certain that the data contains no duplicate keys. `unique_checks` permits but does not require storage engines to ignore duplicate keys.

To get better control over the insertion process, you might insert big tables in pieces:

```sql
INSERT INTO newtable SELECT * FROM oldtable WHERE yourkey > something AND yourkey <= somethingelse;
```

After all records have been inserted, you can rename the tables.

During the conversion of big tables, increase the size of the InnoDB buffer pool to reduce disk I/O, to a maximum of 80% of physical memory. You can also increase the sizes of the InnoDB log files.

Storage Requirements

By this point, as already mentioned, you should already have the `innodb_file_per_table` option enabled, so that if you temporarily make several copies of your data in InnoDB tables, you can recover all that disk space by dropping unneeded tables afterward.

Whether you convert the MyISAM table directly or create a cloned InnoDB table, make sure that you have sufficient disk space to hold both the old and new tables during the process. InnoDB tables require more disk space than MyISAM tables. If an ALTER TABLE operation runs out of space, it starts a rollback, and that can take hours if it is disk-bound. For inserts, InnoDB uses the insert buffer to merge secondary index
Converting Tables from MyISAM to InnoDB

records to indexes in batches. That saves a lot of disk I/O. For rollback, no such mechanism is used, and the rollback can take 30 times longer than the insertion.

In the case of a runaway rollback, if you do not have valuable data in your database, it may be advisable to kill the database process rather than wait for millions of disk I/O operations to complete. For the complete procedure, see Section 14.21.2, “Starting InnoDB on a Corrupted Database”.

Carefully Choose a PRIMARY KEY for Each Table

The PRIMARY KEY clause is a critical factor affecting the performance of MySQL queries and the space usage for tables and indexes. Perhaps you have phoned a financial institution where you are asked for an account number. If you do not have the number, you are asked for a dozen different pieces of information to “uniquely identify” yourself. The primary key is like that unique account number that lets you get straight down to business when querying or modifying the information in a table. Every row in the table must have a primary key value, and no two rows can have the same primary key value.

Here are some guidelines for the primary key, followed by more detailed explanations.

• Declare a PRIMARY KEY for each table. Typically, it is the most important column that you refer to in WHERE clauses when looking up a single row.

• Declare the PRIMARY KEY clause in the original CREATE TABLE statement, rather than adding it later through an ALTER TABLE statement.

• Choose the column and its data type carefully. Prefer numeric columns over character or string ones.

• Consider using an auto-increment column if there is not another stable, unique, non-null, numeric column to use.

• An auto-increment column is also a good choice if there is any doubt whether the value of the primary key column could ever change. Changing the value of a primary key column is an expensive operation, possibly involving rearranging data within the table and within each secondary index.

Consider adding a primary key to any table that does not already have one. Use the smallest practical numeric type based on the maximum projected size of the table. This can make each row slightly more compact, which can yield substantial space savings for large tables. The space savings are multiplied if the table has any secondary indexes, because the primary key value is repeated in each secondary index entry. In addition to reducing data size on disk, a small primary key also lets more data fit into the buffer pool, speeding up all kinds of operations and improving concurrency.

If the table already has a primary key on some longer column, such as a VARCHAR, consider adding a new unsigned AUTO_INCREMENT column and switching the primary key to that, even if that column is not referenced in queries. This design change can produce substantial space savings in the secondary indexes. You can designate the former primary key columns as UNIQUE NOT NULL to enforce the same constraints as the PRIMARY KEY clause, that is, to prevent duplicate or null values across all those columns.

If you spread related information across multiple tables, typically each table uses the same column for its primary key. For example, a personnel database might have several tables, each with a primary key of employee number. A sales database might have some tables with a primary key of customer number, and other tables with a primary key of order number. Because lookups using the primary key are very fast, you can construct efficient join queries for such tables.

If you leave the PRIMARY KEY clause out entirely, MySQL creates an invisible one for you. It is a 6-byte value that might be longer than you need, thus wasting space. Because it is hidden, you cannot refer to it in queries.
Application Performance Considerations

The extra reliability and scalability features of InnoDB do require more disk storage than equivalent MyISAM tables. You might change the column and index definitions slightly, for better space utilization, reduced I/O and memory consumption when processing result sets, and better query optimization plans making efficient use of index lookups.

If you do set up a numeric ID column for the primary key, use that value to cross-reference with related values in any other tables, particularly for join queries. For example, rather than accepting a country name as input and doing queries searching for the same name, do one lookup to determine the country ID, then do other queries (or a single join query) to look up relevant information across several tables. Rather than storing a customer or catalog item number as a string of digits, potentially using up several bytes, convert it to a numeric ID for storing and querying. A 4-byte unsigned INT column can index over 4 billion items (with the US meaning of billion: 1000 million). For the ranges of the different integer types, see Section 11.2.1, “Integer Types (Exact Value) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT”.

Understand Files Associated with InnoDB Tables

InnoDB files require more care and planning than MyISAM files do.

• You must not delete the ibdata files that represent the InnoDB system tablespace.

• Methods of copying or moving InnoDB tables to a different server are described in Section 14.9.2, “Moving or Copying InnoDB Tables to Another Machine”.

14.9.5 AUTO_INCREMENT Handling in InnoDB

InnoDB provides an optimization that significantly improves scalability and performance of SQL statements that insert rows into tables with AUTO_INCREMENT columns. To use the AUTO_INCREMENT mechanism with an InnoDB table, an AUTO_INCREMENT column ai_col must be defined as part of an index such that it is possible to perform the equivalent of an indexed SELECT MAX(ai_col) lookup on the table to obtain the maximum column value. Typically, this is achieved by making the column the first column of some table index.

This section provides background information on the original (“traditional”) implementation of auto-increment locking in InnoDB, explains the configurable locking mechanism, documents the parameter for configuring the mechanism, and describes its behavior and interaction with replication.

14.9.5.1 Traditional InnoDB Auto-Increment Locking

The original implementation of auto-increment handling in InnoDB uses the following strategy to prevent problems when using the binary log for statement-based replication or for certain recovery scenarios.

If you specify an AUTO_INCREMENT column for an InnoDB table, the table handle in the InnoDB data dictionary contains a special counter called the auto-increment counter that is used in assigning new values for the column. This counter is stored only in main memory, not on disk.

InnoDB uses the following algorithm to initialize the auto-increment counter for a table t that contains an AUTO_INCREMENT column named ai_col: After a server startup, for the first insert into a table t, InnoDB executes the equivalent of this statement:

```sql
SELECT MAX(ai_col) FROM t FOR UPDATE;
```

InnoDB increments the value retrieved by the statement and assigns it to the column and to the auto-increment counter for the table. By default, the value is incremented by one. This default can be overridden by the auto_increment_increment configuration setting.
If the table is empty, **InnoDB** uses the value 1. This default can be overridden by the `auto_increment_offset` configuration setting.

If a `SHOW TABLE STATUS` statement examines the table `t` before the auto-increment counter is initialized, **InnoDB** initializes but does not increment the value and stores it for use by later inserts. This initialization uses a normal exclusive-locking read on the table and the lock lasts to the end of the transaction.

**InnoDB** follows the same procedure for initializing the auto-increment counter for a freshly created table.

After the auto-increment counter has been initialized, if you do not explicitly specify a value for an `AUTO_INCREMENT` column, **InnoDB** increments the counter and assigns the new value to the column. If you insert a row that explicitly specifies the column value, and the value is bigger than the current counter value, the counter is set to the specified column value.

If a user specifies `NULL` or 0 for the `AUTO_INCREMENT` column in an `INSERT`, **InnoDB** treats the row as if the value was not specified and generates a new value for it.

The behavior of the auto-increment mechanism is not defined if you assign a negative value to the column, or if the value becomes bigger than the maximum integer that can be stored in the specified integer type.

When accessing the auto-increment counter, **InnoDB** uses a special table-level `AUTO-INC` lock that it keeps to the end of the current SQL statement, not to the end of the transaction. The special lock release strategy was introduced to improve concurrency for inserts into a table containing an `AUTO_INCREMENT` column. Nevertheless, two transactions cannot have the `AUTO-INC` lock on the same table simultaneously, which can have a performance impact if the `AUTO-INC` lock is held for a long time. That might be the case for a statement such as `INSERT INTO t1 ... SELECT ... FROM t2` that inserts all rows from one table into another.

**InnoDB** uses the in-memory auto-increment counter as long as the server runs. When the server is stopped and restarted, **InnoDB** reinitializes the counter for each table for the first `INSERT` to the table, as described earlier.

A server restart also cancels the effect of the `AUTO_INCREMENT = N` table option in `CREATE TABLE` and `ALTER TABLE` statements, which you can use with **InnoDB** tables to set the initial counter value or alter the current counter value.

You may see gaps in the sequence of values assigned to the `AUTO_INCREMENT` column if you roll back transactions that have generated numbers using the counter.

### 14.9.5.2 Configurable **InnoDB** Auto-Increment Locking

As described in the previous section, **InnoDB** uses a special lock called the table-level `AUTO-INC` lock for inserts into tables with `AUTO_INCREMENT` columns. This lock is normally held to the end of the statement (not to the end of the transaction), to ensure that auto-increment numbers are assigned in a predictable and repeatable order for a given sequence of `INSERT` statements.

In the case of statement-based replication, this means that when an SQL statement is replicated on a slave server, the same values are used for the auto-increment column as on the master server. The result of execution of multiple `INSERT` statements is deterministic, and the slave reproduces the same data as on the master. If auto-increment values generated by multiple `INSERT` statements were interleaved, the result of two concurrent `INSERT` statements would be nondeterministic, and could not reliably be propagated to a slave server using statement-based replication.

To make this clear, consider an example that uses this table:

```sql
CREATE TABLE t1 (  c1 INT(11) NOT NULL AUTO_INCREMENT,  c2 VARCHAR(10) DEFAULT NULL,
```

1677
Suppose that there are two transactions running, each inserting rows into a table with an \texttt{AUTO_INCREMENT} column. One transaction is using an \texttt{INSERT \ldots SELECT} statement that inserts 1000 rows, and another is using a simple \texttt{INSERT} statement that inserts one row:

\begin{verbatim}
Tx1: INSERT INTO t1 (c2) SELECT 1000 rows from another table ...
Tx2: INSERT INTO t1 (c2) VALUES ('xxx');
\end{verbatim}

\texttt{InnoDB} cannot tell in advance how many rows will be retrieved from the \texttt{SELECT} in the \texttt{INSERT} statement in \texttt{Tx1}, and it assigns the auto-increment values one at a time as the statement proceeds. With a table-level lock, held to the end of the statement, only one \texttt{INSERT} statement referring to table \texttt{t1} can execute at a time, and the generation of auto-increment numbers by different statements is not interleaved. The auto-increment value generated by the \texttt{Tx1 INSERT \ldots SELECT} statement will be consecutive, and the (single) auto-increment value used by the \texttt{INSERT} statement in \texttt{Tx2} will either be smaller or larger than all those used for \texttt{Tx1}, depending on which statement executes first.

As long as the SQL statements execute in the same order when replayed from the binary log (when using statement-based replication, or in recovery scenarios), the results will be the same as they were when \texttt{Tx1} and \texttt{Tx2} first ran. Thus, table-level locks held until the end of a statement make \texttt{INSERT} statements using auto-increment safe for use with statement-based replication. However, those locks limit concurrency and scalability when multiple transactions are executing insert statements at the same time.

In the preceding example, if there were no table-level lock, the value of the auto-increment column used for the \texttt{INSERT} in \texttt{Tx2} depends on precisely when the statement executes. If the \texttt{INSERT} of \texttt{Tx2} executes while the \texttt{INSERT} of \texttt{Tx1} is running (rather than before it starts or after it completes), the specific auto-increment values assigned by the two \texttt{INSERT} statements are nondeterministic, and may vary from run to run.

\texttt{InnoDB} can avoid using the table-level \texttt{AUTO-INC} lock for a class of \texttt{INSERT} statements where the number of rows is known in advance, and still preserve deterministic execution and safety for statement-based replication. Further, if you are not using the binary log to replay SQL statements as part of recovery or replication, you can entirely eliminate use of the table-level \texttt{AUTO-INC} lock for even greater concurrency and performance, at the cost of permitting gaps in auto-increment numbers assigned by a statement and potentially having the numbers assigned by concurrently executing statements interleaved.

For \texttt{INSERT} statements where the number of rows to be inserted is known at the beginning of processing the statement, \texttt{InnoDB} quickly allocates the required number of auto-increment values without taking any lock, but only if there is no concurrent session already holding the table-level \texttt{AUTO-INC} lock (because that other statement will be allocating auto-increment values one-by-one as it proceeds). More precisely, such an \texttt{INSERT} statement obtains auto-increment values under the control of a mutex (a light-weight lock) that is not held until the statement completes, but only for the duration of the allocation process.

This new locking scheme enables much greater scalability, but it does introduce some subtle differences in how auto-increment values are assigned compared to the original mechanism. To describe the way auto-increment works in \texttt{InnoDB}, the following discussion defines some terms, and explains how \texttt{InnoDB} behaves using different settings of the \texttt{innodb_autoinc_lock_mode} configuration parameter, which you can set at server startup. Additional considerations are described following the explanation of auto-increment locking behavior.

First, some definitions:

- **“INSERT-like” statements**
  
  All statements that generate new rows in a table, including \texttt{INSERT}, \texttt{INSERT \ldots SELECT}, \texttt{REPLACE}, \texttt{REPLACE \ldots SELECT}, and \texttt{LOAD DATA}.
AUTO_INCREMENT Handling in InnoDB

• “Simple inserts”

Statements for which the number of rows to be inserted can be determined in advance (when the statement is initially processed). This includes single-row and multiple-row INSERT and REPLACE statements that do not have a nested subquery, but not INSERT ... ON DUPLICATE KEY UPDATE.

• “Bulk inserts”

Statements for which the number of rows to be inserted (and the number of required auto-increment values) is not known in advance. This includes INSERT ... SELECT, REPLACE ... SELECT, and LOAD DATA statements, but not plain INSERT. InnoDB will assign new values for the AUTO_INCREMENT column one at a time as each row is processed.

• “Mixed-mode inserts”

These are “simple insert” statements that specify the auto-increment value for some (but not all) of the new rows. An example follows, where c1 is an AUTO_INCREMENT column of table t1:

```
INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
```

Another type of “mixed-mode insert” is INSERT ... ON DUPLICATE KEY UPDATE, which in the worst case is in effect an INSERT followed by a UPDATE, where the allocated value for the AUTO_INCREMENT column may or may not be used during the update phase.

There are three possible settings for the innodb_autoinc_lock_mode parameter:

• innodb_autoinc_lock_mode = 0 (“traditional” lock mode)

This lock mode provides the same behavior as before innodb_autoinc_lock_mode existed. For all “INSERT-like” statements, a special table-level AUTO-INC lock is obtained and held to the end of the statement. This assures that the auto-increment values assigned by any given statement are consecutive.

This lock mode is provided for:

• Backward compatibility.
• Performance testing.
• Working around issues with “mixed-mode inserts”, due to the possible differences in semantics described later.

• innodb_autoinc_lock_mode = 1 (“consecutive” lock mode)

This is the default lock mode. In this mode, “bulk inserts” use the special AUTO-INC table-level lock and hold it until the end of the statement. This applies to all INSERT ... SELECT, REPLACE ... SELECT, and LOAD DATA statements. Only one statement holding the AUTO-INC lock can execute at a time.

With this lock mode, “simple inserts” (only) use a new locking model where a light-weight mutex is used during the allocation of auto-increment values, and no table-level AUTO-INC lock is used, unless an AUTO-INC lock is held by another transaction. If another transaction does hold an AUTO-INC lock, a “simple insert” waits for the AUTO-INC lock, as if it too were a “bulk insert”.

This lock mode ensures that, in the presence of INSERT statements where the number of rows is not known in advance (and where auto-increment numbers are assigned as the statement progresses), all auto-increment values assigned by any “INSERT-like” statement are consecutive, and operations are safe for statement-based replication.
Simply put, the important impact of this lock mode is significantly better scalability. This mode is safe for use with statement-based replication. Further, as with “traditional” lock mode, auto-increment numbers assigned by any given statement are consecutive. In this mode, there is no change in semantics compared to “traditional” mode for any statement that uses auto-increment, with one important exception.

The exception is for “mixed-mode inserts”, where the user provides explicit values for an AUTO_INCREMENT column for some, but not all, rows in a multiple-row “simple insert”. For such inserts, InnoDB will allocate more auto-increment values than the number of rows to be inserted. However, all values automatically assigned are consecutively generated (and thus higher than) the auto-increment value generated by the most recently executed previous statement. “Excess” numbers are lost.

- `innodb_autoinc_lock_mode = 2` (“interleaved” lock mode)

In this lock mode, no “INSERT-like” statements use the table-level AUTO_INCREMENT lock, and multiple statements can execute at the same time. This is the fastest and most scalable lock mode, but it is not safe when using statement-based replication or recovery scenarios when SQL statements are replayed from the binary log.

In this lock mode, auto-increment values are guaranteed to be unique and monotonically increasing across all concurrently executing “INSERT-like” statements. However, because multiple statements can be generating numbers at the same time (that is, allocation of numbers is interleaved across statements), the values generated for the rows inserted by any given statement may not be consecutive.

If the only statements executing are “simple inserts” where the number of rows to be inserted is known ahead of time, there will be no gaps in the numbers generated for a single statement, except for “mixed-mode inserts”. However, when “bulk inserts” are executed, there may be gaps in the auto-increment values assigned by any given statement.

The auto-increment locking modes provided by `innodb_autoinc_lock_mode` have several usage implications:

- Using auto-increment with replication

  If you are using statement-based replication, set `innodb_autoinc_lock_mode` to 0 or 1 and use the same value on the master and its slaves. Auto-increment values are not ensured to be the same on the slaves as on the master if you use `innodb_autoinc_lock_mode = 2` (“interleaved”) or configurations where the master and slaves do not use the same lock mode.

  If you are using row-based or mixed-format replication, all of the auto-increment lock modes are safe, since row-based replication is not sensitive to the order of execution of the SQL statements (and the mixed format uses row-based replication for any statements that are unsafe for statement-based replication).

- “Lost” auto-increment values and sequence gaps

  In all lock modes (0, 1, and 2), if a transaction that generated auto-increment values rolls back, those auto-increment values are “lost”. Once a value is generated for an auto-increment column, it cannot be rolled back, whether or not the “INSERT-like” statement is completed, and whether or not the containing transaction is rolled back. Such lost values are not reused. Thus, there may be gaps in the values stored in an AUTO_INCREMENT column of a table.

- Gaps in auto-increment values for “bulk inserts”

  With `innodb_autoinc_lock_mode` set to 0 (“traditional”) or 1 (“consecutive”), the auto-increment values generated by any given statement will be consecutive, without gaps, because the table-level
**AUTO_INCREMENT** lock is held until the end of the statement, and only one such statement can execute at a time.

With `innodb_autoinc_lock_mode` set to 2 ("interleaved"), there may be gaps in the auto-increment values generated by "bulk inserts," but only if there are concurrently executing "INSERT-like" statements.

For lock modes 1 or 2, gaps may occur between successive statements because for bulk inserts the exact number of auto-increment values required by each statement may not be known and overestimation is possible.

- **Auto-increment values assigned by “mixed-mode inserts”**

Consider a "mixed-mode insert," where a “simple insert” specifies the auto-increment value for some (but not all) resulting rows. Such a statement will behave differently in lock modes 0, 1, and 2. For example, assume `c1` is an **AUTO_INCREMENT** column of table `t1`, and that the most recent automatically generated sequence number is 100. Consider the following “mixed-mode insert” statement:

```sql
INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
```

With `innodb_autoinc_lock_mode` set to 0 ("traditional"), the four new rows will be:

<table>
<thead>
<tr>
<th>c1</th>
<th>c2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>a</td>
</tr>
<tr>
<td>101</td>
<td>b</td>
</tr>
<tr>
<td>5</td>
<td>c</td>
</tr>
<tr>
<td>102</td>
<td>d</td>
</tr>
</tbody>
</table>

The next available auto-increment value will be 103 because the auto-increment values are allocated one at a time, not all at once at the beginning of statement execution. This result is true whether or not there are concurrently executing "INSERT-like" statements (of any type).

With `innodb_autoinc_lock_mode` set to 1 ("consecutive"), the four new rows will also be:

<table>
<thead>
<tr>
<th>c1</th>
<th>c2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>a</td>
</tr>
<tr>
<td>101</td>
<td>b</td>
</tr>
<tr>
<td>5</td>
<td>c</td>
</tr>
<tr>
<td>102</td>
<td>d</td>
</tr>
</tbody>
</table>

However, in this case, the next available auto-increment value will be 105, not 103 because four auto-increment values are allocated at the time the statement is processed, but only two are used. This result is true whether or not there are concurrently executing "INSERT-like" statements (of any type).

With `innodb_autoinc_lock_mode` set to mode 2 ("interleaved"), the four new rows will be:

<table>
<thead>
<tr>
<th>c1</th>
<th>c2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>a</td>
</tr>
<tr>
<td>x</td>
<td>b</td>
</tr>
<tr>
<td>5</td>
<td>c</td>
</tr>
<tr>
<td>y</td>
<td>d</td>
</tr>
</tbody>
</table>
InnoDB and FOREIGN KEY Constraints

The values of \( x \) and \( y \) will be unique and larger than any previously generated rows. However, the specific values of \( x \) and \( y \) will depend on the number of auto-increment values generated by concurrently executing statements.

Finally, consider the following statement, issued when the most-recently generated sequence number was the value 4:

```sql
INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
```

With any `innodb_autoinc_lock_mode` setting, this statement will generate a duplicate-key error 23000 (Can't write; duplicate key in table) because 5 will be allocated for the row `(NULL, 'b')` and insertion of the row `(5, 'c')` will fail.

14.9.6 InnoDB and FOREIGN KEY Constraints

This section describes differences in the InnoDB storage engine's handling of foreign keys as compared with that of the MySQL Server.

Foreign Key Definitions

Foreign key definitions for InnoDB tables are subject to the following conditions:

- **InnoDB** permits a foreign key to reference any index column or group of columns. However, in the referenced table, there must be an index where the referenced columns are listed as the first columns in the same order.
- **InnoDB** does not currently support foreign keys for tables with user-defined partitioning. This means that no user-partitioned InnoDB table may contain foreign key references or columns referenced by foreign keys.
- **InnoDB** allows a foreign key constraint to reference a non-unique key. This is an InnoDB extension to standard SQL.

Referential Actions

Referential actions for foreign keys of InnoDB tables are subject to the following conditions:

- While `SET DEFAULT` is allowed by the MySQL Server, it is rejected as invalid by `InnoDB.CREATE TABLE` and `ALTER TABLE` statements using this clause are not allowed for InnoDB tables.
- If there are several rows in the parent table that have the same referenced key value, **InnoDB** acts in foreign key checks as if the other parent rows with the same key value do not exist. For example, if you have defined a `RESTRICT` type constraint, and there is a child row with several parent rows, **InnoDB** does not permit the deletion of any of those parent rows.
- **InnoDB** performs cascading operations through a depth-first algorithm, based on records in the indexes corresponding to the foreign key constraints.
- If `ON UPDATE CASCADE` or `ON UPDATE SET NULL` recurses to update the same table it has previously updated during the cascade, it acts like `RESTRICT`. This means that you cannot use self-referential `ON UPDATE CASCADE` or `ON UPDATE SET NULL` operations. This is to prevent infinite loops resulting from cascaded updates. A self-referential `ON DELETE SET NULL`, on the other hand, is possible, as is a self-referential `ON DELETE CASCADE`. Cascading operations may not be nested more than 15 levels deep.
- Like MySQL in general, in an SQL statement that inserts, deletes, or updates many rows, **InnoDB** checks `UNIQUE` and `FOREIGN KEY` constraints row-by-row. When performing foreign key checks,
Limits on InnoDB Tables

InnoDB sets shared row-level locks on child or parent records it has to look at. InnoDB checks foreign key constraints immediately; the check is not deferred to transaction commit. According to the SQL standard, the default behavior should be deferred checking. That is, constraints are only checked after the entire SQL statement has been processed. Until InnoDB implements deferred constraint checking, some things will be impossible, such as deleting a record that refers to itself using a foreign key.

Foreign Key Usage and Error Information

You can obtain general information about foreign keys and their usage from querying the INFORMATION_SCHEMA.KEY_COLUMN_USAGE table. See also Section 13.1.17.2, "Using FOREIGN KEY Constraints".

In addition to SHOW ERRORS, in the event of a foreign key error involving InnoDB tables (usually Error 150 in the MySQL Server), you can obtain a detailed explanation of the most recent InnoDB foreign key error by checking the output of SHOW ENGINE INNODB STATUS.

14.9.7 Limits on InnoDB Tables

Warning

Do not convert MySQL system tables in the mysql database from MyISAM to InnoDB tables! This is an unsupported operation. If you do this, MySQL does not restart until you restore the old system tables from a backup or re-generate them with the mysql_install_db script.

Warning

It is not a good idea to configure InnoDB to use data files or log files on NFS volumes. Otherwise, the files might be locked by other processes and become unavailable for use by MySQL.

Maximums and Minimums

• A table can contain a maximum of 1000 columns.

• A table can contain a maximum of 64 secondary indexes.

• By default, an index key for a single-column index can be up to 767 bytes. The same length limit applies to any index key prefix. See Section 13.1.13, "CREATE INDEX Syntax". For example, you might hit this limit with a column prefix index of more than 255 characters on a TEXT or VARCHAR column, assuming a UTF-8 character set and the maximum of 3 bytes for each character. When the innodb_large_prefix configuration option is enabled, this length limit is raised to 3072 bytes, for InnoDB tables that use the DYNAMIC and COMPRESSED row formats.

If you specify an index prefix length that is greater than the allowed maximum value, the length is silently reduced to the maximum length. In MySQL 5.6 and later, specifying an index prefix length greater than the maximum length produces an error.

When innodb_large_prefix is enabled, attempting to create an index prefix with a key length greater than 3072 for a REDUNDANT or COMPACT table causes an ER_INDEX_COLUMN_TOO_LONG error.

• The InnoDB internal maximum key length is 3500 bytes, but MySQL itself restricts this to 3072 bytes. This limit applies to the length of the combined index key in a multi-column index.

• The maximum row length, except for variable-length columns (VARBINARY, VARCHAR, BLOB and TEXT), is slightly less than half of a database page. That is, the maximum row length is about 8000 bytes.
**Limits on InnoDB Tables**

**LONGBLOB** and **LONGTEXT** columns must be less than 4GB, and the total row length, including **BLOB** and **TEXT** columns, must be less than 4GB.

If a row is less than half a page long, all of it is stored locally within the page. If it exceeds half a page, variable-length columns are chosen for external off-page storage until the row fits within half a page, as described in Section 14.13.2, “File Space Management”.

The row size for **BLOB** columns that are chosen for external off-page storage should not exceed 10% of the combined **redo log** file size. If the row size exceeds 10% of the combined redo log file size, **InnoDB** could overwrite the most recent checkpoint which may result in lost data during crash recovery. (Bug#69477).

- Although **InnoDB** supports row sizes larger than 65,535 bytes internally, MySQL itself imposes a row-size limit of 65,535 for the combined size of all columns:

  ```sql
  mysql> CREATE TABLE t (a VARCHAR(8000), b VARCHAR(10000),
  -> c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
  -> f VARCHAR(10000), g VARCHAR(10000)) ENGINE=InnoDB;
  ERROR 1118 (42000): Row size too large. The maximum row size for the
  used table type, not counting BLOBs, is 65535. You have to change some
  columns to TEXT or BLOBs
  
  See Section D.10.4, “Limits on Table Column Count and Row Size”.
  ```

- On some older operating systems, files must be less than 2GB. This is not a limitation of **InnoDB** itself, but if you require a large tablespace, you will need to configure it using several smaller data files rather than one or a file large data files.

- The combined size of the **InnoDB** log files must be less than 4GB.

- The minimum tablespace size is slightly larger than 10MB. The maximum tablespace size is four billion database pages (64TB). This is also the maximum size for a table.

- The default database page size in **InnoDB** is 16KB.

### Note

Changing the page size is not a supported operation and there is no guarantee that **InnoDB** will function normally with a page size other than 16KB. Problems compiling or running InnoDB may occur. In particular, **ROW_FORMAT=COMPRESSED** in the Barracuda file format assumes that the page size is at most 16KB and uses 14-bit pointers.

A version of **InnoDB** built for one page size cannot use data files or log files from a version built for a different page size. This limitation could affect restore or downgrade operations using data from MySQL 5.6, which does support page sizes other than 16KB.

**Index Types**

- **InnoDB** tables do not support **FULLTEXT** indexes.

- **InnoDB** tables support spatial data types, but not indexes on them.

**Restrictions on InnoDB Tables**

- **ANALYZE TABLE** determines index cardinality (as displayed in the **Cardinality** column of **SHOW INDEX** output) by doing **random dives** to each of the index trees and updating index cardinality estimates.
Limits on InnoDB Tables

accordingly. Because these are only estimates, repeated runs of ANALYZE TABLE could produce different numbers. This makes ANALYZE TABLE fast on InnoDB tables but not 100% accurate because it does not take all rows into account.

You can change the number of random dives by modifying the innodb_stats_sample_pages system variable.

MySQL uses index cardinality estimates only in join optimization. If some join is not optimized in the right way, you can try using ANALYZE TABLE. In the few cases that ANALYZE TABLE does not produce values good enough for your particular tables, you can use FORCE INDEX with your queries to force the use of a particular index, or set the max_seeks_for_key system variable to ensure that MySQL prefers index lookups over table scans. See Section 5.1.4, “Server System Variables”, and Section B.5.6, “Optimizer-Related Issues”.

- If statements or transactions are running on a table and ANALYZE TABLE is run on the same table followed by a second ANALYZE TABLE operation, the second ANALYZE TABLE operation is blocked until the statements or transactions are completed. This behaviour occurs because ANALYZE TABLE marks the currently loaded table definition as obsolete when ANALYZE TABLE is finished running. New statements or transactions (including a second ANALYZE TABLE statement) must load the new table definition into the table cache, which cannot occur until currently running statements or transactions are completed and the old table definition is purged. Loading multiple concurrent table definitions is not supported.

- SHOW TABLE STATUS does not give accurate statistics on InnoDB tables, except for the physical size reserved by the table. The row count is only a rough estimate used in SQL optimization.

- InnoDB does not keep an internal count of rows in a table because concurrent transactions might “see” different numbers of rows at the same time. To process a SELECT COUNT(*) FROM t statement, InnoDB scans an index of the table, which takes some time if the index is not entirely in the buffer pool. If your table does not change often, using the MySQL query cache is a good solution. To get a fast count, you have to use a counter table you create yourself and let your application update it according to the inserts and deletes it does. If an approximate row count is sufficient, SHOW TABLE STATUS can be used. See InnoDB Performance Tuning Tips.

- On Windows, InnoDB always stores database and table names internally in lowercase. To move databases in a binary format from Unix to Windows or from Windows to Unix, create all databases and tables using lowercase names.

- An AUTO_INCREMENT column ai_col must be defined as part of an index such that it is possible to perform the equivalent of an indexed SELECT MAX(ai_col) lookup on the table to obtain the maximum column value. Typically, this is achieved by making the column the first column of some table index.

- While initializing a previously specified AUTO_INCREMENT column on a table, InnoDB sets an exclusive lock on the end of the index associated with the AUTO_INCREMENT column. While accessing the auto-increment counter, InnoDB uses a specific AUTO-INC table lock mode where the lock lasts only to the end of the current SQL statement, not to the end of the entire transaction. Other clients cannot insert into the table while the AUTO-INC table lock is held. See Section 14.9.5, “AUTO_INCREMENT Handling in InnoDB”.

- When you restart the MySQL server, InnoDB may reuse an old value that was generated for an AUTO_INCREMENT column but never stored (that is, a value that was generated during an old transaction that was rolled back).

- When an AUTO_INCREMENT integer column runs out of values, a subsequent INSERT operation returns a duplicate-key error. This is general MySQL behavior, similar to how MyISAM works.
InnoDB Compressed Tables

- **DELETE FROM tbl_name** does not regenerate the table but instead deletes all rows, one by one.

- Under some conditions, **TRUNCATE tbl_name** for an InnoDB table is mapped to **DELETE FROM tbl_name**. See Section 13.1.33, “TRUNCATE TABLE Syntax”.

- Currently, cascaded foreign key actions do not activate triggers.

- You cannot create a table with a column name that matches the name of an internal InnoDB column (including DB_ROW_ID, DB_TRX_ID, DB_ROLL_PTR, and DB_MIX_ID). The server reports error 1005 and refers to error –1 in the error message. This restriction applies only to use of the names in uppercase.

### Locking and Transactions

- **LOCK TABLES** acquires two locks on each table if **innodb_table_locks=1** (the default). In addition to a table lock on the MySQL layer, it also acquires an InnoDB table lock. Versions of MySQL before 4.1.2 did not acquire InnoDB table locks; the old behavior can be selected by setting **innodb_table_locks=0**. If no InnoDB table lock is acquired, **LOCK TABLES** completes even if some records of the tables are being locked by other transactions.

  As of MySQL 5.5.3, **innodb_table_locks=0** has no effect for tables locked explicitly with **LOCK TABLES ... WRITE**. It still has an effect for tables locked for read or write by **LOCK TABLES ... WRITE** implicitly (for example, through triggers) or by **LOCK TABLES ... READ**.

- All InnoDB locks held by a transaction are released when the transaction is committed or aborted. Thus, it does not make much sense to invoke **LOCK TABLES** on InnoDB tables in **autocommit=1** mode because the acquired InnoDB table locks would be released immediately.

- You cannot lock additional tables in the middle of a transaction because **LOCK TABLES** performs an implicit **COMMIT** and **UNLOCK TABLES**.

- The limit of 1023 concurrent data-modifying transactions has been raised in MySQL 5.5 and above. The limit is now 128 * 1023 concurrent transactions that generate undo records. You can remove any workarounds that require changing the proper structure of your transactions, such as committing more frequently.

### 14.10 InnoDB Compressed Tables

By using the SQL syntax and InnoDB configuration options for **compression**, you can create tables where the data is stored in compressed form. Compression can help to improve both raw performance and scalability. The compression means less data is transferred between disk and memory, and takes up less space on disk and in memory. The benefits are amplified for tables with secondary indexes, because index data is compressed also. Compression can be especially important for SSD storage devices, because they tend to have lower capacity than HDD devices.

#### 14.10.1 Overview of Table Compression

Because processors and cache memories have increased in speed more than disk storage devices, many workloads are **disk-bound**. Data **compression** enables smaller database size, reduced I/O, and improved throughput, at the small cost of increased CPU utilization. Compression is especially valuable for read-intensive applications, on systems with enough RAM to keep frequently used data in memory.

An InnoDB table created with **ROW_FORMAT=COMPRESSED** can use a smaller **page size** on disk than the usual 16KB default. Smaller pages require less I/O to read from and write to disk, which is especially valuable for **SSD** devices.
The page size is specified through the `KEY_BLOCK_SIZE` parameter. The different page size means the table must be in its own `.ibd` file rather than in the system tablespace, which requires enabling the `innodb_file_per_table` option. The level of compression is the same regardless of the `KEY_BLOCK_SIZE` value. As you specify smaller values for `KEY_BLOCK_SIZE`, you get the I/O benefits of increasingly smaller pages. But if you specify a value that is too small, there is additional overhead to reorganize the pages when data values cannot be compressed enough to fit multiple rows in each page. There is a hard limit on how small `KEY_BLOCK_SIZE` can be for a table, based on the lengths of the key columns for each of its indexes. Specify a value that is too small, and the `CREATE TABLE` or `ALTER TABLE` statement fails.

In the buffer pool, the compressed data is held in small pages, with a page size based on the `KEY_BLOCK_SIZE` value. For extracting or updating the column values, MySQL also creates a 16KB page in the buffer pool with the uncompressed data. Within the buffer pool, any updates to the uncompressed page are also re-written back to the equivalent compressed page. You might need to size your buffer pool to accommodate the additional data of both compressed and uncompressed pages, although the uncompressed pages are evicted from the buffer pool when space is needed, and then uncompressed again on the next access.

### 14.10.2 Enabling Compression for a Table

Before creating a compressed table, make sure the `innodb_file_per_table` configuration option is enabled, and `innodb_file_format` is set to `Barracuda`. You can set these parameters in the MySQL configuration file `my.cnf` or `my.ini`, or with the `SET` statement without shutting down the MySQL server.

To enable compression for a table, you use the clauses `ROW_FORMAT=COMPRESSED`, `KEY_BLOCK_SIZE`, or both in a `CREATE TABLE` or `ALTER TABLE` statement.

To create a compressed table, you might use statements like these:

```sql
SET GLOBAL innodb_file_per_table=1;
SET GLOBAL innodb_file_format=Barracuda;
CREATE TABLE t1
  (c1 INT PRIMARY KEY)
  ROW_FORMAT=COMPRESSED
  KEY_BLOCK_SIZE=8;
```

- If you specify `ROW_FORMAT=COMPRESSED`, you can omit `KEY_BLOCK_SIZE`; the default compressed page size of 8KB is used.
- If you specify `KEY_BLOCK_SIZE`, you can omit `ROW_FORMAT=COMPRESSED`; compression is enabled automatically.
- To determine the best value for `KEY_BLOCK_SIZE`, typically you create several copies of the same table with different values for this clause, then measure the size of the resulting `.ibd` files and see how well each performs with a realistic workload.
- For additional performance-related configuration options, see Section 14.10.3, “Tuning Compression for InnoDB Tables”.

The default uncompressed size of InnoDB data pages is 16KB. Depending on the combination of option values, MySQL uses a page size of 1KB, 2KB, 4KB, 8KB, or 16KB for the `.ibd` file of the table. The actual compression algorithm is not affected by the `KEY_BLOCK_SIZE` value; the value determines how large each compressed chunk is, which in turn affects how many rows can be packed into each compressed page.

Setting `KEY_BLOCK_SIZE=16` typically does not result in much compression, since the normal InnoDB page size is 16KB. This setting may still be useful for tables with many long `BLOB`, `VARCHAR` or `TEXT`
columns, because such values often do compress well, and might therefore require fewer overflow pages as described in Section 14.10.5, “How Compression Works for InnoDB Tables”.

All indexes of a table (including the clustered index) are compressed using the same page size, as specified in the `CREATE_TABLE` or `ALTER TABLE` statement. Table attributes such as `ROW_FORMAT` and `KEY_BLOCK_SIZE` are not part of the `CREATE_INDEX` syntax, and are ignored if they are specified (although you see them in the output of the `SHOW CREATE TABLE` statement).

**Restrictions on Compressed Tables**

Because MySQL versions prior to 5.1 cannot process compressed tables, using compression requires specifying the configuration parameter `innodb_file_format=Barracuda`, to avoid accidentally introducing compatibility issues.

Table compression is also not available for the InnoDB system tablespace. The system tablespace (space 0, the `ibdata*` files) can contain user data, but it also contains internal system information, and therefore is never compressed. Thus, compression applies only to tables (and indexes) stored in their own tablespaces, that is, created with the `innodb_file_per_table` option enabled.

Compression applies to an entire table and all its associated indexes, not to individual rows, despite the clause name `ROW_FORMAT`.

**14.10.3 Tuning Compression for InnoDB Tables**

Most often, the internal optimizations described in InnoDB Data Storage and Compression ensure that the system runs well with compressed data. However, because the efficiency of compression depends on the nature of your data, you can make decisions that affect the performance of compressed tables:

- Which tables to compress.
- What compressed page size to use.
- Whether to adjust the size of the buffer pool based on run-time performance characteristics, such as the amount of time the system spends compressing and uncompressing data. Whether the workload is more like a data warehouse (primarily queries) or an OLTP system (mix of queries and DML).
- If the system performs DML operations on compressed tables, and the way the data is distributed leads to expensive compression failures at runtime, you might adjust additional advanced configuration options.

Use the guidelines in this section to help make those architectural and configuration choices. When you are ready to conduct long-term testing and put compressed tables into production, see Section 14.10.4, “Monitoring Compression at Runtime” for ways to verify the effectiveness of those choices under real-world conditions.

**When to Use Compression**

In general, compression works best on tables that include a reasonable number of character string columns and where the data is read far more often than it is written. Because there are no guaranteed ways to predict whether or not compression benefits a particular situation, always test with a specific workload and data set running on a representative configuration. Consider the following factors when deciding which tables to compress.

**Data Characteristics and Compression**
A key determinant of the efficiency of compression in reducing the size of data files is the nature of the data itself. Recall that compression works by identifying repeated strings of bytes in a block of data. Completely randomized data is the worst case. Typical data often has repeated values, and so compresses effectively. Character strings often compress well, whether defined in \texttt{CHAR}, \texttt{VARCHAR}, \texttt{TEXT} or \texttt{BLOB} columns. On the other hand, tables containing mostly binary data (integers or floating point numbers) or data that is previously compressed (for example JPEG or PNG images) may not generally compress well, significantly or at all.

You choose whether to turn on compression for each InnoDB table. A table and all of its indexes use the same (compressed) page size. It might be that the \texttt{primary key} (clustered) index, which contains the data for all columns of a table, compresses more effectively than the secondary indexes. For those cases where there are long rows, the use of compression might result in long column values being stored “off-page”, as discussed in Section 14.12.3, “DYNAMIC and COMPRESSED Row Formats”. Those overflow pages may compress well. Given these considerations, for many applications, some tables compress more effectively than others, and you might find that your workload performs best only with a subset of tables compressed.

To determine whether or not to compress a particular table, conduct experiments. You can get a rough estimate of how efficiently your data can be compressed by using a utility that implements LZ77 compression (such as \texttt{gzip} or WinZip) on a copy of the .ibd file for an uncompressed table. You can expect less compression from a MySQL compressed table than from file-based compression tools, because MySQL compresses data in chunks based on the page size, 16KB by default. In addition to user data, the page format includes some internal system data that is not compressed. File-based compression utilities can examine much larger chunks of data, and so might find more repeated strings in a huge file than MySQL can find in an individual page.

Another way to test compression on a specific table is to copy some data from your uncompressed table to a similar, compressed table (having all the same indexes) and look at the size of the resulting .ibd file. For example:

```sql
use test;
set global innodb_file_per_table=1;
set global innodb_file_format=Barracuda;
set global autocommit=0;
-- Create an uncompressed table with a million or two rows.
create table big_table as select * from information_schema.columns;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
commit;
alter table big_table add id int unsigned not null primary key auto_increment;
show create table big_table\G
select count(id) from big_table;
-- Check how much space is needed for the uncompressed table.
\! ls -1 data/test/big_table.ibd
create table key_block_size_4 like big_table;
alter table key_block_size_4 key_block_size=4 row_format=compressed;
insert into key_block_size_4 select * from big_table;
```
Tuning Compression for InnoDB Tables

```sql
commit;
-- Check how much space is needed for a compressed table
-- with particular compression settings.
\! ls -l data/test/key_block_size_4.ibd
```

This experiment produced the following numbers, which of course could vary considerably depending on your table structure and data:

```plaintext
-rw-rw---- 1 cirrus  staff  310378496 Jan  9 13:44 data/test/big_table.ibd
-rw-rw---- 1 cirrus  staff  83886080 Jan  9 15:10 data/test/key_block_size_4.ibd
```

To see whether compression is efficient for your particular workload, use a MySQL instance with no other compressed tables and run queries against the `INFORMATION_SCHEMA.INNODB_CMP` table. For example, you examine the ratio of successful compression operations to overall compression operations. (In the `INNODB_CMP` table, compare `COMPRESS_OPS` to `COMPRESS_OPS_OK`. See `INNODB_CMP` for more information.) If a high percentage of compression operations complete successfully, the table might be a good candidate for compression.

**Compression and Application and Schema Design**

Decide whether to compress data in your application or in the table; do not use both types of compression for the same data. When you compress the data in the application and store the results in a compressed table, extra space savings are extremely unlikely, and the double compression just wastes CPU cycles.

**Compressing in the Database**

The InnoDB table compression is automatic and applies to all columns and index values. The columns can still be tested with operators such as `LIKE`, and sort operations can still use indexes even when the index values are compressed. Because indexes are often a significant fraction of the total size of a database, compression could result in significant savings in storage, I/O or processor time. The compression and decompression operations happen on the database server, which likely is a powerful system that is sized to handle the expected load.

**Compressing in the Application**

If you compress data such as text in your application, before it is inserted into the database, you might save overhead for data that does not compress well by compressing some columns and not others. This approach uses CPU cycles for compression and uncompression on the client machine rather than the database server, which might be appropriate for a distributed application with many clients, or where the client machine has spare CPU cycles.

**Hybrid Approach**

Of course, it is possible to combine these approaches. For some applications, it may be appropriate to use some compressed tables and some uncompressed tables. It may be best to externally compress some data (and store it in uncompressed InnoDB tables) and allow InnoDB to compress (some of) the other tables in the application. As always, up-front design and real-life testing are valuable in reaching the right decision.

**Workload Characteristics and Compression**

In addition to choosing which tables to compress (and the page size), the workload is another key determinant of performance. If the application is dominated by reads, rather than updates, fewer pages need to be reorganized and recompressed after the index page runs out of room for the per-page
“modification log” that InnoDB maintains for compressed data. If the updates predominantly change non-indexed columns or those containing BLOBs or large strings that happen to be stored “off-page”, the overhead of compression may be acceptable. If the only changes to a table are INSERTS that use a monotonically increasing primary key, and there are few secondary indexes, there is little need to reorganize and recompress index pages. Since InnoDB can “delete-mark” and delete rows on compressed pages “in place” by modifying uncompressed data, DELETE operations on a table are relatively efficient.

For some environments, the time it takes to load data can be as important as run-time retrieval. Especially in data warehouse environments, many tables may be read-only or read-mostly. In those cases, it might or might not be acceptable to pay the price of compression in terms of increased load time, unless the resulting savings in fewer disk reads or in storage cost is significant.

Fundamentally, compression works best when the CPU time is available for compressing and uncompressing data. Thus, if your workload is I/O bound, rather than CPU-bound, you might find that compression can improve overall performance. When you test your application performance with different compression configurations, test on a platform similar to the planned configuration of the production system.

Configuration Characteristics and Compression

Reading and writing database pages from and to disk is the slowest aspect of system performance. Compression attempts to reduce I/O by using CPU time to compress and uncompress data, and is most effective when I/O is a relatively scarce resource compared to processor cycles.

This is often especially the case when running in a multi-user environment with fast, multi-core CPUs. When a page of a compressed table is in memory, InnoDB often uses an additional 16K in the buffer pool for an uncompressed copy of the page. The adaptive LRU algorithm in the InnoDB storage engine attempts to balance the use of memory between compressed and uncompressed pages to take into account whether the workload is running in an I/O-bound or CPU-bound manner. Still, a configuration with more memory dedicated to the InnoDB buffer pool tends to run better when using compressed tables than a configuration where memory is highly constrained.

Choosing the Compressed Page Size

The optimal setting of the compressed page size depends on the type and distribution of data that the table and its indexes contain. The compressed page size should always be bigger than the maximum record size, or operations may fail as noted in Compression of B-Tree Pages.

Setting the compressed page size too large wastes some space, but the pages do not have to be compressed as often. If the compressed page size is set too small, inserts or updates may require time-consuming recompression, and the B-tree nodes may have to be split more frequently, leading to bigger data files and less efficient indexing.

Typically, you set the compressed page size to 8K or 4K bytes. Given that the maximum row size for an InnoDB table is around 8K, KEY_BLOCK_SIZE=8 is usually a safe choice.

14.10.4 Monitoring Compression at Runtime

Overall application performance, CPU and I/O utilization and the size of disk files are good indicators of how effective compression is for your application. This section builds on the performance tuning advice from Section 14.10.3, “Tuning Compression for InnoDB Tables”, and shows how to find problems that might not turn up during initial testing.

To dig deeper into performance considerations for compressed tables, you can monitor compression performance at runtime using the Information Schema tables described in Example 14.1, “Using the
Compression Information Schema Tables. These tables reflect the internal use of memory and the rates of compression used overall.

The **INNODB_CMP** table reports information about compression activity for each compressed page size (**KEY_BLOCK_SIZE**) in use. The information in these tables is system-wide: it summarizes the compression statistics across all compressed tables in your database. You can use this data to help decide whether or not to compress a table by examining these tables when no other compressed tables are being accessed. It involves relatively low overhead on the server, so you might query it periodically on a production server to check the overall efficiency of the compression feature.

The key statistics to consider are the number of, and amount of time spent performing, compression and uncompression operations. Since InnoDB must split B-tree nodes when they are too full to contain the compressed data following a modification, compare the number of “successful” compression operations with the number of such operations overall. Based on the information in the **INNODB_CMP** tables and overall application performance and hardware resource utilization, you might make changes in your hardware configuration, adjust the size of the InnoDB buffer pool, choose a different page size, or select a different set of tables to compress.

If the amount of CPU time required for compressing and uncompressing is high, changing to faster CPUs, or those with more cores, can help improve performance with the same data, application workload and set of compressed tables. Increasing the size of the InnoDB buffer pool might also help performance, so that more uncompressed pages can stay in memory, reducing the need to uncompress pages that exist in memory only in compressed form.

A large number of compression operations overall (compared to the number of **INSERT**, **UPDATE** and **DELETE** operations in your application and the size of the database) could indicate that some of your compressed tables are being updated too heavily for effective compression. If so, choose a larger page size, or be more selective about which tables you compress.

If the number of “successful” compression operations (**COMPRESS_OPS_OK**) is a high percentage of the total number of compression operations (**COMPRESS_OPS**), then the system is likely performing well. If the ratio is low, then InnoDB is reorganizing, recompressing, and splitting B-tree nodes more often than is desirable. In this case, avoid compressing some tables, or increase **KEY_BLOCK_SIZE** for some of the compressed tables. You might turn off compression for tables that cause the number of “compression failures” in your application to be more than 1% or 2% of the total. (Such a failure ratio might be acceptable during a temporary operation such as a data load).

### 14.10.5 How Compression Works for InnoDB Tables

This section describes some internal implementation details about compression for InnoDB tables. The information presented here may be helpful in tuning for performance, but is not necessary to know for basic use of compression.

**Compression Algorithms**

Some operating systems implement compression at the file system level. Files are typically divided into fixed-size blocks that are compressed into variable-size blocks, which easily leads into fragmentation. Every time something inside a block is modified, the whole block is recompressed before it is written to disk. These properties make this compression technique unsuitable for use in an update-intensive database system.

InnoDB implements compression with the help of the well-known zlib library, which implements the LZ77 compression algorithm. This compression algorithm is mature, robust, and efficient in both CPU utilization and in reduction of data size. The algorithm is “lossless”, so that the original uncompressed data can
always be reconstructed from the compressed form. LZ77 compression works by finding sequences of data that are repeated within the data to be compressed. The patterns of values in your data determine how well it compresses, but typical user data often compresses by 50% or more.

Unlike compression performed by an application, or compression features of some other database management systems, InnoDB compression applies both to user data and to indexes. In many cases, indexes can constitute 40-50% or more of the total database size, so this difference is significant. When compression is working well for a data set, the size of the InnoDB data files (the .idb files) is 25% to 50% of the uncompressed size or possibly smaller. Depending on the workload, this smaller database can in turn lead to a reduction in I/O, and an increase in throughput, at a modest cost in terms of increased CPU utilization.

**InnoDB Data Storage and Compression**

All user data in InnoDB tables is stored in pages comprising a B-tree index (the clustered index). In some other database systems, this type of index is called an “index-organized table”. Each row in the index node contains the values of the (user-specified or system-generated) primary key and all the other columns of the table.

Secondary indexes in InnoDB tables are also B-trees, containing pairs of values: the index key and a pointer to a row in the clustered index. The pointer is in fact the value of the primary key of the table, which is used to access the clustered index if columns other than the index key and primary key are required. Secondary index records must always fit on a single B-tree page.

The compression of B-tree nodes (of both clustered and secondary indexes) is handled differently from compression of overflow pages used to store long VARCHAR, BLOB, or TEXT columns, as explained in the following sections.

**Compression of B-Tree Pages**

Because they are frequently updated, B-tree pages require special treatment. It is important to minimize the number of times B-tree nodes are split, as well as to minimize the need to uncompress and recompress their content.

One technique InnoDB uses is to maintain some system information in the B-tree node in uncompressed form, thus facilitating certain in-place updates. For example, this allows rows to be delete-marked and deleted without any compression operation.

In addition, InnoDB attempts to avoid unnecessary uncompression and recompression of index pages when they are changed. Within each B-tree page, the system keeps an uncompressed “modification log” to record changes made to the page. Updates and inserts of small records may be written to this modification log without requiring the entire page to be completely reconstructed.

When the space for the modification log runs out, InnoDB uncompresses the page, applies the changes and recompresses the page. If recompression fails (a situation known as a compression failure), the B-tree nodes are split and the process is repeated until the update or insert succeeds.

Generally, InnoDB requires that each B-tree page can accommodate at least two records. For compressed tables, this requirement has been relaxed. Leaf pages of B-tree nodes (whether of the primary key or secondary indexes) only need to accommodate one record, but that record must fit in uncompressed form, in the per-page modification log. Starting with InnoDB storage engine version 1.0.2, and if innodb_strict_mode is ON, the InnoDB storage engine checks the maximum row size during CREATE TABLE or CREATE INDEX. If the row does not fit, the following error message is issued: ERROR HY000: Too big row.
If you create a table when `innodb_strict_mode` is OFF, and a subsequent `INSERT` or `UPDATE` statement fails to create an index entry that does not fit in the size of the compressed page, the operation fails with `ERROR 42000: Row size too large`. (This error message does not name the index for which the record is too large, or mention the length of the index record or the maximum record size on that particular index page.) To solve this problem, rebuild the table with `ALTER TABLE` and select a larger compressed page size (`KEY_BLOCK_SIZE`), shorten any column prefix indexes, or disable compression entirely with `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPACT`.

**Compressing BLOB, VARCHAR, and TEXT Columns**

In an InnoDB table, `BLOB`, `VARCHAR`, and `TEXT` columns that are not part of the primary key may be stored on separately allocated overflow pages. We refer to these columns as off-page columns. Their values are stored on singly-linked lists of overflow pages.

For tables created in `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`, the values of `BLOB`, `TEXT`, or `VARCHAR` columns may be stored fully off-page, depending on their length and the length of the entire row. For columns that are stored off-page, the clustered index record only contains 20-byte pointers to the overflow pages, one per column. Whether any columns are stored off-page depends on the page size and the total size of the row. When the row is too long to fit entirely within the page of the clustered index, MySQL chooses the longest columns for off-page storage until the row fits on the clustered index page. As noted above, if a row does not fit by itself on a compressed page, an error occurs.

**Note**

For tables created in `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`, `TEXT` and `BLOB` columns that are less than or equal to 40 bytes are always stored in-line.

Tables created in older versions of InnoDB use the Antelope file format, which supports only `ROW_FORMAT=REDUNDANT` and `ROW_FORMAT=COMPACT`. In these formats, MySQL stores the first 768 bytes of `BLOB`, `VARCHAR`, and `TEXT` columns in the clustered index record along with the primary key. The 768-byte prefix is followed by a 20-byte pointer to the overflow pages that contain the rest of the column value.

When a table is in `COMPRESSED` format, all data written to overflow pages is compressed “as is”; that is, InnoDB applies the zlib compression algorithm to the entire data item. Other than the data, compressed overflow pages contain an uncompressed header and trailer comprising a page checksum and a link to the next overflow page, among other things. Therefore, very significant storage savings can be obtained for longer `BLOB`, `TEXT`, or `VARCHAR` columns if the data is highly compressible, as is often the case with text data. Image data, such as JPEG, is typically already compressed and so does not benefit much from being stored in a compressed table; the double compression can waste CPU cycles for little or no space savings.

The overflow pages are of the same size as other pages. A row containing ten columns stored off-page occupies ten overflow pages, even if the total length of the columns is only 8K bytes. In an uncompressed table, ten uncompressed overflow pages occupy 160K bytes. In a compressed table with an 8K page size, they occupy only 80K bytes. Thus, it is often more efficient to use compressed table format for tables with long column values.

Using a 16K compressed page size can reduce storage and I/O costs for `BLOB`, `VARCHAR`, or `TEXT` columns, because such data often compress well, and might therefore require fewer overflow pages, even though the B-tree nodes themselves take as many pages as in the uncompressed form.

**Compression and the InnoDB Buffer Pool**

In a compressed InnoDB table, every compressed page (whether 1K, 2K, 4K or 8K) corresponds to an uncompressed page of 16K bytes. To access the data in a page, InnoDB reads the compressed page.
from disk if it is not already in the buffer pool, then uncompresses the page to its original form. This section
describes how InnoDB manages the buffer pool with respect to pages of compressed tables.

To minimize I/O and to reduce the need to uncompress a page, at times the buffer pool contains both
the compressed and uncompressed form of a database page. To make room for other required database
pages, InnoDB may evict from the buffer pool an uncompressed page, while leaving the compressed page
in memory. Or, if a page has not been accessed in a while, the compressed form of the page might be
written to disk, to free space for other data. Thus, at any given time, the buffer pool might contain both
the compressed and uncompressed forms of the page, or only the compressed form of the page, or neither.

InnoDB keeps track of which pages to keep in memory and which to evict using a least-recently-used
(LRU) list, so that hot (frequently accessed) data tends to stay in memory. When compressed tables are
accessed, MySQL uses an adaptive LRU algorithm to achieve an appropriate balance of compressed
and uncompressed pages in memory. This adaptive algorithm is sensitive to whether the system is
running in an I/O-bound or CPU-bound manner. The goal is to avoid spending too much processing time
uncompressing pages when the CPU is busy, and to avoid doing excess I/O when the CPU has spare
cycles that can be used for uncompressing compressed pages (that may already be in memory). When
the system is I/O-bound, the algorithm prefers to evict the uncompressed copy of a page rather than both
copies, to make more room for other disk pages to become memory resident. When the system is CPU-
bound, MySQL prefers to evict both the compressed and uncompressed page, so that more memory can
be used for “hot” pages and reducing the need to uncompress data in memory only in compressed form.

Compression and the InnoDB Redo Log Files

Before a compressed page is written to a data file, MySQL writes a copy of the page to the redo log (if
it has been recompressed since the last time it was written to the database). This is done to ensure that
redo logs are usable for crash recovery, even in the unlikely case that the zlib library is upgraded and
that change introduces a compatibility problem with the compressed data. Therefore, some increase in
the size of log files, or a need for more frequent checkpoints, can be expected when using compression.
The amount of increase in the log file size or checkpoint frequency depends on the number of times
compressed pages are modified in a way that requires reorganization and recompression.

Note that compressed tables use a different file format for the redo log and the per-table tablespaces than
in MySQL 5.1 and earlier. The MySQL Enterprise Backup product supports this latest Barracuda file format
for compressed InnoDB tables. The older InnoDB Hot Backup product can only back up tables using the
file format Antelope, and thus does not support compressed InnoDB tables.

14.10.6 SQL Compression Syntax Warnings and Errors

Specifying ROW_FORMAT=COMPRESSED or KEY_BLOCK_SIZE in CREATE TABLE or ALTER TABLE
statements produces the following warnings if the Barracuda file format is not enabled. You can view them
with the SHOW WARNINGS statement.

<table>
<thead>
<tr>
<th>Level</th>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Warning</td>
<td>1478</td>
<td>InnoDB: KEY_BLOCK_SIZE requires innodb_file_per_table.</td>
</tr>
<tr>
<td>Warning</td>
<td>1478</td>
<td>InnoDB: KEY_BLOCK_SIZE requires innodb_file_format=1</td>
</tr>
<tr>
<td>Warning</td>
<td>1478</td>
<td>InnoDB: ignoring KEY_BLOCK_SIZE=4.</td>
</tr>
<tr>
<td>Warning</td>
<td>1478</td>
<td>InnoDB: ROW_FORMAT=COMPRESSED requires innodb_file_per_table.</td>
</tr>
<tr>
<td>Warning</td>
<td>1478</td>
<td>InnoDB: assuming ROW_FORMAT=COMPACT.</td>
</tr>
</tbody>
</table>

Notes:
• By default, these messages are only warnings, not errors, and the table is created without compression, as if the options were not specified.

• When innodb_strict_mode is enabled, MySQL generates an error, not a warning, for these cases. The table is not created if the current configuration does not permit using compressed tables.

The “non-strict” behavior lets you import a mysqldump file into a database that does not support compressed tables, even if the source database contained compressed tables. In that case, MySQL creates the table in ROW_FORMAT=COMPACT instead of preventing the operation.

To import the dump file into a new database, and have the tables re-created as they exist in the original database, ensure the server has the proper settings for the configuration parameters innodb_file_format and innodb_file_per_table.

The attribute KEY_BLOCK_SIZE is permitted only when ROW_FORMAT is specified as COMPRESSED or is omitted. Specifying a KEY_BLOCK_SIZE with any other ROW_FORMAT generates a warning that you can view with SHOW WARNINGS. However, the table is non-compressed; the specified KEY_BLOCK_SIZE is ignored.

<table>
<thead>
<tr>
<th>Level</th>
<th>Code</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>Warning</td>
<td>1478</td>
<td>InnoDB: ignoring KEY_BLOCK_SIZE=n unless ROW_FORMAT=COMPRESSED.</td>
</tr>
</tbody>
</table>

If you are running with innodb_strict_mode enabled, the combination of a KEY_BLOCK_SIZE with any ROW_FORMAT other than COMPRESSED generates an error, not a warning, and the table is not created.

Table 14.1, “Meaning of CREATE TABLE and ALTER TABLE options” summarizes how the various options on CREATE TABLE and ALTER TABLE are handled.

Table 14.1 Meaning of CREATE TABLE and ALTER TABLE options

<table>
<thead>
<tr>
<th>Option</th>
<th>Usage</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROW_FORMAT= REDUNDANT</td>
<td>Storage format used prior to MySQL 5.0.3</td>
<td>Less efficient than ROW_FORMAT=COMPACT; for backward compatibility</td>
</tr>
<tr>
<td>ROW_FORMAT= COMPACT</td>
<td>Default storage format since MySQL 5.0.3</td>
<td>Stores a prefix of 768 bytes of long column values in the clustered index page, with the remaining bytes stored in an overflow page</td>
</tr>
<tr>
<td>ROW_FORMAT= DYNAMIC</td>
<td>Available only with innodb_file_format=Barracuda</td>
<td>Store values within the clustered index page if they fit; if not, stores only a 20-byte pointer to an overflow page (no prefix)</td>
</tr>
<tr>
<td>ROW_FORMAT= COMPRESSED</td>
<td>Available only with innodb_file_format=Barracuda</td>
<td>Compresses the table and indexes using zlib to default compressed page size of 8K bytes; implies ROW_FORMAT=DYNAMIC</td>
</tr>
<tr>
<td>KEY_BLOCK_SIZE=n</td>
<td>Available only with innodb_file_format=Barracuda</td>
<td>Specifies compressed page size of 1, 2, 4, 8 or 16 kilobytes; implies ROW_FORMAT=DYNAMIC and ROW_FORMAT=COMPRESSED</td>
</tr>
</tbody>
</table>

Table 14.2, “CREATE/ALTER TABLE Warnings and Errors when InnoDB Strict Mode is OFF” summarizes error conditions that occur with certain combinations of configuration parameters and options on the CREATE_TABLE or ALTER_TABLE statements, and how the options appear in the output of SHOW TABLE STATUS.

When innodb_strict_mode is OFF, InnoDB creates or alters the table, but ignores certain settings as shown below. You can see the warning messages in the MySQL error log. When innodb_strict_mode
is **ON**, these specified combinations of options generate errors, and the table is not created or altered. To see the full description of the error condition, issue the `SHOW ERRORS` statement: example:

```sql
mysql> CREATE TABLE x (id INT PRIMARY KEY, c INT)
    -> ENGINE=INNODB KEY_BLOCK_SIZE=33333;
ERROR 1005 (HY000): Can't create table 'test.x' (errno: 1478)
```

```sql
mysql> SHOW ERRORS;
+-------+------+-------------------------------------------+
| Level | Code | Message                                   |
|-------+------+-------------------------------------------+
| Error | 1478 | InnoDB: invalid KEY_BLOCK_SIZE=33333.     |
| Error | 1005 | Can't create table 'test.x' (errno: 1478) |
+-------+------+-------------------------------------------+
2 rows in set (0.00 sec)
```

### Table 14.2 CREATE/ALTER TABLE Warnings and Errors when InnoDB Strict Mode is OFF

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Warning or Error Condition</th>
<th>Resulting ROW_FORMAT, as shown in SHOW TABLE STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ROW_FORMAT=REDUNDANT</code></td>
<td>None</td>
<td>REDUNDANT</td>
</tr>
<tr>
<td><code>ROW_FORMAT=COMPACT</code></td>
<td>None</td>
<td>COMPACT</td>
</tr>
<tr>
<td><code>ROW_FORMAT=COMPRESSED</code> or <code>ROW_FORMAT=DYNAMIC</code> or <code>KEY_BLOCK_SIZE</code> is specified</td>
<td>Ignored unless both <code>innodb_file_format=Barracuda</code> and <code>innodb_file_per_table</code> are enabled</td>
<td>COMPACT</td>
</tr>
<tr>
<td>Invalid <code>KEY_BLOCK_SIZE</code> is specified (not 1, 2, 4, 8 or 16)</td>
<td><code>KEY_BLOCK_SIZE</code> is ignored</td>
<td>the requested one, or COMPACT by default</td>
</tr>
<tr>
<td><code>ROW_FORMAT=COMPRESSED</code> and valid <code>KEY_BLOCK_SIZE</code> are specified</td>
<td>None; <code>KEY_BLOCK_SIZE</code> specified is used, not the 8K default</td>
<td>COMPRESSED</td>
</tr>
<tr>
<td><code>KEY_BLOCK_SIZE</code> is specified with <code>REDUNDANT</code>, <code>COMPACT</code> or <code>DYNAMIC</code> row format</td>
<td><code>KEY_BLOCK_SIZE</code> is ignored</td>
<td>REDUNDANT, COMPACT or DYNAMIC</td>
</tr>
<tr>
<td><code>ROW_FORMAT</code> is not one of <code>REDUNDANT</code>, <code>COMPACT</code>, <code>DYNAMIC</code> or <code>COMPRESSED</code></td>
<td>Ignored if recognized by the MySQL parser. Otherwise, an error is issued.</td>
<td>COMPACT or N/A</td>
</tr>
</tbody>
</table>

When `innodb_strict_mode` is **ON**, the InnoDB storage engine rejects invalid `ROW_FORMAT` or `KEY_BLOCK_SIZE` parameters. For compatibility with earlier versions of MySQL, strict mode is not enabled by default; instead, MySQL issues warnings (not errors) for ignored invalid parameters.

Note that it is not possible to see the chosen `KEY_BLOCK_SIZE` using `SHOW TABLE STATUS`. The statement `SHOW CREATE TABLE` displays the `KEY_BLOCK_SIZE` (even if it was ignored when creating the table). The real compressed page size of the table cannot be displayed by MySQL.

### 14.11 InnoDB File-Format Management
Enabling File Formats

As InnoDB evolves, new on-disk data structures are sometimes required to support new features. Features such as compressed tables (see Section 14.10, “InnoDB Compressed Tables”), and long variable-length columns stored off-page (see Section 14.12, “InnoDB Row Storage and Row Formats”) require data file formats that are not compatible with prior versions of InnoDB. These features both require use of the new Barracuda file format.

Note

All other new features are compatible with the original Antelope file format and do not require the Barracuda file format.

This section discusses enabling file formats for new InnoDB tables, verifying compatibility of different file formats between MySQL releases, identifying the file format in use, downgrading the file format, and file format names that may be used in the future.

Named File Formats. InnoDB 1.1 uses named file formats to help manage compatibility in upgrade and downgrade situations, or heterogeneous systems running different levels of MySQL. Currently, Antelope and Barracuda file formats are supported. Barracuda is the newest file format. It supports important InnoDB features such as compressed tables and the DYNAMIC row format for more efficient BLOB storage. The original InnoDB file format, which previously did not have a name, is now known as Antelope. Future versions of InnoDB may introduce a series of file formats, identified with the names of animals, in ascending alphabetic order.

14.11.1 Enabling File Formats

The innodb_file_format configuration parameter defines the file format to use for new InnoDB tables. This parameter is only applicable for tables that have their own tablespace, and therefore requires that innodb_file_per_table be enabled.

The innodb_file_format parameter currently supports Antelope and Barracuda file formats. To create new tables that take advantage of features supported by the Barracuda file format, such as table compression or the new DYNAMIC row format, set innodb_file_format to BARRACUDA.

To preclude the use of new features supported by the Barracuda file format that would make your database inaccessible to the built-in InnoDB in MySQL 5.1 and prior releases, omit innodb_file_format or set it to Antelope.

You can set the value of innodb_file_format on the command line when you start mysqld, or in the option file my.cnf (Unix operating systems) or my.ini (Windows). You can also change it dynamically with the SET GLOBAL statement.

mysql> SET GLOBAL innodb_file_format=BARRACUDA;
Query OK, 0 rows affected (0.00 sec)

Although Oracle recommends using the Barracuda format for new tables where practical, in MySQL 5.5 the default file format is still Antelope, for maximum compatibility with replication configurations containing different MySQL releases.

14.11.2 Verifying File Format Compatibility

InnoDB 1.1 incorporates several checks to guard against the possible crashes and data corruptions that might occur if you run an older release of the MySQL server on InnoDB data files using a newer file format.
Verifying File Format Compatibility

These checks take place when the server is started, and when you first access a table. This section describes these checks, how you can control them, and error and warning conditions that might arise.

**Backward Compatibility**

Considerations of backward compatibility only apply when using a recent version of InnoDB (the InnoDB Plugin, or MySQL 5.5 and higher with InnoDB 1.1) alongside an older one (MySQL 5.1 or earlier, with the built-in InnoDB rather than the InnoDB Plugin). To minimize the chance of compatibility issues, you can standardize on the InnoDB Plugin for all your MySQL 5.1 and earlier database servers.

In general, a newer version of InnoDB may create a table or index that cannot safely be read or written with a prior version of InnoDB without risk of crashes, hangs, wrong results or corruptions. InnoDB 1.1 includes a mechanism to guard against these conditions, and to help preserve compatibility among database files and versions of InnoDB. This mechanism lets you take advantage of some new features of an InnoDB release (such as performance improvements and bug fixes), and still preserve the option of using your database with a prior version of InnoDB, by preventing accidental use of new features that create downward-incompatible disk files.

If a version of InnoDB supports a particular file format (whether or not that format is the default), you can query and update any table that requires that format or an earlier format. Only the creation of new tables using new features is limited based on the particular file format enabled. Conversely, if a tablespace contains a table or index that uses a file format that is not supported by the currently running software, it cannot be accessed at all, even for read access.

The only way to “downgrade” an InnoDB tablespace to an earlier file format is to copy the data to a new table, in a tablespace that uses the earlier format. This can be done with the `ALTER TABLE` statement, as described in Section 14.11.4, “Downgrading the File Format”.

The easiest way to determine the file format of an existing InnoDB tablespace is to examine the properties of the table it contains, using the `SHOW TABLE STATUS` command or querying the table `INFORMATION_SCHEMA.TABLES`. If the `Row_format` of the table is reported as 'Compressed' or 'Dynamic', the tablespace containing the table uses the Barracuda format. Otherwise, it uses the prior InnoDB file format, Antelope.

**Internal Details**

Every InnoDB per-table tablespace (represented by a `*.ibd` file) file is labeled with a file format identifier. The system tablespace (represented by the `ibdata` files) is tagged with the “highest” file format in use in a group of InnoDB database files, and this tag is checked when the files are opened.

Creating a compressed table, or a table with `ROW_FORMAT=DYNAMIC`, updates the file header for the corresponding `.ibd` file and the table type in the InnoDB data dictionary with the identifier for the Barracuda file format. From that point forward, the table cannot be used with a version of InnoDB that does not support this new file format. To protect against anomalous behavior, InnoDB version 5.0.21 and later performs a compatibility check when the table is opened. (In many cases, the `ALTER TABLE` statement recreates a table and thus changes its properties. The special case of adding or dropping indexes without rebuilding the table is described in Section 14.14, “InnoDB Fast Index Creation”.)

**Definition of ib-file set**

To avoid confusion, for the purposes of this discussion we define the term “ib-file set” to mean the set of operating system files that InnoDB manages as a unit. The ib-file set includes the following files:

- The system tablespace (one or more `ibdata` files) that contain internal system information (including internal catalogs and undo information) and may include user data and indexes.
14.11.2.1 Compatibility Check When InnoDB Is Started

To prevent possible crashes or data corruptions when InnoDB opens an ib-file set, it checks that it can fully support the file formats in use within the ib-file set. If the system is restarted following a crash, or a “fast shutdown” (i.e., `innodb_fast_shutdown` is greater than zero), there may be on-disk data structures (such as redo or undo entries, or doublewrite pages) that are in a “too-new” format for the current software. During the recovery process, serious damage can be done to your data files if these data structures are accessed. The startup check of the file format occurs before any recovery process begins, thereby preventing consistency issues with the new tables or startup problems for the MySQL server.

Beginning with version InnoDB 1.0.1, the system tablespace records an identifier or tag for the “highest” file format used by any table in any of the tablespaces that is part of the ib-file set. Checks against this file format tag are controlled by the configuration parameter `innodb_file_format_check`, which is ON by default.

If the file format tag in the system tablespace is newer or higher than the highest version supported by the particular currently executing software and if `innodb_file_format_check` is ON, the following error is issued when the server is started:

```
InnoDB: Error: the system tablespace is in a file format that this version doesn’t support
```

You can also set `innodb_file_format` to a file format name. Doing so prevents InnoDB from starting if the current software does not support the file format specified. It also sets the “high water mark” to the value you specify. The ability to set `innodb_file_format_check` will be useful (with future releases of InnoDB) if you manually “downgrade” all of the tables in an ib-file set (as described in Section 14.4, “Downgrading the InnoDB Storage Engine”). You can then rely on the file format check at startup if you subsequently use an older version of InnoDB to access the ib-file set.

In some limited circumstances, you might want to start the server and use an ib-file set that is in a “too new” format (one that is not supported by the software you are using). If you set the configuration parameter `innodb_file_format_check` to OFF, InnoDB opens the database, but issues this warning message in the error log:

```
InnoDB: Warning: the system tablespace is in a file format that this version doesn’t support
```

**Note**

This is a very dangerous setting, as it permits the recovery process to run, possibly corrupting your database if the previous shutdown was a crash or “fast shutdown”. You should only set `innodb_file_format_check` to OFF if you are sure that the
previous shutdown was done with `innodb_fast_shutdown=0`, so that essentially no recovery process occurs. In a future release, this parameter setting may be renamed from `OFF` to `UNSAFE`. (However, until there are newer releases of InnoDB that support additional file formats, even disabling the startup checking is in fact “safe”.)

The parameter `innodb_file_format_check` affects only what happens when a database is opened, not subsequently. Conversely, the parameter `innodb_file_format` (which enables a specific format) only determines whether or not a new table can be created in the enabled format and has no effect on whether or not a database can be opened.

The file format tag is a “high water mark”, and as such it is increased after the server is started, if a table in a “higher” format is created or an existing table is accessed for read or write (assuming its format is supported). If you access an existing table in a format higher than the format the running software supports, the system tablespace tag is not updated, but table-level compatibility checking applies (and an error is issued), as described in Section 14.11.2.2, “Compatibility Check When a Table Is Opened”. Any time the high water mark is updated, the value of `innodb_file_format_check` is updated as well, so the command `SELECT @@innodb_file_format_check;` displays the name of the newest file format known to be used by tables in the currently open ib-file set and supported by the currently executing software.

To best illustrate this behavior, consider the scenario described in Table 14.3, “InnoDB Data File Compatibility and Related InnoDB Parameters”. Imagine that some future version of InnoDB supports the Cheetah format and that an ib-file set has been used with that version.

### Table 14.3 InnoDB Data File Compatibility and Related InnoDB Parameters

#### 14.11.2.2 Compatibility Check When a Table Is Opened

When a table is first accessed, InnoDB (including some releases prior to InnoDB 1.0) checks that the file format of the tablespace in which the table is stored is fully supported. This check prevents crashes or corruptions that would otherwise occur when tables using a “too new” data structure are encountered.
All tables using any file format supported by a release can be read or written (assuming the user has sufficient privileges). The setting of the system configuration parameter `innodb_file_format` can prevent creating a new table that uses specific file formats, even if they are supported by a given release. Such a setting might be used to preserve backward compatibility, but it does not prevent accessing any table that uses any supported format.

As noted in Named File Formats, versions of MySQL older than 5.0.21 cannot reliably use database files created by newer versions if a new file format was used when a table was created. To prevent various error conditions or corruptions, InnoDB checks file format compatibility when it opens a file (for example, upon first access to a table). If the currently running version of InnoDB does not support the file format identified by the table type in the InnoDB data dictionary, MySQL reports the following error:

```sql
ERROR 1146 (42S02): Table 'test.t1' doesn't exist
```

InnoDB also writes a message to the error log:

```sql
InnoDB: table test/t1: unknown table type 33
```

The table type should be equal to the tablespace flags, which contains the file format version as discussed in Section 14.11.3, "Identifying the File Format in Use".

Versions of InnoDB prior to MySQL 4.1 did not include table format identifiers in the database files, and versions prior to MySQL 5.0.21 did not include a table format compatibility check. Therefore, there is no way to ensure proper operations if a table in a “too new” format is used with versions of InnoDB prior to 5.0.21.

The file format management capability in InnoDB 1.0 and higher (tablespace tagging and run-time checks) allows InnoDB to verify as soon as possible that the running version of software can properly process the tables existing in the database.

If you permit InnoDB to open a database containing files in a format it does not support (by setting the parameter `innodb_file_format_check` to OFF), the table-level checking described in this section still applies.

Users are strongly urged not to use database files that contain Barracuda file format tables with releases of InnoDB older than the MySQL 5.1 with the InnoDB Plugin. It is possible to “downgrade” such tables to the Antelope format with the procedure described in Section 14.11.4, “Downgrading the File Format”.

### 14.11.3 Identifying the File Format in Use

After you enable a given `innodb_file_format`, this change applies only to newly created tables rather than existing ones. If you do create a new table, the tablespace containing the table is tagged with the “earliest” or “simplest” file format that is required for the table’s features. For example, if you enable file format Barracuda, and create a new table that is not compressed and does not use `ROW_FORMAT=DYNAMIC`, the new tablespace that contains the table is tagged as using file format Antelope.

It is easy to identify the file format used by a given tablespace or table. The table uses the Barracuda format if the `Row_format` reported by `SHOW CREATE TABLE` or `INFORMATION_SCHEMA.TABLES` is one of ‘Compressed’ or ‘Dynamic’. (The `Row_format` is a separate column; ignore the contents of the `Create_options` column, which may contain the string `ROW_FORMAT`.) If the table in a tablespace uses neither of those features, the file uses the format supported by prior releases of InnoDB, now called file format Antelope. Then, the `Row_format` is one of ‘Redundant’ or ‘Compact’. 

---

**Identifying the File Format in Use**

**14.11.3 Identifying the File Format in Use**

After you enable a given `innodb_file_format`, this change applies only to newly created tables rather than existing ones. If you do create a new table, the tablespace containing the table is tagged with the “earliest” or “simplest” file format that is required for the table’s features. For example, if you enable file format Barracuda, and create a new table that is not compressed and does not use `ROW_FORMAT=DYNAMIC`, the new tablespace that contains the table is tagged as using file format Antelope.

It is easy to identify the file format used by a given tablespace or table. The table uses the Barracuda format if the `Row_format` reported by `SHOW CREATE TABLE` or `INFORMATION_SCHEMA.TABLES` is one of ‘Compressed’ or ‘Dynamic’. (The `Row_format` is a separate column; ignore the contents of the `Create_options` column, which may contain the string `ROW_FORMAT`.) If the table in a tablespace uses neither of those features, the file uses the format supported by prior releases of InnoDB, now called file format Antelope. Then, the `Row_format` is one of ‘Redundant’ or ‘Compact’. 

---

1702
Internal Details

InnoDB has two different file formats (Antelope and Barracuda) and four different row formats (Redundant, Compact, Dynamic, and Compressed). The Antelope file format contains Redundant and Compact row formats. A tablespace that uses the Barracuda file format uses either the Dynamic or Compressed row format.

File and row format information is written in the tablespace flags (a 32-bit number) in the *.ibd file in the 4 bytes starting at position 54 of the file, most significant byte first (the first byte of the file is byte zero). On some systems, you can display these bytes in hexadecimal with the command od -t x1 -j 54 -N 4 tablename.ibd. If all bytes are zero, the tablespace uses the Antelope file format, which is the format used by the standard InnoDB storage engine up to MySQL 5.1.

The first 6 bits of the tablespace flags can be described this way:

- Bit 0: Zero for Antelope and no other bits will be set. One for Barracuda, and other bits may be set.
- Bits 1 to 4: A 4 bit number representing the compressed page size. zero = not compressed, 1 = 1k, 2 = 2k, 3 = 4k, 4 = 8k.
- Bit 5: Same value as Bit 0, zero for Antelope, and one for Barracuda. If Bit 0 and Bit 5 are set and Bits 1 to 4 are not, the row format is “Dynamic”.

Until MySQL 5.6, no other bits are set in the tablespace flags. If bits 6 to 31 are not zero, the tablespace is corrupt or is not an InnoDB tablespace file.

14.11.4 Downgrading the File Format

Each InnoDB tablespace file (with a name matching *.ibd) is tagged with the file format used to create its table and indexes. The way to downgrade the tablespace is to re-create the table and its indexes. The easiest way to recreate a table and its indexes is to use the command:

```sql
ALTER TABLE t ROW_FORMAT=COMPACT;
```

on each table that you want to downgrade. The COMPACT row format uses the file format Antelope. It was introduced in MySQL 5.0.3.

14.11.5 Future InnoDB File Formats

The file format used by the standard built-in InnoDB in MySQL 5.1 is the Antelope format. The file format introduced with InnoDB Plugin 1.0 is the Barracuda format. Although no new features have been announced that would require additional new file formats, the InnoDB file format mechanism allows for future enhancements.

For the sake of completeness, these are the file format names that might be used for future file formats: Antelope, Barracuda, Cheetah, Dragon, Elk, Fox, Gazelle, Hornet, Impala, Jaguar, Kangaroo, Leopard, Moose, Nautilus, Ocelot, Porpoise, Quail, Rabbit, Shark, Tiger, Urchin, Viper, Whale, Xenops, Yak and Zebra. These file formats correspond to the internal identifiers 0..25.

14.12 InnoDB Row Storage and Row Formats

This section discusses how certain InnoDB features, such as table compression and off-page storage of long columns, are controlled by the ROW_FORMAT clause of the CREATE TABLE statement. It discusses
Overview of InnoDB Row Storage

considerations for choosing the right row format and compatibility of row formats between MySQL releases.

14.12.1 Overview of InnoDB Row Storage

The storage for rows and associated columns affects performance for queries and DML operations. As more rows fit into a single disk page, queries and index lookups can work faster, less cache memory is required in the InnoDB buffer pool, and less I/O is required to write out updated values for the numeric and short string columns.

The data in each InnoDB table is divided into pages. The pages that make up each table are arranged in a tree data structure called a B-tree index. Table data and secondary indexes both use this type of structure. The B-tree index that represents an entire table is known as the clustered index, which is organized according to the primary key columns. The nodes of the index data structure contain the values of all the columns in that row (for the clustered index) or the index columns and the primary key columns (for secondary indexes).

Variable-length columns are an exception to this rule. Columns such as BLOB and VARCHAR that are too long to fit on a B-tree page are stored on separately allocated disk pages called overflow pages. We call such columns off-page columns. The values of these columns are stored in singly-linked lists of overflow pages, and each such column has its own list of one or more overflow pages. In some cases, all or a prefix of the long column value is stored in the B-tree, to avoid wasting storage and eliminating the need to read a separate page.

The Barracuda file format provides a new option (KEY_BLOCK_SIZE) to control how much column data is stored in the clustered index, and how much is placed on overflow pages.

The next section describes the clauses you can use with the CREATE TABLE and ALTER TABLE statements to control how these variable-length columns are represented: ROW_FORMAT and KEY_BLOCK_SIZE. To use these clauses, you might also need to change the settings for the innodb_file_per_table and innodb_file_format configuration options.

14.12.2 Specifying the Row Format for a Table

You specify the row format for a table with the ROW_FORMAT clause of the CREATE TABLE and ALTER TABLE statements. For example:

```sql
CREATE TABLE t1 (f1 int unsigned) ROW_FORMAT=DYNAMIC ENGINE=INNODB;
```

InnoDB ROW_FORMAT options include COMPACT, REDUNDANT, DYNAMIC, and COMPRESSED. For InnoDB tables, rows are stored in COMPACT format (ROW_FORMAT=COMPACT) by default. Refer to the CREATE TABLE documentation for additional information about the ROW_FORMAT table option.

The physical row structure for InnoDB tables is dependant on the ROW_FORMAT that you specify. See Section 14.5.13.6, “Physical Row Structure” for more information.

14.12.3 DYNAMIC and COMPRESSED Row Formats

This section discusses the DYNAMIC and COMPRESSED row formats for InnoDB tables. You can only create these kinds of tables when the innodb_file_format configuration option is set to Barracuda. (The Barracuda file format also allows the COMPACT and REDUNDANT row formats.)

When a table is created with ROW_FORMAT=DYNAMIC or ROW_FORMAT=COMPRESSED, long column values are stored fully off-page, and the clustered index record contains only a 20-byte pointer to the overflow page.
Whether any columns are stored off-page depends on the page size and the total size of the row. When the row is too long, InnoDB chooses the longest columns for off-page storage until the clustered index record fits on the B-tree page. TEXT and BLOB columns that are less than or equal to 40 bytes are always stored in-line.

The DYNAMIC row format maintains the efficiency of storing the entire row in the index node if it fits (as do the COMPACT and REDUNDANT formats), but this new format avoids the problem of filling B-tree nodes with a large number of data bytes of long columns. The DYNAMIC format is based on the idea that if a portion of a long data value is stored off-page, it is usually most efficient to store all of the value off-page. With DYNAMIC format, shorter columns are likely to remain in the B-tree node, minimizing the number of overflow pages needed for any given row.

The COMPRESSED row format uses similar internal details for off-page storage as the DYNAMIC row format, with additional storage and performance considerations from the table and index data being compressed and using smaller page sizes. With the COMPRESSED row format, the option KEY_BLOCK_SIZE controls how much column data is stored in the clustered index, and how much is placed on overflow pages. For full details about the COMPRESSED row format, see Section 14.11, “InnoDB Compressed Tables”.

14.12.4 COMPACT and REDUNDANT Row Formats

Early versions of InnoDB used an unnamed file format (now called Antelope) for database files. With that file format, tables are defined with ROW_FORMAT=COMPACT or ROW_FORMAT=REDUNDANT. InnoDB stores up to the first 768 bytes of variable-length columns (such as BLOB and VARCHAR) in the index record within the B-tree node, with the remainder stored on the overflow pages.

To preserve compatibility with those prior versions, tables created with the newest InnoDB default to the COMPACT row format. See Section 14.12.3, “DYNAMIC and COMPRESSED Row Formats” for information about the newer DYNAMIC and COMPRESSED row formats.

With the Antelope file format, if the value of a column is 768 bytes or less, no overflow page is needed, and some savings in I/O may result, since the value is in the B-tree node. This works well for relatively short BLOBS, but may cause B-tree nodes to fill with data rather than key values, reducing their efficiency. Tables with many BLOB columns could cause B-tree nodes to become too full of data, and contain too few rows, making the entire index less efficient than if the rows were shorter or if the column values were stored off-page.

14.13 InnoDB Disk I/O and File Space Management

As a DBA, you must manage disk I/O to keep the I/O subsystem from becoming saturated, and manage disk space to avoid filling up storage devices. The ACID design model requires a certain amount of I/O that might seem redundant, but helps to ensure data reliability. Within these constraints, InnoDB tries to optimize the database work and the organization of disk files to minimize the amount of disk I/O. Sometimes, I/O is postponed until the database is not busy, or until everything needs to be brought to a consistent state, such as during a database restart after a fast shutdown.

This section discusses the main considerations for I/O and disk space with the default kind of MySQL tables (also known as InnoDB tables):

• Controlling the amount of background I/O used to improve query performance.
• Enabling or disabling features that provide extra durability at the expense of additional I/O.
• Organizing tables into many small files, a few larger files, or a combination of both.
• Balancing the size of redo log files against the I/O activity that occurs when the log files become full.
• How to reorganize a table for optimal query performance.

14.13.1 InnoDB Disk I/O

InnoDB uses asynchronous disk I/O where possible, by creating a number of threads to handle I/O operations, while permitting other database operations to proceed while the I/O is still in progress. On Linux and Windows platforms, InnoDB uses the available OS and library functions to perform “native” asynchronous I/O. On other platforms, InnoDB still uses I/O threads, but the threads may actually wait for I/O requests to complete; this technique is known as “simulated” asynchronous I/O.

Read-Ahead

If InnoDB can determine there is a high probability that data might be needed soon, it performs read-ahead operations to bring that data into the buffer pool so that it is available in memory. Making a few large read requests for contiguous data can be more efficient than making several small, spread-out requests. There are two read-ahead heuristics in InnoDB:

• In sequential read-ahead, if InnoDB notices that the access pattern to a segment in the tablespace is sequential, it posts in advance a batch of reads of database pages to the I/O system.

• In random read-ahead, if InnoDB notices that some area in a tablespace seems to be in the process of being fully read into the buffer pool, it posts the remaining reads to the I/O system.

Doublewrite Buffer

InnoDB uses a novel file flush technique involving a structure called the doublewrite buffer. It adds safety to recovery following an operating system crash or a power outage, and improves performance on most varieties of Unix by reducing the need for fsync() operations.

Before writing pages to a data file, InnoDB first writes them to a contiguous tablespace area called the doublewrite buffer. Only after the write and the flush to the doublewrite buffer has completed does InnoDB write the pages to their proper positions in the data file. If the operating system crashes in the middle of a page write (causing a torn page condition), InnoDB can later find a good copy of the page from the doublewrite buffer during recovery.

14.13.2 File Space Management

The data files that you define in the configuration file form the InnoDB system tablespace. The files are logically concatenated to form the tablespace. There is no striping in use. Currently, you cannot define where within the tablespace your tables are allocated. In a newly created tablespace, InnoDB allocates space starting from the first data file.

To avoid the issues that come with storing all tables and indexes inside the system tablespace, you can turn on the innodb_file_per_table configuration option, which stores each newly created table in a separate tablespace file (with extension .ibd). For tables stored this way, there is less fragmentation within the disk file, and when the table is truncated, the space is returned to the operating system rather than still being reserved by InnoDB within the system tablespace.

Pages, Extents, Segments, and Tablespaces

Each tablespace consists of database pages with a default size of 16KB. The pages are grouped into extents of size 1MB (64 consecutive pages). The “files” inside a tablespace are called segments in InnoDB. (These segments are different from the rollback segment, which actually contains many tablespace segments.)
When a segment grows inside the tablespace, InnoDB allocates the first 32 pages to it one at a time. After that, InnoDB starts to allocate whole extents to the segment. InnoDB can add up to 4 extents at a time to a large segment to ensure good sequentiality of data.

Two segments are allocated for each index in InnoDB. One is for nonleaf nodes of the B-tree, the other is for the leaf nodes. Keeping the leaf nodes contiguous on disk enables better sequential I/O operations, because these leaf nodes contain the actual table data.

Some pages in the tablespace contain bitmaps of other pages, and therefore a few extents in an InnoDB tablespace cannot be allocated to segments as a whole, but only as individual pages.

When you ask for available free space in the tablespace by issuing a \texttt{SHOW TABLE STATUS} statement, InnoDB reports the extents that are definitely free in the tablespace. InnoDB always reserves some extents for cleanup and other internal purposes; these reserved extents are not included in the free space.

When you delete data from a table, InnoDB contracts the corresponding B-tree indexes. Whether the freed space becomes available for other users depends on whether the pattern of deletes frees individual pages or extents to the tablespace. Dropping a table or deleting all rows from it is guaranteed to release the space to other users, but remember that deleted rows are physically removed only by the purge operation, which happens automatically some time after they are no longer needed for transaction rollbacks or consistent reads. (See Section 14.5.12, "InnoDB Multi-Versioning").

To see information about the tablespace, use the Tablespace Monitor. See Section 14.18, "InnoDB Monitors".

**How Pages Relate to Table Rows**

The maximum row length, except for variable-length columns (\texttt{VARBINARY}, \texttt{VARCHAR}, \texttt{BLOB} and \texttt{TEXT}), is slightly less than half of a database page. That is, the maximum row length is about 8000 bytes. \texttt{LONGBLOB} and \texttt{LONGTEXT} columns must be less than 4GB, and the total row length, including \texttt{BLOB} and \texttt{TEXT} columns, must be less than 4GB.

If a row is less than half a page long, all of it is stored locally within the page. If it exceeds half a page, variable-length columns are chosen for external off-page storage until the row fits within half a page. For a column chosen for off-page storage, InnoDB stores the first 768 bytes locally in the row, and the rest externally into overflow pages. Each such column has its own list of overflow pages. The 768-byte prefix is accompanied by a 20-byte value that stores the true length of the column and points into the overflow list where the rest of the value is stored.

**14.13.3 InnoDB Checkpoints**

Making your log files very large may reduce disk I/O during checkpointing. It often makes sense to set the total size of the log files as large as the buffer pool or even larger. Although in the past large log files could make crash recovery take excessive time, starting with MySQL 5.5, performance enhancements to crash recovery make it possible to use large log files with fast startup after a crash. (Strictly speaking, this performance improvement is available for MySQL 5.1 with the InnoDB Plugin 1.0.7 and higher. It is with MySQL 5.5 that this improvement is available in the default InnoDB storage engine.)

**How Checkpoint Processing Works**

InnoDB implements a checkpoint mechanism known as fuzzy checkpointing. InnoDB flushes modified database pages from the buffer pool in small batches. There is no need to flush the buffer pool in one single batch, which would disrupt processing of user SQL statements during the checkpointing process.

During crash recovery, InnoDB looks for a checkpoint label written to the log files. It knows that all modifications to the database before the label are present in the disk image of the database. Then InnoDB scans the log files forward from the checkpoint, applying the logged modifications to the database.
InnoDB writes to its log files on a rotating basis. It also writes checkpoint information to the first log file at each checkpoint. All committed modifications that make the database pages in the buffer pool different from the images on disk must be available in the log files in case InnoDB has to do a recovery. This means that when InnoDB starts to reuse a log file, it has to make sure that the database page images on disk contain the modifications logged in the log file that InnoDB is going to reuse. In other words, InnoDB must create a checkpoint and this often involves flushing of modified database pages to disk.

14.13.4 Defragmenting a Table

Random insertions into or deletions from a secondary index can cause the index to become fragmented. Fragmentation means that the physical ordering of the index pages on the disk is not close to the index ordering of the records on the pages, or that there are many unused pages in the 64-page blocks that were allocated to the index.

One symptom of fragmentation is that a table takes more space than it "should" take. How much that is exactly, is difficult to determine. All InnoDB data and indexes are stored in B-trees, and their fill factor may vary from 50% to 100%. Another symptom of fragmentation is that a table scan such as this takes more time than it "should" take:

```
SELECT COUNT(*) FROM t WHERE non_indexed_column <> 12345;
```

The preceding query requires MySQL to perform a full table scan, the slowest type of query for a large table.

To speed up index scans, you can periodically perform a "null" ALTER TABLE operation, which causes MySQL to rebuild the table:

```
ALTER TABLE tbl_name ENGINE=INNODB
```

Another way to perform a defragmentation operation is to use mysqldump to dump the table to a text file, drop the table, and reload it from the dump file.

If the insertions into an index are always ascending and records are deleted only from the end, the InnoDB filespace management algorithm guarantees that fragmentation in the index does not occur.

14.13.5 Reclaiming Disk Space with TRUNCATE TABLE

To reclaim operating system disk space when truncating an InnoDB table, the table must be stored in its own .ibd file. For a table to be stored in its own .ibd file, innodb_file_per_table must enabled when the table is created. Additionally, there cannot be a foreign key constraint between the table being truncated and other tables, otherwise the TRUNCATE TABLE operation fails. This is a change from previous behavior, which would transform the TRUNCATE operation to a DELETE operation that removes all rows and triggers ON DELETE operations on child tables. A foreign key constraint between two columns in the same table, however, is permitted.

When a table is truncated, it is dropped and re-created in a new .ibd file (previous versions of InnoDB would keep the existing .idb file), and the freed space is returned to the operating system. This is in contrast to truncating InnoDB tables that are stored within the InnoDB system tablespace (tables created when innodb_file_per_table=OFF), where only InnoDB can use the freed space after the table is truncated.

The ability to truncate tables and return disk space to the operating system also means that physical backups can be smaller. Truncating tables that are stored in the system tablespace (tables created when innodb_file_per_table=OFF) leaves blocks of unused space in the system tablespace.
14.14 **InnoDB Fast Index Creation**

In MySQL 5.5 and higher, or in MySQL 5.1 with the InnoDB Plugin, creating and dropping secondary indexes does not copy the contents of the entire table, making this operation much more efficient than with prior releases.

### 14.14.1 Overview of Fast Index Creation

With MySQL 5.5 and higher, or MySQL 5.1 with the InnoDB Plugin, creating and dropping secondary indexes for InnoDB tables is much faster than before. Historically, adding or dropping an index on a table with existing data could be very slow. The `CREATE INDEX` and `DROP INDEX` statements worked by creating a new, empty table defined with the requested set of indexes, then copying the existing rows to the new table one-by-one, updating the indexes as the rows are inserted. After all rows from the original table were copied, the old table was dropped and the copy was renamed with the name of the original table.

The performance speedup for fast index creation applies to secondary indexes, not to the primary key index. The rows of an InnoDB table are stored in a clustered index organized based on the primary key, forming what some database systems call an "index-organized table". Because the table structure is so closely tied to the primary key, redefining the primary key still requires copying the data.

This new mechanism also means that you can generally speed the overall process of creating and loading an indexed table by creating the table with only the clustered index, and adding the secondary indexes after the data is loaded.

Although no syntax changes are required in the `CREATE INDEX` or `DROP INDEX` commands, some factors affect the performance, space usage, and semantics of this operation (see Section 14.14.6, "Limitations of Fast Index Creation").

### 14.14.2 Examples of Fast Index Creation

It is possible to create multiple indexes on a table with one `ALTER TABLE` statement. This is relatively efficient, because the clustered index of the table needs to be scanned only once (although the data is sorted separately for each new index). For example:

```sql
CREATE TABLE T1(A INT PRIMARY KEY, B INT, C CHAR(1)) ENGINE=InnoDB;
INSERT INTO T1 VALUES (1,2,'a'), (2,3,'b'), (3,2,'c'), (4,3,'d'), (5,2,'e');
COMMIT;
ALTER TABLE T1 ADD INDEX (B), ADD UNIQUE INDEX (C);
```

The above statements create table `T1` with the clustered index (primary key) on column `A`, insert several rows, and then build two new indexes on columns `B` and `C`. If there were many rows inserted into `T1` before the `ALTER TABLE` statement, this approach is much more efficient than creating all the secondary indexes before loading the data.

You can also create the indexes one at a time, but then the clustered index of the table is scanned (as well as sorted) once for each `CREATE INDEX` statement. Thus, the following statements are not as efficient as the `ALTER TABLE` statement above, even though neither requires recreating the clustered index for table `T1`:

```sql
CREATE INDEX B ON T1 (B);
CREATE UNIQUE INDEX C ON T1 (C);
```

Dropping InnoDB secondary indexes also does not require any copying of table data. You can equally quickly drop multiple indexes with a single `ALTER TABLE` statement or multiple `DROP INDEX` statements:
Implementation Details of Fast Index Creation

14.14.3 Implementation Details of Fast Index Creation

InnoDB has two types of indexes: the clustered index and secondary indexes. Since the clustered index contains the data values in its B-tree nodes, adding or dropping a clustered index does involve copying the data, and creating a new copy of the table. A secondary index, however, contains only the index key and the value of the primary key. This type of index can be created or dropped without copying the data in the clustered index. Because each secondary index contains copies of the primary key values (used to access the clustered index when needed), when you change the definition of the primary key, all secondary indexes are recreated as well.

Dropping a secondary index is simple. Only the internal InnoDB system tables and the MySQL data dictionary tables are updated to reflect the fact that the index no longer exists. InnoDB returns the storage used for the index to the tablespace that contained it, so that new indexes or additional table rows can use the space.

To add a secondary index to an existing table, InnoDB scans the table, and sorts the rows using memory buffers and temporary files in order by the values of the secondary index key columns. The B-tree is then built in key-value order, which is more efficient than inserting rows into an index in random order. Because the B-tree nodes are split when they fill, building the index in this way results in a higher fill-factor for the index, making it more efficient for subsequent access.

14.14.4 Concurrency Considerations for Fast Index Creation

While an InnoDB secondary index is being created or dropped, the table is locked in shared mode. Any writes to the table are blocked, but the data in the table can be read. When you alter the clustered index of a table, the table is locked in exclusive mode, because the data must be copied. Thus, during the creation of a new clustered index, all operations on the table are blocked.

A CREATE INDEX or ALTER TABLE statement for an InnoDB table always waits for currently executing transactions that are accessing the table to commit or roll back. ALTER TABLE statements that redefine an InnoDB primary key wait for all SELECT statements that access the table to complete, or their containing transactions to commit. No transactions whose execution spans the creation of the index can be accessing the table, because the original table is dropped when the clustered index is restructured.

Once a CREATE INDEX or ALTER TABLE statement that creates an InnoDB secondary index begins executing, queries can access the table for read access, but cannot update the table. If an ALTER
How Crash Recovery Works with Fast Index Creation

The \texttt{TABLE} statement is changing the clustered index for an InnoDB table, all queries wait until the operation completes.

A newly-created InnoDB secondary index contains only the committed data in the table at the time the \texttt{CREATE INDEX} or \texttt{ALTER TABLE} statement begins to execute. It does not contain any uncommitted values, old versions of values, or values marked for deletion but not yet removed from the old index.

Because a newly-created index contains only information about data current at the time the index was created, queries that need to see data that was deleted or changed before the index was created cannot use the index. The only queries that could be affected by this limitation are those executing in transactions that began before the creation of the index was begun. For such queries, unpredictable results could occur. Newer queries can use the index.

14.14.5 How Crash Recovery Works with Fast Index Creation

Although no data is lost if the server crashes while an \texttt{ALTER TABLE} statement is executing, the crash recovery process is different for clustered indexes and secondary indexes.

If the server crashes while creating an InnoDB secondary index, upon recovery, MySQL drops any partially created indexes. You must re-run the \texttt{ALTER TABLE} or \texttt{CREATE INDEX} statement.

When a crash occurs during the creation of an InnoDB clustered index, recovery is more complicated, because the data in the table must be copied to an entirely new clustered index. Remember that all InnoDB tables are stored as clustered indexes. In the following discussion, we use the word table and clustered index interchangeably.

MySQL creates the new clustered index by copying the existing data from the original InnoDB table to a temporary table that has the desired index structure. Once the data is completely copied to this temporary table, the original table is renamed with a different temporary table name. The temporary table comprising the new clustered index is renamed with the name of the original table, and the original table is dropped from the database.

If a system crash occurs while creating a new clustered index, no data is lost, but you must complete the recovery process using the temporary tables that exist during the process. Since it is rare to re-create a clustered index or re-define primary keys on large tables, or to encounter a system crash during this operation, this manual does not provide information on recovering from this scenario. Contact MySQL support.

14.14.6 Limitations of Fast Index Creation

Take the following considerations into account when creating or dropping InnoDB indexes:

- During index creation, files are written to the temporary directory (\texttt{$TMPDIR}$ on Unix, \texttt{%TEMP%} on Windows, or the value of the \texttt{--tmpdir} configuration variable). Each temporary file is large enough to hold one column that makes up the new index, and each one is removed as soon as it is merged into the final index.

- An \texttt{ALTER TABLE} statement that contains \texttt{DROP INDEX} and \texttt{ADD INDEX} clauses that both name the same index uses a table copy, not Fast Index Creation.

- The table is copied, rather than using Fast Index Creation when you create an index on a \texttt{TEMPORARY TABLE}. This has been reported as MySQL Bug #39833.

- To avoid consistency issues between the InnoDB data dictionary and the MySQL data dictionary, the table is copied, rather than using Fast Index Creation when you use the \texttt{ALTER TABLE ... RENAME COLUMN} syntax.
• The statement `ALTER IGNORE TABLE t ADD UNIQUE INDEX` does not delete duplicate rows. This has been reported as MySQL Bug #40344. The `IGNORE` keyword is ignored. If any duplicate rows exist, the operation fails with the following error message:

```
ERROR 23000: Duplicate entry '347' for key 'pl'
```

• As noted above, a newly-created index contains only information about data current at the time the index was created. Therefore, you should not run queries in a transaction that might use a secondary index that did not exist at the beginning of the transaction. There is no way for InnoDB to access “old” data that is consistent with the rest of the data read by the transaction. See the discussion of locking in Section 14.14.4, “Concurrency Considerations for Fast Index Creation”.

Prior to InnoDB storage engine 1.0.4, unexpected results could occur if a query attempts to use an index created after the start of the transaction containing the query. If an old transaction attempts to access a “too new” index, InnoDB storage engine 1.0.4 and later reports an error:

```
ERROR HY000: Table definition has changed, please retry transaction
```

As the error message suggests, committing (or rolling back) the transaction, and restarting it, cures the problem.

• InnoDB storage engine 1.0.2 introduces some improvements in error handling when users attempt to drop indexes. See Section 14.21.5, “InnoDB Error Codes” for information related to errors 1025, 1553, and 42000.

• MySQL 5.5 does not support efficient creation or dropping of `FOREIGN KEY` constraints. Therefore, if you use `ALTER TABLE` to add or remove a `REFERENCES` constraint, the child table is copied, rather than using Fast Index Creation.

• `OPTIMIZE TABLE` for an InnoDB table is mapped to an `ALTER TABLE` operation to rebuild the table and update index statistics and free unused space in the clustered index. This operation does not use fast index creation. Secondary indexes are not created as efficiently because keys are inserted in the order they appeared in the primary key.

### 14.15 InnoDB Startup Options and System Variables

This section describes the InnoDB-related command options and system variables.

• System variables that are true or false can be enabled at server startup by naming them, or disabled by using a `--skip-` prefix. For example, to enable or disable InnoDB checksums, you can use `--innodb_checksums` or `--skip-innodb_checksums` on the command line, or `innodb_checksums` or `skip-innodb_checksums` in an option file.

• System variables that take a numeric value can be specified as `--var_name=value` on the command line or as `var_name=value` in option files.

• Many system variables can be changed at runtime (see Section 5.1.5.2, “Dynamic System Variables”).

• For information about `GLOBAL` and `SESSION` variable scope modifiers, refer to the `SET` statement documentation.

• Certain options control the locations and layout of the InnoDB data files. Section 14.6, “InnoDB Configuration” explains how to use these options.

• Some options, which you might not use initially, help tune InnoDB performance characteristics based on machine capacity and your database `workload`.
For more information on specifying options and system variables, see Section 4.2.3, “Specifying Program Options”.

### InnoDB Command Options

#### --ignore-built-in-innodb

**Deprecated** 5.5.22

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>Option-File Format</th>
<th>System Variable Name</th>
<th>Variable Scope</th>
<th>Dynamic Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>--ignore-built-in-innodb</td>
<td>ignore-built-in-innodb</td>
<td>ignore_builtin_innodb</td>
<td>Global</td>
<td>No</td>
</tr>
</tbody>
</table>

In MySQL 5.1, this option caused the server to behave as if the built-in InnoDB were not present, which enabled InnoDB Plugin to be used instead. In MySQL 5.5, InnoDB is the default storage engine and InnoDB Plugin is not used, so this option has no effect. As of MySQL 5.5.22, it is deprecated and its use results in a warning.

#### --innodb [=value]

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>Option-File Format</th>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>--innodb [=value]</td>
<td>innodb</td>
<td>enumeration</td>
</tr>
</tbody>
</table>

Controls loading of the InnoDB storage engine, if the server was compiled with InnoDB support. This option has a tristate format, with possible values of OFF, ON, or FORCE. See Section 5.1.8.1, "Installing and Uninstalling Plugins".

To disable InnoDB, use `--innodb=OFF` or `--skip-innodb`. In this case, because the default storage engine is InnoDB, the server will not start unless you also use `--default-storage-engine` to set the default to some other engine.

#### --innodb-status-file

<table>
<thead>
<tr>
<th>Name</th>
<th>Cmd-Line</th>
<th>Option File</th>
<th>System Var</th>
<th>Status Var</th>
<th>Var Scope</th>
<th>Dynamic</th>
</tr>
</thead>

</tr>
</tbody>
</table>
### InnoDB System Variables

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-status-file</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>innodb-status-file</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Controls whether InnoDB creates a file named `innodb_status.pid` in the MySQL data directory. If enabled, InnoDB periodically writes the output of `SHOW ENGINE INNODB STATUS` to this file.

By default, the file is not created. To create it, start `mysqld` with the `--innodb-status-file=1` option. The file is deleted during normal shutdown.

- **--skip-innodb**

Disable the InnoDB storage engine. See the description of `--innodb`.

#### InnoDB System Variables

- **ignore_builtin_innodb**

<table>
<thead>
<tr>
<th>Deprecated</th>
<th>5.5.22</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--ignore-builtin-innodb</td>
</tr>
<tr>
<td>Option-File Format</td>
<td>ignore-builtin-innodb</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>ignore_bUILTIN_INNODB</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
</tbody>
</table>

See the description of `--ignore-builtin-innodb` under "InnoDB Command Options" earlier in this section.

- **innodb_adaptive_flushing**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_adaptive_flushing=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>innodb_adaptive_flushing</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>innodb_adaptive_flushing</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>ON</td>
</tr>
</tbody>
</table>

Specifies whether to dynamically adjust the rate of flushing dirty pages in the InnoDB buffer pool based on the workload. Adjusting the flush rate dynamically is intended to avoid bursts of I/O activity. This setting is enabled by default. See Section 14.16.2.2, "Configuring the Rate of InnoDB Buffer Pool."
InnoDB System Variables

For general I/O tuning advice, see Section 8.5.7, “Optimizing InnoDB Disk I/O”.

- **innodb_adaptive_hash_index**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_adaptive_hash_index=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>innodb_adaptive_hash_index</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>innodb_adaptive_hash_index</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Whether the InnoDB adaptive hash index is enabled or disabled. It may be desirable, depending on your workload, to dynamically enable or disable adaptive hash indexing to improve query performance. Because the adaptive hash index may not be useful for all workloads, conduct benchmarks with it both enabled and disabled, using realistic workloads. See Section 14.5.13.5, “Adaptive Hash Indexes” for details.

This variable is enabled by default. As of MySQL 5.5, You can modify this parameter using the SET GLOBAL statement, without restarting the server. Changing the setting requires the SUPER privilege. You can also use --skip-innodb_adaptive_hash_index at server startup to disable it.

Disabling the adaptive hash index empties the hash table immediately. Normal operations can continue while the hash table is emptied, and executing queries that were using the hash table access the index B-trees directly instead. When the adaptive hash index is re-enabled, the hash table is populated again during normal operation.

- **innodb_additional_mem_pool_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_additional_mem_pool_size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>innodb_additional_mem_pool_size</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>innodb_additional_mem_pool_size</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

The size in bytes of a memory pool InnoDB uses to store data dictionary information and other internal data structures. The more tables you have in your application, the more memory you need to allocate here. If InnoDB runs out of memory in this pool, it starts to allocate memory from the operating system and writes warning messages to the MySQL error log. The default value is 8MB.

This variable relates to the InnoDB internal memory allocator, which is unused if innodb_use_sys_malloc is enabled.
**InnoDB System Variables**

- **innodb_autoextend_increment**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_autoextend_increment=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>innodb_autoextend_increment</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>innodb_autoextend_increment</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>64</td>
</tr>
<tr>
<td>Range</td>
<td>1 .. 1000</td>
</tr>
</tbody>
</table>

  The increment size (in MB) for extending the size of an auto-extending system tablespace file when it becomes full. The default value is 8. This variable does not affect the per-table tablespace files that are created if you use `innodb_file_per_table=1`. Those files are auto-extending regardless of the value of `innodb_autoextend_increment`. The initial extensions are by small amounts, after which extensions occur in increments of 4MB.

- **innodb_autoinc_lock_mode**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_autoinc_lock_mode=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>innodb_autoinc_lock_mode</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>innodb_autoinc_lock_mode</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Valid Values</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>2</td>
</tr>
</tbody>
</table>

  The lock mode to use for generating auto-increment values. The permissible values are 0, 1, or 2, for “traditional”, “consecutive”, or “interleaved” lock mode, respectively. Section 14.9.5, “AUTO_INCREMENT Handling in InnoDB”, describes the characteristics of these modes.

  This variable has a default of 1 (“consecutive” lock mode).

- **innodb_buffer_pool_instances**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.5.4</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--innodb_buffer_pool_instances=#</td>
</tr>
<tr>
<td>Option-File Format</td>
<td>innodb_buffer_pool_instances</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>innodb_buffer_pool_instances</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
</tbody>
</table>

  Implemented for 5.5.4.

  The number of buffer pool instances to use. The default is 1. String values are not supported. With 5.5.11, the value can be specified as one or more comma-separated numbers.
InnoDB System Variables

<table>
<thead>
<tr>
<th>Dynamic Variable</th>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Platform Bit Size</td>
</tr>
<tr>
<td></td>
<td>32</td>
</tr>
<tr>
<td></td>
<td>64</td>
</tr>
</tbody>
</table>

The number of regions that the InnoDB buffer pool is divided into. For systems with buffer pools in the multi-gigabyte range, dividing the buffer pool into separate instances can improve concurrency, by reducing contention as different threads read and write to cached pages. Each page that is stored in or read from the buffer pool is assigned to one of the buffer pool instances randomly, using a hashing function. Each buffer pool manages its own free lists, flush lists, LRUs, and all other data structures connected to a buffer pool, and is protected by its own buffer pool mutex.

This option takes effect only when you set the `innodb_buffer_pool_size` to a size of 1GB or more. The total size you specify is divided among all the buffer pools. For best efficiency, specify a combination of `innodb_buffer_pool_instances` and `innodb_buffer_pool_size` so that each buffer pool instance is at least 1GB.

- `innodb_buffer_pool_size`

The size in bytes of the buffer pool, the memory area where InnoDB caches table and index data. The default value is 128MB. The maximum value depends on the CPU architecture; the maximum is 4294967295 ($2^{32}-1$) on 32-bit systems and 18446744073709551615 ($2^{64}-1$) on 64-bit systems. On 32-bit systems, the CPU architecture and operating system may impose a lower practical maximum size than the stated maximum. When the size of the buffer pool is greater than 1GB, setting `innodb_buffer_pool_instances` to a value greater than 1 can improve the scalability on a busy server.
InnoDB System Variables

The larger you set this value, the less disk I/O is needed to access the same data in tables more than once. On a dedicated database server, you might set this to up to 80% of the machine physical memory size. Be prepared to scale back this value if these other issues occur:

- Competition for physical memory might cause paging in the operating system.
- InnoDB reserves additional memory for buffers and control structures, so that the total allocated space is approximately 10% greater than the specified size.
- The address space must be contiguous, which can be an issue on Windows systems with DLLs that load at specific addresses.
- The time to initialize the buffer pool is roughly proportional to its size. On large installations, this initialization time might be significant. For example, on a modern Linux x86_64 server, initialization of a 10GB buffer pool takes approximately 6 seconds. See Section 8.9.1, “The InnoDB Buffer Pool”.

- `innodb_change_buffering`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_change_buffering=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>innodb_change_buffering</td>
</tr>
<tr>

</tr>
<tr>
<td>Valid Values</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

Whether InnoDB performs change buffering, an optimization that delays write operations to secondary indexes so that the I/O operations can be performed sequentially. The permitted values are `inserts` (buffer insert operations), `deletes` (buffer delete operations; strictly speaking, the writes that mark index records for later deletion during a purge operation), `changes` (buffer insert and delete-marking operations), `purges` (buffer purge operations, the writes when deleted index entries are finally garbage-collected), `all` (buffer insert, delete-marking, and purge operations) and `none` (do not buffer any operations). The default is `all`. For details, see Section 14.16.5, “Configuring InnoDB Change Buffering”.  

1721
InnoDB can use checksum validation on all pages read from the disk to ensure extra fault tolerance against broken hardware or data files. This validation is enabled by default. However, under some rare circumstances (such as when running benchmarks) this extra safety feature is unneeded and can be disabled with `--skip-innodb-checksums`.

### innodb_checksums

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb_checksums</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>innodb_checksums</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>innodb_checksums</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>ON</td>
</tr>
</tbody>
</table>

InnoDB can use checksum validation on all pages read from the disk to ensure extra fault tolerance against broken hardware or data files. This validation is enabled by default. However, under some rare circumstances (such as when running benchmarks) this extra safety feature is unneeded and can be disabled with `--skip-innodb-checksums`.

### innodb_commit_concurrency

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb_commit_concurrency=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>innodb_commit_concurrency</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>innodb_commit_concurrency</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 .. 1000</td>
</tr>
</tbody>
</table>

The number of threads that can commit at the same time. A value of 0 (the default) permits any number of transactions to commit simultaneously.

The value of `innodb_commit_concurrency` cannot be changed at runtime from zero to nonzero or vice versa. The value can be changed from one nonzero value to another.

### innodb_concurrency_tickets

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb_concurrency_tickets=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>innodb_concurrency_tickets</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>innodb_concurrency_tickets</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>500</td>
</tr>
<tr>
<td>Range</td>
<td>1 .. 4294967295</td>
</tr>
</tbody>
</table>
InnoDB System Variables

Determines the number of threads that can enter InnoDB concurrently. A thread is placed in a queue when it tries to enter InnoDB if the number of threads has already reached the concurrency limit. When a thread is permitted to enter InnoDB, it is given a number of “free tickets” equal to the value of `innodb_concurrency_tickets`, and the thread can enter and leave InnoDB freely until it has used up its tickets. After that point, the thread again becomes subject to the concurrency check (and possible queuing) the next time it tries to enter InnoDB. The default value is 500.

- `innodb_data_file_path`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_data_file_path=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>innodb_data_file_path</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>innodb_data_file_path</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>ibdata1:10M:autoextend</td>
</tr>
</tbody>
</table>

The paths to individual InnoDB data files and their sizes. The full directory path to each data file is formed by concatenating `innodb_data_home_dir` to each path specified here. The file sizes are specified KB, MB or GB (1024MB) by appending `K`, `M` or `G` to the size value. If specifying data file size in kilobytes (KB), do so in multiples of 1024. Otherwise, KB values are rounded off to nearest megabyte (MB) boundary. The sum of the sizes of the files must be at least slightly larger than 10MB. If you do not specify `innodb_data_file_path`, the default behavior is to create a single auto-extending data file, slightly larger than 10MB, named `ibdata1`. The size limit of individual files is determined by your operating system. You can set the file size to more than 4GB on those operating systems that support big files. You can also use raw disk partitions as data files. For detailed information on configuring InnoDB tablespace files, see Section 14.6, "InnoDB Configuration".

- `innodb_data_home_dir`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_data_home_dir=path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>innodb_data_home_dir</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>innodb_data_home_dir</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>directory name</td>
</tr>
</tbody>
</table>

The common part of the directory path for all InnoDB data files in the system tablespace. This setting does not affect the location of file-per-table tablespaces when `innodb_file_per_table` is enabled. The default value is the MySQL data directory. If you specify the value as an empty string, you can use absolute file paths in `innodb_data_file_path`.

- `innodb_doublewrite`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb-doublewrite</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>innodb_doublewrite</td>
</tr>
</tbody>
</table>
InnoDB System Variables

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>innodb_doublewrite</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
</tbody>
</table>

If this variable is enabled (the default), InnoDB stores all data twice, first to the doublewrite buffer, and then to the actual data files. This variable can be turned off with --skip-innodb_doublewrite for benchmarks or cases when top performance is needed rather than concern for data integrity or possible failures.

- innodb_fast_shutdown

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_fast_shutdown[=#]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>innodb_fast_shutdown</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>innodb_fast_shutdown</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Valid Values</td>
<td>0, 1, 2</td>
</tr>
</tbody>
</table>

The InnoDB shutdown mode. If the value is 0, InnoDB does a slow shutdown, a full purge and an insert buffer merge before shutting down. If the value is 1 (the default), InnoDB skips these operations at shutdown, a process known as a fast shutdown. If the value is 2, InnoDB flushes its logs and shuts down cold, as if MySQL had crashed; no committed transactions are lost, but the crash recovery operation makes the next startup take longer.

The slow shutdown can take minutes, or even hours in extreme cases where substantial amounts of data are still buffered. Use the slow shutdown technique before upgrading or downgrading between MySQL major releases, so that all data files are fully prepared in case the upgrade process updates the file format.

Use innodb_fast_shutdown=2 in emergency or troubleshooting situations, to get the absolute fastest shutdown if data is at risk of corruption.

- innodb_file_format

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_file_format=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>innodb_file_format</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>innodb_file_format</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>(&lt;= 5.5.6)</td>
</tr>
</tbody>
</table>
### InnoDB System Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>string</th>
<th>Default</th>
<th>Antelope</th>
<th>Barracuda</th>
</tr>
</thead>
<tbody>
<tr>
<td>Valid Values</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Permitted Values (&gt;= 5.5.7)</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>string</td>
<td>Default</td>
<td>Antelope</td>
<td>Barracuda</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The **file format** to use for new InnoDB tables. Currently, **Antelope** and **Barracuda** are supported. This applies only for tables that have their own **tablespace**, so for it to have an effect, **innodb_file_per_table** must be enabled. The **Barracuda** file format is required for certain InnoDB features such as table **compression**.

Be aware that **ALTER TABLE** operations that recreate InnoDB tables (**ALTER OFFLINE**) will use the current **innodb_file_format** setting (the conditions outlined above still apply).

- **innodb_file_format_check**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_file_format_check=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>innodb_file_format_check</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>innodb_file_format_check</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

#### Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>string</th>
<th>Default</th>
<th>Antelope</th>
<th>Barracuda</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

As of MySQL 5.5.5, this variable can be set to 1 or 0 at server startup to enable or disable whether InnoDB checks the **file format** tag in the **system tablespace** (for example, **Antelope** or **Barracuda**). If the tag is checked and is higher than that supported by the current version of InnoDB, an error occurs and InnoDB does not start. If the tag is not higher, InnoDB sets the value of **innodb_file_format_max** to the file format tag.

Before MySQL 5.5.5, this variable can be set to 1 or 0 at server startup to enable or disable whether InnoDB checks the file format tag in the shared tablespace. If the tag is checked and is higher than that supported by the current version of InnoDB, an error occurs and InnoDB does not start. If the tag is not higher, InnoDB sets the value of **innodb_file_format_check** to the file format tag, which is the value seen at runtime.
**InnoDB System Variables**

**Note**
Despite the default value sometimes being displayed as ON or OFF, always use the numeric values 1 or 0 to turn this option on or off in your configuration file or command line.

- **innodb_file_format_max**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.5.5</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--innodb_file_format_max=#</code></td>
</tr>
<tr>
<td>Option-File Format</td>
<td><code>innodb_file_format_max</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>innodb_file_format_max</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>Antelope</td>
</tr>
<tr>
<td>Valid Values</td>
<td>Antelope, Barracuda</td>
</tr>
</tbody>
</table>

At server startup, InnoDB sets the value of this variable to the file format tag in the system tablespace (for example, Antelope or Barracuda). If the server creates or opens a table with a “higher” file format, it sets the value of `innodb_file_format_max` to that format.

This variable was added in MySQL 5.5.5.

- **innodb_file_per_table**

<table>
<thead>
<tr>

<td>OFF</td>
</tr>
</tbody>
</table>

When `innodb_file_per_table` is disabled, InnoDB stores the data for all tables and indexes in the ibdata files that make up the system tablespace. This setting reduces the performance overhead of filesystem operations for operations such as DROP TABLE or TRUNCATE TABLE. It is most appropriate for a server environment where entire storage devices are devoted to MySQL data. Because the system tablespace never shrinks, and is shared across all databases in an instance, avoid loading huge
amounts of temporary data on a space-constrained system when `innodb_file_per_table=OFF`. Set up a separate instance in such cases, so that you can drop the entire instance to reclaim the space.

When `innodb_file_per_table` is enabled, InnoDB stores data and indexes for each newly created table in a separate `.ibd` file, rather than in the system tablespace. The storage for these InnoDB tables is reclaimed when the tables are dropped or truncated. This setting enables several other InnoDB features, such as table compression. See Section 14.8.2, “InnoDB File-Per-Table Mode” for details about such features as well as advantages and disadvantages of using file-per-table tablespaces.

Be aware that enabling `innodb_file_per_table` also means that an `ALTER TABLE` operation will move InnoDB table from the system tablespace to an individual `.ibd` file in cases where `ALTER TABLE` recreates the table (ALTER OFFLINE).

In MySQL 5.5 and higher, the configuration parameter `innodb_file_per_table` is dynamic, and can be set `ON` or `OFF` using `SET GLOBAL`. Previously, the only way to set this parameter was in the MySQL configuration file (`my.cnf` or `my.ini`), and changing it required shutting down and restarting the server.

Dynamically changing the value of this parameter requires the `SUPER` privilege and immediately affects the operation of all connections.

- `innodb_flush_log_at_trx_commit`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb_flush_log_at_trx_commit[=#]</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>innodb_flush_log_at_trx_commit</code></td>
</tr>

</tr>
<tr>
<td>2</td>
<td></td>
</tr>
</tbody>
</table>

Controls the balance between strict ACID compliance for commit operations, and higher performance that is possible when commit-related I/O operations are rearranged and done in batches. You can achieve better performance by changing the default value, but then you can lose up to one second worth of transactions in a crash.

- The default value of 1 is required for full ACID compliance. With this value, the log buffer is written out to the log file at each transaction commit and the flush to disk operation is performed on the log file.

- With a value of 0, any `mysqld` process crash can erase the last second of transactions. The log buffer is written out to the log file once per second and the flush to disk operation is performed on the log file, but nothing is done at a transaction commit.

- With a value of 2, an operating system crash or a power outage can erase the last second of commit records. The log buffer is written out to the file at each commit, but the flush to disk operation is not performed on it. However, the flushing on the log file takes place once per second also when the value is 2. Note that the once-per-second flushing is not 100% guaranteed to happen every second, due to process scheduling issues.
InnoDB System Variables

- InnoDB's crash recovery works regardless of the value. Transactions are either applied entirely or erased entirely.

For the greatest possible durability and consistency in a replication setup using InnoDB with transactions, use `innodb_flush_log_at_trx_commit=1` and `sync_binlog=1` in your master server `my.cnf` file.

Caution

Many operating systems and some disk hardware fool the flush-to-disk operation. They may tell `mysqld` that the flush has taken place, even though it has not. Then the durability of transactions is not guaranteed even with the setting 1, and in the worst case a power outage can even corrupt InnoDB data. Using a battery-backed disk cache in the SCSI disk controller or in the disk itself speeds up file flushes, and makes the operation safer. You can also try using the Unix command `hdparm` to disable the caching of disk writes in hardware caches, or use some other command specific to the hardware vendor.

- `innodb_flush_method`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb_flush_method=name</code></th>
</tr>
</thead>
<tbody>
<tr>

</thead>
<tbody>
<tr>
<td><strong>O_DSYNC</strong></td>
<td></td>
</tr>
<tr>
<td><strong>O_DIRECT</strong></td>
<td></td>
</tr>
</tbody>
</table>

Controls the system calls used to flush data to the InnoDB data files and log files, which can influence I/O throughput. This variable is relevant only for Unix and Linux systems. On Windows systems, the flush method is always async_unbuffered and cannot be changed.

By default, InnoDB uses the fsync() system call to flush both the data and log files. If innodb_flush_method option is set to O_DSYNC, InnoDB uses O_SYNC to open and flush the log files, and fsync() to flush the data files. If O_DIRECT is specified (available on some GNU/Linux versions, FreeBSD, and Solaris), InnoDB uses O_DIRECT (or directio() on Solaris) to open the data files, and uses fsync() to flush both the data and log files. Note that InnoDB uses fsync() instead of fdatasync(), and it does not use O_DSYNC by default because there have been problems with it on many varieties of Unix.

Depending on hardware configuration, setting innodb_flush_method to O_DIRECT can either have either a positive or negative effect on performance. Benchmark your particular configuration to decide which setting to use. The mix of read and write operations in your workload can also affect which setting performs better for you. For example, on a system with a hardware RAID controller and battery-backed write cache, O_DIRECT can help to avoid double buffering between the InnoDB buffer pool and the operating system's filesystem cache. On some systems where InnoDB data and log files are located on a SAN, the default value or O_DSYNC might be faster for a read-heavy workload with mostly SELECT statements. Always test this parameter with the same type of hardware and workload that reflects your production environment. For general I/O tuning advice, see Section 8.5.7, “Optimizing InnoDB Disk I/O”.

Formerly, a value of fdatasync also specified the default behavior. This value was removed, due to confusion that a value of fdatasync caused fsync() system calls rather than fdatasync() for flushing. To obtain the default value now, do not set any value for innodb_flush_method at startup.

• innodb_force_load_corrupted

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.5.18</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--innodb_force_load_corrupted</td>
</tr>
<tr>

<td>No</td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Lets InnoDB load tables at startup that are marked as corrupted. Use only during troubleshooting, to recover data that is otherwise inaccessible. When troubleshooting is complete, turn this setting back off and restart the server.

• innodb_force_recovery

| Command-Line Format | --innodb_force_recovery=# |
| Option-File Format | innodb_force_recovery |
| System Variable Name | innodb_force_recovery |
The crash recovery mode, typically only changed in serious troubleshooting situations. Possible values are from 0 to 6. The meanings of these values are described in Section 14.21.2, “Starting InnoDB on a Corrupted Database”.

Warning

Only set this variable greater than 0 in an emergency situation, to dump your tables from a corrupt database. As a safety measure, InnoDB prevents any changes to its data when this variable is greater than 0.

- innodb_io_capacity

The innodb_io_capacity parameter sets an upper limit on the I/O activity performed by the InnoDB background tasks, such as flushing pages from the buffer pool and merging data from the insert buffer. The default value is 200. For busy systems capable of higher I/O rates, you can set a higher value at server startup, to help the server handle the background maintenance work associated with a high rate of row changes. For systems with individual 5400 RPM or 7200 RPM drives, you might lower the value to the former default of 100.

The innodb_io_capacity limit is a total limit for all buffer pool instances. When dirty pages are flushed, the innodb_io_capacity limit is divided equally among buffer pool instances.
InnoDB System Variables

This parameter should be set to approximately the number of I/O operations that the system can perform per second. Ideally, keep this setting as low as practical, but not so low that these background activities fall behind. If the value is too high, data is removed from the buffer pool and insert buffer too quickly to provide significant benefit from the caching.

The value represents an estimated proportion of the I/O operations per second (IOPS) available to older-generation disk drives that could perform about 100 IOPS. The current default of 200 reflects that modern storage devices are capable of much higher I/O rates.

In general, you can increase the value as a function of the number of drives used for InnoDB I/O, particularly fast drives capable of high numbers of IOPS. For example, systems that use multiple disks or solid-state disks for InnoDB are likely to benefit from the ability to control this parameter.

Although you can specify a very high number, in practice such large values have little if any benefit; for example, a value of one million would be considered very high.

You can set the `innodb_io_capacity` value to any number 100 or greater, and the default value is 200. You can set the value of this parameter in the MySQL option file (`my.cnf` or `my.ini`) or change it dynamically with the `SET GLOBAL` command, which requires the `SUPER` privilege.

See Section 14.16.9, “Configuring the InnoDB Master Thread I/O Rate” for more guidelines about this option. For general information about InnoDB I/O performance, see Section 8.5.7, “Optimizing InnoDB Disk I/O”.

- **innodb_large_prefix**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.5.14</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--innodb_large_prefix</code></td>
</tr>
<tr>
<td>Option-File Format</td>
<td><code>innodb_large_prefix</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>innodb_large_prefix</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type boolean</td>
</tr>
<tr>
<td></td>
<td>Default OFF</td>
</tr>
</tbody>
</table>

Enable this option to allow index key prefixes longer than 767 bytes (up to 3072 bytes), for InnoDB tables that use the `DYNAMIC` and `COMpressed` row formats. (Creating such tables also requires the option values `innodb_file_format=barracuda` and `innodb_file_per_table=true`.) See Section 14.9.7, “Limits on InnoDB Tables” for the relevant maximums associated with index key prefixes under various settings.

For tables using the `REdundant` and `Compact` row formats, this option does not affect the allowed key prefix length. It does introduce a new error possibility. When this setting is enabled, attempting to create an index prefix with a key length greater than 3072 for a `REdundant` or `Compact` table causes an `ER_INDEX_COLUMN_TOO_LONG` error.

- **innodb_lock_wait_timeout**

  | Command-Line Format | `--innodb_lock_wait_timeout=#` |
  | Option-File Format  | `innodb_lock_wait_timeout` |
InnoDB System Variables

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>innodb_lock_wait_timeout</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>50</td>
</tr>
<tr>
<td>Range</td>
<td>1 .. 1073741824</td>
</tr>
</tbody>
</table>

The length of time in seconds an InnoDB transaction waits for a row lock before giving up. The default value is 50 seconds. A transaction that tries to access a row that is locked by another InnoDB transaction waits at most this many seconds for write access to the row before issuing the following error:

```
ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction
```

When a lock wait timeout occurs, the current statement is rolled back (not the entire transaction). To have the entire transaction roll back, start the server with the `--innodb_rollback_on_timeout` option. See also Section 14.21.4, “InnoDB Error Handling”.

You might decrease this value for highly interactive applications or OLTP systems, to display user feedback quickly or put the update into a queue for processing later. You might increase this value for long-running back-end operations, such as a transform step in a data warehouse that waits for other large insert or update operations to finish.

`innodb_lock_wait_timeout` applies to InnoDB row locks only. A MySQL table lock does not happen inside InnoDB and this timeout does not apply to waits for table locks.

The lock wait timeout value does not apply to deadlocks, because InnoDB detects them immediately and rolls back one of the deadlocked transactions.

As of MySQL 5.5, `innodb_lock_wait_timeout` can be set at runtime with the `SET GLOBAL` or `SET SESSION` statement. Changing the `GLOBAL` setting requires the `SUPER` privilege and affects the operation of all clients that subsequently connect. Any client can change the `SESSION` setting for `innodb_lock_wait_timeout`, which affects only that client.

- `innodb_locks_unsafe_for_binlog`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb_locks_unsafe_for_binlog</code></th>

<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>OFF</td>
</tr>
</tbody>
</table>

This variable affects how InnoDB uses gap locking for searches and index scans. Normally, InnoDB uses an algorithm called next-key locking that combines index-row locking with gap locking.
InnoDB System Variables

InnoDB performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. In addition, a next-key lock on an index record also affects the “gap” before that index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record \( R \) in an index, another session cannot insert a new index record in the gap immediately before \( R \) in the index order. See Section 14.5.6, “InnoDB Record, Gap, and Next-Key Locks”.

By default, the value of \texttt{innodb_locks_unsafe_for_binlog} is 0 (disabled), which means that gap locking is enabled: InnoDB uses next-key locks for searches and index scans. To enable the variable, set it to 1. This causes gap locking to be disabled: InnoDB uses only index-record locks for searches and index scans.

Enabling \texttt{innodb_locks_unsafe_for_binlog} does not disable the use of gap locking for foreign-key constraint checking or duplicate-key checking.

The effect of enabling \texttt{innodb_locks_unsafe_for_binlog} is similar to but not identical to setting the transaction isolation level to \texttt{READ COMMITTED}:

- Enabling \texttt{innodb_locks_unsafe_for_binlog} is a global setting and affects all sessions, whereas the isolation level can be set globally for all sessions, or individually per session.

- \texttt{innodb_locks_unsafe_for_binlog} can be set only at server startup, whereas the isolation level can be set at startup or changed at runtime.

\texttt{READ COMMITTED} therefore offers finer and more flexible control than \texttt{innodb_locks_unsafe_for_binlog}. For additional details about the effect of isolation level on gap locking, see Section 13.3.6, “SET TRANSACTION Syntax”.

Enabling \texttt{innodb_locks_unsafe_for_binlog} may cause phantom problems because other sessions can insert new rows into the gaps when gap locking is disabled. Suppose that there is an index on the \texttt{id} column of the \texttt{child} table and that you want to read and lock all rows from the table having an identifier value larger than 100, with the intention of updating some column in the selected rows later:

```sql
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

The query scans the index starting from the first record where \texttt{id} is greater than 100. If the locks set on the index records in that range do not lock out inserts made in the gaps, another session can insert a new row into the table. Consequently, if you were to execute the same \texttt{SELECT} again within the same transaction, you would see a new row in the result set returned by the query. This also means that if new items are added to the database, InnoDB does not guarantee serializability. Therefore, if \texttt{innodb_locks_unsafe_for_binlog} is enabled, InnoDB guarantees at most an isolation level of \texttt{READ COMMITTED}. (Conflict serializability is still guaranteed.) For additional information about phantoms, see Section 14.5.7, “Avoiding the Phantom Problem Using Next-Key Locking”.

Enabling \texttt{innodb_locks_unsafe_for_binlog} has additional effects:

- For \texttt{UPDATE} or \texttt{DELETE} statements, InnoDB holds locks only for rows that it updates or deletes. Record locks for nonmatching rows are released after MySQL has evaluated the \texttt{WHERE} condition. This greatly reduces the probability of deadlocks, but they can still happen.

- For \texttt{UPDATE} statements, if a row is already locked, InnoDB performs a “semi-consistent” read, returning the latest committed version to MySQL so that MySQL can determine whether the row matches the \texttt{WHERE} condition of the \texttt{UPDATE}. If the row matches (must be updated), MySQL reads the row again and this time InnoDB either locks it or waits for a lock on it.
Consider the following example, beginning with this table:

```
CREATE TABLE t (a INT NOT NULL, b INT) ENGINE = InnoDB;
INSERT INTO t VALUES (1,2),(2,3),(3,2),(4,3),(5,2);
COMMIT;
```

In this case, table has no indexes, so searches and index scans use the hidden clustered index for record locking (see Section 14.5.13.2, “Clustered and Secondary Indexes”).

Suppose that one client performs an **UPDATE** using these statements:

```
SET autocommit = 0;
UPDATE t SET b = 5 WHERE b = 3;
```

Suppose also that a second client performs an **UPDATE** by executing these statements following those of the first client:

```
SET autocommit = 0;
UPDATE t SET b = 4 WHERE b = 2;
```

As *InnoDB* executes each **UPDATE**, it first acquires an exclusive lock for each row, and then determines whether to modify it. If *InnoDB* does not modify the row and **innodb_locks_unsafe_for_binlog** is enabled, it releases the lock. Otherwise, *InnoDB* retains the lock until the end of the transaction. This affects transaction processing as follows.

If **innodb_locks_unsafe_for_binlog** is disabled, the first **UPDATE** acquires x-locks and does not release any of them:

- `x-lock(1,2); retain x-lock`
- `x-lock(2,3); update(2,3) to (2,5); retain x-lock`
- `x-lock(3,2); retain x-lock`
- `x-lock(4,3); update(4,3) to (4,5); retain x-lock`
- `x-lock(5,2); retain x-lock`

The second **UPDATE** blocks as soon as it tries to acquire any locks (because first update has retained locks on all rows), and does not proceed until the first **UPDATE** commits or rolls back:

```
x-lock(1,2); block and wait for first UPDATE to commit or roll back
```

If **innodb_locks_unsafe_for_binlog** is enabled, the first **UPDATE** acquires x-locks and releases those for rows that it does not modify:

```
x-lock(1,2); unlock(1,2)
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); unlock(3,2)
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); unlock(5,2)
```

For the second **UPDATE**, *InnoDB* does a “semi-consistent” read, returning the latest committed version of each row to MySQL so that MySQL can determine whether the row matches the **WHERE** condition of the **UPDATE**:

```
x-lock(1,2); update(1,2) to (1,4); retain x-lock
x-lock(2,3); unlock(2,3)
```
InnoDB System Variables

x-lock(3,2); update(3,2) to (3,4); retain x-lock
x-lock(4,3); unlock(4,3)
x-lock(5,2); update(5,2) to (5,4); retain x-lock

• **innodb_log_buffer_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_log_buffer_size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>innodb_log_buffer_size</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>innodb_log_buffer_size</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>

</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>8388608</td>
</tr>
<tr>
<td>Range</td>
<td>262144 .. 4294967295</td>
</tr>
</tbody>
</table>

The size in bytes of the buffer that InnoDB uses to write to the log files on disk. The default value is 8MB. A large log buffer enables large transactions to run without a need to write the log to disk before the transactions commit. Thus, if you have transactions that update, insert, or delete many rows, making the log buffer larger saves disk I/O. For general I/O tuning advice, see Section 8.5.7, “Optimizing InnoDB Disk I/O”.

• **innodb_log_file_size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_log_file_size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>innodb_log_file_size</td>
</tr>
<tr>

</thead>
<tbody>
<tr>
<td>Default</td>
<td>5242880</td>
</tr>
<tr>
<td>Range</td>
<td>1048576 .. 4GB / innodb_log_files_in_group</td>
</tr>
</tbody>
</table>

The size in bytes of each log file in a log group. The combined size of log files (innodb_log_file_size * innodb_log_files_in_group) cannot exceed a maximum value that is slightly less than 4GB. A pair of 2047 MB log files, for example, would allow you to approach the range limit but not exceed it. The default value is 5MB. Sensible values range from 1MB to 1/N-th of the size of the buffer pool, where N is the number of log files in the group. The larger the value, the less checkpoint flush activity is needed in the buffer pool, saving disk I/O. Larger log files also make crash recovery slower, although improvements to recovery performance in MySQL 5.5 and higher make the log file size less of a consideration. For general I/O tuning advice, see Section 8.5.7, “Optimizing InnoDB Disk I/O”.

• **innodb_log_files_in_group**

<table>

</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Type</td>
</tr>
</tbody>
</table>

The directory path to the InnoDB redo log files, whose number is specified by `innodb_log_files_in_group`. If you do not specify any InnoDB log variables, the default is to create two files named `ib_logfile0` and `ib_logfile1` in the MySQL data directory. Their size is given by the size of the `innodb_log_file_size` system variable.

- `innodb_max_dirty_pages_pct`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb_max_dirty_pages_pctl=#</code></th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

This variable controls how to delay **INSERT**, **UPDATE**, and **DELETE** operations when purge operations are lagging (see Section 14.5.12, “InnoDB Multi-Versioning”). The default value is 0 (no delays).

The InnoDB transaction system maintains a list of transactions that have index records delete-marked by **UPDATE** or **DELETE** operations. The length of this list represents the purge_lag value. When purge_lag exceeds innodb_max_purge_lag, each **INSERT**, **UPDATE**, and **DELETE** operation is delayed by $((\text{purge}_\text{lag}/\text{innodb}_\text{max}_\text{purge}_\text{lag})\times10)\text{--5 milliseconds.}$ The delay is computed in the beginning of a purge batch, every ten seconds. The operations are not delayed if purge cannot run because of an old consistent read view that could see the rows to be purged.

A typical setting for a problematic workload might be 1 million, assuming that transactions are small, only 100 bytes in size, and it is permissible to have 100MB of unpurged InnoDB table rows.

The lag value is displayed as the history list length in the TRANSACTIONS section of InnoDB Monitor output. For example, if the output includes the following lines, the lag value is 20:

```
------------
TRANSACTIONS
------------
Trx id counter 0 290328385
Purge done for trx's n:o < 0 290315608 undo n:o < 0 17
History list length 20
```

For general I/O tuning advice, see Section 8.5.7, “Optimizing InnoDB Disk I/O”.

- **innodb_mirrored_log_groups**

  Has no effect.

- **innodb_old_blocks_pct**

<table>
<thead>

</thead>
<tbody>
<tr>
<td>5 .. 95</td>
</tr>
</tbody>
</table>
InnoDB System Variables

Specifies the approximate percentage of the InnoDB buffer pool used for the old block sublist. The range of values is 5 to 95. The default value is 37 (that is, 3/8 of the pool). See Section 14.16.2.3, “Making the Buffer Pool Scan Resistant” for more information. See Section 8.9.1, “The InnoDB Buffer Pool” for information about buffer pool management, such as the LRU algorithm and eviction policies.

- **innodb_old_blocks_time**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_old_blocks_time=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>innodb_old_blocks_time</td>

<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Default</td>
</tr>
<tr>
<td>Range</td>
</tr>
</tbody>
</table>

Non-zero values protect against the buffer pool being filled up by data that is referenced only for a brief period, such as during a full table scan. Increasing this value offers more protection against full table scans interfering with data cached in the buffer pool.

Specifies how long in milliseconds (ms) a block inserted into the old sublist must stay there after its first access before it can be moved to the new sublist. If the value is 0, a block inserted into the old sublist moves immediately to the new sublist the first time it is accessed, no matter how soon after insertion the access occurs. If the value is greater than 0, blocks remain in the old sublist until an access occurs at least that many ms after the first access. For example, a value of 1000 causes blocks to stay in the old sublist for 1 second after the first access before they become eligible to move to the new sublist.

This variable is often used in combination with innodb_old_blocks_pct. See Section 14.16.2.3, “Making the Buffer Pool Scan Resistant” for more information. See Section 8.9.1, “The InnoDB Buffer Pool” for information about buffer pool management, such as the LRU algorithm and eviction policies.

- **innodb_open_files**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_open_files=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>innodb_open_files</td>
</tr>
<tr>

<td>innodb_open_files</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Default</td>
</tr>
<tr>
<td>Range</td>
</tr>
</tbody>
</table>

This variable is relevant only if you use multiple InnoDB tablespaces. It specifies the maximum number of .ibd files that MySQL can keep open at one time. The minimum value is 10. The default value is 300.
InnoDB System Variables

The file descriptors used for .ibd files are for InnoDB tables only. They are independent of those specified by the --open-files-limit server option, and do not affect the operation of the table cache.

- innodb_print_all_deadlocks

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.5.30</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--innodb_print_all_deadlocks=#</td>
</tr>
<tr>
<td>Option-File Format</td>
<td>innodb_print_all_deadlocks</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>innodb_print_all_deadlocks</td>
</tr>
<tr>
<td>Variable Scope</td>

<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>OFF</td>
</tr>
</tbody>
</table>

When this option is enabled, information about all deadlocks in InnoDB user transactions is recorded in the mysql error log. Otherwise, you see information about only the last deadlock, using the SHOW ENGINE INNODB STATUS command. An occasional InnoDB deadlock is not necessarily an issue, because InnoDB detects the condition immediately, and rolls back one of the transactions automatically. You might use this option to troubleshoot why deadlocks are happening if an application does not have appropriate error-handling logic to detect the rollback and retry its operation. A large number of deadlocks might indicate the need to restructure transactions that issue DML or SELECT ... FOR UPDATE statements for multiple tables, so that each transaction accesses the tables in the same order, thus avoiding the deadlock condition.

- innodb_purge_batch_size

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.5.4</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--innodb_purge_batch_size=#</td>
</tr>
<tr>

</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

### Permitted Values (>= 5.5.4)

<table>
<thead>
<tr>
<th>Type</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 .. 1</td>
</tr>
</tbody>
</table>

The number of background threads devoted to the InnoDB purge operation. Currently, can only be 0 (the default) or 1. The default value of 0 signifies that the purge operation is performed as part of the master thread. Running the purge operation in its own thread can reduce internal contention within InnoDB, improving scalability. Currently, the performance gain might be minimal because the background thread might encounter different kinds of contention than before. This feature primarily lays the groundwork for future performance work.

- `innodb_random_read_ahead`

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.5.16</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--innodb_random_read_ahead=#</code></td>
</tr>
<tr>
<td>Option-File Format</td>
<td><code>innodb_random_read_ahead</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>innodb_random_read_ahead</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

### Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Enables the random read-ahead technique for optimizing InnoDB I/O. Random read-ahead functionality was removed from the InnoDB Plugin (version 1.0.4) and was therefore not included in MySQL 5.5.0 when InnoDB Plugin became the “built-in” version of InnoDB. Random read-ahead was reintroduced in MySQL 5.1.59 and 5.5.16 and higher along with the `innodb_random_read_ahead` configuration option, which is disabled by default.

See Section 14.16.2.1, “Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)” for details about the performance considerations for the different types of read-ahead requests. For general I/O tuning advice, see Section 8.5.7, “Optimizing InnoDB Disk I/O”.

- `innodb_read_ahead_threshold`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--innodb_read_ahead_threshold=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>innodb_read_ahead_threshold</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>innodb_read_ahead_threshold</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

---

1740
Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>56</td>
</tr>
<tr>
<td>Range</td>
<td>0 .. 64</td>
</tr>
</tbody>
</table>

Controls the sensitivity of linear read-ahead that InnoDB uses to prefetch pages into the buffer pool. If InnoDB reads at least innodb_read_ahead_threshold pages sequentially from an extent (64 pages), it initiates an asynchronous read for the entire following extent. The permissible range of values is 0 to 64. The default is 56: InnoDB must read at least 56 pages sequentially from an extent to initiate an asynchronous read for the following extent.

Knowing how many pages are read through this read-ahead mechanism, and how many of them are evicted from the buffer pool without ever being accessed, can be useful to help fine-tune the innodb_read_ahead_threshold parameter. As of MySQL 5.5, SHOW ENGINE INNODB STATUS output displays counter information from the Innodb_buffer_pool_read_ahead and Innodb_buffer_pool_read_ahead_evicted global status variables. These variables indicate the number of pages brought into the buffer pool by read-ahead requests, and the number of such pages evicted from the buffer pool without ever being accessed respectively. These counters provide global values since the last server restart.

SHOW ENGINE INNODB STATUS also shows the rate at which the read-ahead pages are read in and the rate at which such pages are evicted without being accessed. The per-second averages are based on the statistics collected since the last invocation of SHOW ENGINE INNODB STATUS and are displayed in the BUFFER POOL AND MEMORY section of the output.

See Section 14.16.2.1, “Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)” for more information. For general I/O tuning advice, see Section 8.5.7, “Optimizing InnoDB Disk I/O”.

- innodb_read_io_threads

Command-Line Format

--innodb_read_io_threads=#

Option-File Format

innodb_read_io_threads

System Variable Name

innodb_read_io_threads

Variable Scope

Global

Dynamic Variable

No

Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>4</td>
</tr>
<tr>
<td>Range</td>
<td>1 .. 64</td>
</tr>
</tbody>
</table>

The number of I/O threads for read operations in InnoDB. The default value is 4. Its counterpart for write threads is innodb_write_io_threads. See Section 14.16.7, “Configuring the Number of Background InnoDB I/O Threads” for more information. For general I/O tuning advice, see Section 8.5.7, “Optimizing InnoDB Disk I/O”.

**Note**

On Linux systems, running multiple MySQL servers (typically more than 12) with default settings for innodb_read_io_threads, innodb_write_io_threads, and the Linux aio-max-rr setting can exceed
InnoDB System Variables

system limits. Ideally, increase the aio-max-nr setting; as a workaround, you might reduce the settings for one or both of the MySQL configuration options.

- **innodb_replication_delay**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_replication_delay=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>innodb_replication_delay</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>innodb_replication_delay</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>
  
  Permitted Values
  - Type: numeric
  - Default: 0
  - Range: 0 .. 4294967295

  The replication thread delay (in ms) on a slave server if innodb_thread_concurrency is reached.

- **innodb_rollback_on_timeout**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_rollback_on_timeout</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>innodb_rollback_on_timeout</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>innodb_rollback_on_timeout</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>
  
  Permitted Values
  - Type: boolean
  - Default: OFF

  In MySQL 5.5, InnoDB rolls back only the last statement on a transaction timeout by default. If --innodb_rollback_on_timeout is specified, a transaction timeout causes InnoDB to abort and rollback the entire transaction (the same behavior as in MySQL 4.1).

- **innodb_rollback_segments**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.5.11</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--innodb_rollback_segments=#</td>
</tr>
<tr>
<td>Option-File Format</td>
<td>innodb_rollback_segments</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>innodb_rollback_segments</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>
  
  Permitted Values
  - Type: numeric
  - Default: 128
  - Range: 1 .. 128

1742
InnoDB System Variables

Defines how many of the rollback segments in the system tablespace that InnoDB uses within a transaction. You might reduce this value from its default of 128 if a smaller number of rollback segments performs better for your workload.

- **innodb_spin_wait_delay**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_spin_wait_delay=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>innodb_spin_wait_delay</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>innodb_spin_wait_delay</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>6</td>
</tr>
<tr>
<td>Range</td>
<td>0 .. 4294967295</td>
</tr>
</tbody>
</table>

The maximum delay between polls for a spin lock. The low-level implementation of this mechanism varies depending on the combination of hardware and operating system, so the delay does not correspond to a fixed time interval. The default value is 6. See Section 14.16.11, “Configuring Spin Lock Polling” for more information.

- **innodb_stats_method**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.5.10</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--innodb_stats_method=name</td>
</tr>
<tr>
<td>Option-File Format</td>
<td>innodb_stats_method</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>innodb_stats_method</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>enumeration</td>
</tr>
<tr>
<td>Default</td>
<td>nulls_equal</td>
</tr>
<tr>
<td>Valid Values</td>
<td>nulls_equal</td>
</tr>
<tr>
<td></td>
<td>nulls_unequal</td>
</tr>
<tr>
<td></td>
<td>nulls_ignored</td>
</tr>
</tbody>
</table>

How the server treats NULL values when collecting statistics about the distribution of index values for InnoDB tables. This variable has three possible values, nulls_equal, nulls_unequal, and nulls_ignored. For nulls_equal, all NULL index values are considered equal and form a single value group that has a size equal to the number of NULL values. For nulls_unequal, NULL values are considered unequal, and each NULL forms a distinct value group of size 1. For nulls_ignored, NULL values are ignored.

The method that is used for generating table statistics influences how the optimizer chooses indexes for query execution, as described in Section 8.3.7, “InnoDB and MyISAM Index Statistics Collection”.

- **innodb_stats_on_metadata**
InnoDB System Variables

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.5.4</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--innodb_stats_on_metadata</td>
</tr>
<tr>
<td>Option-File Format</td>
<td>innodb_stats_on_metadata</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>innodb_stats_on_metadata</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

When this variable is enabled (which is the default, as before the variable was created), InnoDB updates statistics when metadata statements such as SHOW TABLE STATUS or SHOW INDEX are run, or when accessing the INFORMATION_SCHEMA tables TABLES or STATISTICS. (These updates are similar to what happens for ANALYZE TABLE.) When disabled, InnoDB does not update statistics during these operations. Disabling this variable can improve access speed for schemas that have a large number of tables or indexes. It can also improve the stability of execution plans for queries that involve InnoDB tables.

To change the setting, issue the statement SET GLOBAL innodb_stats_on_metadata=mode, where mode is either ON or OFF (or 1 or 0). Changing this setting requires the SUPER privilege and immediately affects the operation of all connections.

• innodb_stats_sample_pages

| Command-Line Format | --innodb_stats_sample_pages=# |
| Option-File Format | innodb_stats_sample_pages |
| System Variable Name | innodb_stats_sample_pages |
| Variable Scope | Global |
| Dynamic Variable | Yes |

Permitted Values

| Type | numeric |
| Default | 8 |
| Range | 1 .. 2**64-1 |

The number of index pages to sample for index distribution statistics such as are calculated by ANALYZE TABLE. The default value is 8. For additional information, see Section 14.16.15, “Configuring Optimizer Statistics Parameters”.

Setting a high value for innodb_stats_sample_pages could result in lengthy ANALYZE TABLE execution time. To estimate the number of database pages accessed by ANALYZE TABLE, see Section 14.16.16, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”.

• innodb_strict_mode

| Command-Line Format | --innodb_strict_mode=# |
| Option-File Format | innodb_strict_mode |
### InnoDB System Variables

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>innodb_strict_mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>OFF</td>
</tr>
</tbody>
</table>

When `innodb_strict_mode` is ON, InnoDB returns errors rather than warnings for certain conditions. The default value is OFF.

**Strict mode** helps guard against ignored typos and syntax errors in SQL, or other unintended consequences of various combinations of operational modes and SQL statements. When `innodb_strict_mode` is ON, InnoDB raises error conditions in certain cases, rather than issuing a warning and processing the specified statement (perhaps with unintended behavior). This is analogous to `sql_mode` in MySQL, which controls what SQL syntax MySQL accepts, and determines whether it silently ignores errors, or validates input syntax and data values.

The `innodb_strict_mode` setting affects the handling of syntax errors for `CREATE TABLE`, `ALTER TABLE` and `CREATE INDEX` statements. `innodb_strict_mode` also enables a record size check, so that an `INSERT` or `UPDATE` never fails due to the record being too large for the selected page size.

Oracle recommends enabling `innodb_strict_mode` when using `ROW_FORMAT` and `KEY_BLOCK_SIZE` clauses on `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements. When `innodb_strict_mode` is OFF, InnoDB ignores conflicting clauses and creates the table or index, with only a warning in the message log. The resulting table might have different behavior than you intended, such as having no compression when you tried to create a compressed table. When `innodb_strict_mode` is ON, such problems generate an immediate error and the table or index is not created, avoiding a troubleshooting session later.

You can turn `innodb_strict_mode` ON or OFF on the command line when you start `mysqld`, or in the configuration file `my.cnf` or `my.ini`. You can also enable or disable `innodb_strict_mode` at runtime with the statement `SET [GLOBAL|SESSION] innodb_strict_mode=mode`, where `mode` is either ON or OFF. Changing the `GLOBAL` setting requires the `SUPER` privilege and affects the operation of all clients that subsequently connect. Any client can change the `SESSION` setting for `innodb_strict_mode`, and the setting affects only that client.

- `innodb_support_xa`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_support_xa</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>innodb_support_xa</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>innodb_support_xa</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Enables InnoDB support for two-phase commit in XA transactions, causing an extra disk flush for transaction preparation. This setting is the default. The XA mechanism is used internally and is essential for any server that has its binary log turned on and is accepting changes to its data from more than one
InnoDB System Variables

thread. If you turn it off, transactions can be written to the binary log in a different order from the one in which the live database is committing them. This can produce different data when the binary log is replayed in disaster recovery or on a replication slave. Do not turn it off on a replication master server unless you have an unusual setup where only one thread is able to change data.

For a server that is accepting data changes from only one thread, it is safe and recommended to turn off this option to improve performance for InnoDB tables. For example, you can turn it off on replication slaves where only the replication SQL thread is changing data.

You can also turn off this option if you do not need it for safe binary logging or replication, and you also do not use an external XA transaction manager.

• **innodb_sync_spin_loops**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_sync_spin_loops=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>innodb_sync_spin_loops</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>innodb_sync_spin_loops</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Permitted Values

- **Type**: numeric
- **Default**: 30
- **Range**: 0 .. 4294967295

The number of times a thread waits for an InnoDB mutex to be freed before the thread is suspended. The default value is 30.

• **innodb_table_locks**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--innodb_table_locks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>innodb_table_locks</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>innodb_table_locks</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Permitted Values

- **Type**: boolean
- **Default**: TRUE

If `autocommit = 0`, InnoDB honors `LOCK TABLES`; MySQL does not return from `LOCK TABLES ... WRITE` until all other threads have released all their locks to the table. The default value of `innodb_table_locks` is 1, which means that `LOCK TABLES` causes InnoDB to lock a table internally if `autocommit = 0`.

As of MySQL 5.5.3, `innodb_table_locks = 0` has no effect for tables locked explicitly with `LOCK TABLES ... WRITE`. It still has an effect for tables locked for read or write by `LOCK TABLES ... WRITE` implicitly (for example, through triggers) or by `LOCK TABLES ... READ`.

• **innodb_thread_concurrency**
### InnoDB System Variables

#### innodb_thread_concurrency

**Command-Line Format**

```
--innodb_thread_concurrency=#
```

**Option-File Format**

```
innodb_thread_concurrency
```

**System Variable Name**

```
innodb_thread_concurrency
```

**Variable Scope**

Global

**Dynamic Variable**

Yes

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 .. 1000</td>
</tr>
</tbody>
</table>

*InnoDB* tries to keep the number of operating system threads concurrently inside *InnoDB* less than or equal to the limit given by this variable. Once the number of threads reaches this limit, additional threads are placed into a wait state within a FIFO queue for execution. Threads waiting for locks are not counted in the number of concurrently executing threads.

The correct value for this variable is dependent on environment and workload. Try a range of different values to determine what value works for your applications. A recommended value is 2 times the number of CPUs plus the number of disks.

The range of this variable is 0 to 1000. A value of 0 (the default) is interpreted as infinite concurrency (no concurrency checking). Disabling thread concurrency checking enables *InnoDB* to create as many threads as it needs. A value of 0 also disables the queries inside *InnoDB* and queries in queue counters in the ROW OPERATIONS section of SHOW ENGINE INNODB STATUS output.

#### innodb_thread_sleep_delay

Specifies whether to use the Linux asynchronous I/O subsystem. This variable applies to Linux systems only, and cannot be changed while the server is running. Normally, you do not need to touch this option, because it is enabled by default.

As of MySQL 5.5, the asynchronous I/O capability that InnoDB has on Windows systems is available on Linux systems. (Other Unix-like systems continue to use synchronous I/O calls.) This feature improves the scalability of heavily I/O-bound systems, which typically show many pending reads/writes in the output of the command `SHOW ENGINE INNODB STATUS\G`.

Running with a large number of InnoDB I/O threads, and especially running multiple such instances on the same server machine, can exceed capacity limits on Linux systems. In this case, you may receive the following error:

```
EAGAIN: The specified maxevents exceeds the user's limit of available events.
```

You can typically address this error by writing a higher limit to `/proc/sys/fs/aio-max-nr`.

However, if a problem with the asynchronous I/O subsystem in the OS prevents InnoDB from starting, you can start the server with `innodb_use_native_aio=0` disabled (use `innodb_use_native_aio=0` in the option file). This option may also be turned off automatically during startup if InnoDB detects a potential problem such as a combination of `tmpdir` location, `tmpfs` filesystem, and Linux kernel that does not support AIO on `tmpfs`.

This variable was added in MySQL 5.5.4.

- `innodb_use_sys_malloc`

<table>
<thead>
<tr>

<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

### Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>4</td>
</tr>
<tr>
<td>Range</td>
<td>1 .. 64</td>
</tr>
</tbody>
</table>

The number of I/O threads for write operations in InnoDB. The default value is 4. Its counterpart for read threads is innodb_read_io_threads. See Section 14.16.7, “Configuring the Number of Background InnoDB I/O Threads” for more information. For general I/O tuning advice, see Section 8.5.7, “Optimizing InnoDB Disk I/O”.

#### Note

On Linux systems, running multiple MySQL servers (typically more than 12) with default settings for innodb_read_io_threads, innodb_write_io_threads, and the Linux aio-max-nr setting can exceed system limits. Ideally, increase the aio-max-nr setting; as a workaround, you might reduce the settings for one or both of the MySQL configuration options.

You should also take into consideration the value of sync_binlog, which controls synchronization of the binary log to disk.

For general I/O tuning advice, see Section 8.5.7, “Optimizing InnoDB Disk I/O”.

### 14.15.1 Changes to InnoDB Startup Options and System Variables

#### 14.15.1.1 New Parameters
New InnoDB Plugin and InnoDB 1.1 Parameters

Throughout the course of development of InnoDB 1.1 and its predecessor, the InnoDB Plugin, the following configuration parameters were introduced. The InnoDB storage engine version in which each parameter was introduced is provided (where applicable). Starting in MySQL 5.5.30, separate version numbering for the InnoDB storage engine was discontinued in favor of MySQL server version numbering. See Section 14.15, “InnoDB Startup Options and System Variables” for parameter descriptions and the MySQL release in which parameters were added.

- innodb_adaptive_flushing: introduced in InnoDB storage engine 1.0.4
- innodb_buffer_pool_instances
- innodb_change_buffering: introduced in InnoDB storage engine 1.0.3
- innodb_file_format: introduced in InnoDB storage engine 1.0.1
- innodb_file_format_check: introduced in InnoDB storage engine 1.0.1
- innodb_file_format_max
- innodb_io_capacity: introduced in InnoDB storage engine 1.0.4
- innodb_old_blocks_pct: introduced in InnoDB storage engine 1.0.5
- innodb_old_blocks_time: introduced in InnoDB storage engine 1.0.5
- innodb_purge_batch_size
- innodb_purge_threads
- innodb_read_ahead_threshold: introduced in InnoDB storage engine 1.0.4
- innodb_read_io_threads: introduced in InnoDB storage engine 1.0.4
- innodb_spin_wait_delay: introduced in InnoDB storage engine 1.0.4
- innodb_stats_sample_pages: introduced in InnoDB storage engine 1.0.2
- innodb_strict_mode: introduced in InnoDB storage engine 1.0.2
- innodb_use_native_aio
- innodb_use_sys_malloc: introduced in InnoDB storage engine 1.0.3
- innodb_write_io_threads: introduced in InnoDB storage engine 1.0.4

New InnoDB Parameters in MySQL 5.5

The following InnoDB configuration parameters were added in MySQL 5.5. Some of the parameters listed below may have also been added to other MySQL versions. See Section 14.15, “InnoDB Startup Options and System Variables” for parameter descriptions and the specific release in which parameters were added.

- innodb_buffer_pool_instances
- innodb_file_format_max
- innodb_force_load_corrupted
• `innodb_large_prefix`
• `innodb_print_all_deadlocks`
• `innodb_purge_batch_size`
• `innodb_purge_threads`
• `innodb_random_read_ahead`
• `innodb_rollback_segments`
• `innodb_stats_method`
• `innodb_stats_on_metadata`
• `innodb_use_native_aio`

### 14.15.1.2 Deprecated Parameters

• `innodb_file_io_threads`

This parameter was deprecated in InnoDB storage engine 1.0.4 and replaced by `innodb_read_io_threads` and `innodb_write_io_threads`. See Section 14.16.7, “Configuring the Number of Background InnoDB I/O Threads” for additional information.

• `ignore_builtin_innodb`: removed in MySQL 5.5.22.

### 14.15.1.3 Parameters with New Defaults

For better out-of-the-box performance, default values for the following InnoDB configuration parameters were changed in MySQL 5.5. See Section 14.15, “InnoDB Startup Options and System Variables” for information about new parameter defaults and the specific release that changes took effect.

• `innodb_change_buffering`

• `innodb_file_format`

• `innodb_file_format_check`

• `innodb_file_per_table`

### 14.16 InnoDB Performance

This section provides information about InnoDB features and enhancements related to performance and scalability.

Tips and guidelines for tuning InnoDB tables are provided in the optimization chapter. See Section 8.5, “Optimizing for InnoDB Tables”.

### 14.16.1 Overview of InnoDB Performance

InnoDB has always been highly efficient, and includes several unique architectural elements to assure high performance and scalability. The latest InnoDB storage engine includes new features that take advantage of advances in operating systems and hardware platforms, such as multi-core processors and improved memory allocation systems. In addition, new configuration options let you better control some InnoDB internal subsystems to achieve the best performance with your workload.
Starting with MySQL 5.5 and InnoDB 1.1, the built-in InnoDB storage engine within MySQL is upgraded to the full feature set and performance of the former InnoDB Plugin. This change makes InnoDB performance and scalability features that were available with the former InnoDB Plugin available to a much wider audience than before, and eliminates the separate installation step of the InnoDB Plugin. After learning about the InnoDB performance features in this section, continue with Chapter 8, Optimization to learn the best practices for overall MySQL performance, and Section 8.5, “Optimizing for InnoDB Tables” in particular for InnoDB tips and guidelines.

14.16.2 InnoDB Buffer Pool Configuration

This section provides performance related configuration information for the InnoDB buffer pool. For additional information, see Section 8.9.1, “The InnoDB Buffer Pool”.

14.16.2.1 Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)

A read-ahead request is an I/O request to prefetch multiple pages in the buffer pool asynchronously, in anticipation that these pages will be needed soon. The requests bring in all the pages in one extent. InnoDB uses two read-ahead algorithms to improve I/O performance:

**Linear** read-ahead is a technique that predicts what pages might be needed soon based on pages in the buffer pool being accessed sequentially. You control when InnoDB performs a read-ahead operation by adjusting the number of sequential page accesses required to trigger an asynchronous read request, using the configuration parameter `innodb_read_ahead_threshold`. Before this parameter was added, InnoDB would only calculate whether to issue an asynchronous prefetch request for the entire next extent when it read in the last page of the current extent.

The configuration parameter `innodb_read_ahead_threshold` controls how sensitive InnoDB is in detecting patterns of sequential page access. If the number of pages read sequentially from an extent is greater than or equal to `innodb_read_ahead_threshold`, InnoDB initiates an asynchronous read-ahead operation of the entire following extent. It can be set to any value from 0-64. The default value is 56. The higher the value, the more strict the access pattern check. For example, if you set the value to 48, InnoDB would only trigger an asynchronous read-ahead request when 48 pages in the current extent have been accessed sequentially. If the value is 8, InnoDB would trigger an asynchronous read-ahead even if as few as 8 pages in the extent were accessed sequentially. You can set the value of this parameter in the MySQL configuration file, or change it dynamically with the `SET GLOBAL` command, which requires the SUPER privilege.

**Random** read-ahead is a technique that predicts when pages might be needed soon based on pages already in the buffer pool, regardless of the order in which those pages were read. If 13 consecutive pages from the same extent are found in the buffer pool, InnoDB asynchronously issues a request to prefetch the remaining pages of the extent.

Random read-ahead functionality was removed from the InnoDB Plugin (version 1.0.4) and was therefore not included in MySQL 5.5.0 when InnoDB Plugin became the “built-in” version of InnoDB. Random read-ahead was reintroduced in MySQL 5.1.59 and 5.5.16 and higher along with the `innodb_random_read_ahead` configuration option, which is disabled by default. To enable this feature, set the configuration variable `innodb_random_read_ahead` to ON.

The `SHOW ENGINE INNODB STATUS` command displays statistics to help you evaluate the effectiveness of the read-ahead algorithm. Statistics include counter information for the `Innodb_buffer_pool_read_ahead` and `Innodb_buffer_pool_read_ahead_evicted` global status variables. This information can be useful when fine-tuning the `innodb_random_read_ahead` setting.

For more information about I/O performance, see Section 8.5.7, “Optimizing InnoDB Disk I/O” and Section 8.11.3, “Optimizing Disk I/O”.
InnoDB Buffer Pool Configuration

14.16.2.2 Configuring the Rate of **InnoDB** Buffer Pool Flushing

InnoDB performs certain tasks in the background, including flushing of **dirty pages** (those pages that have been changed but are not yet written to the database files) from the buffer pool, a task performed by the **master thread**. Currently, InnoDB aggressively flushes buffer pool pages if the percentage of dirty pages in the buffer pool exceeds `innodb_max_dirty_pages_pct`.

InnoDB uses an algorithm to estimate the required rate of flushing, based on the speed of redo log generation and the current rate of flushing. The intent is to smooth overall performance by ensuring that buffer flush activity keeps up with the need to keep the buffer pool “clean”. Automatically adjusting the rate of flushing can help to avoid sudden dips in throughput, when excessive buffer pool flushing limits the I/O capacity available for ordinary read and write activity.

InnoDB uses its log files in a circular fashion. Before reusing a portion of a log file, InnoDB flushes to disk all dirty buffer pool pages whose redo entries are contained in that portion of the log file, a process known as a **sharp checkpoint**. If a workload is write-intensive, it generates a lot of redo information, all written to the log file. If all available space in the log files is used up, a sharp checkpoint occurs, causing a temporary reduction in throughput. This situation can happen even though `innodb_max_dirty_pages_pct` is not reached.

InnoDB uses a heuristic-based algorithm to avoid such a scenario, by measuring the number of dirty pages in the buffer pool and the rate at which redo is being generated. Based on these numbers, InnoDB decides how many dirty pages to flush from the buffer pool each second. This self-adapting algorithm is able to deal with sudden changes in the workload.

Internal benchmarking has also shown that this algorithm not only maintains throughput over time, but can also improve overall throughput significantly.

Because adaptive flushing can significantly affect the I/O pattern of a workload, the `innodb_adaptive_flushing` configuration parameter lets you turn off this feature. The default value for `innodb_adaptive_flushing` is **TRUE**, enabling the adaptive flushing algorithm. You can set the value of this parameter in the MySQL option file (**my.cnf** or **my.ini**) or change it dynamically with the `SET GLOBAL` command, which requires the **SUPER** privilege.

For more information about InnoDB I/O performance, see Section 8.5.7, “Optimizing **InnoDB** Disk I/O”.

14.16.2.3 Making the Buffer Pool Scan Resistant

Rather than using a strictly **LRU** algorithm, InnoDB uses a technique to minimize the amount of data that is brought into the buffer pool and never accessed again. The goal is to make sure that frequently accessed (“hot”) pages remain in the buffer pool, even as **read-ahead** and **full table scans** bring in new blocks that might or might not be accessed afterward.

Newly read blocks are inserted into the middle of the LRU list. All newly read pages are inserted at a location that by default is 3/8 from the tail of the LRU list. The pages are moved to the front of the list (the most-recently used end) when they are accessed in the buffer pool for the first time. Thus pages that are never accessed never make it to the front portion of the LRU list, and “age out” sooner than with a strict LRU approach. This arrangement divides the LRU list into two segments, where the pages downstream of the insertion point are considered “old” and are desirable victims for LRU eviction.

For an explanation of the inner workings of the InnoDB buffer pool and the specifics of its LRU replacement algorithm, see Section 8.9.1, “The **InnoDB** Buffer Pool”.

You can control the insertion point in the LRU list, and choose whether InnoDB applies the same optimization to blocks brought into the buffer pool by table or index scans. The configuration parameter
**InnoDB Buffer Pool Configuration**

`innodb_old_blocks_pct` controls the percentage of "old" blocks in the LRU list. The default value of `innodb_old_blocks_pct` is 37, corresponding to the original fixed ratio of 3/8. The value range is 5 (new pages in the buffer pool age out very quickly) to 95 (only 5% of the buffer pool is reserved for hot pages, making the algorithm close to the familiar LRU strategy).

The optimization that keeps the buffer pool from being churned by read-ahead can avoid similar problems due to table or index scans. In these scans, a data page is typically accessed a few times in quick succession and is never touched again. The configuration parameter `innodb_old_blocks_time` specifies the time window (in milliseconds) after the first access to a page during which it can be accessed without being moved to the front (most-recently used end) of the LRU list. The default value of `innodb_old_blocks_time` is 0, corresponding to the original behavior of moving a page to the most-recently used end of the buffer pool list when it is first accessed in the buffer pool. Increasing this value makes more and more blocks likely to age out faster from the buffer pool.

Both `innodb_old_blocks_pct` and `innodb_old_blocks_time` are dynamic, global and can be specified in the MySQL option file (my.cnf or my.ini) or changed at runtime with the `SET GLOBAL` command. Changing the setting requires the `SUPER` privilege.

To help you gauge the effect of setting these parameters, the `SHOW ENGINE INNODB STATUS` command reports additional statistics. The `BUFFER POOL AND MEMORY` section looks like:

```plaintext
Total memory allocated 1107296256; in additional pool allocated 0
Dictionary memory allocated 80360
Buffer pool size 65535
Free buffers 0
Database pages 63920
Old database pages 23600
Modified db pages 34969
Pending reads 32
Pending writes: LRU 0, flush list 0, single page 0
Pages made young 414946, not young 2930673
1274.75 youngs/s, 16521.90 non-youngs/s
Pages read 486005, created 3178, written 160585
2132.37 reads/s, 3.40 creates/s, 323.74 writes/s
Buffer pool hit rate 950 / 1000, young-making rate 30 / 1000 not 392 / 1000
Pages read ahead 1510.10/s, evicted without access 0.00/s
LRU len: 63920, unzip_LRU len: 0
I/O sum[43690]:cur[221], unzip sum[0]:cur[0]
```

- **Old database pages** is the number of pages in the "old" segment of the LRU list.
- **Pages made young** and **not young** is the total number of "old" pages that have been made young or not respectively.
- **younsgs/s** and **non-young/s** is the rate at which page accesses to the "old" pages have resulted in making such pages young or otherwise respectively since the last invocation of the command.
- **young-making rate** and **not** provides the same rate but in terms of overall buffer pool accesses instead of accesses just to the "old" pages.

**Note**

Per second averages provided in InnoDB Monitor output are based on the elapsed time between the current time and the last time InnoDB Monitor output was printed.

Because the effects of these parameters can vary widely based on your hardware configuration, your data, and the details of your workload, always benchmark to verify the effectiveness before changing these settings in any performance-critical or production environment.
In mixed workloads where most of the activity is OLTP type with periodic batch reporting queries which result in large scans, setting the value of `innodb_old_blocks_time` during the batch runs can help keep the working set of the normal workload in the buffer pool.

When scanning large tables that cannot fit entirely in the buffer pool, setting `innodb_old_blocks_pct` to a small value keeps the data that is only read once from consuming a significant portion of the buffer pool. For example, setting `innodb_old_blocks_pct=5` restricts this data that is only read once to 5% of the buffer pool.

When scanning small tables that do fit into memory, there is less overhead for moving pages around within the buffer pool, so you can leave `innodb_old_blocks_pct` at its default value, or even higher, such as `innodb_old_blocks_pct=50`.

The effect of the `innodb_old_blocks_time` parameter is harder to predict than the `innodb_old_blocks_pct` parameter, is relatively small, and varies more with the workload. To arrive at an optimal value, conduct your own benchmarks if the performance improvement from adjusting `innodb_old_blocks_pct` is not sufficient.

For more information about the InnoDB buffer pool, see Section 8.9.1, “The InnoDB Buffer Pool”.

### 14.16.2.4 Using Multiple Buffer Pool Instances

For systems with buffer pools in the multi-gigabyte range, dividing the buffer pool into separate instances can improve concurrency, by reducing contention as different threads read and write to cached pages. This feature is typically intended for systems with a buffer pool size in the multi-gigabyte range. Multiple buffer pool instances are configured using the `innodb_buffer_pool_instances` configuration option, and you might also adjust the `innodb_buffer_pool_size` value.

When the InnoDB buffer pool is large, many data requests can be satisfied by retrieving from memory. You might encounter bottlenecks from multiple threads trying to access the buffer pool at once. You can enable multiple buffer pools to minimize this contention. Each page that is stored in or read from the buffer pool is assigned to one of the buffer pools randomly, using a hashing function. Each buffer pool manages its own free lists, flush lists, LRUs, and all other data structures connected to a buffer pool, and is protected by its own buffer pool mutex.

To enable multiple buffer pool instances, set the `innodb_buffer_pool_instances` configuration option to a value greater than 1 (the default) up to 64 (the maximum). This option takes effect only when you set the `innodb_buffer_pool_size` to a size of 1 gigabyte or more. The total size you specify is divided among all the buffer pools. For best efficiency, specify a combination of `innodb_buffer_pool_instances` and `innodb_buffer_pool_size` so that each buffer pool instance is at least 1 gigabyte.

For more information about the InnoDB buffer pool, see Section 8.9.1, “The InnoDB Buffer Pool”.

### 14.16.3 InnoDB Mutex and Read/Write Lock Implementation

In MySQL and InnoDB, multiple threads of execution access shared data structures. InnoDB synchronizes these accesses with its own implementation of mutexes and read/write locks. InnoDB has historically protected the internal state of a read/write lock with an InnoDB mutex. On Unix and Linux platforms, the internal state of an InnoDB mutex is protected by a Pthreads mutex, as in IEEE Std 1003.1c (POSIX.1c).

On many platforms, there is a more efficient way to implement mutexes and read/write locks. Atomic operations can often be used to synchronize the actions of multiple threads more efficiently than Pthreads. Each operation to acquire or release a lock can be done in fewer CPU instructions, and thus result in less
wasted time when threads are contending for access to shared data structures. This in turn means greater scalability on multi-core platforms.

InnoDB implements mutexes and read/write locks with the built-in functions provided by the GNU Compiler Collection (GCC) for atomic memory access instead of using the Pthreads approach previously used. More specifically, an InnoDB that is compiled with GCC version 4.1.2 or later uses the atomic builtins instead of a pthread_mutex_t to implement InnoDB mutexes and read/write locks.

On 32-bit Microsoft Windows, InnoDB has implemented mutexes (but not read/write locks) with hand-written assembler instructions. Beginning with Microsoft Windows 2000, functions for Interlocked Variable Access are available that are similar to the built-in functions provided by GCC. On Windows 2000 and higher, InnoDB makes use of the Interlocked functions. Unlike the old hand-written assembler code, the new implementation supports read/write locks and 64-bit platforms.

Solaris 10 introduced library functions for atomic operations, and InnoDB uses these functions by default. When MySQL is compiled on Solaris 10 with a compiler that does not support the built-in functions provided by the GNU Compiler Collection (GCC) for atomic memory access, InnoDB uses the library functions.

This change improves the scalability of InnoDB on multi-core systems. This feature is enabled out-of-the-box on the platforms where it is supported. You do not have to set any parameter or option to take advantage of the improved performance. On platforms where the GCC, Windows, or Solaris functions for atomic memory access are not available, InnoDB uses the traditional Pthreads method of implementing mutexes and read/write locks.

When MySQL starts, InnoDB writes a message to the log file indicating whether atomic memory access is used for mutexes, for mutexes and read/write locks, or neither. If suitable tools are used to build InnoDB and the target CPU supports the atomic operations required, InnoDB uses the built-in functions for mutexing. If, in addition, the compare-and-swap operation can be used on thread identifiers (pthread_t), then InnoDB uses the instructions for read-write locks as well.

Note
If you are building from source, ensure that the build process properly takes advantage of your platform capabilities.

For more information about the performance implications of locking, see Section 8.10, “Optimizing Locking Operations”.

14.16.4 Configuring the Memory Allocator for InnoDB

When InnoDB was developed, the memory allocators supplied with operating systems and run-time libraries were often lacking in performance and scalability. At that time, there were no memory allocator libraries tuned for multi-core CPUs. Therefore, InnoDB implemented its own memory allocator in the mem subsystem. This allocator is guarded by a single mutex, which may become a bottleneck. InnoDB also implements a wrapper interface around the system allocator (malloc and free) that is likewise guarded by a single mutex.

Today, as multi-core systems have become more widely available, and as operating systems have matured, significant improvements have been made in the memory allocators provided with operating systems. New memory allocators perform better and are more scalable than they were in the past. The leading high-performance memory allocators include Hoard, libumem, mtmalloc, ptmalloc, tbbmalloc, and TCMalloc. Most workloads, especially those where memory is frequently allocated and released (such as multi-table joins), benefit from using a more highly tuned memory allocator as opposed to the internal, InnoDB-specific memory allocator.
You can control whether InnoDB uses its own memory allocator or an allocator of the operating system, by setting the value of the system configuration parameter `innodb_use_sys_malloc` in the MySQL option file (`my.cnf` or `my.ini`). If set to `ON` or `1` (the default), InnoDB uses the `malloc` and `free` functions of the underlying system rather than manage memory pools itself. This parameter is not dynamic, and takes effect only when the system is started. To continue to use the InnoDB memory allocator, set `innodb_use_sys_malloc` to `0`.

**Note**

When the InnoDB memory allocator is disabled, InnoDB ignores the value of the parameter `innodb_additional_mem_pool_size`. The InnoDB memory allocator uses an additional memory pool for satisfying allocation requests without having to fall back to the system memory allocator. When the InnoDB memory allocator is disabled, all such allocation requests are fulfilled by the system memory allocator.

On Unix-like systems that use dynamic linking, replacing the memory allocator may be as easy as making the environment variable `LD_PRELOAD` or `LD_LIBRARY_PATH` point to the dynamic library that implements the allocator. On other systems, some relinking may be necessary. Please refer to the documentation of the memory allocator library of your choice.

Since InnoDB cannot track all memory use when the system memory allocator is used (`innodb_use_sys_malloc` is `ON`), the section “BUFFER POOL AND MEMORY” in the output of the `SHOW ENGINE INNODB STATUS` command only includes the buffer pool statistics in the “Total memory allocated”. Any memory allocated using the `mem` subsystem or using `ut_malloc` is excluded.

For more information about the performance implications of InnoDB memory usage, see Section 8.9, “Buffering and Caching”.

### 14.16.5 Configuring InnoDB Change Buffering

When `INSERT`, `UPDATE`, and `DELETE` operations are done to a table, often the values of indexed columns (particularly the values of secondary keys) are not in sorted order, requiring substantial I/O to bring secondary indexes up to date. InnoDB has an insert buffer that caches changes to secondary index entries when the relevant page is not in the buffer pool, thus avoiding I/O operations by not reading in the page from the disk. The buffered changes are merged when the page is loaded to the buffer pool, and the updated page is later flushed to disk using the normal mechanism. The InnoDB main thread merges buffered changes when the server is nearly idle, and during a slow shutdown.

Because it can result in fewer disk reads and writes, this feature is most valuable for workloads that are I/O-bound, for example applications with a high volume of DML operations such as bulk inserts.

However, the insert buffer occupies a part of the buffer pool, reducing the memory available to cache data pages. If the working set almost fits in the buffer pool, or if your tables have relatively few secondary indexes, it may be useful to disable insert buffering. If the working set entirely fits in the buffer pool, insert buffering does not impose any extra overhead, because it only applies to pages that are not in the buffer pool.

You can control the extent to which InnoDB performs insert buffering with the system configuration parameter `innodb_change_buffering`. You can turn on and off buffering for inserts, delete operations (when index records are initially marked for deletion) and purge operations (when index records are physically deleted). An update operation is represented as a combination of an insert and a delete. In MySQL 5.5 and higher, the default value is changed from `inserts` to `all`. 
The allowed values of `innodb_change_buffering` are:

- **all**
  The default value: buffer inserts, delete-marking operations, and purges.

- **none**
  Do not buffer any operations.

- **inserts**
  Buffer insert operations.

- **deletes**
  Buffer delete-marking operations.

- **changes**
  Buffer both inserts and delete-marking.

- **purges**
  Buffer the physical deletion operations that happen in the background.

You can set the value of this parameter in the MySQL option file (`my.cnf` or `my.ini`) or change it dynamically with the `SET GLOBAL` command, which requires the `SUPER` privilege. Changing the setting affects the buffering of new operations; the merging of already buffered entries is not affected.

For more information about speeding up `INSERT`, `UPDATE`, and `DELETE` statements, see Section 8.2.2, “Optimizing DML Statements”.

### 14.16.6 Configuring Thread Concurrency for InnoDB

**InnoDB** uses operating system threads to process requests from user transactions. (Transactions may issue many requests to **InnoDB** before they commit or roll back.) On modern operating systems and servers with multi-core processors, where context switching is efficient, most workloads run well without any limit on the number of concurrent threads. Scalability improvements in MySQL 5.5 and up reduce the need to limit the number of concurrently executing threads inside **InnoDB**.

In situations where it is helpful to minimize context switching between threads, **InnoDB** can use a number of techniques to limit the number of concurrently executing operating system threads (and thus the number of requests that are processed at any one time). When **InnoDB** receives a new request from a user session, if the number of threads concurrently executing is at a pre-defined limit, the new request sleeps for a short time before it tries again. A request that cannot be rescheduled after the sleep is put in a first-in/first-out queue and eventually is processed. Threads waiting for locks are not counted in the number of concurrently executing threads.

You can limit the number of concurrent threads by setting the configuration parameter `innodb_thread_concurrency`. Once the number of executing threads reaches this limit, additional threads sleep for a number of microseconds, set by the configuration parameter `innodb_thread_sleep_delay`, before being placed into the queue.

The default value for `innodb_thread_concurrency` and the implied default limit on the number of concurrent threads has been changed in various releases of MySQL and **InnoDB**. Currently, the default value of `innodb_thread_concurrency` is 0, so that by default there is no limit on the number of concurrently executing threads, as shown in Table 14.5, "Changes to `innodb_thread_concurrency`".
### Configuring the Number of Background InnoDB I/O Threads

InnoDB uses background threads to service various types of I/O requests. You can configure the number of background threads that service read and write I/O on data pages, using the configuration parameters `innodb_read_io_threads` and `innodb_write_io_threads`. These parameters signify the number of background threads used for read and write requests respectively. They are effective on all supported platforms. You can set the value of these parameters in the MySQL option file (`my.cnf` or `my.ini`); you cannot change them dynamically. The default value for these parameters is 4 and the permissible values range from 1-64.

These parameters replace `innodb_file_io_threads` from earlier versions of MySQL. If you try to set a value for this obsolete parameter, a warning is written to the log file and the value is ignored. This parameter only applied to Windows platforms. (On non-Windows platforms, there was only one thread each for read and write.)

The purpose of this change is to make InnoDB more scalable on high end systems. Each background thread can handle up to 256 pending I/O requests. A major source of background I/O is the read-ahead requests. InnoDB tries to balance the load of incoming requests in such way that most of the background

---

**Table 14.5 Changes to `innodb_thread_concurrency`**

<table>
<thead>
<tr>
<th>InnoDB Version</th>
<th>MySQL Version</th>
<th>Default value</th>
<th>Default limit of concurrent threads</th>
<th>Value to allow unlimited threads</th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-in Earlier than 5.1.11</td>
<td>20</td>
<td>No limit</td>
<td>20 or higher</td>

<td>0</td>
<td></td>
</tr>
<tr>
<td>InnoDB 1.0.3 and newer (corresponding to Plugin)</td>
<td>0</td>
<td>No limit</td>
<td>0</td>
<td></td>
</tr>
</tbody>
</table>

Note that InnoDB causes threads to sleep only when the number of concurrent threads is limited. When there is no limit on the number of threads, all contend equally to be scheduled. That is, if `innodb_thread_concurrency` is 0, the value of `innodb_thread_sleep_delay` is ignored.

When there is a limit on the number of threads, InnoDB reduces context switching overhead by permitting multiple requests made during the execution of a single SQL statement to enter InnoDB without observing the limit set by `innodb_thread_concurrency`. Since an SQL statement (such as a join) may comprise multiple row operations within InnoDB, InnoDB assigns “tickets” that allow a thread to be scheduled repeatedly with minimal overhead.

When a new SQL statement starts, a thread has no tickets, and it must observe `innodb_thread_concurrency`. Once the thread is entitled to enter InnoDB, it is assigned a number of tickets that it can use for subsequently entering InnoDB. If the tickets run out, `innodb_thread_concurrency` is observed again and further tickets are assigned. The number of tickets to assign is specified by the global option `innodb_concurrency_tickets`, which is 500 by default. A thread that is waiting for a lock is given one ticket once the lock becomes available.

The correct values of these variables depend on your environment and workload. Try a range of different values to determine what value works for your applications. Before limiting the number of concurrently executing threads, review configuration options that may improve the performance of InnoDB on multi-core and multi-processor computers, such as `innodb_use_sys_malloc` and `innodb_adaptive_hash_index`.

For general performance information about MySQL thread handling, see `Section 8.11.5.1, “How MySQL Uses Threads for Client Connections”`.

### 14.16.7 Configuring the Number of Background InnoDB I/O Threads

InnoDB uses background threads to service various types of I/O requests. You can configure the number of background threads that service read and write I/O on data pages, using the configuration parameters `innodb_read_io_threads` and `innodb_write_io_threads`. These parameters signify the number of background threads used for read and write requests respectively. They are effective on all supported platforms. You can set the value of these parameters in the MySQL option file (`my.cnf` or `my.ini`); you cannot change them dynamically. The default value for these parameters is 4 and the permissible values range from 1-64.

These parameters replace `innodb_file_io_threads` from earlier versions of MySQL. If you try to set a value for this obsolete parameter, a warning is written to the log file and the value is ignored. This parameter only applied to Windows platforms. (On non-Windows platforms, there was only one thread each for read and write.)

The purpose of this change is to make InnoDB more scalable on high end systems. Each background thread can handle up to 256 pending I/O requests. A major source of background I/O is the read-ahead requests. InnoDB tries to balance the load of incoming requests in such way that most of the background

---

1759
14.16.8 Group Commit

InnoDB, like any other ACID-compliant database engine, flushes the redo log of a transaction before it is committed. Historically, InnoDB used group commit functionality to group multiple such flush requests together to avoid one flush for each commit. With group commit, InnoDB issues a single write to the log file to perform the commit action for multiple user transactions that commit at about the same time, significantly improving throughput.

Group commit in InnoDB worked until MySQL 4.x, and works once again with MySQL 5.1 with the InnoDB Plugin, and MySQL 5.5 and higher. The introduction of support for the distributed transactions and Two Phase Commit (2PC) in MySQL 5.0 interfered with the InnoDB group commit functionality. This issue is now resolved.

The group commit functionality inside InnoDB works with the Two Phase Commit protocol in MySQL. Re-enabling of the group commit functionality fully ensures that the ordering of commit in the MySQL binlog and the InnoDB logfile is the same as it was before. It means it is totally safe to use the MySQL Enterprise Backup product with InnoDB 1.0.4 (that is, the InnoDB Plugin with MySQL 5.1) and above. When the binlog is enabled, you typically also set the configuration option `sync_binlog=0`, because group commit for the binary log is only supported if it is set to 0.

Group commit is transparent; you do not need to do anything to take advantage of this significant performance improvement.

For more information about performance of `COMMIT` and other transactional operations, see Section 8.5.2, “Optimizing InnoDB Transaction Management”.

14.16.9 Configuring the InnoDB Master Thread I/O Rate

The master thread in InnoDB is a thread that performs various tasks in the background. Most of these tasks are I/O related, such as flushing dirty pages from the buffer pool or writing changes from the insert buffer to the appropriate secondary indexes. The master thread attempts to perform these tasks in a way that does not adversely affect the normal working of the server. It tries to estimate the free I/O bandwidth available and tune its activities to take advantage of this free capacity. Historically, InnoDB has used a hard coded value of 100 IOPs (input/output operations per second) as the total I/O capacity of the server.

The parameter `innodb_io_capacity` indicates the overall I/O capacity available to InnoDB. This parameter should be set to approximately the number of I/O operations that the system can perform per second. The value depends on your system configuration. When `innodb_io_capacity` is set, the master threads estimates the I/O bandwidth available for background tasks based on the set value. Setting the value to 100 reverts to the old behavior.

You can set the value of `innodb_io_capacity` to any number 100 or greater. The default value is 200, reflecting that the performance of typical modern I/O devices is higher than in the early days of MySQL. Typically, values around the previous default of 100 are appropriate for consumer-level storage devices, such as hard drives up to 7200 RPMs. Faster hard drives, RAID configurations, and SSDs benefit from higher values.

The `innodb_io_capacity` setting is a total limit for all buffer pool instances. When dirty pages are flushed, the `innodb_io_capacity` limit is divided equally among buffer pool instances. For more information, see the `innodb_io_capacity` system variable description.
You can set the value of this parameter in the MySQL option file (my.cnf or my.ini) or change it dynamically with the SET GLOBAL command, which requires the SUPER privilege.

For more information about InnoDB I/O performance, see Section 8.5.7, “Optimizing InnoDB Disk I/O”.

### 14.16.10 Using the PAUSE Instruction in InnoDB Spin Loops

Synchronization inside InnoDB frequently involves the use of spin loops: while waiting, InnoDB executes a tight loop of instructions repeatedly to avoid having the InnoDB process and threads be rescheduled by the operating system. If the spin loops are executed too quickly, system resources are wasted, imposing a performance penalty on transaction throughput. Most modern processors implement the PAUSE instruction for use in spin loops, so the processor can be more efficient.

InnoDB uses a PAUSE instruction in its spin loops on all platforms where such an instruction is available. This technique increases overall performance with CPU-bound workloads, and has the added benefit of minimizing power consumption during the execution of the spin loops.

You do not have to do anything to take advantage of this performance improvement.

For performance considerations for InnoDB locking operations, see Section 8.10, “Optimizing Locking Operations”.

### 14.16.11 Configuring Spin Lock Polling

Many InnoDB mutexes and rw-locks are reserved for a short time. On a multi-core system, it can be more efficient for a thread to continuously check if it can acquire a mutex or rw-lock for a while before sleeping. If the mutex or rw-lock becomes available during this polling period, the thread can continue immediately, in the same time slice. However, too-frequent polling by multiple threads of a shared object can cause “cache ping pong”, different processors invalidating portions of each others' cache. InnoDB minimizes this issue by waiting a random time between subsequent polls. The delay is implemented as a busy loop.

You can control the maximum delay between testing a mutex or rw-lock using the parameter innodb_spin_wait_delay. The duration of the delay loop depends on the C compiler and the target processor. (In the 100MHz Pentium era, the unit of delay was one microsecond.) On a system where all processor cores share a fast cache memory, you might reduce the maximum delay or disable the busy loop altogether by setting innodb_spin_wait_delay=0. On a system with multiple processor chips, the effect of cache invalidation can be more significant and you might increase the maximum delay.

The default value of innodb_spin_wait_delay is 6. The spin wait delay is a dynamic global parameter that you can specify in the MySQL option file (my.cnf or my.ini) or change at runtime with the command SET GLOBAL innodb_spin_wait_delay=delay, where delay is the desired maximum delay. Changing the setting requires the SUPER privilege.

For performance considerations for InnoDB locking operations, see Section 8.10, “Optimizing Locking Operations”.

### 14.16.12 InnoDB Integration with MySQL Performance Schema

Starting with InnoDB 1.1 with MySQL 5.5, you can profile certain internal InnoDB operations using the MySQL Performance Schema feature. This type of tuning is primarily for expert users, those who push the limits of MySQL performance, read the MySQL source code, and evaluate optimization strategies to overcome performance bottlenecks. DBAs can also use this feature for capacity planning, to see whether their typical workload encounters any performance bottlenecks with a particular combination of CPU, RAM, and disk storage; and if so, to judge whether performance can be improved by increasing the capacity of some part of the system.

To use this feature to examine InnoDB performance:
Better Scalability with Multiple Rollback Segments

- You must be running MySQL 5.5 or higher with the Performance Schema feature available and enabled, as described in Section 22.2, “Performance Schema Configuration”. Since the Performance Schema feature introduces some performance overhead, you should use it on a test or development system rather than on a production system.

- You must be running InnoDB 1.1 or higher.

- You must be generally familiar with how to use the Performance Schema feature, for example to query tables in the performance_schema database.

- Examine the following kinds of InnoDB objects by querying the appropriate performance_schema tables. The items associated with InnoDB all contain the substring innodb in the EVENT_NAME column.

For the definitions of the *_instances tables, see Section 22.7.3, “Performance Schema Instance Tables”. For the definitions of the *_summary_* tables, see Section 22.7.5, “Performance Schema Summary Tables”. For the definition of the thread table, see Section 22.7.6, “Performance Schema Miscellaneous Tables”. For the definition of the *_current_* and *_history_* tables, see Section 22.7.4, “Performance Schema Wait Event Tables”.

- Mutexes in the mutex_instances table. (Mutexes and RW-locks related to the InnoDB buffer pool are not included in this coverage; the same applies to the output of the SHOW ENGINE INNODB MUTEX command.)

- RW-locks in the rwlock_instances table.

- File I/O operations in the file_instances, file_summary_by_event_name, and file_summary_by_instance tables.

- Threads in the PROCESSLIST table.

- During performance testing, examine the performance data in the events_waits_current and events_waits_history_long tables. If you are interested especially in InnoDB-related objects, use the clause WHERE EVENT_NAME LIKE '%innodb%' to see just those entries; otherwise, examine the performance statistics for the overall MySQL server.

For more information about the MySQL Performance Schema, see Chapter 22, MySQL Performance Schema.

14.16.13 Better Scalability with Multiple Rollback Segments

Starting in InnoDB 1.1 with MySQL 5.5, the limit on concurrent transactions is greatly expanded, removing a bottleneck with the InnoDB rollback segment that affected high-capacity systems. The limit applies to concurrent transactions that change any data; read-only transactions do not count against that maximum.

The single rollback segment is now divided into 128 segments, each of which can support up to 1023 transactions that perform writes, for a total of approximately 128K concurrent transactions. The original transaction limit was 1023.

Each transaction is assigned to one of the rollback segments, and remains tied to that rollback segment for the duration. This enhancement improves both scalability (higher number of concurrent transactions) and performance (less contention when different transactions access the rollback segments).

To take advantage of this feature, you do not need to create any new database or tables, or reconfigure anything. You must do a slow shutdown before upgrading from MySQL 5.1 or earlier, or some time afterward. InnoDB makes the required changes inside the system tablespace automatically, the first time you restart after performing a slow shutdown.
For more information about performance of InnoDB under high transactional load, see Section 8.5.2, “Optimizing InnoDB Transaction Management”.

14.16.14 Configuring InnoDB Purge Scheduling

Starting in InnoDB 1.1 with MySQL 5.5, the purge operations (a type of garbage collection) that InnoDB performs automatically can be done in a separate thread, rather than as part of the master thread. This change improves scalability, because the main database operations run independently from maintenance work happening in the background.

To enable this feature, set the configuration option `innodb_purge_threads` to 1, as opposed to the default of 0, which combines the purge operation into the master thread.

You might not notice a significant speedup, because the purge thread might encounter new types of contention; the single purge thread really lays the groundwork for further tuning and possibly multiple purge threads in the future. There is another new configuration option, `innodb_purge_batch_size` with a default of 20 and maximum of 5000. This option is mainly intended for experimentation and tuning of purge operations, and should not be interesting to typical users.

For more information about InnoDB I/O performance, see Section 8.5.7, “Optimizing InnoDB Disk I/O”.

14.16.15 Configuring Optimizer Statistics Parameters

The MySQL query optimizer uses estimated statistics about key distributions to choose the indexes for an execution plan, based on the relative selectivity of the index. Certain operations cause InnoDB to sample random pages from each index on a table to estimate the cardinality of the index. (This technique is known as random dives.) These operations include the `ANALYZE TABLE` statement, the `SHOW TABLE STATUS` statement, and accessing the table for the first time after a restart.

To give you control over the quality of the statistics estimate (and thus better information for the query optimizer), you can now change the number of sampled pages using the parameter `innodb_stats_sample_pages`. Previously, the number of sampled pages was always 8, which could be insufficient to produce an accurate estimate, leading to poor index choices by the query optimizer. This technique is especially important for large tables and tables used in joins. Unnecessary full table scans for such tables can be a substantial performance issue.

You can set the global parameter `innodb_stats_sample_pages`, at runtime. The default value for this parameter is 8, preserving the same behavior as in past releases.

Note

The value of `innodb_stats_sample_pages` affects the index sampling for all tables and indexes. There are the following potentially significant impacts when you change the index sample size:

- Small values like 1 or 2 can result in very inaccurate estimates of cardinality.
- Increasing the `innodb_stats_sample_pages` value might require more disk reads. Values much larger than 8 (say, 100), can cause a big slowdown in the time it takes to open a table or execute `SHOW TABLE STATUS`.
- The optimizer might choose very different query plans based on different estimates of index selectivity.

To disable the cardinality estimation for metadata statements such as `SHOW TABLE STATUS` or `SHOW INDEX`, or when accessing the `INFORMATION_SCHEMA.TABLES` or `INFORMATION_SCHEMA.STATISTICS` tables, execute the statement `SET GLOBAL`
innodb_stats_on_metadata=OFF (or 0). The ability to set this option dynamically is also relatively new.

All InnoDB tables are opened, and the statistics are re-estimated for all associated indexes, when the mysql client starts with the --auto-rehash setting on (the default). To improve the start up time of the mysql client, you can turn auto-rehash off using the --disable-auto-rehash option. The auto-rehash feature enables automatic name completion of database, table, and column names for interactive users.

Whatever value of innodb_stats_sample_pages works best for a system, set the option and leave it at that value. Choose a value that results in reasonably accurate estimates for all tables in your database without requiring excessive I/O. Because the statistics are automatically recalculated at various times other than on execution of ANALYZE TABLE, it does not make sense to increase the index sample size, run ANALYZE TABLE, then decrease sample size again. The more accurate statistics calculated by ANALYZE running with a high value of innodb_stats_sample_pages can be wiped away later.

Although it is not possible to specify the sample size on a per-table basis, smaller tables generally require fewer index samples than larger tables do. If your database has many large tables, consider using a higher value for innodb_stats_sample_pages than if you have mostly smaller tables.

14.16.16 Estimating ANALYZE TABLE Complexity for InnoDB Tables

ANALYZE TABLE complexity for InnoDB tables is dependent on:

- The number of pages sampled, as defined by innodb_stats_sample_pages.
- The number of indexed columns in a table
- The number of partitions. If a table has no partitions, the number of partitions is considered to be 1.

Using these parameters, an approximate formula for estimating ANALYZE TABLE complexity would be:

\[
\text{innodb_stats_sample_pages} \times \text{number of indexed columns in a table} \times \text{number of partitions}
\]

Typically, the greater the resulting value, the greater the execution time for ANALYZE TABLE.

For more information about the innodb_stats_sample_pages configuration parameter, see Section 14.16.15, “Configuring Optimizer Statistics Parameters”.

14.17 InnoDB INFORMATION_SCHEMA Tables

The INFORMATION_SCHEMA is a MySQL feature that provides access to database metadata.

This section provides information and usage examples for a subset of InnoDB-related INFORMATION_SCHEMA tables related to compression, transactions, and locking. For a complete list of InnoDB INFORMATION_SCHEMA tables, see Section 21.28, “INFORMATION_SCHEMA Tables for InnoDB”.

The INFORMATION_SCHEMA tables are themselves plugins to the MySQL server, and must be activated by INSTALL statements. If they are installed, but the InnoDB storage engine plugin is not installed, these tables appear to be empty.

14.17.1 Information Schema Tables about Compression

Two new pairs of Information Schema tables can give you some insight into how well compression is working overall. One pair of tables contains information about the number of compression operations and the amount of time spent performing compression. Another pair of tables contains information on the way memory is allocated for compression.
14.17.1.1 INNODB_CMP and INNODB_CMP_RESET

The INNODB_CMP and INNODB_CMP_RESET tables contain status information on the operations related to compressed tables, which are covered in Section 14.10, “InnoDB Compressed Tables”. The compressed page size is in the column PAGE_SIZE.

These two tables have identical contents, but reading from INNODB_CMP_RESET resets the statistics on compression and uncompression operations. For example, if you archive the output of INNODB_CMP_RESET every 60 minutes, you see the statistics for each hourly period. If you monitor the output of INNODB_CMP (making sure never to read INNODB_CMP_RESET), you see the cumulated statistics since InnoDB was started.

For the table definition, see Table 21.1, “Columns of INNODB_CMP and INNODB_CMP_RESET”.

14.17.1.2 INNODB_CMPMEM and INNODB_CMPMEM_RESET

The INNODB_CMPMEM and INNODB_CMPMEM_RESET tables contain status information on the compressed pages that reside in the buffer pool. Please consult Section 14.10, “InnoDB Compressed Tables” for further information on compressed tables and the use of the buffer pool. The INNODB_CMP and INNODB_CMP_RESET tables should provide more useful statistics on compression.

Internal Details

InnoDB uses a buddy allocator system to manage memory allocated to pages of various sizes, from 1KB to 16KB. Each row of the two tables described here corresponds to a single page size.

These two tables have identical contents, but reading from INNODB_CMPMEM_RESET resets the statistics on relocation operations. For example, if every 60 minutes you archived the output of INNODB_CMPMEM_RESET, it would show the hourly statistics. If you never read INNODB_CMPMEM_RESET and monitored the output of INNODB_CMPMEM instead, it would show the cumulated statistics since InnoDB was started.

For the table definition, see Table 21.2, “Columns of INNODB_CMPMEM and INNODB_CMPMEM_RESET”.

14.17.1.3 Using the Compression Information Schema Tables

Example 14.1 Using the Compression Information Schema Tables

The following is sample output from a database that contains compressed tables (see Section 14.10, “InnoDB Compressed Tables”, INNODB_CMP, and INNODB_CMPMEM).

The following table shows the contents of INFORMATION_SCHEMA.INNODB_CMP under a light workload. The only compressed page size that the buffer pool contains is 8K. Compressing or uncompressing pages has consumed less than a second since the time the statistics were reset, because the columns COMPRESS_TIME and UNCOMPRESS_TIME are zero.

<table>
<thead>
<tr>
<th>page size</th>
<th>compress ops</th>
<th>compress ops ok</th>
<th>compress time</th>
<th>uncompress ops</th>
<th>uncompress time</th>
</tr>
</thead>
<tbody>
<tr>
<td>1024</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>2048</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>4096</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>8192</td>
<td>1048</td>
<td>921</td>
<td>0</td>
<td>61</td>
<td>0</td>
</tr>
<tr>
<td>16384</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

According to INNODB_CMPMEM, there are 6169 compressed 8KB pages in the buffer pool.
The following table shows the contents of INFORMATION_SCHEMA.INNODB_CMPMEM under a light workload. Some memory is unusable due to fragmentation of the InnoDB memory allocator for compressed pages: \( \text{SUM(PAGE\_SIZE*PAGES\_FREE)} = 6784 \). This is because small memory allocation requests are fulfilled by splitting bigger blocks, starting from the 16K blocks that are allocated from the main buffer pool, using the buddy allocation system. The fragmentation is this low because some allocated blocks have been relocated (copied) to form bigger adjacent free blocks. This copying of \( \text{SUM(PAGE\_SIZE*RELOCATION\_OPS)} \) bytes has consumed less than a second \( \text{SUM(RELOCATION\_TIME)} = 0 \).

14.17.2 Information Schema Tables about Transactions

Three InnoDB-related Information Schema tables make it easy to monitor transactions and diagnose possible locking problems. The three tables are INNODB_TRX, INNODB_LOCKS, and INNODB_LOCK_WAITS.

- **INNODB_TRX**

  Contains information about every transaction currently executing inside InnoDB, including whether the transaction is waiting for a lock, when the transaction started, and the particular SQL statement the transaction is executing.

  For the table definition, see Table 21.3, “INNODB_TRX Columns”.

- **INNODB_LOCKS**

  Each transaction in InnoDB that is waiting for another transaction to release a lock (INNODB_TRX.TRX_STATE='LOCK WAIT') is blocked by exactly one “blocking lock request”. That blocking lock request is for a row or table lock held by another transaction in an incompatible mode. The waiting or blocked transaction cannot proceed until the other transaction commits or rolls back, thereby releasing the requested lock. For every blocked transaction, INNODB_LOCKS contains one row that describes each lock the transaction has requested, and for which it is waiting. INNODB_LOCKS also contains one row for each lock that is blocking another transaction, whatever the state of the transaction that holds the lock (RUNNING, 'LOCK WAIT', 'ROLLING_BACK' or 'COMMITTING'). The lock that is blocking a transaction is always held in a mode (read vs. write, shared vs. exclusive) incompatible with the mode of requested lock.

  For the table definition, see Table 21.4, “INNODB_LOCKS Columns”.

- **INNODB_LOCK_WAITS**

  Using this table, you can tell which transactions are waiting for a given lock, or for which lock a given transaction is waiting. This table contains one or more rows for each blocked transaction, indicating the lock it has requested and any locks that are blocking that request. The REQUESTED_LOCK_ID refers to the lock that a transaction is requesting, and the BLOCKING_LOCK_ID refers to the lock (held by another transaction) that is preventing the first transaction from proceeding. For any given blocked transaction, all rows in INNODB_LOCK_WAITS have the same value for REQUESTED_LOCK_ID and different values for BLOCKING_LOCK_ID.
14.17.2.1 Using the Transaction Information Schema Tables

Example 14.2 Identifying Blocking Transactions

It is sometimes helpful to be able to identify which transaction is blocking another. You can use the Information Schema tables to find out which transaction is waiting for another, and which resource is being requested.

Suppose you have the following scenario, with three users running concurrently. Each user (or session) corresponds to a MySQL thread, and executes one transaction after another. Consider the state of the system when these users have issued the following commands, but none has yet committed its transaction:

• User A:

  ```sql
  BEGIN;
  SELECT a FROM t FOR UPDATE;
  SELECT SLEEP(100);
  ```

• User B:

  ```sql
  SELECT b FROM t FOR UPDATE;
  ```

• User C:

  ```sql
  SELECT c FROM t FOR UPDATE;
  ```

In this scenario, you can use this query to see who is waiting for whom:

```sql
SELECT r.trx_id waiting_trx_id,  
  r.trx_mysql_thread_id waiting_thread,  
  r.trx_query waiting_query,  
  b.trx_id blocking_trx_id,  
  b.trx_mysql_thread_id blocking_thread,  
  b.trx_query blocking_query  
FROM       information_schema.innodb_lock_waits w  
INNER JOIN information_schema.innodb_trx b ON  
  b.trx_id = w.blocking_trx_id  
INNER JOIN information_schema.innodb_trx r ON  
  r.trx_id = w.requesting_trx_id;
```

<table>
<thead>
<tr>
<th>waiting trx id</th>
<th>waiting thread</th>
<th>waiting query</th>
<th>blocking trx id</th>
<th>blocking thread</th>
<th>blocking query</th>
</tr>
</thead>
<tbody>
<tr>
<td>A4</td>
<td>6</td>
<td>SELECT b FROM t FOR UPDATE</td>
<td>A3</td>
<td>5</td>
<td>SELECT SLEEP(100)</td>
</tr>
<tr>
<td>A5</td>
<td>7</td>
<td>SELECT c FROM t FOR UPDATE</td>
<td>A3</td>
<td>5</td>
<td>SELECT SLEEP(100)</td>
</tr>
<tr>
<td>A5</td>
<td>7</td>
<td>SELECT c FROM t FOR UPDATE</td>
<td>A4</td>
<td>6</td>
<td>SELECT b FROM t FOR UPDATE</td>
</tr>
</tbody>
</table>

In the above result, you can identify users by the “waiting query” or “blocking query”. As you can see:

• User B (trx id 'A4', thread 6) and User C (trx id 'A5', thread 7) are both waiting for User A (trx id 'A3', thread 5).
• User C is waiting for User B as well as User A.

You can see the underlying data in the tables `INNODB_TRX`, `INNODB_LOCKS`, and `INNODB_LOCK_WAITS`.

The following table shows some sample contents of `INFORMATION_SCHEMA.INNODB_TRX`.

<table>
<thead>

</tbody>
</table>

Example 14.3 More Complex Example of Transaction Data in Information Schema Tables

Sometimes you would like to correlate the internal InnoDB locking information with session-level information maintained by MySQL. For example, you might like to know, for a given InnoDB transaction ID, the corresponding MySQL session ID and name of the user that may be holding a lock, and thus blocking another transaction.

The following output from the `INFORMATION_SCHEMA` tables is taken from a somewhat loaded system.

As can be seen in the following tables, there are several transactions running.

The following `INNODB_LOCKS` and `INNODB_LOCK_WAITS` tables shows that:

• Transaction `77F` (executing an `INSERT`) is waiting for transactions `77E`, `77D` and `77B` to commit.
• Transaction `77E` (executing an `INSERT`) is waiting for transactions `77D` and `77B` to commit.
• Transaction `77D` (executing an `INSERT`) is waiting for transaction `77B` to commit.
• Transaction `77B` (executing an `INSERT`) is waiting for transaction `77A` to commit.
• Transaction `77A` is running, currently executing `SELECT`.
• Transaction `E56` (executing an `INSERT`) is waiting for transaction `E55` to commit.
• Transaction **E55** (executing an **INSERT**) is waiting for transaction **19C** to commit.

• Transaction **19C** is running, currently executing an **INSERT**.

Note that there may be an inconsistency between queries shown in the two tables **INNODB_TRX.TRX_QUERY** and **PROCESSLIST.INFO**. The current transaction ID for a thread, and the query being executed in that transaction, may be different in these two tables for any given thread. See Section 14.17.3.3, "Possible Inconsistency with **PROCESSLIST**" for an explanation.

The following table shows the contents of **INFORMATION_SCHEMA.PROCESSLIST** in a system running a heavy **workload**.

<table>
<thead>

</table>
14.17.3 Special Locking Considerations for InnoDB INFORMATION_SCHEMA Tables

14.17.3.1 Understanding InnoDB Locking

When a transaction updates a row in a table, or locks it with SELECT FOR UPDATE, InnoDB establishes a list or queue of locks on that row. Similarly, InnoDB maintains a list of locks on a table for table-level locks transactions hold. If a second transaction wants to update a row or lock a table already locked by a prior transaction in an incompatible mode, InnoDB adds a lock request for the row to the corresponding queue. For a lock to be acquired by a transaction, all incompatible lock requests previously entered into the lock queue for that row or table must be removed (the transactions holding or requesting those locks either commit or roll back).

A transaction may have any number of lock requests for different rows or tables. At any given time, a transaction may be requesting a lock that is held by another transaction, in which case it is blocked by that other transaction. The requesting transaction must wait for the transaction that holds the blocking lock to commit or rollback. If a transaction is not waiting for a lock, it is in the 'RUNNING' state. If a transaction is waiting for a lock, it is in the 'LOCK WAIT' state.

The INNODB_LOCKS table holds one or more row for each 'LOCK WAIT' transaction, indicating any lock requests that are preventing its progress. This table also contains one row describing each lock in a queue of locks pending for a given row or table. The INNODB_LOCK_WAITS table shows which locks already held by a transaction are blocking locks requested by other transactions.

14.17.3.2 Granularity of INFORMATION_SCHEMA Data

The data exposed by the transaction and locking tables represent a glimpse into fast-changing data. This is not like other (user) tables, where the data changes only when application-initiated updates occur. The underlying data is internal system-managed data, and can change very quickly.

For performance reasons, and to minimize the chance of misleading JOINs between the INFORMATION_SCHEMA tables, InnoDB collects the required transaction and locking information into an intermediate buffer whenever a SELECT on any of the tables is issued. This buffer is refreshed only if more than 0.1 seconds has elapsed since the last time the buffer was read. The data needed to fill the three tables is fetched atomically and consistently and is saved in this global internal buffer, forming a point-in-time "snapshot". If multiple table accesses occur within 0.1 seconds (as they almost certainly do when MySQL processes a join among these tables), then the same snapshot is used to satisfy the query.

A correct result is returned when you JOIN any of these tables together in a single query, because the data for the three tables comes from the same snapshot. Because the buffer is not refreshed with every query of any of these tables, if you issue separate queries against these tables within a tenth of a second, the results are the same from query to query. On the other hand, two separate queries of the same or different
InnoDB Monitors

Tables issued more than a tenth of a second apart may see different results, since the data come from different snapshots.

Because InnoDB must temporarily stall while the transaction and locking data is collected, too frequent queries of these tables can negatively impact performance as seen by other users.

As these tables contain sensitive information (at least INNODB_LOCKS.LOCK_DATA and INNODB_TRX.TRX_QUERY), for security reasons, only the users with the PROCESS privilege are allowed to SELECT from them.

14.17.3.3 Possible Inconsistency with PROCESSLIST

As just described, while the transaction and locking data is correct and consistent when these INFORMATION_SCHEMA tables are populated. For example, the query in INNODB_TRX is always consistent with the rest of INNODB_TRX, INNODB_LOCKS and INNODB_LOCK_WAITS when the data comes from the same snapshot. However, the underlying data changes so fast that similar glimpses at other, similarly fast-changing data, may not be in synchrony. Thus, you should be careful in comparing the data in the InnoDB transaction and locking tables with that in the PROCESSLIST table. The data from the PROCESSLIST table does not come from the same snapshot as the data about locking and transactions. Even if you issue a single SELECT (joining INNODB_TRX and PROCESSLIST, for example), the content of those tables is generally not consistent. INNODB_TRX may reference rows that are not present in PROCESSLIST or the currently executing SQL query of a transaction, shown in INNODB_TRX.TRX_QUERY may differ from the one in PROCESSLIST.INFO.

14.18 InnoDB Monitors

InnoDB monitors provide information about the InnoDB internal state. This information is useful for performance tuning.

14.18.1 InnoDB Monitor Types

There are four types of InnoDB monitors:

- The standard InnoDB Monitor displays the following types of information:
  - Table and record locks held by each active transaction.
  - Lock waits of a transaction.
  - Semaphore waits of threads.
  - Pending file I/O requests.
  - Buffer pool statistics.
  - Purge and insert buffer merge activity of the main InnoDB thread.
- The InnoDB Lock Monitor is like the standard InnoDB Monitor but also provides extensive lock information.
- The InnoDB Tablespace Monitor prints a list of file segments in the shared tablespace and validates the tablespace allocation data structures.
- The InnoDB Table Monitor prints the contents of the InnoDB internal data dictionary.

For additional information about InnoDB monitors, see:
14.18.2 Enabling InnoDB Monitors

When you enable InnoDB monitors for periodic output, InnoDB writes their output to the `mysqld` server standard error output (`stderr`). In this case, no output is sent to clients. When switched on, InnoDB monitors print data about every 15 seconds. Server output usually is directed to the error log (see Section 5.2.2, “The Error Log”). This data is useful in performance tuning. On Windows, start the server from a command prompt in a console window with the `--console` option if you want to direct the output to the window rather than to the error log.

InnoDB sends diagnostic output to `stderr` or to files rather than to `stdout` or fixed-size memory buffers, to avoid potential buffer overflows. As a side effect, the output of `SHOW ENGINE INNODB STATUS` is written to a status file in the MySQL data directory every fifteen seconds. The name of the file is `innodb_status.pid`, where `pid` is the server process ID. InnoDB removes the file for a normal shutdown. If abnormal shutdowns have occurred, instances of these status files may be present and must be removed manually. Before removing them, you might want to examine them to see whether they contain useful information about the cause of abnormal shutdowns. The `innodb_status.pid` file is created only if the configuration option `innodb-status-file=1` is set.

InnoDB monitors should be enabled only when you actually want to see monitor information because output generation does result in some performance decrement. Also, if you enable monitor output by creating the associated table, your error log may become quite large if you forget to remove the table later.

Note

To assist with troubleshooting, InnoDB temporarily enables standard InnoDB Monitor output under certain conditions. For more information, see Section 14.21, “InnoDB Troubleshooting”.

Each monitor begins with a header containing a timestamp and the monitor name. For example:

```
LOCK MONITOR OUTPUT
```

The header for the standard InnoDB Monitor (`INNODB MONITOR OUTPUT`) is also used for the Lock Monitor because the latter produces the same output with the addition of extra lock information.

Enabling an InnoDB monitor for periodic output involves using a `CREATE TABLE` statement to create a specially named InnoDB table that is associated with the monitor. For example, to enable the standard InnoDB Monitor, you would create an InnoDB table named `innodb_monitor`.

Using `CREATE TABLE` syntax is just a way to pass a command to the InnoDB engine through MySQL's SQL parser. The only things that matter are the table name and that it be an InnoDB table. The structure of the table is not relevant. If you shut down the server, the monitor does not restart automatically when you restart the server. Drop the monitor table and issue a new `CREATE TABLE` statement to start the monitor.

The `PROCESS` privilege is required to start or stop the InnoDB monitors.

Enabling the Standard InnoDB Monitor

To enable the standard InnoDB Monitor for periodic output, create the `innodb_monitor` table:
CREATE TABLE innodb_monitor (a INT) ENGINE=INNODB;

To disable the standard InnoDB Monitor, drop the table:

DROP TABLE innodb_monitor;

Obtaining Standard InnoDB Monitor Output On Demand

As an alternative to enabling the standard InnoDB Monitor for periodic output, you can obtain standard InnoDB Monitor output on demand using the `SHOW ENGINE INNODB STATUS` SQL statement, which fetches the output to your client program. If you are using the mysql interactive client, the output is more readable if you replace the usual semicolon statement terminator with \G:

```
mysql> SHOW ENGINE INNODB STATUS\G
```

Enabling the InnoDB Lock Monitor

To enable the InnoDB Lock Monitor for periodic output, create the innodb_lock_monitor table:

CREATE TABLE innodb_lock_monitor (a INT) ENGINE=INNODB;

To disable the InnoDB Lock Monitor, drop the table:

DROP TABLE innodb_lock_monitor;

Enabling the InnoDB Tablespace Monitor

To enable the InnoDB Tablespace Monitor for periodic output, create the innodb_tablespace_monitor table:

CREATE TABLE innodb_tablespace_monitor (a INT) ENGINE=INNODB;

To disable the standard InnoDB Tablespace Monitor, drop the table:

DROP TABLE innodb_tablespace_monitor;

Enabling the InnoDB Table Monitor

To enable the InnoDB Table Monitor for periodic output, create the innodb_table_monitor table:

CREATE TABLE innodb_table_monitor (a INT) ENGINE=INNODB;

To disable the InnoDB Table Monitor, drop the table:

DROP TABLE innodb_table_monitor;

14.18.3 InnoDB Standard Monitor and Lock Monitor Output

The Lock Monitor is the same as the standard Monitor except that it includes additional lock information. Enabling either monitor for periodic output turns on the same output stream, but the stream includes extra information if the Lock Monitor is enabled. For example, if you enable the standard InnoDB Monitor and InnoDB Lock Monitor, that turns on a single output stream. The stream includes extra lock information until you disable the Lock Monitor.
Example standard InnoDB Monitor output:

```
SHOW ENGINE INNODB STATUS\G
*************************** 1. row ***************************

END OF INNODB MONITOR OUTPUT
--------------------------------------

Standard InnoDB Monitor output is limited to 1MB when produced using the SHOW ENGINE INNODB STATUS statement. This limit does not apply to output written to the server’s error output.

Some notes on the output sections:

Status
This section shows the timestamp, the monitor name, and the number of seconds that per-second averages are based on. The number of seconds is the elapsed time between the current time and the last time InnoDB Monitor output was printed.

**BACKGROUND THREAD**

The `srv_master_thread` lines shows work done by the main background thread.

**SEMAPHORES**

This section reports threads waiting for a semaphore and statistics on how many times threads have needed a spin or a wait on a mutex or a rw-lock semaphore. A large number of threads waiting for semaphores may be a result of disk I/O, or contention problems inside InnoDB. Contention can be due to heavy parallelism of queries or problems in operating system thread scheduling. Setting the `innodb_thread_concurrency` system variable smaller than the default value might help in such situations. The `Spin rounds per wait` line shows the number of spinlock rounds per OS wait for a mutex.

**LATEST FOREIGN KEY ERROR**

This section provides information about the most recent foreign key constraint error. It is not present if no such error has occurred. The contents include the statement that failed as well as information about the constraint that failed and the referenced and referencing tables.

**LATEST DETECTED DEADLOCK**

This section provides information about the most recent deadlock. It is not present if no deadlock has occurred. The contents show which transactions are involved, the statement each was attempting to execute, the locks they have and need, and which transaction InnoDB decided to roll back to break the deadlock. The lock modes reported in this section are explained in Section 14.5.3, "InnoDB Lock Modes".

**TRANSACTIONS**

If this section reports lock waits, your applications might have lock contention. The output can also help to trace the reasons for transaction deadlocks.

**FILE I/O**

This section provides information about threads that InnoDB uses to perform various types of I/O. The first few of these are dedicated to general InnoDB processing. The contents also display information for pending I/O operations and statistics for I/O performance.

The number of these threads are controlled by the `innodb_read_io_threads` and `innodb_write_io_threads` parameters. See Section 14.15, "InnoDB Startup Options and System Variables".

**INSERT BUFFER AND ADAPTIVE HASH INDEX**

This section shows the status of the InnoDB insert buffer and adaptive hash index. (See Section 14.5.13.4, "Insert Buffering", and Section 14.5.13.5, "Adaptive Hash Indexes".) The contents include the number of operations performed for each, plus statistics for hash index performance.

**LOG**

This section displays information about the InnoDB log. The contents include the current log sequence number, how far the log has been flushed to disk, and the position at which InnoDB last took a checkpoint. (See Section 14.13.3, "InnoDB Checkpoints".) The section also displays information about pending writes and write performance statistics.
InnoDB Tablespace Monitor Output

BUFFER POOL AND MEMORY

This section gives you statistics on pages read and written. You can calculate from these numbers how many data file I/O operations your queries currently are doing.

For additional information about the operation of the buffer pool, see Section 8.9.1, “The InnoDB Buffer Pool”.

ROW OPERATIONS

This section shows what the main thread is doing, including the number and performance rate for each type of row operation.

In MySQL 5.5, output from the standard InnoDB Monitor includes additional sections compared to the output for previous versions. For details, see Section 1.4.3, “Diagnostic and Monitoring Capabilities”.

14.18.4 InnoDB Tablespace Monitor Output

The InnoDB Tablespace Monitor prints information about the file segments in the shared tablespace and validates the tablespace allocation data structures. The Tablespace Monitor does not describe file-per-table tablespaces created with the innodb_file_per_table option.

Example InnoDB Tablespace Monitor output:

```
090408 21:28:09 INNODB TABLESPACE MONITOR OUTPUT
FILE SPACE INFO: id 0
  size 13440, free limit 3136, free extents 28
  not full frag extents 2: used pages 78, full frag extents 3
  first seg id not used 0 23845
SEGMENT id 0 1 space 0; page 2; res 96 used 46; full ext 0
  fragm pages 32; free extents 0; not full extents 1: pages 14
SEGMENT id 0 2 space 0; page 2; res 1 used 1; full ext 0
  fragm pages 1; free extents 0; not full extents 0: pages 0
SEGMENT id 0 3 space 0; page 2; res 1 used 1; full ext 0
  fragm pages 1; free extents 0; not full extents 0: pages 0 ...
SEGMENT id 0 15 space 0; page 2; res 160 used 160; full ext 2
  fragm pages 32; free extents 0; not full extents 0: pages 0
SEGMENT id 0 488 space 0; page 2; res 1 used 1; full ext 0
  fragm pages 1; free extents 0; not full extents 0: pages 0
SEGMENT id 0 17 space 0; page 2; res 1 used 1; full ext 0
  fragm pages 1; free extents 0; not full extents 0: pages 0 ...
SEGMENT id 0 171 space 0; page 2; res 592 used 481; full ext 7
  fragm pages 16; free extents 0; not full extents 2: pages 17
SEGMENT id 0 172 space 0; page 2; res 1 used 1; full ext 0
  fragm pages 1; free extents 0; not full extents 0: pages 0
SEGMENT id 0 173 space 0; page 2; res 96 used 44; full ext 0
  fragm pages 32; free extents 0; not full extents 1: pages 12 ...
SEGMENT id 0 601 space 0; page 2; res 1 used 1; full ext 0
  fragm pages 1; free extents 0; not full extents 0: pages 0
NUMBER of file segments: 73
Validating tablespace
Validation ok
END OF INNODB TABLESPACE MONITOR OUTPUT
```

The Tablespace Monitor output includes information about the shared tablespace as a whole, followed by a list containing a breakdown for each segment within the tablespace.
In this example using the default page size, the tablespace consists of database pages that are 16KB each. The pages are grouped into extents of size 1MB (64 consecutive pages).

The initial part of the output that displays overall tablespace information has this format:

```
FILE SPACE INFO: id 0
size 13440, free limit 3136, free extents 28
not full frag extents 2: used pages 78, full frag extents 3
first seg id not used 0 23845
```

Overall tablespace information includes these values:

- **id**: The tablespace ID. A value of 0 refers to the shared tablespace.
- **size**: The current tablespace size in pages.
- **free limit**: The minimum page number for which the free list has not been initialized. Pages at or above this limit are free.
- **free extents**: The number of free extents.
- **not full frag extents, used pages**: The number of fragment extents that are not completely filled, and the number of pages in those extents that have been allocated.
- **full frag extents**: The number of completely full fragment extents.
- **first seg id not used**: The first unused segment ID.

Individual segment information has this format:

```
SEGMENT id 0 15 space 0; page 2; res 160 used 160; full ext 2
fragm pages 32; free extents 0; not full extents 0: pages 0
```

Segment information includes these values:

- **id**: The segment ID.
- **space, page**: The tablespace number and page within the tablespace where the segment “inode” is located. A tablespace number of 0 indicates the shared tablespace. InnoDB uses inodes to keep track of segments in the tablespace. The other fields displayed for a segment (id, res, and so forth) are derived from information in the inode.
- **res**: The number of pages allocated (reserved) for the segment.
- **used**: The number of allocated pages in use by the segment.
- **full ext**: The number of extents allocated for the segment that are completely used.
- **fragm pages**: The number of initial pages that have been allocated to the segment.
- **free extents**: The number of extents allocated for the segment that are completely unused.
- **not full extents**: The number of extents allocated for the segment that are partially used.
- **pages**: The number of pages used within the not-full extents.

When a segment grows, it starts as a single page, and InnoDB allocates the first pages for it one at a time, up to 32 pages (this is the fragm pages value). After that, InnoDB allocates complete extents. InnoDB can add up to 4 extents at a time to a large segment to ensure good sequentiality of data.
For the example segment shown earlier, it has 32 fragment pages, plus 2 full extents (64 pages each), for a total of 160 pages used out of 160 pages allocated. The following segment has 32 fragment pages and one partially full extent using 14 pages for a total of 46 pages used out of 96 pages allocated:

```
SEGMENT id 0 1 space 0; page 2; res 96 used 46; full ext 0
fragm pages 32; free extents 0; not full extents 1: pages 14
```

It is possible for a segment that has extents allocated to it to have a `fragm pages` value less than 32 if some of the individual pages have been deallocated subsequent to extent allocation.

### 14.18.5 InnoDB Table Monitor Output

The InnoDB Table Monitor prints the contents of the InnoDB internal data dictionary.

The output contains one section per table. The `SYS_FOREIGN` and `SYS_FOREIGN_COLS` sections are for internal data dictionary tables that maintain information about foreign keys. There are also sections for the Table Monitor table and each user-created InnoDB table. Suppose that the following two tables have been created in the `test` database:

```
CREATE TABLE parent
(
  par_id    INT NOT NULL,
  fname      CHAR(20),
  lname      CHAR(20),
  PRIMARY KEY (par_id),
  UNIQUE INDEX (lname, fname)
) ENGINE = INNODB;

CREATE TABLE child
(
  par_id      INT NOT NULL,
  child_id    INT NOT NULL,
  name        VARCHAR(40),
  birth       DATE,
  weight      DECIMAL(10,2),
  misc_info   VARCHAR(255),
  last_update TIMESTAMP,
  PRIMARY KEY (par_id, child_id),
  INDEX (name),
  FOREIGN KEY (par_id) REFERENCES parent (par_id)
  ON DELETE CASCADE
  ON UPDATE CASCADE
) ENGINE = INNODB;
```

Then the Table Monitor output will look something like this (reformatted slightly):

```
090420 12:09:32 INNODB TABLE MONITOR OUTPUT

TABLE: name SYS_FOREIGN, id 0 11, columns 7, indexes 3, appr.rows 1
COLUMNS: ID: DATA_VARCHAR DATA_ENGLISH len 0;
         FOR_NAME: DATA_VARCHAR DATA_ENGLISH len 0;
         REF_NAME: DATA_VARCHAR DATA_ENGLISH len 0;
         N_COLS: DATA_INT len 4;
         DB_ROW_ID: DATA_SYS prtype 256 len 6;
         DB_TRX_ID: DATA_SYS prtype 257 len 6;
INDEX: name ID_IND, id 0 11, fields 1/6, uniq 1, type 3
        root page 46, appr.key vals 1, leaf pages 1, size pages 1
FIELDS: ID ID DB_TRX_ID DB_ROLL_PTR FOR_NAME REF_NAME N_COLS
INDEX: name FOR_IND, id 0 12, fields 1/2, uniq 2, type 0
        root page 47, appr.key vals 1, leaf pages 1, size pages 1
```
For each table, Table Monitor output contains a section that displays general information about the table and specific information about its columns, indexes, and foreign keys.

The general information for each table includes the table name (in \texttt{db_name/tbl_name} format except for internal tables), its ID, the number of columns and indexes, and an approximate row count.
The **COLUMNS** part of a table section lists each column in the table. Information for each column indicates its name and data type characteristics. Some internal columns are added by InnoDB, such as **DB_ROW_ID** (row ID), **DB_TRX_ID** (transaction ID), and **DB_ROLL_PTR** (a pointer to the rollback/undo data).

- **DATA_xxx**: These symbols indicate the data type. There may be multiple **DATA_xxx** symbols for a given column.
- **prtype**: The column’s “precise” type. This field includes information such as the column data type, character set code, nullability, signedness, and whether it is a binary string. This field is described in the `innobase/include/data0type.h` source file.
- **len**: The column length in bytes.

Each **INDEX** part of the table section provides the name and characteristics of one table index:

- **name**: The index name. If the name is **PRIMARY**, the index is a primary key. If the name is **GEN_CLUST_INDEX**, the index is the clustered index that is created automatically if the table definition doesn’t include a primary key or non-**NULL** unique index. See Section 14.5.13.2, “Clustered and Secondary Indexes”.
- **id**: The index ID.
- **fields**: The number of fields in the index, as a value in **m/n** format:
  - **m** is the number of user-defined columns; that is, the number of columns you would see in the index definition in a **CREATE TABLE** statement.
  - **n** is the total number of index columns, including those added internally. For the clustered index, the total includes the other columns in the table definition, plus any columns added internally. For a secondary index, the total includes the columns from the primary key that are not part of the secondary index.
- **uniq**: The number of leading fields that are enough to determine index values uniquely.
- **type**: The index type. This is a bit field. For example, 1 indicates a clustered index and 2 indicates a unique index, so a clustered index (which always contains unique values), will have a **type** value of 3. An index with a **type** value of 0 is neither clustered nor unique. The flag values are defined in the `innobase/include/dict0mem.h` source file.
- **root page**: The index root page number.
- **appr. key vals**: The approximate index cardinality.
- **leaf pages**: The approximate number of leaf pages in the index.
- **size pages**: The approximate total number of pages in the index.
- **FIELDS**: The names of the fields in the index. For a clustered index that was generated automatically, the field list begins with the internal **DB_ROW_ID** (row ID) field. **DB_TRX_ID** and **DB_ROLL_PTR** are always added internally to the clustered index, following the fields that comprise the primary key. For a secondary index, the final fields are those from the primary key that are not part of the secondary index.

The end of the table section lists the **FOREIGN KEY** definitions that apply to the table. This information appears whether the table is a referencing or referenced table.

**14.19 InnoDB Backup and Recovery**

The key to safe database management is making regular backups. Depending on your data volume, number of MySQL servers, and database workload, you can use these techniques, alone or in
combination: hot backup with MySQL Enterprise Backup; cold backup by copying files while the MySQL server is shut down; physical backup for fast operation (especially for restore); logical backup with mysqldump for smaller data volumes or to record the structure of schema objects.

Hot Backups

The mysqlbackup command, part of the MySQL Enterprise Backup component, lets you back up a running MySQL instance, including InnoDB and MyISAM tables, with minimal disruption to operations while producing a consistent snapshot of the database. When mysqlbackup is copying InnoDB tables, reads and writes to both InnoDB and MyISAM tables can continue. During the copying of MyISAM tables, reads (but not writes) to those tables are permitted. MySQL Enterprise Backup can also create compressed backup files, and back up subsets of tables and databases. In conjunction with MySQL’s binary log, users can perform point-in-time recovery. MySQL Enterprise Backup is part of the MySQL Enterprise subscription. For more details, see Section 25.2, “MySQL Enterprise Backup”.

Cold Backups

If you can shut down your MySQL server, you can make a binary backup that consists of all files used by InnoDB to manage its tables. Use the following procedure:

1. Do a slow shutdown of the MySQL server and make sure that it stops without errors.
2. Copy all InnoDB data files (ibdata files and .ibd files) into a safe place.
3. Copy all the .frm files for InnoDB tables to a safe place.
4. Copy all InnoDB log files (ib_logfile files) to a safe place.
5. Copy your my.cnf configuration file or files to a safe place.

Alternative Backup Types

In addition to making binary backups as just described, regularly make dumps of your tables with mysqldump. A binary file might be corrupted without you noticing it. Dumped tables are stored into text files that are human-readable, so spotting table corruption becomes easier. Also, because the format is simpler, the chance for serious data corruption is smaller. mysqldump also has a --single-transaction option for making a consistent snapshot without locking out other clients. See Section 7.3.1, “Establishing a Backup Policy”.

Replication works with InnoDB tables, so you can use MySQL replication capabilities to keep a copy of your database at database sites requiring high availability.

Performing Recovery

To recover your InnoDB database to the present from the time at which the binary backup was made, you must run your MySQL server with binary logging turned on, even before taking the backup. To achieve point-in-time recovery after restoring a backup, you can apply changes from the binary log that occurred after the backup was made. See Section 7.5, “Point-in-Time (Incremental) Recovery Using the Binary Log”.

To recover from a crash of your MySQL server, the only requirement is to restart it. InnoDB automatically checks the logs and performs a roll-forward of the database to the present. InnoDB automatically rolls back uncommitted transactions that were present at the time of the crash. During recovery, mysqld displays output something like this:

```
InnoDB: Database was not shut down normally.
InnoDB: Starting recovery from log files...
```
If your database becomes corrupted or disk failure occurs, you must perform the recovery using a backup. In the case of corruption, first find a backup that is not corrupted. After restoring the base backup, do a point-in-time recovery from the binary log files using `mysqlbinlog` and `mysql` to restore the changes that occurred after the backup was made.

In some cases of database corruption, it is enough just to dump, drop, and re-create one or a few corrupt tables. You can use the `CHECK TABLE` SQL statement to check whether a table is corrupt, although `CHECK TABLE` naturally cannot detect every possible kind of corruption. You can use the Tablespace Monitor to check the integrity of the file space management inside the tablespace files.

In some cases, apparent database page corruption is actually due to the operating system corrupting its own file cache, and the data on disk may be okay. It is best first to try restarting your computer. Doing so may eliminate errors that appeared to be database page corruption. If MySQL still has trouble starting because of InnoDB Consistency problems, see Section 14.21.2, “Starting InnoDB on a Corrupted Database” for steps to start the instance in a diagnostic mode where you can dump the data.

14.19.1 The InnoDB Recovery Process

InnoDB crash recovery consists of several steps:

The first step, applying the redo log, is performed during initialization, before accepting any connections. If all changes were flushed from the buffer pool to the tablespaces (`ibdata*` and `*.ibd` files) at the time of the shutdown or crash, the redo log application can be skipped. If the redo log files are missing at startup, InnoDB skips the redo log application.

Removing redo logs to speed up the recovery process is not recommended, even if some data loss is acceptable. Removing redo logs should only ever be considered an option after a clean shutdown is performed, with `innodb_fast_shutdown` set to 0 or 1.

The remaining steps after redo log application do not depend on the redo log (other than for logging the writes) and are performed in parallel with normal processing. These include:

- **Rolling back incomplete transactions**: Any transactions that were active at the time of crash or fast shutdown. The time it takes to roll back an incomplete transaction can be three or four times the amount of time a transaction is active before it is interrupted, depending on server load.

You cannot cancel transactions that are in the process of being rolled back. In extreme cases, when rolling back transactions is expected to take a long time, it may be faster to start InnoDB with an `innodb_force_recovery` setting of 3 or greater.
InnoDB and MySQL Replication

- **Insert buffer** merge: Applying changes from the insert buffer (part of the system tablespace) to leaf pages of secondary indexes, as the index pages are read to the buffer pool.

- **Purge**: Deleting delete-marked records that are no longer visible for any active transaction.

Of these, only rollback of incomplete transactions is special to crash recovery. The insert buffer merge and the purge are performed during normal processing.

In most situations, even if the MySQL server was killed unexpectedly in the middle of heavy activity, the recovery process happens automatically and no action is needed from the DBA. If a hardware failure or severe system error corrupted InnoDB data, MySQL might refuse to start. In that case, see Section 14.21.2, “Starting InnoDB on a Corrupted Database” for the steps to troubleshoot such an issue.

14.20 InnoDB and MySQL Replication

MySQL replication works for InnoDB tables as it does for MyISAM tables. It is also possible to use replication in a way where the storage engine on the slave is not the same as the original storage engine on the master. For example, you can replicate modifications to an InnoDB table on the master to a MyISAM table on the slave.

To set up a new slave for a master, make a copy of the InnoDB tablespace and the log files, as well as the .frm files of the InnoDB tables, and move the copies to the slave. If the innodb_file_per_table option is enabled, copy the .ibd files as well. For the proper procedure to do this, see Section 14.19, “InnoDB Backup and Recovery”.

To make a new slave without taking down the master or an existing slave, use the MySQL Enterprise Backup product. If you can shut down the master or an existing slave, take a cold backup of the InnoDB tablespaces and log files and use that to set up a slave.

Transactions that fail on the master do not affect replication at all. MySQL replication is based on the binary log where MySQL writes SQL statements that modify data. A transaction that fails (for example, because of a foreign key violation, or because it is rolled back) is not written to the binary log, so it is not sent to slaves. See Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”.

Replication and **CASCADE**. Cascading actions for InnoDB tables on the master are replicated on the slave only if the tables sharing the foreign key relation use InnoDB on both the master and slave. This is true whether you are using statement-based or row-based replication. Suppose that you have started replication, and then create two tables on the master using the following **CREATE TABLE** statements:

```sql
CREATE TABLE fc1 (  
  i INT PRIMARY KEY,  
  j INT  
) ENGINE = InnoDB;

CREATE TABLE fc2 (  
  m INT PRIMARY KEY,  
  n INT,  
  FOREIGN KEY ni (n) REFERENCES fc1 (i)  
    ON DELETE CASCADE  
) ENGINE = InnoDB;
```

Suppose that the slave does not have InnoDB support enabled. If this is the case, then the tables on the slave are created, but they use the MyISAM storage engine, and the FOREIGN KEY option is ignored. Now we insert some rows into the tables on the master:
InnoDB and MySQL Replication

master> INSERT INTO fc1 VALUES (1, 1), (2, 2);
Query OK, 2 rows affected (0.09 sec)
Records: 2 Duplicates: 0 Warnings: 0

master> INSERT INTO fc2 VALUES (1, 1), (2, 2), (3, 1);
Query OK, 3 rows affected (0.19 sec)
Records: 3 Duplicates: 0 Warnings: 0

At this point, on both the master and the slave, table fc1 contains 2 rows, and table fc2 contains 3 rows, as shown here:

master> SELECT * FROM fc1;
+---+------+
| i | j    |
+---+------+
| 1 |    1 |
| 2 |    2 |
+---+------+
2 rows in set (0.00 sec)

master> SELECT * FROM fc2;
+---+---+
| m | n |
+---+---+
| 1 | 1 |
| 2 | 2 |
| 3 | 1 |
+---+---+
3 rows in set (0.00 sec)

slave> SELECT * FROM fc1;
+---+------+
| i | j    |
+---+------+
| 1 |    1 |
| 2 |    2 |
+---+------+
2 rows in set (0.00 sec)

slave> SELECT * FROM fc2;
+---+---+
| m | n |
+---+---+
| 1 | 1 |
| 2 | 2 |
| 3 | 1 |
+---+---+
3 rows in set (0.00 sec)

Now suppose that you perform the following DELETE statement on the master:

master> DELETE FROM fc1 WHERE i=1;
Query OK, 1 row affected (0.09 sec)

Due to the cascade, table fc2 on the master now contains only 1 row:

master> SELECT * FROM fc2;
+---+---+
| m | n |
+---+---+
| 2 | 2 |
+---+---+
1 row in set (0.00 sec)
However, the cascade does not propagate on the slave because on the slave the DELETE for fc1 deletes no rows from fc2. The slave's copy of fc2 still contains all of the rows that were originally inserted:

```
slave> SELECT * FROM fc2;
+---+---+
| m | n |
|---+---|
| 1 | 1 |
| 3 | 1 |
| 2 | 2 |
+---+---+
3 rows in set (0.00 sec)
```

This difference is due to the fact that the cascading deletes are handled internally by the InnoDB storage engine, which means that none of the changes are logged.

## 14.21 InnoDB Troubleshooting

The following general guidelines apply to troubleshooting InnoDB problems:

- When an operation fails or you suspect a bug, look at the MySQL server error log (see Section 5.2.2, “The Error Log”).

- If the failure is related to a deadlock, run with the `innodb_print_all_deadlocks` option enabled so that details about each InnoDB deadlock are printed to the MySQL server error log.

- Issues relating to the InnoDB data dictionary include failed CREATE TABLE statements (orphaned table files), inability to open .InnoDB files, and system cannot find the path specified errors. For information about these sorts of problems and errors, see Section 14.21.3, “Troubleshooting InnoDB Data Dictionary Operations”.

- When troubleshooting, it is usually best to run the MySQL server from the command prompt, rather than through `mysqld_safe` or as a Windows service. You can then see what `mysqld` prints to the console, and so have a better grasp of what is going on. On Windows, start `mysqld` with the `--console` option to direct the output to the console window.

- Enable the InnoDB Monitors to obtain information about a problem (see Section 14.18, “InnoDB Monitors”). If the problem is performance-related, or your server appears to be hung, you should enable the standard Monitor to print information about the internal state of InnoDB. If the problem is with locks, enable the Lock Monitor. If the problem is in creation of tables or other data dictionary operations, enable the Table Monitor to print the contents of the InnoDB internal data dictionary. To see tablespace information enable the Tablespace Monitor.

   InnoDB temporarily enables standard InnoDB Monitor output under the following conditions:

   - A long semaphore wait
   - InnoDB cannot find free blocks in the buffer pool
   - Over 67% of the buffer pool is occupied by lock heaps or the adaptive hash index
   - If you suspect that a table is corrupt, run `CHECK TABLE` on that table.

### 14.21.1 Troubleshooting InnoDB I/O Problems

The troubleshooting steps for InnoDB I/O problems depend on when the problem occurs: during startup of the MySQL server, or during normal operations when a DML or DDL statement fails due to problems at the file system level.
Initialization Problems

If something goes wrong when InnoDB attempts to initialize its tablespace or its log files, delete all files created by InnoDB: all ibdata files and all iblogfile files. If you already created some InnoDB tables, also delete the corresponding .frm files for these tables, and any .ibd files if you are using multiple tablespaces, from the MySQL database directories. Then try the InnoDB database creation again. For easiest troubleshooting, start the MySQL server from a command prompt so that you see what is happening.

Runtime Problems

If InnoDB prints an operating system error during a file operation, usually the problem has one of the following solutions:

• Make sure the InnoDB data file directory and the InnoDB log directory exist.

• Make sure mysqld has access rights to create files in those directories.

• Make sure mysqld can read the proper my.cnf or my.ini option file, so that it starts with the options that you specified.

• Make sure the disk is not full and you are not exceeding any disk quota.

• Make sure that the names you specify for subdirectories and data files do not clash.

• Doublecheck the syntax of the innodb_data_home_dir and innodb_data_file_path values. In particular, any MAX value in the innodb_data_file_path option is a hard limit, and exceeding that limit causes a fatal error.

14.21.2 Starting InnoDB on a Corrupted Database

To investigate database page corruption, you might dump your tables from the database with SELECT ... INTO OUTFILE. Usually, most of the data obtained in this way is intact. Serious corruption might cause SELECT * FROM tbl_name statements or InnoDB background operations to crash or assert, or even cause InnoDB roll-forward recovery to crash. In such cases, use the innodb_force_recovery option to force the InnoDB storage engine to start up while preventing background operations from running, so that you can dump your tables. For example, you can add the following line to the [mysqld] section of your option file before restarting the server:

```
[mysqld]
in iidb_force_recovery = 1
```

Warning

Before using innodb_force_recovery ensure that you have a backup copy of your database in case you need to start over. You should always begin by setting innodb_force_recovery to a lower value. Incrementally increase the setting as required. Only use an innodb_force_recovery setting of 3 or greater on a production server instance after you have successfully tested the setting on separate physical copy of your database.

innodb_force_recovery is 0 by default (normal startup without forced recovery). The permissible nonzero values for innodb_force_recovery are 1 to 6. A larger value includes the functionality of lesser values. For example, a value of 3 includes all of the functionality of values 1 and 2. If you are able to dump your tables with an option value of at most 3, then you are relatively safe that only some data on corrupt individual pages is lost. A value of 6 is considered drastic because database pages are left in an obsolete state, which in turn may introduce more corruption into B-trees and other database structures.
• **1 (SRV_FORCE_IGNORE_CORRUPT)**
  Lets the server run even if it detects a corrupt page. Tries to make `SELECT * FROM tbl_name` jump over corrupt index records and pages, which helps in dumping tables.

• **2 (SRV_FORCE_NO_BACKGROUND)**
  Prevents the master thread and any purge threads from running. If a crash would occur during the purge operation, this recovery value prevents it.

• **3 (SRV_FORCE_NO_TRX_UNDO)**
  Does not run transaction rollbacks after crash recovery.

• **4 (SRV_FORCE_NO_IBUF_MERGE)**
  Prevents insert buffer merge operations. If they would cause a crash, does not do them. Does not calculate table statistics.

• **5 (SRV_FORCE_NO_UNDO_LOG_SCAN)**
  Does not look at undo logs when starting the database: InnoDB treats even incomplete transactions as committed.

• **6 (SRV_FORCE_NO_LOG_REDO)**
  Does not do the redo log roll-forward in connection with recovery.

If corruption within the table data prevents you from dumping the entire table contents, a query with an `ORDER BY primary_key DESC` clause might be able to dump the portion of the table after the corrupted part.

If a high `innodb_force_recovery` value is required to start InnoDB, there may be corrupted data structures that could cause complex queries (queries containing `WHERE`, `ORDER BY`, or other clauses) to fail. In this case, you may only be able to run basic `SELECT * FROM t` queries.

*The database must not otherwise be used with any nonzero value of `innodb_force_recovery`.*

As a safety measure, InnoDB prevents `INSERT`, `UPDATE`, or `DELETE` operations when `innodb_force_recovery` is greater than 0.

You can `SELECT` from tables to dump them, or `DROP` or `CREATE` tables even if forced recovery is used. If you know that a given table is causing a crash on rollback, you can drop it. You can also use this to stop a runaway rollback caused by a failing mass import or `ALTER_TABLE`: kill the `mysqld` process and set `innodb_force_recovery` to 3 to bring the database up without the rollback, then `DROP` the table that is causing the runaway rollback.

### 14.21.3 Troubleshooting InnoDB Data Dictionary Operations

Information about table definitions is stored both in the `.frm` files, and in the InnoDB data dictionary. If you move `.frm` files around, or if the server crashes in the middle of a data dictionary operation, these sources of information can become inconsistent.

#### Problem with CREATE TABLE

A symptom of an out-of-sync data dictionary is that a `CREATE TABLE` statement fails. If this occurs, look in the server's error log. If the log says that the table already exists inside the InnoDB internal data dictionary, you have an orphaned table inside the InnoDB tablespace files that has no corresponding `.frm` file. The error message looks like this:
Troubleshooting InnoDB Data Dictionary Operations

You can drop the orphaned table by following the instructions given in the error message. If you are still unable to use `DROP TABLE` successfully, the problem may be due to name completion in the MySQL client. To work around this problem, start the MySQL client with the `--skip-auto-rehash` option and try `DROP TABLE` again. (With name completion on, MySQL tries to construct a list of table names, which fails when a problem such as just described exists.)

**Problem Opening Table**

Another symptom of an out-of-sync data dictionary is that MySQL prints an error that it cannot open a .InnoDB file:

```
ERROR 1016: Can't open file: 'child2.InnoDB'. (errno: 1)
```

In the error log you can find a message like this:

```
InnoDB: Cannot find table test/child2 from the internal data dictionary
InnoDB: of InnoDB though the .frm file for the table exists. Maybe you
InnoDB: have deleted and recreated InnoDB data files but have forgotten
InnoDB: to delete the corresponding .frm files of InnoDB tables?
```

This means that there is an orphaned .frm file without a corresponding table inside InnoDB. You can drop the orphaned .frm file by deleting it manually.

**Orphaned Intermediate Tables**

If MySQL crashes in the middle of an `ALTER TABLE` operation, you may be left with an orphaned intermediate table. Intermediate table names begin with "#sql-". In your data directory you will see an #sql-*.ibd file and an accompanying #sql-*.frm file with the same name. The intermediate table is also listed in Table Monitor output.

If both the #sql-*.ibd and #sql-*.frm files appear in your data directory, drop the intermediate table by issuing a `DROP TABLE` statement, prefixing the name of the table with `#mysql50#` and enclosing the table name in backticks. For example:

```
mysql> DROP TABLE `#mysql50##sql-1291_3`;
Query OK, 0 rows affected (0.01 sec)
```

The `#mysql50#` prefix tells MySQL to ignore file name safe encoding introduced in MySQL 5.1. Enclosing the table name in backticks is required to perform SQL statements on table names with special characters such as "."

If there is no table format file (#sql-*.frm file) in your data directory or the `DROP TABLE` operation fails, create a new .frm file that matches the table schema of the #sql-*.ibd file (it must have the same columns and indexes defined). To do this, perform the following steps:

1. Determine if the #sql-*.ibd file has a pre-ALTER or post-ALTER schema definition. You can view the columns and indexes of the intermediate table using the Table Monitor.
2. Once you have determined if the `#sql-*`.ibd file has a pre-ALTER or post-ALTER schema definition, create a matching `#sql-*`.frm file in a different database directory. For example, if an intermediate table has a post-ALTER schema definition, create an .frm file that matches the altered schema definition:

```sql
mysql> CREATE TABLE tmp LIKE employees.salaries; ALTER TABLE tmp DROP COLUMN to_date;
Query OK, 0 rows affected (0.02 sec)
Query OK, 0 rows affected (0.06 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

3. Copy the .frm file to the database directory where the orphaned table is located and rename it to match the name of the `#sql-*`.ibd file

```bash
shell> cp tmp.frm employees/#sql-sql-1291_3.frm
```

4. Drop the intermediate table by issuing a DROP TABLE statement, prefixing the name of the table with `#mysql50#` and enclosing the table name in backticks. For example:

```sql
mysql> DROP TABLE `#mysql50##sql-1291_3`;
Query OK, 0 rows affected (0.01 sec)
```

**Problem with Missing Tablespace**

With `innodb_file_per_table` enabled, the following message might occur if the .frm or .ibd files (or both) are missing:

```
InnoDB: in InnoDB data dictionary has tablespace id N,
InnoDB: but tablespace with that id or name does not exist. Have
InnoDB: you deleted or moved .ibd files?
InnoDB: This may also be a table created with CREATE TEMPORARY TABLE
InnoDB: whose .ibd and .frm files MySQL automatically removed, but the
InnoDB: table still exists in the InnoDB internal data dictionary.
```

If this occurs, try the following procedure to resolve the problem:

1. Create a matching .frm file in some other database directory and copy it to the database directory where the orphan table is located.

2. Issue DROP TABLE for the original table. That should successfully drop the table and InnoDB should print a warning to the error log that the .ibd file was missing.

**14.21.4 InnoDB Error Handling**

Error handling in InnoDB is not always the same as specified in the SQL standard. According to the standard, any error during an SQL statement should cause rollback of that statement. InnoDB sometimes rolls back only part of the statement, or the whole transaction. The following items describe how InnoDB performs error handling:

- If you run out of file space in a *tablespace*, a MySQL *Table is full* error occurs and InnoDB rolls back the SQL statement.

- A transaction deadlock causes InnoDB to roll back the entire transaction. Retry the whole transaction when this happens.

A lock wait timeout causes InnoDB to roll back only the single statement that was waiting for the lock and encountered the timeout. (To have the entire transaction roll back, start the server with the `--innodb.rollback_on_timeout` option.) Retry the statement if using the current behavior, or the entire transaction if using `--innodb.rollback_on_timeout`. 
Both deadlocks and lock wait timeouts are normal on busy servers and it is necessary for applications to be aware that they may happen and handle them by retrying. You can make them less likely by doing as little work as possible between the first change to data during a transaction and the commit, so the locks are held for the shortest possible time and for the smallest possible number of rows. Sometimes splitting work between different transactions may be practical and helpful.

When a transaction rollback occurs due to a deadlock or lock wait timeout, it cancels the effect of the statements within the transaction. But if the start-transaction statement was `START TRANSACTION` or `BEGIN` statement, rollback does not cancel that statement. Further SQL statements become part of the transaction until the occurrence of `COMMIT`, `ROLLBACK`, or some SQL statement that causes an implicit commit.

- A duplicate-key error rolls back the SQL statement, if you have not specified the `IGNORE` option in your statement.
- A `row too long` error rolls back the SQL statement.
- Other errors are mostly detected by the MySQL layer of code (above the InnoDB storage engine level), and they roll back the corresponding SQL statement. Locks are not released in a rollback of a single SQL statement.

During implicit rollbacks, as well as during the execution of an explicit `ROLLBACK` SQL statement, `SHOW PROCESSLIST` displays `Rolling back` in the `State` column for the relevant connection.

### 14.21.5 InnoDB Error Codes

The following is a nonexhaustive list of common InnoDB-specific errors that you may encounter, with information about why each occurs and how to resolve the problem.

- **1005 (ER_CANT_CREATE_TABLE)**
  Cannot create table. If the error message refers to error 150, table creation failed because a foreign key constraint was not correctly formed. If the error message refers to error –1, table creation probably failed because the table includes a column name that matched the name of an internal InnoDB table.

- **1016 (ER_CANT_OPEN_FILE)**
  Cannot find the InnoDB table from the InnoDB data files, although the .frm file for the table exists. See Section 14.21.3, “Troubleshooting InnoDB Data Dictionary Operations”.

- **ERROR 1025 (HY000): Error on rename of './db2/#sql-18eb_3' to './db2/foo'(errno: 150)**
  This error message is reported when you attempt to drop the last index that can enforce a particular referential constraint. As of MySQL 5.5, this error message has been replaced by ERROR 1553.

- **1114 (ER_RECORD_FILE_FULL)**
  InnoDB has run out of free space in the tablespace. Reconfigure the tablespace to add a new data file.

- **1205 (ER_LOCK_WAIT_TIMEOUT)**
  Lock wait timeout expired. The statement that waited too long was rolled back (not the entire transaction). You can increase the value of the `innodb_lock_wait_timeout` configuration option if SQL statements should wait longer for other transactions to complete, or decrease it if too many long-running transactions are causing locking problems and reducing concurrency on a busy system.
InnoDB Error Codes

• 1206 (ER_LOCK_TABLE_FULL)

The total number of locks exceeds the amount of memory InnoDB devotes to managing locks. To avoid this error, increase the value of innodb_buffer_pool_size. Within an individual application, a workaround may be to break a large operation into smaller pieces. For example, if the error occurs for a large INSERT, perform several smaller INSERT operations.

• 1213 (ER_LOCK_DEADLOCK)

The transaction encountered a deadlock and was automatically rolled back so that your application could take corrective action. To recover from this error, run all the operations in this transaction again. A deadlock occurs when requests for locks arrive in inconsistent order between transactions. The transaction that was rolled back released all its locks, and the other transaction can now get all the locks it requested. Thus when you re-run the transaction that was rolled back, it might have to wait for other transactions to complete, but typically the deadlock does not recur. If you encounter frequent deadlocks, make the sequence of locking operations (LOCK TABLES, SELECT ... FOR UPDATE, and so on) consistent between the different transactions or applications that experience the issue. See Section 14.5.11, “How to Cope with Deadlocks” for details.

• 1216 (ER_NO_REFERENCED_ROW)

You are trying to add a row but there is no parent row, and a foreign key constraint fails. Add the parent row first.

• 1217 (ER_ROW_IS_REFERENCED)

You are trying to delete a parent row that has children, and a foreign key constraint fails. Delete the children first.

• ERROR 1553 (HY000): Cannot drop index 'fooIdx': needed in a foreign key constraint

This error message, which replaces ERROR 1025, is reported when you attempt to drop the last index that can enforce a particular referential constraint.

For optimal performance with DML statements, InnoDB requires an index to exist on foreign key columns, so that UPDATE and DELETE operations on a parent table can easily check whether corresponding rows exist in the child table. MySQL creates or drops such indexes automatically when needed, as a side-effect of CREATE TABLE, CREATE INDEX, and ALTER TABLE statements.

When you drop an index, InnoDB checks whether the index is not used for checking a foreign key constraint. It is still OK to drop the index if there is another index that can be used to enforce the same constraint. InnoDB prevents you from dropping the last index that can enforce a particular referential constraint.

• ERROR 42000: This table type requires a primary key

Prior to MySQL 5.5, this error would be reported when attempting to drop an implicit clustered index (the first UNIQUE NOT NULL index) if the table did not contain a PRIMARY KEY.

This error should no longer be reported as of MySQL 5.5. For tables without an explicit PRIMARY KEY, InnoDB creates an implicit clustered index using the first columns of the table that are declared UNIQUE and NOT NULL. When you drop such an index, InnoDB now automatically copies the table and rebuilds the index using a different UNIQUE NOT NULL group of columns or a system-generated key. Since this operation changes the primary key, it uses the slow method of copying the table and re-creating the index, rather than the Fast Index Creation technique from Section 14.14.3, “Implementation Details of Fast Index Creation”.

1794
14.21.6 Operating System Error Codes

To print the error message for an operating system error number, you can use one of the following options. The `perror` program is provided with the MySQL distribution.

$ perror 123
$ perl -MPOSIX -le 'print strerror 123'
$ python -c 'import os; print os.strerror(123)'

- Linux System Error Codes

The following table provides a partial list of Linux system error codes.

<table>
<thead>
<tr>
<th>Number</th>
<th>Macro</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>EPERM</td>
<td>Operation not permitted</td>
</tr>
<tr>
<td>2</td>
<td>ENOENT</td>
<td>No such file or directory</td>
</tr>
<tr>
<td>3</td>
<td>ESRCH</td>
<td>No such process</td>
</tr>
<tr>
<td>4</td>
<td>EINTR</td>
<td>Interrupted system call</td>
</tr>
<tr>
<td>5</td>
<td>EIO</td>
<td>I/O error</td>
</tr>
<tr>
<td>6</td>
<td>ENXIO</td>
<td>No such device or address</td>
</tr>
<tr>
<td>7</td>
<td>E2BIG</td>
<td>Arg list too long</td>
</tr>
<tr>
<td>8</td>
<td>ENOEXEC</td>
<td>Exec format error</td>
</tr>
<tr>
<td>9</td>
<td>EBADF</td>
<td>Bad file number</td>
</tr>
<tr>
<td>10</td>
<td>ECHILD</td>
<td>No child processes</td>
</tr>
<tr>
<td>11</td>
<td>EAGAIN</td>
<td>Try again</td>
</tr>
<tr>
<td>12</td>
<td>ENOMEM</td>
<td>Out of memory</td>
</tr>
<tr>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>ERROR_INVALID_FUNCTION</td>
<td>Incorrect function.</td>
</tr>
<tr>
<td>2</td>
<td>ERROR_FILE_NOT_FOUND</td>
<td>The system cannot find the file specified.</td>
</tr>
<tr>
<td>3</td>
<td>ERROR_PATH_NOT_FOUND</td>
<td>The system cannot find the path specified.</td>
</tr>
<tr>
<td>4</td>
<td>ERROR_TOO_MANY_OPEN_FILES</td>
<td>The system cannot open the file.</td>
</tr>
<tr>
<td>5</td>
<td>ERROR_ACCESS_DENIED</td>
<td>Access is denied.</td>
</tr>
<tr>
<td>6</td>
<td>ERROR_INVALID_HANDLE</td>
<td>The handle is invalid.</td>
</tr>
<tr>
<td>7</td>
<td>ERROR_ARENA_TRASHED</td>
<td>The storage control blocks were destroyed.</td>
</tr>
<tr>
<td>8</td>
<td>ERROR_NOT_ENOUGH_MEMORY</td>
<td>Not enough storage is available to process this command.</td>
</tr>
<tr>
<td>9</td>
<td>ERROR_INVALID_BLOCK</td>
<td>The storage control block address is invalid.</td>
</tr>
<tr>
<td>10</td>
<td>ERROR_BAD_ENVIRONMENT</td>
<td>The environment is incorrect.</td>
</tr>
<tr>
<td>11</td>
<td>ERROR_BAD_FORMAT</td>
<td>An attempt was made to load a program with an incorrect format.</td>
</tr>
<tr>
<td>12</td>
<td>ERROR_INVALID_ACCESS</td>
<td>The access code is invalid.</td>
</tr>
<tr>
<td>13</td>
<td>ERROR_INVALID_DATA</td>
<td>The data is invalid.</td>
</tr>
<tr>
<td>14</td>
<td>ERROR_OUTOFMEMORY</td>
<td>Not enough storage is available to complete this operation.</td>
</tr>
<tr>
<td>15</td>
<td>ERROR_INVALID_DRIVE</td>
<td>The system cannot find the drive specified.</td>
</tr>
<tr>
<td>16</td>
<td>ERROR_CURRENT_DIR</td>
<td>The directory cannot be removed.</td>
</tr>
<tr>
<td>17</td>
<td>ERROR_NOT_SAME_DRIVE</td>
<td>The system cannot move the file to a different disk drive.</td>
</tr>
<tr>
<td>18</td>
<td>ERROR_NO_MORE_FILES</td>
<td>There are no more files.</td>
</tr>
<tr>
<td>19</td>
<td>ERROR_WRITE_PROTECT</td>
<td>The media is write protected.</td>
</tr>
<tr>
<td>20</td>
<td>ERROR_BAD_UNIT</td>
<td>The system cannot find the device specified.</td>
</tr>
<tr>
<td>21</td>
<td>ERROR_NOT_READY</td>
<td>The device is not ready.</td>
</tr>
<tr>
<td>22</td>
<td>ERROR_BAD_COMMAND</td>
<td>The device does not recognize the command.</td>
</tr>
<tr>
<td>23</td>
<td>ERROR_CRC</td>
<td>Data error (cyclic redundancy check).</td>
</tr>
<tr>
<td>24</td>
<td>ERROR_BAD_LENGTH</td>
<td>The program issued a command but the command length is incorrect.</td>
</tr>
<tr>
<td>25</td>
<td>ERROR_SEEK</td>
<td>The drive cannot locate a specific area or track on the disk.</td>
</tr>
<tr>
<td>26</td>
<td>ERROR_NOT_DOS_DISK</td>
<td>The specified disk or diskette cannot be accessed.</td>
</tr>
<tr>
<td>27</td>
<td>ERROR_sector_not_found</td>
<td>The drive cannot find the sector requested.</td>
</tr>
<tr>
<td>28</td>
<td>ERROR_OUT_OF_PAPER</td>
<td>The printer is out of paper.</td>
</tr>
<tr>
<td>29</td>
<td>ERROR_WRITE_FAULT</td>
<td>The system cannot write to the specified device.</td>
</tr>
<tr>
<td>30</td>

Storage engines are MySQL components that handle the SQL operations for different table types. MySQL storage engines include both those that handle transaction-safe tables and those that handle nontransaction-safe tables. InnoDB is the default storage engine as of MySQL 5.5.5 (The CREATE TABLE statement in MySQL 5.5 creates InnoDB tables by default.)

MySQL uses a pluggable storage engine architecture that enables storage engines to be loaded into and unloaded from a running MySQL server.

To determine which storage engines your server supports, use the SHOW ENGINES statement. The value in the Support column indicates whether an engine can be used. A value of YES, NO, or DEFAULT indicates that an engine is available, not available, or available and currently set as the default storage engine.

```
mysql> SHOW ENGINES
                         *************************** 1. row ***************************
                             Engine: PERFORMANCE_SCHEMA
                             Support: YES
                             Comment: Performance Schema
                             Transactions: NO
                             XA: NO
                             Savepoints: NO
                         *************************** 2. row ***************************
                             Engine: InnoDB
```
This chapter covers use cases for special-purpose MySQL storage engines. It does not cover the default InnoDB storage engine or the NDB storage engine which are covered in Chapter 14, *The InnoDB Storage Engine* and Chapter 18, *MySQL Cluster NDB 7.2*. For advanced users, this chapter also contains a description of the pluggable storage engine architecture (see Section 15.2, “Overview of MySQL Storage Engine Architecture”).

For information about storage engine support offered in commercial MySQL Server binaries, see *MySQL Enterprise Server 5.5*, on the MySQL Web site. The storage engines available might depend on which edition of Enterprise Server you are using.

For answers to some commonly asked questions about MySQL storage engines, see Section A.2, “MySQL 5.5 FAQ: Storage Engines”.

## MySQL 5.5 Supported Storage Engines

- **InnoDB**: The default storage engine as of MySQL 5.5.5. InnoDB is a transaction-safe (ACID compliant) storage engine for MySQL that has commit, rollback, and crash-recovery capabilities to protect user data. InnoDB row-level locking (without escalation to coarser granularity locks) and Oracle-style consistent nonlocking reads increase multi-user concurrency and performance. InnoDB stores user data in clustered indexes to reduce I/O for common queries based on primary keys. To maintain data integrity, InnoDB also supports FOREIGN KEY referential-integrity constraints. For more information about InnoDB, see Chapter 14, *The InnoDB Storage Engine*.

- **MyISAM**: The MySQL storage engine that is used the most in Web, data warehousing, and other application environments. MyISAM is supported in all MySQL configurations, and is the default storage engine prior to MySQL 5.5.5.

- **Memory**: Stores all data in RAM for extremely fast access in environments that require quick lookups of reference and other like data. This engine was formerly known as the HEAP engine.

- **Merge**: Enables a MySQL DBA or developer to logically group a series of identical MyISAM tables and reference them as one object. Good for VLDB environments such as data warehousing.
MySQL 5.5 Supported Storage Engines

- **Archive**: Provides the perfect solution for storing and retrieving large amounts of seldom-referenced historical, archived, or security audit information.

- **Federated**: Offers the ability to link separate MySQL servers to create one logical database from many physical servers. Very good for distributed or data mart environments.

- **NDB** (also known as **NDBCLUSTER**)—This clustered database engine is particularly suited for applications that require the highest possible degree of uptime and availability.

**Note**

The NDB storage engine is not supported in standard MySQL 5.5 releases. Currently supported MySQL Cluster releases include MySQL Cluster NDB 7.0 and MySQL Cluster NDB 7.1, which are based on MySQL 5.1, and MySQL Cluster NDB 7.2, which is based on MySQL 5.5. While based on MySQL Server, these releases also contain support for NDB.

- **CSV**: The CSV storage engine stores data in text files using comma-separated values format. You can use the CSV engine to easily exchange data between other software and applications that can import and export in CSV format.

- **Blackhole**: The Blackhole storage engine accepts but does not store data and retrievals always return an empty set. The functionality can be used in distributed database design where data is automatically replicated, but not stored locally.

- **Example**: The Example storage engine is “stub” engine that does nothing. You can create tables with this engine, but no data can be stored in them or retrieved from them. The purpose of this engine is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.

It is important to remember that you are not restricted to using the same storage engine for an entire server or schema: you can use a different storage engine for each table in your schema.

### Choosing a Storage Engine

The various storage engines provided with MySQL are designed with different use cases in mind. To use the pluggable storage architecture effectively, it is good to have an idea of the advantages and disadvantages of the various storage engines. The following table provides an overview of some storage engines provided with MySQL:

<table>

---

- ^a InnoDB utilizes hash indexes internally for its Adaptive Hash Index feature.
- ^b InnoDB support for FULLTEXT indexes is available in MySQL 5.6.4 and higher.
- ^c Compressed MyISAM tables are supported only when using the compressed row format. Tables using the compressed row format with MyISAM are read only.
- ^d Compressed InnoDB tables require the InnoDB Barracuda file format.
- ^e Implemented in the server (via encryption functions), rather than in the storage engine.
- ^f Implemented in the server, rather than in the storage engine.
- ^g Implemented in the server, rather than in the storage engine.
15.1 Setting the Storage Engine

When you create a new table, you can specify which storage engine to use by adding an `ENGINE` table option to the `CREATE TABLE` statement:

```sql
-- ENGINE=INNODB not needed as of 5.5.5 unless you have set a different default storage engine.
CREATE TABLE t1 (i INT) ENGINE = INNODB;
-- Simple table definitions can be switched from one to another.
CREATE TABLE t2 (i INT) ENGINE = CSV;
CREATE TABLE t3 (i INT) ENGINE = MEMORY;
```

If you omit the `ENGINE` option, the default storage engine is used. The default engine is InnoDB as of MySQL 5.5.5 (MyISAM before 5.5.5). You can specify the default engine by using the `--default-storage-engine` server startup option, or by setting the `default-storage-engine` option in the `my.cnf` configuration file.

You can set the default storage engine to be used during the current session by setting the `default_storage_engine` variable:

```sql
SET default_storage_engine=MYISAM;
```

When MySQL is installed on Windows using the MySQL Configuration Wizard, the InnoDB or MyISAM storage engine can be selected as the default. See Section 2.3.6.5, "The Database Usage Dialog".

To convert a table from one storage engine to another, use an `ALTER TABLE` statement that indicates the new engine:

```sql
ALTER TABLE t ENGINE = MYISAM;
```

See Section 13.1.17, "CREATE TABLE Syntax", and Section 13.1.7, "ALTER TABLE Syntax".

If you try to use a storage engine that is not compiled in or that is compiled in but deactivated, MySQL instead creates a table using the default storage engine. This behavior is convenient when you want to copy tables between MySQL servers that support different storage engines. (For example, in a replication setup, perhaps your master server supports transactional storage engines for increased safety, but the slave servers use only nontransactional storage engines for greater speed.)

This automatic substitution of the default storage engine for unavailable engines can be confusing for new MySQL users. A warning is generated whenever a storage engine is automatically changed. To prevent this from happening if the desired engine is unavailable, enable the `NO_ENGINE_SUBSTITUTION` SQL mode. In this case, an error occurs instead of a warning and the table is not created or altered if the desired engine is unavailable. See Section 5.1.7, "Server SQL Modes".

For new tables, MySQL always creates an `.frm` file to hold the table and column definitions. The table's index and data may be stored in one or more other files, depending on the storage engine. The server creates the `.frm` file above the storage engine level. Individual storage engines create any additional files required for the tables that they manage. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in Section 9.2.3, "Mapping of Identifiers to File Names".

A database may contain tables of different types. That is, tables need not all be created with the same storage engine.
15.2 Overview of MySQL Storage Engine Architecture

The MySQL pluggable storage engine architecture enables a database professional to select a specialized storage engine for a particular application need while being completely shielded from the need to manage any specific application coding requirements. The MySQL server architecture isolates the application programmer and DBA from all of the low-level implementation details at the storage level, providing a consistent and easy application model and API. Thus, although there are different capabilities across different storage engines, the application is shielded from these differences.

The pluggable storage engine architecture provides a standard set of management and support services that are common among all underlying storage engines. The storage engines themselves are the components of the database server that actually perform actions on the underlying data that is maintained at the physical server level.

This efficient and modular architecture provides huge benefits for those wishing to specifically target a particular application need—such as data warehousing, transaction processing, or high availability situations—while enjoying the advantage of utilizing a set of interfaces and services that are independent of any one storage engine.

The application programmer and DBA interact with the MySQL database through Connector APIs and service layers that are above the storage engines. If application changes bring about requirements that demand the underlying storage engine change, or that one or more storage engines be added to support new needs, no significant coding or process changes are required to make things work. The MySQL server architecture shields the application from the underlying complexity of the storage engine by presenting a consistent and easy-to-use API that applies across storage engines.

15.2.1 Pluggable Storage Engine Architecture

MySQL Server uses a pluggable storage engine architecture that enables storage engines to be loaded into and unloaded from a running MySQL server.

Plugging in a Storage Engine

Before a storage engine can be used, the storage engine plugin shared library must be loaded into MySQL using the INSTALL PLUGIN statement. For example, if the EXAMPLE engine plugin is named example and the shared library is named ha_example.so, you load it with the following statement:

```sql
mysql> INSTALL PLUGIN example SONAME 'ha_example.so';
```

To install a pluggable storage engine, the plugin file must be located in the MySQL plugin directory, and the user issuing the INSTALL PLUGIN statement must have INSERT privilege for the mysql.plugin table.

The shared library must be located in the MySQL server plugin directory, the location of which is given by the plugin_dir system variable.

Unplugging a Storage Engine

To unplug a storage engine, use the UNINSTALL PLUGIN statement:

```sql
mysql> UNINSTALL PLUGIN example;
```

If you unplug a storage engine that is needed by existing tables, those tables become inaccessible, but will still be present on disk (where applicable). Ensure that there are no tables using a storage engine before you unplug the storage engine.
15.2.2 The Common Database Server Layer

A MySQL pluggable storage engine is the component in the MySQL database server that is responsible for performing the actual data I/O operations for a database as well as enabling and enforcing certain feature sets that target a specific application need. A major benefit of using specific storage engines is that you are only delivered the features needed for a particular application, and therefore you have less system overhead in the database, with the end result being more efficient and higher database performance. This is one of the reasons that MySQL has always been known to have such high performance, matching or beating proprietary monolithic databases in industry standard benchmarks.

From a technical perspective, what are some of the unique supporting infrastructure components that are in a storage engine? Some of the key feature differentiations include:

- **Concurrency:** Some applications have more granular lock requirements (such as row-level locks) than others. Choosing the right locking strategy can reduce overhead and therefore improve overall performance. This area also includes support for capabilities such as multi-version concurrency control or “snapshot” read.

- **Transaction Support:** Not every application needs transactions, but for those that do, there are very well defined requirements such as ACID compliance and more.

- **Referential Integrity:** The need to have the server enforce relational database referential integrity through DDL defined foreign keys.

- **Physical Storage:** This involves everything from the overall page size for tables and indexes as well as the format used for storing data to physical disk.

- **Index Support:** Different application scenarios tend to benefit from different index strategies. Each storage engine generally has its own indexing methods, although some (such as B-tree indexes) are common to nearly all engines.

- **Memory Caches:** Different applications respond better to some memory caching strategies than others, so although some memory caches are common to all storage engines (such as those used for user connections or MySQL’s high-speed Query Cache), others are uniquely defined only when a particular storage engine is put in play.

- **Performance Aids:** This includes multiple I/O threads for parallel operations, thread concurrency, database checkpointing, bulk insert handling, and more.

- **Miscellaneous Target Features:** This may include support for geospatial operations, security restrictions for certain data manipulation operations, and other similar features.

Each set of the pluggable storage engine infrastructure components are designed to offer a selective set of benefits for a particular application. Conversely, avoiding a set of component features helps reduce unnecessary overhead. It stands to reason that understanding a particular application's set of requirements and selecting the proper MySQL storage engine can have a dramatic impact on overall system efficiency and performance.

15.3 The **MyISAM** Storage Engine

Before MySQL 5.5.5, **MyISAM** is the default storage engine. (The default was changed to **InnoDB** in MySQL 5.5.5.) **MyISAM** is based on the older (and no longer available) **ISAM** storage engine but has many useful extensions.

</tbody>
</table>

<sup>a</sup>Compressed MyISAM tables are supported only when using the compressed row format. Tables using the compressed row format with MyISAM are read only.

<sup>b</sup>Implemented in the server (via encryption functions), rather than in the storage engine.

<sup>c</sup>Implemented in the server, rather than in the storage engine.

<sup>d</sup>Implemented in the server, rather than in the storage engine.

Each MyISAM table is stored on disk in three files. The files have names that begin with the table name and have an extension to indicate the file type. An .frm file stores the table format. The data file has an .MYD (MYData) extension. The index file has an .MYI (MYIndex) extension.

To specify explicitly that you want a MyISAM table, indicate that with an ENGINE table option:

```sql
CREATE TABLE t (i INT) ENGINE = MYISAM;
```

As of MySQL 5.5.5, it is normally necessary to use ENGINE to specify the MyISAM storage engine because InnoDB is the default engine. Before 5.5.5, this is unnecessary because MyISAM is the default engine unless the default has been changed. To ensure that MyISAM is used in situations where the default might have been changed, include the ENGINE option explicitly.

You can check or repair MyISAM tables with the mysqlcheck client or myisamchk utility. You can also compress MyISAM tables with myisampack to take up much less space. See Section 4.5.3, "mysqlcheck — A Table Maintenance Program", Section 4.6.3, "myisamchk — MyISAM Table-Maintenance Utility", and Section 4.6.5, "myisampack — Generate Compressed, Read-Only MyISAM Tables".

MyISAM tables have the following characteristics:

- All data values are stored with the low byte first. This makes the data machine and operating system independent. The only requirements for binary portability are that the machine uses two’s-complement signed integers and IEEE floating-point format. These requirements are widely used among mainstream machines. Binary compatibility might not be applicable to embedded systems, which sometimes have peculiar processors.

  There is no significant speed penalty for storing data low byte first; the bytes in a table row normally are unaligned and it takes little more processing to read an unaligned byte in order than in reverse order. Also, the code in the server that fetches column values is not time critical compared to other code.

- All numeric key values are stored with the high byte first to permit better index compression.

- Large files (up to 63-bit file length) are supported on file systems and operating systems that support large files.

- There is a limit of \(2^{32}\times2^{2}\) (1.844E+19) rows in a MyISAM table.

- The maximum number of indexes per MyISAM table is 64.
The maximum number of columns per index is 16.

- The maximum key length is 1000 bytes. This can also be changed by changing the source and recompiling. For the case of a key longer than 250 bytes, a larger key block size than the default of 1024 bytes is used.

- When rows are inserted in sorted order (as when you are using an AUTO_INCREMENT column), the index tree is split so that the high node only contains one key. This improves space utilization in the index tree.

- Internal handling of one AUTO_INCREMENT column per table is supported. MyISAM automatically updates this column for INSERT and UPDATE operations. This makes AUTO_INCREMENT columns faster (at least 10%). Values at the top of the sequence are not reused after being deleted. (When an AUTO_INCREMENT column is defined as the last column of a multiple-column index, reuse of values deleted from the top of a sequence does occur.) The AUTO_INCREMENT value can be reset with ALTER TABLE or myisamchk.

- Dynamic-sized rows are much less fragmented when mixing deletes with updates and inserts. This is done by automatically combining adjacent deleted blocks and by extending blocks if the next block is deleted.

- MyISAM supports concurrent inserts: If a table has no free blocks in the middle of the data file, you can INSERT new rows into it at the same time that other threads are reading from the table. A free block can occur as a result of deleting rows or an update of a dynamic length row with more data than its current contents. When all free blocks are used up (filled in), future inserts become concurrent again. See Section 8.10.3, “Concurrent Inserts”.

- You can put the data file and index file in different directories on different physical devices to get more speed with the DATA DIRECTORY and INDEX DIRECTORY table options to CREATE TABLE. See Section 13.1.17, “CREATE TABLE Syntax”.

- BLOB and TEXT columns can be indexed.

- NULL values are permitted in indexed columns. This takes 0 to 1 bytes per key.

- Each character column can have a different character set. See Section 10.1, “Character Set Support”.

- There is a flag in the MyISAM index file that indicates whether the table was closed correctly. If mysqld is started with the --myisam-recover-options option, MyISAM tables are automatically checked when opened, and are repaired if the table wasn't closed properly.

- myisamchk marks tables as checked if you run it with the --update-state option. myisamchk --fast checks only those tables that don't have this mark.

- myisamchk --analyze stores statistics for portions of keys, as well as for entire keys.

- myisampack can pack BLOB and VARCHAR columns.

MyISAM also supports the following features:

- Support for a true VARCHAR type; a VARCHAR column starts with a length stored in one or two bytes.

- Tables with VARCHAR columns may have fixed or dynamic row length.

- The sum of the lengths of the VARCHAR and CHAR columns in a table may be up to 64KB.

- Arbitrary length UNIQUE constraints.

- `--myisam-recover-options=mode`

Set the mode for automatic recovery of crashed MyISAM tables.
MyISAM Startup Options

• `--delay-key-write=ALL`

  Don't flush key buffers between writes for any MyISAM table.

  **Note**
  If you do this, you should not access MyISAM tables from another program (such as from another MySQL server or with myisamchk) when the tables are in use. Doing so risks index corruption. Using `--external-locking` does not eliminate this risk.

The following system variables affect the behavior of MyISAM tables. For additional information, see Section 5.1.4, “Server System Variables”.

• `bulk_insert_buffer_size`

  The size of the tree cache used in bulk insert optimization.

  **Note**
  This is a limit per thread!

• `myisam_max_sort_file_size`

  The maximum size of the temporary file that MySQL is permitted to use while re-creating a MyISAM index (during REPAIR TABLE, ALTER TABLE, or LOAD DATA INFILE). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

• `myisam_sort_buffer_size`

  Set the size of the buffer used when recovering tables.

  Automatic recovery is activated if you start `mysqld` with the `--myisam-recover-options` option. In this case, when the server opens a MyISAM table, it checks whether the table is marked as crashed or whether the open count variable for the table is not 0 and you are running the server with external locking disabled. If either of these conditions is true, the following happens:

  • The server checks the table for errors.
  • If the server finds an error, it tries to do a fast table repair (with sorting and without re-creating the data file).
  • If the repair fails because of an error in the data file (for example, a duplicate-key error), the server tries again, this time re-creating the data file.
  • If the repair still fails, the server tries once more with the old repair option method (write row by row without sorting). This method should be able to repair any type of error and has low disk space requirements.

  If the recovery wouldn't be able to recover all rows from previously completed statements and you didn't specify `FORCE` in the value of the `--myisam-recover-options` option, automatic repair aborts with an error message in the error log:

  

  ```
  Error: Couldn't repair table: test.g00pages
  ```

  If you specify `FORCE`, a warning like this is written instead:
Note that if the automatic recovery value includes BACKUP, the recovery process creates files with names of the form `tbl_name-datetime.BAK`. You should have a `cron` script that automatically moves these files from the database directories to backup media.

### 15.3.2 Space Needed for Keys

**MyISAM** tables use B-tree indexes. You can roughly calculate the size for the index file as \((\text{key_length} + 4)/0.67\), summed over all keys. This is for the worst case when all keys are inserted in sorted order and the table doesn't have any compressed keys.

String indexes are space compressed. If the first index part is a string, it is also prefix compressed. Space compression makes the index file smaller than the worst-case figure if a string column has a lot of trailing space or is a `VARCHAR` column that is not always used to the full length. Prefix compression is used on keys that start with a string. Prefix compression helps if there are many strings with an identical prefix.

In **MyISAM** tables, you can also prefix compress numbers by specifying the `PACK_KEYS=1` table option when you create the table. Numbers are stored with the high byte first, so this helps when you have many integer keys that have an identical prefix.

### 15.3.3 **MyISAM** Table Storage Formats

**MyISAM** supports three different storage formats. Two of them, fixed and dynamic format, are chosen automatically depending on the type of columns you are using. The third, compressed format, can be created only with the `myisampack` utility (see Section 4.6.5, "myisampack — Generate Compressed, Read-Only MyISAM Tables").

When you use `CREATE TABLE` or `ALTER TABLE` for a table that has no `BLOB` or `TEXT` columns, you can force the table format to `FIXED` or `DYNAMIC` with the `ROW_FORMAT` table option.

You can decompress (unpack) compressed **MyISAM** tables using `myisamchk --unpack`; see Section 4.6.3, "myisamchk — MyISAM Table-Maintenance Utility", for more information.

#### 15.3.3.1 Static (Fixed-Length) Table Characteristics

Static format is the default for **MyISAM** tables. It is used when the table contains no variable-length columns (`VARCHAR`, `VARBINARY`, `BLOB`, or `TEXT`). Each row is stored using a fixed number of bytes.

Of the three **MyISAM** storage formats, static format is the simplest and most secure (least subject to corruption). It is also the fastest of the on-disk formats due to the ease with which rows in the data file can be found on disk: To look up a row based on a row number in the index, multiply the row number by the row length to calculate the row position. Also, when scanning a table, it is very easy to read a constant number of rows with each disk read operation.

The security is evidenced if your computer crashes while the MySQL server is writing to a fixed-format **MyISAM** file. In this case, `myisamchk` can easily determine where each row starts and ends, so it can usually reclaim all rows except the partially written one. Note that **MyISAM** table indexes can always be reconstructed based on the data rows.

**Note**

Fixed-length row format is only available for tables without `BLOB` or `TEXT` columns. Creating a table with these columns with an explicit `ROW_FORMAT` clause will not raise an error or warning; the format specification will be ignored.
Static-format tables have these characteristics:

- **CHAR** and **VARCHAR** columns are space-padded to the specified column width, although the column type is not altered. **BINARY** and **VARBINARY** columns are padded with **0x00** bytes to the column width.

- Very quick.

- Easy to cache.

- Easy to reconstruct after a crash, because rows are located in fixed positions.

- Reorganization is unnecessary unless you delete a huge number of rows and want to return free disk space to the operating system. To do this, use `OPTIMIZE TABLE` or `myisamchk -r`.

- Usually require more disk space than dynamic-format tables.

### 15.3.3.2 Dynamic Table Characteristics

Dynamic storage format is used if a **MyISAM** table contains any variable-length columns (**VARCHAR**, **VARBINARY**, **BLOB**, or **TEXT**), or if the table was created with the **ROW_FORMAT=dynamic** table option.

Dynamic format is a little more complex than static format because each row has a header that indicates how long it is. A row can become fragmented (stored in noncontiguous pieces) when it is made longer as a result of an update.

You can use `OPTIMIZE TABLE` or `myisamchk -r` to defragment a table. If you have fixed-length columns that you access or change frequently in a table that also contains some variable-length columns, it might be a good idea to move the variable-length columns to other tables just to avoid fragmentation.

Dynamic-format tables have these characteristics:

- All string columns are dynamic except those with a length less than four.

- Each row is preceded by a bitmap that indicates which columns contain the empty string (for string columns) or zero (for numeric columns). Note that this does not include columns that contain **NULL** values. If a string column has a length of zero after trailing space removal, or a numeric column has a value of zero, it is marked in the bitmap and not saved to disk. Nonempty strings are saved as a length byte plus the string contents.

- Much less disk space usually is required than for fixed-length tables.

- Each row uses only as much space as is required. However, if a row becomes larger, it is split into as many pieces as are required, resulting in row fragmentation. For example, if you update a row with information that extends the row length, the row becomes fragmented. In this case, you may have to run `OPTIMIZE TABLE` or `myisamchk -r` from time to time to improve performance. Use `myisamchk -ei` to obtain table statistics.

- More difficult than static-format tables to reconstruct after a crash, because rows may be fragmented into many pieces and links (fragments) may be missing.

- The expected row length for dynamic-sized rows is calculated using the following expression:

\[
3 + \frac{(\text{number of columns} + 7)}{8} + \frac{(\text{number of char columns})}{8} + (\text{packed size of numeric columns}) + (\text{length of strings})
\]
MyISAM Table Problems

15.3.3.3 Compressed Table Characteristics

Compressed storage format is a read-only format that is generated with the `myisampack` tool. Compressed tables can be uncompressed with `myisamchk`.

Compressed tables have the following characteristics:

- Compressed tables take very little disk space. This minimizes disk usage, which is helpful when using slow disks (such as CD-ROMs).

- Each row is compressed separately, so there is very little access overhead. The header for a row takes up one to three bytes depending on the biggest row in the table. Each column is compressed differently. There is usually a different Huffman tree for each column. Some of the compression types are:
  - Suffix space compression.
  - Prefix space compression.
  - Numbers with a value of zero are stored using one bit.
  - If values in an integer column have a small range, the column is stored using the smallest possible type. For example, a `BIGINT` column (eight bytes) can be stored as a `TINYINT` column (one byte) if all its values are in the range from \(-128\) to \(127\).
  - If a column has only a small set of possible values, the data type is converted to `ENUM`.
  - A column may use any combination of the preceding compression types.

- Can be used for fixed-length or dynamic-length rows.

**Note**

While a compressed table is read only, and you cannot therefore update or add rows in the table, DDL (Data Definition Language) operations are still valid. For example, you may still use `DROP` to drop the table, and `TRUNCATE TABLE` to empty the table.

15.3.4 MyISAM Table Problems

The file format that MySQL uses to store data has been extensively tested, but there are always circumstances that may cause database tables to become corrupted. The following discussion describes how this can happen and how to handle it.

15.3.4.1 Corrupted MyISAM Tables

Even though the MyISAM table format is very reliable (all changes to a table made by an SQL statement are written before the statement returns), you can still get corrupted tables if any of the following events occur:

- The `mysqld` process is killed in the middle of a write.
• An unexpected computer shutdown occurs (for example, the computer is turned off).

• Hardware failures.

• You are using an external program (such as `myisamchk`) to modify a table that is being modified by the server at the same time.

• A software bug in the MySQL or MyISAM code.

Typical symptoms of a corrupt table are:

• You get the following error while selecting data from the table:

```
Incorrect key file for table: '...'. Try to repair it
```

• Queries don't find rows in the table or return incomplete results.

You can check the health of a MyISAM table using the `CHECK TABLE` statement, and repair a corrupted MyISAM table with `REPAIR TABLE`. When `mysqld` is not running, you can also check or repair a table with the `myisamchk` command. See Section 13.7.2.2, "CHECK TABLE Syntax", Section 13.7.2.5, "REPAIR TABLE Syntax", and Section 4.6.3, "myisamchk — MyISAM Table-Maintenance Utility".

If your tables become corrupted frequently, you should try to determine why this is happening. The most important thing to know is whether the table became corrupted as a result of a server crash. You can verify this easily by looking for a recent restarted `mysqld` message in the error log. If there is such a message, it is likely that table corruption is a result of the server dying. Otherwise, corruption may have occurred during normal operation. This is a bug. You should try to create a reproducible test case that demonstrates the problem. See Section B.5.4.2, "What to Do If MySQL Keeps Crashing", and Section 24.4, "Debugging and Porting MySQL".

### 15.3.4.2 Problems from Tables Not Being Closed Properly

Each MyISAM index file (`.MYI` file) has a counter in the header that can be used to check whether a table has been closed properly. If you get the following warning from `CHECK TABLE` or `myisamchk`, it means that this counter has gone out of sync:

```
clients are using or haven't closed the table properly
```

This warning doesn't necessarily mean that the table is corrupted, but you should at least check the table.

The counter works as follows:

• The first time a table is updated in MySQL, a counter in the header of the index files is incremented.

• The counter is not changed during further updates.

• When the last instance of a table is closed (because a `FLUSH TABLES` operation was performed or because there is no room in the table cache), the counter is decremented if the table has been updated at any point.

• When you repair the table or check the table and it is found to be okay, the counter is reset to zero.

• To avoid problems with interaction with other processes that might check the table, the counter is not decremented on close if it was zero.

In other words, the counter can become incorrect only under these conditions:
• A **MyISAM** table is copied without first issuing `LOCK TABLES` and `FLUSH TABLES`.

• MySQL has crashed between an update and the final close. (Note that the table may still be okay, because MySQL always issues writes for everything between each statement.)

• A table was modified by `myisamchk --recover` or `myisamchk --update-state` at the same time that it was in use by `mysqld`.

• Multiple `mysqld` servers are using the table and one server performed a `REPAIR TABLE` or `CHECK TABLE` on the table while it was in use by another server. In this setup, it is safe to use `CHECK TABLE`, although you might get the warning from other servers. However, `REPAIR TABLE` should be avoided because when one server replaces the data file with a new one, this is not known to the other servers.

  In general, it is a bad idea to share a data directory among multiple servers. See [Section 5.3, “Running Multiple MySQL Instances on One Machine”](#), for additional discussion.

## 15.4 The **MEMORY** Storage Engine

The **MEMORY** storage engine (formerly known as **HEAP**) creates special-purpose tables with contents that are stored in memory. Because the data is vulnerable to crashes, hardware issues, or power outages, only use these tables as temporary work areas or read-only caches for data pulled from other tables.

<table>

| Implemented in the server, rather than in the storage engine. |

**When to Use **MEMORY** or MySQL Cluster.** Developers looking to deploy applications that use the **MEMORY** storage engine for important, highly available, or frequently updated data should consider whether MySQL Cluster is a better choice. A typical use case for the **MEMORY** engine involves these characteristics:

• Operations involving transient, non-critical data such as session management or caching. When the MySQL server halts or restarts, the data in **MEMORY** tables is lost.

• In-memory storage for fast access and low latency. Data volume can fit entirely in memory without causing the operating system to swap out virtual memory pages.

• A read-only or read-mostly data access pattern (limited updates).

MySQL Cluster offers the same features as the **MEMORY** engine with higher performance levels, and provides additional features not available with **MEMORY**:

1814
Performance Characteristics

• Row-level locking and multiple-thread operation for low contention between clients.

• Scalability even with statement mixes that include writes.

• Optional disk-backed operation for data durability.

• Shared-nothing architecture and multiple-host operation with no single point of failure, enabling 99.999% availability.

• Automatic data distribution across nodes; application developers need not craft custom sharding or partitioning solutions.

• Support for variable-length data types (including BLOB and TEXT) not supported by MEMORY.

For a white paper with more detailed comparison of the MEMORY storage engine and MySQL Cluster, see Scaling Web Services with MySQL Cluster: An Alternative to the MySQL Memory Storage Engine. This white paper includes a performance study of the two technologies and a step-by-step guide describing how existing MEMORY users can migrate to MySQL Cluster.

Performance Characteristics

MEMORY performance is constrained by contention resulting from single-thread execution and table lock overhead when processing updates. This limits scalability when load increases, particularly for statement mixes that include writes.

Despite the in-memory processing for MEMORY tables, they are not necessarily faster than InnoDB tables on a busy server, for general-purpose queries, or under a read/write workload. In particular, the table locking involved with performing updates can slow down concurrent usage of MEMORY tables from multiple sessions.

Depending on the kinds of queries performed on a MEMORY table, you might create indexes as either the default hash data structure (for looking up single values based on a unique key), or a general-purpose B-tree data structure (for all kinds of queries involving equality, inequality, or range operators such as less than or greater than). The following sections illustrate the syntax for creating both kinds of indexes. A common performance issue is using the default hash indexes in workloads where B-tree indexes are more efficient.

Physical Characteristics of MEMORY Tables

The MEMORY storage engine associates each table with one disk file, which stores the table definition (not the data). The file name begins with the table name and has an extension of .frm.

MEMORY tables have the following characteristics:

• Space for MEMORY tables is allocated in small blocks. Tables use 100% dynamic hashing for inserts. No overflow area or extra key space is needed. No extra space is needed for free lists. Deleted rows are put in a linked list and are reused when you insert new data into the table. MEMORY tables also have none of the problems commonly associated with deletes plus inserts in hashed tables.

• MEMORY tables use a fixed-length row-storage format. Variable-length types such as VARCHAR are stored using a fixed length.

• MEMORY tables cannot contain BLOB or TEXT columns.

• MEMORY includes support for AUTO_INCREMENT columns.
DDL Operations for **MEMORY** Tables

- Non-TEMPORARY **MEMORY** tables are shared among all clients, just like any other non-TEMPORARY table.

**DDL Operations for **MEMORY** Tables**

To create a **MEMORY** table, specify the clause `ENGINE=MEMORY` on the `CREATE TABLE` statement.

```sql
CREATE TABLE t (i INT) ENGINE = MEMORY;
```

As indicated by the engine name, **MEMORY** tables are stored in memory. They use hash indexes by default, which makes them very fast for single-value lookups, and very useful for creating temporary tables. However, when the server shuts down, all rows stored in **MEMORY** tables are lost. The tables themselves continue to exist because their definitions are stored in `.frm` files on disk, but they are empty when the server restarts.

This example shows how you might create, use, and remove a **MEMORY** table:

```sql
mysql> CREATE TABLE test ENGINE=MEMORY
    -> SELECT ip, SUM(downloads) AS down
    -> FROM log_table GROUP BY ip;
mysql> SELECT COUNT(ip), AVG(down) FROM test;
mysql> DROP TABLE test;
```

The maximum size of **MEMORY** tables is limited by the `max_heap_table_size` system variable, which has a default value of 16MB. To enforce different size limits for **MEMORY** tables, change the value of this variable. The value in effect for `CREATE TABLE`, or a subsequent `ALTER TABLE` or `TRUNCATE TABLE`, is the value used for the life of the table. A server restart also sets the maximum size of existing **MEMORY** tables to the global `max_heap_table_size` value. You can set the size for individual tables as described later in this section.

**Indexes**

The **MEMORY** storage engine supports both **HASH** and **BTREE** indexes. You can specify one or the other for a given index by adding a `USING` clause as shown here:

```sql
CREATE TABLE lookup
  (id INT, INDEX USING HASH (id))
ENGINE = MEMORY;
CREATE TABLE lookup
  (id INT, INDEX USING BTREE (id))
ENGINE = MEMORY;
```

For general characteristics of B-tree and hash indexes, see Section 8.3.1, “How MySQL Uses Indexes”.

**MEMORY** tables can have up to 64 indexes per table, 16 columns per index and a maximum key length of 3072 bytes.

If a **MEMORY** table hash index has a high degree of key duplication (many index entries containing the same value), updates to the table that affect key values and all deletes are significantly slower. The degree of this slowdown is proportional to the degree of duplication (or, inversely proportional to the index cardinality). You can use a **BTREE** index to avoid this problem.

**MEMORY** tables can have nonunique keys. (This is an uncommon feature for implementations of hash indexes.)

Columns that are indexed can contain **NULL** values.
User-Created and Temporary Tables

**MEMORY** table contents are stored in memory, which is a property that **MEMORY** tables share with internal temporary tables that the server creates on the fly while processing queries. However, the two types of tables differ in that **MEMORY** tables are not subject to storage conversion, whereas internal temporary tables are:

- If an internal temporary table becomes too large, the server automatically converts it to on-disk storage, as described in Section 8.4.4, “How MySQL Uses Internal Temporary Tables”.
- User-created **MEMORY** tables are never converted to disk tables.

### Loading Data

To populate a **MEMORY** table when the MySQL server starts, you can use the `--init-file` option. For example, you can put statements such as `INSERT INTO ... SELECT` or `LOAD DATA INFILE` into this file to load the table from a persistent data source. See Section 5.1.3, “Server Command Options”, and Section 13.2.6, “LOAD DATA INFILE Syntax”.

For loading data into **MEMORY** tables accessed by other sessions concurrently, **MEMORY** supports `INSERT DELAYED`. See Section 13.2.5.2, “INSERT DELAYED Syntax”.

### **MEMORY** Tables and Replication

A server’s **MEMORY** tables become empty when it is shut down and restarted. If the server is a replication master, its slaves are not aware that these tables have become empty, so you see out-of-date content if you select data from the tables on the slaves. To synchronize master and slave **MEMORY** tables, when a **MEMORY** table is used on a master for the first time since it was started, a `DELETE` statement is written to the master’s binary log, to empty the table on the slaves also. The slave still has outdated data in the table during the interval between the master’s restart and its first use of the table. To avoid this interval when a direct query to the slave could return stale data, use the `--init-file` option to populate the **MEMORY** table on the master at startup.

### Managing Memory Use

The server needs sufficient memory to maintain all **MEMORY** tables that are in use at the same time.

Memory is not reclaimed if you delete individual rows from a **MEMORY** table. Memory is reclaimed only when the entire table is deleted. Memory that was previously used for deleted rows is re-used for new rows within the same table. To free all the memory used by a **MEMORY** table when you no longer require its contents, execute `DELETE` or `TRUNCATE TABLE` to remove all rows, or remove the table altogether using `DROP TABLE`. To free up the memory used by deleted rows, use `ALTER TABLE ENGINE=MEMORY` to force a table rebuild.

The memory needed for one row in a **MEMORY** table is calculated using the following expression:

\[
\text{SUM\_OVER\_ALL\_BTREE\_KEYS}(\text{max\_length\_of\_key} + \text{sizeof(char\*) } \times 4) \\
+ \text{SUM\_OVER\_ALL\_HASH\_KEYS}(\text{sizeof(char\*) } \times 2) \\
+ \text{ALIGN}(\text{length\_of\_row} + 1, \text{sizeof(char\*)})
\]

`ALIGN()` represents a round-up factor to cause the row length to be an exact multiple of the `char` pointer size. `sizeof(char*)` is 4 on 32-bit machines and 8 on 64-bit machines.

As mentioned earlier, the **max_heap_table_size** system variable sets the limit on the maximum size of **MEMORY** tables. To control the maximum size for individual tables, set the session value of this variable.
before creating each table. (Do not change the global `max_heap_table_size` value unless you intend
the value to be used for `MEMORY` tables created by all clients.) The following example creates two `MEMORY`
tables, with a maximum size of 1MB and 2MB, respectively:

```
mysql> SET max_heap_table_size = 1024*1024;
Query OK, 0 rows affected (0.00 sec)
mysql> CREATE TABLE t1 (id INT, UNIQUE(id)) ENGINE = MEMORY;
Query OK, 0 rows affected (0.01 sec)
mysql> SET max_heap_table_size = 1024*1024*2;
Query OK, 0 rows affected (0.00 sec)
mysql> CREATE TABLE t2 (id INT, UNIQUE(id)) ENGINE = MEMORY;
Query OK, 0 rows affected (0.00 sec)
```

Both tables revert to the server's global `max_heap_table_size` value if the server restarts.

You can also specify a `MAX_ROWS` table option in `CREATE TABLE` statements for `MEMORY` tables to provide
a hint about the number of rows you plan to store in them. This does not enable the table to grow beyond
the `max_heap_table_size` value, which still acts as a constraint on maximum table size. For maximum
flexibility in being able to use `MAX_ROWS`, set `max_heap_table_size` at least as high as the value to
which you want each `MEMORY` table to be able to grow.

**Additional Resources**

### 15.5 The **CSV** Storage Engine

The **CSV** storage engine stores data in text files using comma-separated values format.

The **CSV** storage engine is always compiled into the MySQL server.

To examine the source for the **CSV** engine, look in the `storage/csv` directory of a MySQL source
distribution.

When you create a **CSV** table, the server creates a table format file in the database directory. The file
begins with the table name and has an `.frm` extension. The storage engine also creates a data file. Its
name begins with the table name and has a `.CSV` extension. The data file is a plain text file. When you
store data into the table, the storage engine saves it into the data file in comma-separated values format.

```
mysql> CREATE TABLE test (i INT NOT NULL, c CHAR(10) NOT NULL)
    ->     ENGINE = CSV;
Query OK, 0 rows affected (0.12 sec)
mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 0
mysql> SELECT * FROM test;
+----+------------+
| i  | c          |
+----+------------+
| 1  | record one |
| 2  | record two |
+----+------------+
2 rows in set (0.00 sec)
```
Creating a CSV table also creates a corresponding Metafile that stores the state of the table and the number of rows that exist in the table. The name of this file is the same as the name of the table with the extension CSM.

If you examine the test.CSV file in the database directory created by executing the preceding statements, its contents should look like this:

"1","record one"
"2","record two"

This format can be read, and even written, by spreadsheet applications such as Microsoft Excel or StarOffice Calc.

### 15.5.1 Repairing and Checking CSV Tables

The CSV storage engines supports the **CHECK** and **REPAIR** statements to verify and if possible repair a damaged CSV table.

When running the **CHECK** statement, the CSV file will be checked for validity by looking for the correct field separators, escaped fields (matching or missing quotation marks), the correct number of fields compared to the table definition and the existence of a corresponding CSV metafile. The first invalid row discovered will report an error. Checking a valid table produces output like that shown below:

```sql
mysql> check table csvtest;
+--------------+-------+----------+----------+
| Table        | Op    | Msg_type | Msg_text |
+--------------+-------+----------+----------+
| test.csvtest | check | status   | OK       |
+--------------+-------+----------+----------+
1 row in set (0.00 sec)
```

A check on a corrupted table returns a fault:

```sql
mysql> check table csvtest;
+--------------+-------+----------+----------+
| Table        | Op    | Msg_type | Msg_text |
+--------------+-------+----------+----------+
| test.csvtest | check | error    | Corrupt  |
+--------------+-------+----------+----------+
1 row in set (0.01 sec)
```

If the check fails, the table is marked as crashed (corrupt). Once a table has been marked as corrupt, it is automatically repaired when you next run **CHECK** or execute a **SELECT** statement. The corresponding corrupt status and new status will be displayed when running **CHECK**:  

```sql
mysql> check table csvtest;
+--------------+-------+----------+----------------------------+
| Table        | Op    | Msg_type | Msg_text                   |
+--------------+-------+----------+----------------------------+
| test.csvtest | check | warning  | Table is marked as crashed |
| test.csvtest | check | status   | OK                         |
+--------------+-------+----------+----------------------------+
2 rows in set (0.08 sec)
```

To repair a table you can use **REPAIR**, this copies as many valid rows from the existing CSV data as possible, and then replaces the existing CSV file with the recovered rows. Any rows beyond the corrupted data are lost.

```sql
mysql> repair table csvtest;
+---------------------------------------------+----------+
|                                           | Msg_type |
+---------------------------------------------+----------+
|                                           | OK       |
+---------------------------------------------+----------+
```
Warning

Note that during repair, only the rows from the CSV file up to the first damaged row are copied to the new table. All other rows from the first damaged row to the end of the table are removed, even valid rows.

15.5.2 CSV Limitations

The CSV storage engine does not support indexing.

Partitioning is not supported for tables using the CSV storage engine.

All tables that you create using the CSV storage engine must have the NOT NULL attribute on all columns. However, for backward compatibility, you can continue to use tables with nullable columns that were created in previous MySQL releases. (Bug #32050)

15.6 The ARCHIVE Storage Engine

The ARCHIVE storage engine is used for storing large amounts of data without indexes in a very small footprint.

Table 15.5 ARCHIVE Storage Engine Features

<table>
<thead>
<tr>
<th>Feature</th>
<th>Value</th>
<th>Value</th>
<th>Value</th>
<th>Table</th>
</tr>

</tr>
</tbody>
</table>

a Implemented in the server (via encryption functions), rather than in the storage engine.
b Implemented in the server, rather than in the storage engine.
c Implemented in the server, rather than in the storage engine.

The ARCHIVE storage engine is included in MySQL binary distributions. To enable this storage engine if you build MySQL from source, invoke CMake with the -DWITH_ARCHIVE_STORAGE_ENGINE option.

To examine the source for the ARCHIVE engine, look in the storage/archive directory of a MySQL source distribution.

You can check whether the ARCHIVE storage engine is available with the SHOW ENGINES statement.

When you create an ARCHIVE table, the server creates a table format file in the database directory. The file begins with the table name and has an .frm extension. The storage engine creates other files, all
having names beginning with the table name. The data file has an extension of .ARZ. An .ARN file may appear during optimization operations.

The ARCHIVE engine supports INSERT and SELECT, but not DELETE, REPLACE, or UPDATE. It does support ORDER BY operations, BLOB columns, and basically all but spatial data types (see Section 11.5.1, “Spatial Data Types”). The ARCHIVE engine uses row-level locking.

The ARCHIVE engine supports the AUTO_INCREMENT column attribute. The AUTO_INCREMENT column can have either a unique or nonunique index. Attempting to create an index on any other column results in an error. The ARCHIVE engine also supports the AUTO_INCREMENT table option in CREATE TABLE statements to specify the initial sequence value for a new table or reset the sequence value for an existing table, respectively.

ARCHIVE does not support inserting a value into an AUTO_INCREMENT column less than the current maximum column value. Attempts to do so result in an ER_DUP_KEY error.

The ARCHIVE engine ignores BLOB columns if they are not requested and scans past them while reading.

Storage: Rows are compressed as they are inserted. The ARCHIVE engine uses zlib lossless data compression (see http://www.zlib.net/). You can use OPTIMIZE TABLE to analyze the table and pack it into a smaller format (for a reason to use OPTIMIZE TABLE, see later in this section). The engine also supports CHECK TABLE. There are several types of insertions that are used:

• An INSERT statement just pushes rows into a compression buffer, and that buffer flushes as necessary. The insertion into the buffer is protected by a lock. A SELECT forces a flush to occur, unless the only insertions that have come in were INSERT DELAYED (those flush as necessary). See Section 13.2.5.2, “INSERT DELAYED Syntax”.

• A bulk insert is visible only after it completes, unless other inserts occur at the same time, in which case it can be seen partially. A SELECT never causes a flush of a bulk insert unless a normal insert occurs while it is loading.

Retrieval: On retrieval, rows are uncompressed on demand; there is no row cache. A SELECT operation performs a complete table scan: When a SELECT occurs, it finds out how many rows are currently available and reads that number of rows. SELECT is performed as a consistent read. Note that lots of SELECT statements during insertion can deteriorate the compression, unless only bulk or delayed inserts are used. To achieve better compression, you can use OPTIMIZE TABLE or REPAIR TABLE. The number of rows in ARCHIVE tables reported by SHOW TABLE STATUS is always accurate. See Section 13.7.2.4, “OPTIMIZE TABLE Syntax”, Section 13.7.2.5, “REPAIR TABLE Syntax”, and Section 13.7.5.37, “SHOW TABLE STATUS Syntax”.

Additional Resources

• A forum dedicated to the ARCHIVE storage engine is available at http://forums.mysql.com/list.php?112.

15.7 The BLACKHOLE Storage Engine

The BLACKHOLE storage engine acts as a “black hole” that accepts data but throws it away and does not store it. Retrievals always return an empty result:

```
mysql> CREATE TABLE test(i INT, c CHAR(10)) ENGINE = BLACKHOLE;
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 0
```
mysql> SELECT * FROM test;
Empty set (0.00 sec)

To enable the BLACKHOLE storage engine if you build MySQL from source, invoke CMake with the `-DWITH_BLACKHOLE_STORAGE_ENGINE` option.

To examine the source for the BLACKHOLE engine, look in the `sql` directory of a MySQL source distribution.

When you create a BLACKHOLE table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. There are no other files associated with the table.

The BLACKHOLE storage engine supports all kinds of indexes. That is, you can include index declarations in the table definition.

You can check whether the BLACKHOLE storage engine is available with the `SHOW ENGINES` statement.

Inserts into a BLACKHOLE table do not store any data, but if statement based binary logging is enabled, the SQL statements are logged and replicated to slave servers. This can be useful as a repeater or filter mechanism.

**Note**

When using the row based format for the binary log, updates and deletes are skipped, and neither logged nor applied. For this reason, you should use `STATEMENT` for the binary logging format, and not `ROW` or `MIXED`.

Suppose that your application requires slave-side filtering rules, but transferring all binary log data to the slave first results in too much traffic. In such a case, it is possible to set up on the master host a “dummy” slave process whose default storage engine is BLACKHOLE, depicted as follows:

![Diagram of master and dummy slave process](image)

The master writes to its binary log. The “dummy” `mysqld` process acts as a slave, applying the desired combination of `replicate-do-*` and `replicate-ignore-*` rules, and writes a new, filtered binary log of its own. (See Section 17.1.3, “Replication and Binary Logging Options and Variables”.) This filtered log is provided to the slave.
The **BLACKHOLE** Storage Engine

The dummy process does not actually store any data, so there is little processing overhead incurred by running the additional `mysqld` process on the replication master host. This type of setup can be repeated with additional replication slaves.

**INSERT** triggers for **BLACKHOLE** tables work as expected. However, because the **BLACKHOLE** table does not actually store any data, **UPDATE** and **DELETE** triggers are not activated: The **FOR EACH ROW** clause in the trigger definition does not apply because there are no rows.

Other possible uses for the **BLACKHOLE** storage engine include:

- Verification of dump file syntax.
- Measurement of the overhead from binary logging, by comparing performance using **BLACKHOLE** with and without binary logging enabled.
- **BLACKHOLE** is essentially a “no-op” storage engine, so it could be used for finding performance bottlenecks not related to the storage engine itself.

The **BLACKHOLE** engine is transaction-aware, in the sense that committed transactions are written to the binary log and rolled-back transactions are not.

**Blackhole Engine and Auto Increment Columns**

The Blackhole engine is a no-op engine. Any operations performed on a table using Blackhole will have no effect. This should be born in mind when considering the behavior of primary key columns that auto increment. The engine will not automatically increment field values, and does not retain auto increment field state. This has important implications in replication.

Consider the following replication scenario where all three of the following conditions apply:

1. On a master server there is a blackhole table with an auto increment field that is a primary key.
2. On a slave the same table exists but using the MyISAM engine.
3. Inserts are performed into the master's table without explicitly setting the auto increment value in the **INSERT** statement itself or through using a **SET INSERT_ID** statement.

In this scenario replication will fail with a duplicate entry error on the primary key column.

In statement based replication, the value of **INSERT_ID** in the context event will always be the same. Replication will therefore fail due to trying insert a row with a duplicate value for a primary key column.

In row based replication, the value that the engine returns for the row always be the same for each insert. This will result in the slave attempting to replay two insert log entries using the same value for the primary key column, and so replication will fail.

**Column Filtering**

When using row-based replication, (**binlog_format=ROW**), a slave where the last columns are missing from a table is supported, as described in the section [Section 17.4.1.9, “Replication with Differing Table Definitions on Master and Slave”](#).

This filtering works on the slave side, that is, the columns are copied to the slave before they are filtered out. There are at least two cases where it is not desirable to copy the columns to the slave:

1. If the data is confidential, so the slave server should not have access to it.
2. If the master has many slaves, filtering before sending to the slaves may reduce network traffic.
The **MERGE** Storage Engine

Master column filtering can be achieved using the **BLACKHOLE** engine. This is carried out in a way similar to how master table filtering is achieved - by using the **BLACKHOLE** engine and the `-replicate-do-table` or `-replicate-ignore-table` option.

The setup for the master is:

```sql
CREATE TABLE t1 (public_col_1, ..., public_col_N,
secret_col_1, ..., secret_col_M) ENGINE=MyISAM;
```

The setup for the trusted slave is:

```sql
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=BLACKHOLE;
```

The setup for the untrusted slave is:

```sql
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=MyISAM;
```

### 15.8 The **MERGE** Storage Engine

The **MERGE** storage engine, also known as the **MRG_MyISAM** engine, is a collection of identical **MyISAM** tables that can be used as one. “Identical” means that all tables have identical column and index information. You cannot merge **MyISAM** tables in which the columns are listed in a different order, do not have exactly the same columns, or have the indexes in different order. However, any or all of the **MyISAM** tables can be compressed with `myisampack`. See Section 4.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”. Differences in table options such as **AVG_ROW_LENGTH**, **MAX_ROWS**, or **PACK_KEYS** do not matter.

An alternative to a **MERGE** table is a partitioned table, which stores partitions of a single table in separate files. Partitioning enables some operations to be performed more efficiently and is not limited to the **MyISAM** storage engine. For more information, see Chapter 19, **Partitioning**.

When you create a **MERGE** table, MySQL creates two files on disk. The files have names that begin with the table name and have an extension to indicate the file type. An `.frm` file stores the table format, and an `.MRG` file contains the names of the underlying **MyISAM** tables that should be used as one. The tables do not have to be in the same database as the **MERGE** table.

You can use **SELECT**, **DELETE**, **UPDATE**, and **INSERT** on **MERGE** tables. You must have **SELECT**, **DELETE**, and **UPDATE** privileges on the **MyISAM** tables that you map to a **MERGE** table.

**Note**

The use of **MERGE** tables entails the following security issue: If a user has access to **MyISAM** table `t`, that user can create a **MERGE** table `m` that accesses `t`. However, if the user's privileges on `t` are subsequently revoked, the user can continue to access `t` by doing so through `m`.

Use of **DROP TABLE** with a **MERGE** table drops only the **MERGE** specification. The underlying tables are not affected.

To create a **MERGE** table, you must specify a `UNION=(list-of-tables)` option that indicates which **MyISAM** tables to use. You can optionally specify an **INSERT_METHOD** option to control how inserts into the **MERGE** table take place. Use a value of `FIRST` or `LAST` to cause inserts to be made in the first or last underlying table, respectively. If you specify no **INSERT_METHOD** option or if you specify it with a value of `NO`, inserts into the **MERGE** table are not permitted and attempts to do so result in an error.

The following example shows how to create a **MERGE** table:
Note that column `a` is indexed as a **PRIMARY KEY** in the underlying **MyISAM** tables, but not in the **MERGE** table. There it is indexed but not as a **PRIMARY KEY** because a **MERGE** table cannot enforce uniqueness over the set of underlying tables. (Similarly, a column with a **UNIQUE** index in the underlying tables should be indexed in the **MERGE** table but not as a **UNIQUE** index.)

After creating the **MERGE** table, you can use it to issue queries that operate on the group of tables as a whole:

```sql
mysql> SELECT * FROM total;
+---+---------+
<table>
<thead>
<tr>
<th>a</th>
<th>message</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Testing</td>
</tr>
<tr>
<td>2</td>
<td>table</td>
</tr>
<tr>
<td>3</td>
<td>t1</td>
</tr>
<tr>
<td>1</td>
<td>Testing</td>
</tr>
<tr>
<td>2</td>
<td>table</td>
</tr>
<tr>
<td>3</td>
<td>t2</td>
</tr>
</tbody>
</table>
+---+---------+
```

To remap a **MERGE** table to a different collection of **MyISAM** tables, you can use one of the following methods:

- **DROP** the **MERGE** table and re-create it.

- **Use** `ALTER TABLE tbl_name UNION=(...)` to change the list of underlying tables.

  It is also possible to use `ALTER TABLE ... UNION=()` (that is, with an empty **UNION** clause) to remove all of the underlying tables. However, in this case, the table is effectively empty and inserts fail because there is no underlying table to take new rows. Such a table might be useful as a template for creating new **MERGE** tables with `CREATE TABLE ... LIKE`.

The underlying table definitions and indexes must conform closely to the definition of the **MERGE** table. Conformance is checked when a table that is part of a **MERGE** table is opened, not when the **MERGE** table is created. If any table fails the conformance checks, the operation that triggered the opening of the table fails. This means that changes to the definitions of tables within a **MERGE** may cause a failure when the **MERGE** table is accessed. The conformance checks applied to each table are:

- The underlying table and the **MERGE** table must have the same number of columns.

- The column order in the underlying table and the **MERGE** table must match.

- Additionally, the specification for each corresponding column in the parent **MERGE** table and the underlying tables are compared and must satisfy these checks:
  - The column type in the underlying table and the **MERGE** table must be equal.
• The column length in the underlying table and the **MERGE** table must be equal.

• The column of the underlying table and the **MERGE** table can be **NULL**.

• The underlying table must have at least as many indexes as the **MERGE** table. The underlying table may have more indexes than the **MERGE** table, but cannot have fewer.

**Note**

A known issue exists where indexes on the same columns must be in identical order, in both the **MERGE** table and the underlying **MyISAM** table. See Bug #33653.

Each index must satisfy these checks:

• The index type of the underlying table and the **MERGE** table must be the same.

• The number of index parts (that is, multiple columns within a compound index) in the index definition for the underlying table and the **MERGE** table must be the same.

• For each index part:
  • Index part lengths must be equal.
  • Index part types must be equal.
  • Index part languages must be equal.
  • Check whether index parts can be **NULL**.

If a **MERGE** table cannot be opened or used because of a problem with an underlying table, **CHECK TABLE** displays information about which table caused the problem.

**Additional Resources**

**15.8.1 **MERGE** Table Advantages and Disadvantages**

**MERGE** tables can help you solve the following problems:

• Easily manage a set of log tables. For example, you can put data from different months into separate tables, compress some of them with **myisampack**, and then create a **MERGE** table to use them as one.

• Obtain more speed. You can split a large read-only table based on some criteria, and then put individual tables on different disks. A **MERGE** table structured this way could be much faster than using a single large table.

• Perform more efficient searches. If you know exactly what you are looking for, you can search in just one of the underlying tables for some queries and use a **MERGE** table for others. You can even have many different **MERGE** tables that use overlapping sets of tables.

• Perform more efficient repairs. It is easier to repair individual smaller tables that are mapped to a **MERGE** table than to repair a single large table.

• Instantly map many tables as one. A **MERGE** table need not maintain an index of its own because it uses the indexes of the individual tables. As a result, **MERGE** table collections are very fast to create or remap.
(You must still specify the index definitions when you create a **MERGE** table, even though no indexes are created.)

- If you have a set of tables from which you create a large table on demand, you can instead create a **MERGE** table from them on demand. This is much faster and saves a lot of disk space.

- Exceed the file size limit for the operating system. Each **MyISAM** table is bound by this limit, but a collection of **MyISAM** tables is not.

- You can create an alias or synonym for a **MyISAM** table by defining a **MERGE** table that maps to that single table. There should be no really notable performance impact from doing this (only a couple of indirect calls and `memcpy()` calls for each read).

The disadvantages of **MERGE** tables are:

- You can use only identical **MyISAM** tables for a **MERGE** table.

- Some **MyISAM** features are unavailable in **MERGE** tables. For example, you cannot create **FULLTEXT** indexes on **MERGE** tables. (You can create **FULLTEXT** indexes on the underlying **MyISAM** tables, but you cannot search the **MERGE** table with a full-text search.)

- If the **MERGE** table is nontemporary, all underlying **MyISAM** tables must be nontemporary. If the **MERGE** table is temporary, the **MyISAM** tables can be any mix of temporary and nontemporary.

- **MERGE** tables use more file descriptors than **MyISAM** tables. If 10 clients are using a **MERGE** table that maps to 10 tables, the server uses $(10 \times 10) + 10$ file descriptors. (10 data file descriptors for each of the 10 clients, and 10 index file descriptors shared among the clients.)

- Index reads are slower. When you read an index, the **MERGE** storage engine needs to issue a read on all underlying tables to check which one most closely matches a given index value. To read the next index value, the **MERGE** storage engine needs to search the read buffers to find the next value. Only when one index buffer is used up does the storage engine need to read the next index block. This makes **MERGE** indexes much slower on `eq_ref` searches, but not much slower on `ref` searches. For more information about `eq_ref` and `ref`, see Section 13.8.2, "EXPLAIN Syntax".

15.8.2 **MERGE** Table Problems

The following are known problems with **MERGE** tables:

- In versions of MySQL Server prior to 5.1.23, it was possible to create temporary merge tables with nontemporary child **MyISAM** tables.

  From versions 5.1.23, **MERGE** children were locked through the parent table. If the parent was temporary, it was not locked and so the children were not locked either. Parallel use of the **MyISAM** tables corrupted them.

- If you use **ALTER TABLE** to change a **MERGE** table to another storage engine, the mapping to the underlying tables is lost. Instead, the rows from the underlying **MyISAM** tables are copied into the altered table, which then uses the specified storage engine.

- The **INSERT_METHOD** table option for a **MERGE** table indicates which underlying **MyISAM** table to use for inserts into the **MERGE** table. However, use of the **AUTO_INCREMENT** table option for that **MyISAM** table has no effect for inserts into the **MERGE** table until at least one row has been inserted directly into the **MyISAM** table.

- A **MERGE** table cannot maintain uniqueness constraints over the entire table. When you perform an **INSERT**, the data goes into the first or last **MyISAM** table (as determined by the **INSERT_METHOD**
option). MySQL ensures that unique key values remain unique within that MyISAM table, but not over all the underlying tables in the collection.

- Because the MERGE engine cannot enforce uniqueness over the set of underlying tables, REPLACE does not work as expected. The two key facts are:
  - REPLACE can detect unique key violations only in the underlying table to which it is going to write (which is determined by the INSERT_METHOD option). This differs from violations in the MERGE table itself.
  - If REPLACE detects a unique key violation, it will change only the corresponding row in the underlying table it is writing to; that is, the first or last table, as determined by the INSERT_METHOD option.

Similar considerations apply for INSERT ... ON DUPLICATE KEY UPDATE.

- MERGE tables do not support partitioning. That is, you cannot partition a MERGE table, nor can any of a MERGE table’s underlying MyISAM tables be partitioned.

- You should not use ANALYZE TABLE, REPAIR TABLE, OPTIMIZE TABLE, ALTER TABLE, DROP TABLE, DELETE without a WHERE clause, or TRUNCATE TABLE on any of the tables that are mapped into an open MERGE table. If you do so, the MERGE table may still refer to the original table and yield unexpected results. To work around this problem, ensure that no MERGE tables remain open by issuing a FLUSH TABLES statement prior to performing any of the named operations.

The unexpected results include the possibility that the operation on the MERGE table will report table corruption. If this occurs after one of the named operations on the underlying MyISAM tables, the corruption message is spurious. To deal with this, issue a FLUSH TABLES statement after modifying the MyISAM tables.

- DROP TABLE on a table that is in use by a MERGE table does not work on Windows because the MERGE storage engine’s table mapping is hidden from the upper layer of MySQL. Windows does not permit open files to be deleted, so you first must flush all MERGE tables (with FLUSH TABLES) or drop the MERGE table before dropping the table.

- The definition of the MyISAM tables and the MERGE table are checked when the tables are accessed (for example, as part of a SELECT or INSERT statement). The checks ensure that the definitions of the tables and the parent MERGE table definition match by comparing column order, types, sizes and associated indexes. If there is a difference between the tables, an error is returned and the statement fails. Because these checks take place when the tables are opened, any changes to the definition of a single table, including column changes, column ordering, and engine alterations will cause the statement to fail.

- The order of indexes in the MERGE table and its underlying tables should be the same. If you use ALTER TABLE to add a UNIQUE index to a table used in a MERGE table, and then use ALTER TABLE to add a nonunique index on the MERGE table, the index ordering is different for the tables if there was already a nonunique index in the underlying table. (This happens because ALTER TABLE puts UNIQUE indexes before nonunique indexes to facilitate rapid detection of duplicate keys.) Consequently, queries on tables with such indexes may return unexpected results.

- If you encounter an error message similar to ERROR 1017 (HY000): Can't find file: 'tbl_name.MRG' (errno: 2), it generally indicates that some of the underlying tables do not use the MyISAM storage engine. Confirm that all of these tables are MyISAM.

- The maximum number of rows in a MERGE table is $2^{64}$ (~1.844E+19; the same as for a MyISAM table). It is not possible to merge multiple MyISAM tables into a single MERGE table that would have more than this number of rows.

- The MERGE storage engine does not support INSERT DELAYED statements.
15.9 The **FEDERATED** Storage Engine

The **FEDERATED** storage engine lets you access data from a remote MySQL database without using replication or cluster technology. Querying a local **FEDERATED** table automatically pulls the data from the remote (federated) tables. No data is stored on the local tables.

To include the **FEDERATED** storage engine if you build MySQL from source, invoke **CMake** with the `-DWITH_FEDERATED_STORAGE_ENGINE` option.

The **FEDERATED** storage engine is not enabled by default in the running server; to enable **FEDERATED**, you must start the MySQL server binary using the `--federated` option.

To examine the source for the **FEDERATED** engine, look in the `storage/federated` directory of a MySQL source distribution.

15.9.1 **FEDERATED** Storage Engine Overview

When you create a table using one of the standard storage engines (such as **MyISAM**, **CSV** or **InnoDB**), the table consists of the table definition and the associated data. When you create a **FEDERATED** table, the table definition is the same, but the physical storage of the data is handled on a remote server.

A **FEDERATED** table consists of two elements:

- A *remote server* with a database table, which in turn consists of the table definition (stored in the `.frm` file) and the associated table. The table type of the remote table may be any type supported by the remote `mysqld` server, including **MyISAM** or **InnoDB**.

- A *local server* with a database table, where the table definition matches that of the corresponding table on the remote server. The table definition is stored within the `.frm` file. However, there is no data file on the local server. Instead, the table definition includes a connection string that points to the remote table.

When executing queries and statements on a **FEDERATED** table on the local server, the operations that would normally insert, update or delete information from a local data file are instead sent to the remote server.
server for execution, where they update the data file on the remote server or return matching rows from the remote server.

The basic structure of a FEDERATED table setup is shown in Figure 15.1, “FEDERATED Table Structure”.

![FEDERATED Table Structure Diagram]

When a client issues an SQL statement that refers to a FEDERATED table, the flow of information between the local server (where the SQL statement is executed) and the remote server (where the data is physically stored) is as follows:

1. The storage engine looks through each column that the FEDERATED table has and constructs an appropriate SQL statement that refers to the remote table.

2. The statement is sent to the remote server using the MySQL client API.

3. The remote server processes the statement and the local server retrieves any result that the statement produces (an affected-rows count or a result set).

4. If the statement produces a result set, each column is converted to internal storage engine format that the FEDERATED engine expects and can use to display the result to the client that issued the original statement.

The local server communicates with the remote server using MySQL client C API functions. It invokes `mysql_real_query()` to send the statement. To read a result set, it uses `mysql_store_result()` and fetches rows one at a time using `mysql_fetch_row()`.

### 15.9.2 How to Create FEDERATED Tables

To create a FEDERATED table you should follow these steps:

1. Create the table on the remote server. Alternatively, make a note of the table definition of an existing table, perhaps using the `SHOW CREATE TABLE` statement.

2. Create the table on the local server with an identical table definition, but adding the connection information that links the local table to the remote table.

For example, you could create the following table on the remote server:

```sql
CREATE TABLE test_table (
    id INT(20) NOT NULL AUTO_INCREMENT,
    name VARCHAR(32) NOT NULL DEFAULT '',
```
To create the local table that will be federated to the remote table, there are two options available. You can either create the local table and specify the connection string (containing the server name, login, password) to be used to connect to the remote table using the `CONNECTION`, or you can use an existing connection that you have previously created using the `CREATE SERVER` statement.

**Important**

When you create the local table it *must* have an identical field definition to the remote table.

**Note**

You can improve the performance of a `FEDERATED` table by adding indexes to the table on the host. The optimization will occur because the query sent to the remote server will include the contents of the `WHERE` clause and will be sent to the remote server and subsequently executed locally. This reduces the network traffic that would otherwise request the entire table from the server for local processing.

### 15.9.2.1 Creating a `FEDERATED` Table Using `CONNECTION`

To use the first method, you must specify the `CONNECTION` string after the engine type in a `CREATE TABLE` statement. For example:

```sql
CREATE TABLE federated_table (
    id     INT(20) NOT NULL AUTO_INCREMENT,
    name   VARCHAR(32) NOT NULL DEFAULT '',
    other  INT(20) NOT NULL DEFAULT '0',
    PRIMARY KEY (id),
    INDEX name (name),
    INDEX other_key (other)
) ENGINE=FEDERATED
DEFAULT CHARSET=latin1
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```

**Note**

`CONNECTION` replaces the `COMMENT` used in some previous versions of MySQL.

The `CONNECTION` string contains the information required to connect to the remote server containing the table that will be used to physically store the data. The connection string specifies the server name, login credentials, port number and database/table information. In the example, the remote table is on the server `remote_host`, using port 9306. The name and port number should match the host name (or IP address) and port number of the remote MySQL server instance you want to use as your remote table.

The format of the connection string is as follows:

```sql
scheme://user_name[:password@]host_name[:port_num]/db_name.tbl_name
```

Where:
How to Create **FEDERATED** Tables

- **scheme**: A recognized connection protocol. Only mysql is supported as the `scheme` value at this point.
- **user_name**: The user name for the connection. This user must have been created on the remote server, and must have suitable privileges to perform the required actions (**SELECT**, **INSERT**, **UPDATE**, and so forth) on the remote table.
- **password**: (Optional) The corresponding password for `user_name`.
- **host_name**: The host name or IP address of the remote server.
- **port_num**: (Optional) The port number for the remote server. The default is 3306.
- **db_name**: The name of the database holding the remote table.
- **tbl_name**: The name of the remote table. The name of the local and the remote table do not have to match.

Sample connection strings:

```sql
CONNECTION='mysql://username:password@hostname:port/database/tablename'
CONNECTION='mysql://username@hostname/database/tablename'
CONNECTION='mysql://username:password@hostname/database/tablename'
```

### 15.9.2.2 Creating a **FEDERATED** Table Using **CREATE SERVER**

If you are creating a number of **FEDERATED** tables on the same server, or if you want to simplify the process of creating **FEDERATED** tables, you can use the **CREATE SERVER** statement to define the server connection parameters, just as you would with the **CONNECTION** string.

The format of the **CREATE SERVER** statement is:

```sql
CREATE SERVER server_name
FOREIGN DATA WRAPPER wrapper_name
OPTIONS (option [, option] ...)
```

The `server_name` is used in the connection string when creating a new **FEDERATED** table.

For example, to create a server connection identical to the **CONNECTION** string:

```sql
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```

You would use the following statement:

```sql
CREATE SERVER fedlink
FOREIGN DATA WRAPPER mysql
OPTIONS (USER 'fed_user', HOST 'remote_host', PORT 9306, DATABASE 'federated');
```

To create a **FEDERATED** table that uses this connection, you still use the **CONNECTION** keyword, but specify the name you used in the **CREATE SERVER** statement.

```sql
CREATE TABLE test_table (  id INT(20) NOT NULL AUTO_INCREMENT,  name VARCHAR(32) NOT NULL DEFAULT '',  other INT(20) NOT NULL DEFAULT '0',  PRIMARY KEY (id),  INDEX name (name),  INDEX other_key (other) ) ENGINE=FEDERATED
```
The connection name in this example contains the name of the connection (`fedlink`) and the name of the table (`test_table`) to link to, separated by a slash. If you specify only the connection name without a table name, the table name of the local table is used instead.

For more information on `CREATE SERVER`, see Section 13.1.16, "CREATE SERVER Syntax".

The `CREATE SERVER` statement accepts the same arguments as the `CONNECTION` string. The `CREATE SERVER` statement updates the rows in the `mysql.servers` table. See the following table for information on the correspondence between parameters in a connection string, options in the `CREATE SERVER` statement, and the columns in the `mysql.servers` table. For reference, the format of the `CONNECTION` string is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name.tbl_name
```

<table>
<thead>
<tr>
<th>Description</th>
<th><code>CONNECTION</code> string</th>
<th><code>CREATE SERVER</code> option</th>

</table>

15.9.3 **FEDERATED** Storage Engine Notes and Tips

You should be aware of the following points when using the FEDERATED storage engine:

- **FEDERATED** tables may be replicated to other slaves, but you must ensure that the slave servers are able to use the user/password combination that is defined in the `CONNECTION` string (or the row in the `mysql.servers` table) to connect to the remote server.

The following items indicate features that the FEDERATED storage engine does and does not support:

- The remote server must be a MySQL server.
- The remote table that a FEDERATED table points to must exist before you try to access the table through the FEDERATED table.
- It is possible for one FEDERATED table to point to another, but you must be careful not to create a loop.
- A FEDERATED table does not support indexes per se. Because access to the table is handled remotely, it is the remote table that supports the indexes. Care should be taken when creating a FEDERATED table since the index definition from an equivalent MyISAM or other table may not be supported. For example, creating a FEDERATED table with an index prefix on `VARCHAR`, `TEXT` or `BLOB` columns will fail. The following definition in MyISAM is valid:

  ```sql
  CREATE TABLE `T1`(`A` VARCHAR(100),UNIQUE KEY(`A`(30))) ENGINE=MYISAM;
  ```

  The key prefix in this example is incompatible with the FEDERATED engine, and the equivalent statement will fail:
CREATE TABLE `T1`(`A` VARCHAR(100), UNIQUE KEY(`A`(30))) ENGINE=FEDERATED CONNECTION='MYSQL://127.0.0.1:3306/TEST/T1';

If possible, you should try to separate the column and index definition when creating tables on both the remote server and the local server to avoid these index issues.

- Internally, the implementation uses SELECT, INSERT, UPDATE, and DELETE, but not HANDLER.

- The FEDERATED storage engine supports SELECT, INSERT, UPDATE, DELETE, TRUNCATE TABLE, and indexes. It does not support ALTER TABLE, or any Data Definition Language statements that directly affect the structure of the table, other than DROP TABLE. The current implementation does not use prepared statements.

- FEDERATED accepts INSERT ... ON DUPLICATE KEY UPDATE statements, but if a duplicate-key violation occurs, the statement fails with an error.

- Performance on a FEDERATED table when performing bulk inserts (for example, on a INSERT INTO ... SELECT ... statement) is slower than with other table types because each selected row is treated as an individual INSERT statement on the FEDERATED table.

- Transactions are not supported.

- FEDERATED performs bulk-insert handling such that multiple rows are sent to the remote table in a batch. This provides a performance improvement and enables the remote table to perform improvement. Also, if the remote table is transactional, it enables the remote storage engine to perform statement rollback properly should an error occur. This capability has the following limitations:
  - The size of the insert cannot exceed the maximum packet size between servers. If the insert exceeds this size, it is broken into multiple packets and the rollback problem can occur.
  - Bulk-insert handling does not occur for INSERT ... ON DUPLICATE KEY UPDATE.
  - There is no way for the FEDERATED engine to know if the remote table has changed. The reason for this is that this table must work like a data file that would never be written to by anything other than the database system. The integrity of the data in the local table could be breached if there was any change to the remote database.
  - When using a CONNECTION string, you cannot use an '@' character in the password. You can get round this limitation by using the CREATE SERVER statement to create a server connection.
  - The insert_id and timestamp options are not propagated to the data provider.
  - Any DROP TABLE statement issued against a FEDERATED table drops only the local table, not the remote table.
  - FEDERATED tables do not work with the query cache.
  - User-defined partitioning is not supported for FEDERATED tables.

**15.9.4 FEDERATED Storage Engine Resources**

The following additional resources are available for the FEDERATED storage engine:

**15.10 The EXAMPLE Storage Engine**
The EXAMPLE storage engine is a stub engine that does nothing. Its purpose is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.

To enable the EXAMPLE storage engine if you build MySQL from source, invoke CMake with the -DWITH_EXAMPLE_STORAGE_ENGINE option.

To examine the source for the EXAMPLE engine, look in the storage/example directory of a MySQL source distribution.

When you create an EXAMPLE table, the server creates a table format file in the database directory. The file begins with the table name and has an .frm extension. No other files are created. No data can be stored into the table. Retrievals return an empty result.

```
mysql> CREATE TABLE test (i INT) ENGINE = EXAMPLE;
Query OK, 0 rows affected (0.78 sec)

mysql> INSERT INTO test VALUES(1),(2),(3);
ERROR 1031 (HY000): Table storage engine for 'test' doesn't have this option

mysql> SELECT * FROM test;
Empty set (0.31 sec)
```

The EXAMPLE storage engine does not support indexing.

15.11 Other Storage Engines

Other storage engines may be available from third parties and community members that have used the Custom Storage Engine interface.

Third party engines are not supported by MySQL. For further information, documentation, installation guides, bug reporting or for any help or assistance with these engines, please contact the developer of the engine directly.

For more information on developing a customer storage engine that can be used with the Pluggable Storage Engine Architecture, see MySQL Internals: Writing a Custom Storage Engine.

Data is the currency of today’s web, mobile, social, enterprise and cloud applications. Ensuring data is always available is a top priority for any organization. Minutes of downtime can result in significant loss of revenue and reputation.

There is no “one size fits all” approach to delivering High Availability (HA). Unique application attributes, business requirements, operational capabilities and legacy infrastructure can all influence HA technology selection. And technology is only one element in delivering HA: people and processes are just as critical as the technology itself.

MySQL is deployed into many applications demanding availability and scalability. Availability refers to the ability to cope with, and if necessary recover from, failures on the host, including failures of MySQL, the operating system, or the hardware and maintenance activity that may otherwise cause downtime. Scalability refers to the ability to spread both the database and the load of your application queries across multiple MySQL servers.

Because each application has different operational and availability requirements, MySQL offers a range of certified and supported solutions, delivering the appropriate levels of High Availability (HA) and scalability to meet service level requirements. Such solutions extend from replication, through virtualization and geographically redundant, multi-data center solutions delivering 99.999% uptime.

Selecting the right high availability solution for an application largely depends on:

• The level of availability required.
• The type of application being deployed.
• Accepted best practices within your own environment.

The primary solutions supported by MySQL include:

• MySQL Replication. Learn more: Chapter 17, *Replication*

• MySQL Cluster. Learn more: Chapter 18, *MySQL Cluster NDB 7.2*

• Oracle VM Template for MySQL. Learn more: Section 16.1, “Oracle VM Template for MySQL Enterprise Edition”.

• MySQL with DRBD with Corosync and Pacemaker. Learn more: Section 16.2, “Overview of MySQL with DRBD/Pacemaker/Corosync/Oracle Linux”.

• MySQL with Windows Failover Clustering. Learn more: Section 16.3, “Overview of MySQL with Windows Failover Clustering”.

• MySQL with Solaris Cluster. Learn more about Solaris Cluster.

Further options are available using third-party solutions.

Each architecture used to achieve highly available database services is differentiated by the levels of uptime it offers. These architectures can be grouped into three main categories:

• Data Replication.

• Clustered & Virtualized Systems.

• Shared-Nothing, Geographically-Replicated Clusters.

As illustrated in the following figure, each of these architectures offers progressively higher levels of uptime, which must be balanced against potentially greater levels of cost and complexity that each can incur. Simply deploying a high availability architecture is not a guarantee of actually delivering HA. In fact, a poorly implemented and maintained shared-nothing cluster could easily deliver lower levels of availability than a simple data replication solution.
The following table compares the HA and Scalability capabilities of the various MySQL solutions:

### Oracle VM Template for MySQL Enterprise Edition

Virtualization is a key technology to enable data center efficiency and high availability while providing the foundation for cloud computing. Integrating MySQL Enterprise Edition with Oracle Linux, the Oracle VM Template is the fastest, easiest, and most reliable way to provision virtualized MySQL instances, enabling users to meet the explosive demand for highly available services.

The Oracle VM Template enables rapid deployment and eliminates manual configuration efforts. It provides a preinstalled and pre-configured virtualized MySQL 5.5 Enterprise Edition software image running on Oracle Linux and Oracle VM, certified for production use. The MySQL software image has undergone extensive integration and quality assurance testing as part of the development process.

In addition to rapid provisioning, MySQL users also benefit from the integrated high availability features of Oracle VM which are designed to enable organizations to meet stringent SLA (Service Level Agreement) demands through a combination of:

- **Automatic recovery from failures**, with Oracle VM automatically restarting failed instances on available servers in the server pool after outages of the physical server, VM or MySQL database.
- **Live Migration**, enabling operations staff to move running instances of MySQL to alternative hosts within a server pool during maintenance operations.

16.1 Oracle VM Template for MySQL Enterprise Edition
Overview of MySQL with DRBD/Pacemaker/Corosync/Oracle Linux

Instructions for the creation, deployment and use of the Oracle VM Template for MySQL Enterprise Edition are available from:

- The README file accompanying the download of the Template.

To download the Oracle VM Template for MySQL Enterprise, go to https://edelivery.oracle.com/oraclevm and follow these instructions:

- Complete your registration information (Name, Company Name, Email Address and Country) and click on the download agreement.
- Select "Oracle VM Templates" from the "Select a Product Pack" pull-down menu and click "Go".
- Select MySQL Enterprise from the list of Oracle VM Templates.
- Download and unzip the files and refer to the README for further instructions.

16.2 Overview of MySQL with DRBD/Pacemaker/Corosync/Oracle Linux

DRBD (Distributed Replication Block Device) is one of the leading solutions for MySQL HA (High Availability). When combined with Pacemaker and Corosync, users have:

- An end-to-end, integrated stack of mature and proven open source technologies, fully supported by Oracle (as part of MySQL Enterprise Edition).
- Automatic failover and recovery for service continuity.
- Mirroring, via synchronous replication, to ensure failover between nodes without the risk of losing committed transactions.
- Building of HA clusters from commodity hardware, without the requirement for shared-storage.

The following figure illustrates the stack that can be used to deliver a level of High Availability for the MySQL service.

At the lowest level, 2 hosts are required in order to provide physical redundancy; if using a virtual environment, those 2 hosts should be on different physical machines. It is an important feature that no shared storage is required. At any point in time, the services will be active on one host and in standby mode on the other.

Pacemaker and Corosync combine to provide the clustering layer that sits between the services and the underlying hosts and operating systems. Pacemaker is responsible for starting and stopping services, ensuring that they are running on exactly one host, thus delivering high availability and avoiding data corruption. Corosync provides the underlying messaging infrastructure between the nodes that enables Pacemaker to do its job; it also handles the nodes membership within the cluster and informs Pacemaker of any changes.
The core Pacemaker process does not have built-in knowledge of the specific services to be managed; instead, it uses agents that provide a wrapper for the service-specific actions. For example, in this solution
we use agents for Virtual IP Addresses, MySQL and DRBD: these are all existing agents and come packaged with Pacemaker.

The essential services managed by Pacemaker in this configuration are DRBD, MySQL and the Virtual IP Address that applications use to connect to the active MySQL service.

DRBD synchronizes data at the block device (typically a spinning or solid state disk) – transparent to the application, database and even the file system. DRBD requires the use of a journaling file system such as ext3 or ext4. For this solution, it acts in an active-standby mode: at any point in time, the directories being managed by DRBD are accessible for reads and writes on exactly one of the two hosts and inaccessible (even for reads) on the other. Any changes made on the active host are synchronously replicated to the standby host by DRBD.

Download the following guide for detailed instructions on installing, configuring, provisioning and testing the complete MySQL and DRBD stack, including:

- MySQL Database.
- DRBD kernel module and userland utilities.
- Pacemaker and Corosync cluster messaging and management processes.
- Oracle Linux operating system.

**Support for DRBD**

The complete DRBD stack for MySQL has been certified by Oracle. Commercial support, which provides a single point of contact for the entire stack, whether issues relate to the operating system, DRBD, clustering software or MySQL, is available to those who have both MySQL Enterprise Edition and Oracle Linux Premier Support contracts.

**16.3 Overview of MySQL with Windows Failover Clustering**

Microsoft Windows is consistently ranked as the top development platform for MySQL, based on surveys of the MySQL user community.

MySQL Enterprise Edition is certified and supported with Windows Server 2008 R2 Failover Clustering (WSFC), enabling organizations to safely deploy business-critical applications demanding high levels of availability using Microsoft's native Windows clustering services.

The following figure illustrates the integration of MySQL with Windows Server Failover Clustering to provide a highly available service:
Figure 16.3 Typical MySQL HA Configuration with Windows Server Failover Clustering

In this architecture, MySQL is deployed in an Active / Passive configuration. Failures of either MySQL or the underlying server are automatically detected and the MySQL instance is restarted on the Passive node. Applications accessing the database, as well as any MySQL replication slaves, can automatically reconnect to the new MySQL process using the same Virtual IP address once MySQL recovery has completed and it starts accepting connections.

MySQL with Windows Failover Clustering requires at least 2 servers within the cluster together with shared storage (for example, FC-AL SAN or iSCSI disks).

The MySQL binaries and data files are stored in the shared storage and Windows Failover Clustering ensures that only one of the cluster nodes will access those files at any point in time.

Clients connect to the MySQL service through a Virtual IP Address (VIP). In the event of failover they experience a brief loss of connection, but otherwise do not need to be aware that the failover has happened, other than to handle the failure of any transactions that were active when the failover occurred.
You can learn more about configuring MySQL with Windows Server Failover Clustering from the whitepaper posted here: http://www.mysql.com/why-mysql/white-papers/mysql_wp_windows_failover_clustering.php

For background and usage information about Windows Server Failover Clustering, see these pages on the Microsoft Technet site:

- Failover Clustering
- Failover Clusters in Windows Server 2008 R2

### 16.4 Using MySQL within an Amazon EC2 Instance

The Amazon Elastic Compute Cloud (EC2) service provides virtual servers that you can build and deploy to run a variety of different applications and services, including MySQL. The EC2 service is based around the Xen framework, supporting x86, Linux based, platforms with individual instances of a virtual machine referred to as an Amazon Machine Image (AMI). You have complete (root) access to the AMI instance that you create, enabling you to configure and install your AMI in any way you choose.

To use EC2, you create an AMI based on the configuration and applications that you intend to use, and upload the AMI to the Amazon Simple Storage Service (S3). From the S3 resource, you can deploy one or more copies of the AMI to run as an instance within the EC2 environment. The EC2 environment provides management and control of the instance and contextual information about the instance while it is running.

Because you can create and control the AMI, the configuration, and the applications, you can deploy and create any environment you choose. This includes a basic MySQL server in addition to more extensive replication, HA and scalability scenarios that enable you to take advantage of the EC2 environment, and the ability to deploy additional instances as the demand for your MySQL services and applications grow.

To aid the deployment and distribution of work, three different Amazon EC2 instances are available, small (identified as `m1.small`), large (`m1.large`) and extra large (`m1.xlarge`). These different types provide different levels of computing power measured in EC2 computer units (ECU). A summary of the different instance configurations is shown in the following table.

<table>
<thead>
<tr>
<th>EC2 Attribute</th>
<th>Small</th>

The typical model for deploying and using MySQL within the EC2 environment is to create a basic AMI that you can use to hold your database data and application. Once the basic environment for your database and application has been created you can then choose to deploy the AMI to a suitable instance. Here the flexibility of having an AMI that can be re-deployed from the small to the large or extra large EC2 instance makes it easy to upgrade the hardware environment without rebuilding your application or database stack.

To get started with MySQL on EC2, including information on how to set up and install MySQL within an EC2 installation and how to port and migrate your data to the running instance, see Section 16.4.1, “Setting Up MySQL on an EC2 AMI”.

1845
For tips and advice on how to create a scalable EC2 environment using MySQL, including guides on setting up replication, see Section 16.4.3, “Deploying a MySQL Database Using EC2”.

### 16.4.1 Setting Up MySQL on an EC2 AMI

There are many different ways of setting up an EC2 AMI with MySQL, including using any of the pre-configured AMIs supplied by Amazon.

The default *Getting Started* AMI provided by Amazon uses Fedora Core 4, and you can install MySQL by using *yum*:

```bash
shell> yum install mysql
```

This installs both the MySQL server and the Perl DBD::mysql driver for the Perl DBI API.

Alternatively, you can use one of the AMIs that include MySQL within the standard installation.

Finally, you can also install a standard version of MySQL downloaded from the MySQL Web site. The installation process and instructions are identical to any other installation of MySQL on Linux. See Chapter 2, *Installing and Upgrading MySQL*.

The standard configuration for MySQL places the data files in the default location, `/var/lib/mysql`. The default data directory on an EC2 instance is `/mnt` (although on the large and extra large instance you can alter this configuration). You must edit `/etc/my.cnf` to set the `datadir` option to point to the larger storage area.

#### Important

The first time you use the main storage location within an EC2 instance it needs to be initialized. The initialization process starts automatically the first time you write to the device. You can start using the device right away, but the write performance of the new device is significantly lower on the initial writes until the initialization process has finished.

To avoid this problem when setting up a new instance, you should start the initialization process before populating your MySQL database. One way to do this is to use `dd` to write to the file system:

```bash
root-shell> dd if=/dev/zero of=initialize bs=1024M count=50
```

The preceding creates a 50GB on the file system and starts the initialization process. Delete the file once the process has finished.

The initialization process can be time-consuming. On the small instance, initialization takes between two and three hours. For the large and extra large drives, the initialization can be 10 or 20 hours, respectively.

In addition to configuring the correct storage location for your MySQL data files, also consider setting the following other settings in your instance before you save the instance configuration for deployment:

- Set the MySQL server ID, so that when you use it for replication, the ID information is set correctly.
- Enabling binary logging, so that replication can be initialized without starting and stopping the server.
- Set the caching and memory parameters for your storage engines. There are no limitations or restrictions on what storage engines you use in your EC2 environment. Choose a configuration, possibly
using one of the standard configurations provided with MySQL appropriate for the instance on which you expect to deploy. The large and extra large instances have RAM that can be dedicated to caching. Be aware that if you choose to install memcached on the servers as part of your application stack you must ensure there is enough memory for both MySQL and memcached.

Once you have configured your AMI with MySQL and the rest of your application stack, save the AMI so that you can deploy and reuse the instance.

Once you have your application stack configured in an AMI, populating your MySQL database with data should be performed by creating a dump of your database using mysqldump, transferring the dump to the EC2 instance, and then reloading the information into the EC2 instance database.

Before using your instance with your application in a production situation, be aware of the limitations of the EC2 instance environment. See Section 16.4.2, "EC2 Instance Limitations". To begin using your MySQL AMI, consult the notes on deployment. See Section 16.4.3, "Deploying a MySQL Database Using EC2".

16.4.2 EC2 Instance Limitations

Be aware of the following limitations of the EC2 instances before deploying your applications. Although these shouldn't affect your ability to deploy within the Amazon EC2 environment, they may alter the way you setup and configure your environment to support your application.

- Data stored within instances is not persistent. If you create an instance and populate the instance with data, then the data only remains in place while the machine is running, and does not survive a reboot. If you shut down the instance, any data it contained is lost.

  To ensure that you do not lose information, take regular backups using mysqldump. If the data being stored is critical, consider using replication to keep a "live" backup of your data in the event of a failure. When creating a backup, write the data to the Amazon S3 service to avoid the transfer charges applied when copying data offsite.

- EC2 instances are not persistent. If the hardware on which an instance is running fails, the instance is shut down. This can lead to loss of data or service.

  However, if you use EBS, you can attach an EBS storage volume to an EC2 instance, and that EBS volume is persistent. Like a disk, an EBS volume can fail, but it is possible to create point-in-time snapshots of the volume. Snapshots are persisted to Amazon S3 and can be used to restore data in the event of volume failure.

- To replicate your EC2 instances to a non-EC2 environment, be aware of the transfer costs to and from the EC2 service. Data transfer between different EC2 instances is free, so using replication within the EC2 environment does not incur additional charges.

- Certain HA features are either not directly supported, or have limiting factors or problems that could reduce their utility. For example, using DRBD or MySQL Cluster might not work. The default storage configuration is also not redundant. You can use software-based RAID to improve redundancy, but this implies a further performance hit.

16.4.3 Deploying a MySQL Database Using EC2

Because you cannot guarantee the uptime and availability of your EC2 instances, when deploying MySQL within the EC2 environment, use an approach that enables you to easily distribute work among your EC2 instances. There are a number of ways of doing this. Using sharding techniques, where you split the application across multiple servers dedicating specific blocks of your dataset and users to different servers is an effective way of doing this. As a general rule, it is easier to create more EC2 instances to support more users than to upgrade the instance to a larger machine.
The EC2 architecture works best when you treat the EC2 instances as temporary, cache-based solutions, rather than as a long-term, high availability solution. In addition to using multiple machines, take advantage of other services, such as memcached to provide additional caching for your application to help reduce the load on the MySQL server so that it can concentrate on writes. On the large and extra large instances within EC2, the RAM available can provide a large memory cache for data.

Most types of scale-out topology that you would use with your own hardware can be used and applied within the EC2 environment. However, use the limitations and advice already given to ensure that any potential failures do not lose you any data. Also, because the relative power of each EC2 instance is so low, be prepared to alter your application to use sharding and add further EC2 instances to improve the performance of your application.

For example, take the typical scale-out environment shown following, where a single master replicates to one or more slaves (three in this example), with a web server running on each replication slave.

You can reproduce this structure completely within the EC2 environment, using an EC2 instance for the master, and one instance for each of the web and MySQL slave servers.

Note

Within the EC2 environment, internal (private) IP addresses used by the EC2 instances are constant. Always use these internal addresses and names when communicating between instances. Only use public IP addresses when communicating with the outside world - for example, when publicizing your application.

To ensure reliability of your database, add at least one replication slave dedicated to providing an active backup and storage to the Amazon S3 facility. You can see an example of this in the following topology.
Using memcached within your EC2 instances should provide better performance. The large and extra large instances have a significant amount of RAM. To use memcached in your application, when loading information from the database, first check whether the item exists in the cache. If the data you are looking for exists in the cache, use it. If not, reload the data from the database and populate the cache.

Sharding divides up data in your entire database by allocating individual machines or machine groups to provide a unique set of data according to an appropriate group. For example, you might put all users with a surname ending in the letters A-D onto a single server. When a user connects to the application and their surname is known, queries can be redirected to the appropriate MySQL server.

When using sharding with EC2, separate the web server and MySQL server into separate EC2 instances, and then apply the sharding decision logic into your application. Once you know which MySQL server you should be using for accessing the data you then distribute queries to the appropriate server. You can see a sample of this in the following illustration.
Warning

With sharding and EC2, be careful that the potential for failure of an instance does not affect your application. If the EC2 instance that provides the MySQL server for a particular shard fails, then all of the data on that shard becomes unavailable.

16.5 Using ZFS Replication

To support high availability environments, providing an instant copy of the information on both the currently active machine and the hot backup is a critical part of the HA solution. There are many solutions to this problem, including Chapter 17, Replication and Section 16.2, “Overview of MySQL with DRBD/Pacemaker/Corosync/Oracle Linux”.

The ZFS file system provides functionality to create a snapshot of the file system contents, transfer the snapshot to another machine, and extract the snapshot to recreate the file system. You can create a snapshot at any time, and you can create as many snapshots as you like. By continually creating, transferring, and restoring snapshots, you can provide synchronization between one or more machines in a fashion similar to DRBD.

The following example shows a simple Solaris system running with a single ZFS pool, mounted at /scratchpool:

```
<table>
<thead>
<tr>
<th>Filesystem</th>
<th>size</th>
<th>used</th>
<th>avail</th>
<th>capacity</th>
<th>Mounted on</th>
</tr>
</thead>
<tbody>
<tr>
<td>/dev/dsk/c0d0s0</td>
<td>4.6G</td>
<td>3.7G</td>
<td>886M</td>
<td>82%</td>
<td>/</td>
</tr>
<tr>
<td>/devices</td>
<td>0K</td>
<td>0K</td>
<td>0K</td>
<td>0%</td>
<td>/devices</td>
</tr>
</tbody>
</table>
```
The MySQL data is stored in a directory on `/scratchpool`. To help demonstrate some of the basic replication functionality, there are also other items stored in `/scratchpool` as well:

```
total 17
drwxr-xr-x 31 root     bin           50 Jul 21 07:32 DTT/
drwxr-xr-x  4 root     bin            5 Jul 21 07:32 SUNWmlib/
drwxr-xr-x 14 root     sys           16 Nov  5 09:56 SUNWspro/
drwxrwrxwx 19 1000     1000          40 Nov  6 19:16 emacs-22.1/
```

To create a snapshot of the file system, you use `zfs snapshot`, specifying the pool and the snapshot name:

```
root-shell> zfs snapshot scratchpool@snap1
```

To list the snapshots already taken:

```
root-shell> zfs list -t snapshot
NAME                USED  AVAIL  REFER  MOUNTPOINT
scratchpool@snap1      0      -  24.5K  -
scratchpool@snap2      0      -  24.5K  -
```

The snapshots themselves are stored within the file system metadata, and the space required to keep them varies as time goes on because of the way the snapshots are created. The initial creation of a snapshot is very quick, because instead of taking an entire copy of the data and metadata required to hold the entire snapshot, ZFS records only the point in time and metadata of when the snapshot was created. As more changes to the original file system are made, the size of the snapshot increases because more space is required to keep the record of the old blocks. If you create lots of snapshots, say one per day, and then delete the snapshots from earlier in the week, the size of the newer snapshots might also increase, as the changes that make up the newer state have to be included in the more recent snapshots, rather than being spread over the seven snapshots that make up the week.

You cannot directly back up the snapshots because they exist within the file system metadata rather than as regular files. To get the snapshot into a format that you can copy to another file system, tape, and so on, you use the `zfs send` command to create a stream version of the snapshot.

For example, to write the snapshot out to a file:

```
root-shell> zfs send scratchpool@snap1 >/backup/scratchpool-snap1
```

Or tape:

```
root-shell> zfs send scratchpool@snap1 >/dev/rmt/0
```

You can also write out the incremental changes between two snapshots using `zfs send`:  

---

1851
Using ZFS for File System Replication

16.5.1 Using ZFS for File System Replication

Because `zfs send` and `zfs recv` use streams to exchange data, you can use them to replicate information from one system to another by combining `zfs send`, `ssh`, and `zfs recv`.

For example, to copy a snapshot of the `scratchpool` file system to a new file system called `slavepool` on a new server, you would use the following command. This sequence combines the snapshot of `scratchpool`, the transmission to the slave machine (using `ssh` with login credentials), and the recovery of the snapshot on the slave using `zfs recv`:

```bash
root-shell> zfs send scratchpool@snap1 | ssh id@host pfexec zfs recv -F slavepool
```

The first part of the pipeline, `zfs send scratchpool@snap1`, streams the snapshot. The `ssh` command, and the command that it executes on the other server, `pfexec zfs recv -F slavepool`, receives the streamed snapshot data and writes it to `slavepool`. In this instance, I've specified the `-F` option which forces the snapshot data to be applied, and is therefore destructive. This is fine, as I'm creating the first version of my replicated file system.

On the slave machine, the replicated file system contains the exact same content:

```bash
root-shell> ls -al /slavepool/
```

```
total 23
drwxr-xr-x  6 root root  7 Nov  8 09:13 ./
drwxr-xr-x 29 root root 34 Nov  9 07:06 ../
drwxr-xr-x 31 root bin 50 Jul 21 07:32 DTT/
drwxr-xr-x  4 root bin  5 Jul 21 07:32 SUNWmlib/
drwxr-xr-x 14 root sys 16 Nov  5 09:56 SUNWspro/
drwxrwxrwx 19 1000 1000 40 Nov  6 19:16 emacs-22.1/
```

Once a snapshot has been created, to synchronize the file system again, you create a new snapshot and then use the incremental snapshot feature of `zfs send` to send the changes between the two snapshots to the slave machine again:

```bash
root-shell> zfs send -i scratchpool@snap1 scratchpool@snap2 | ssh id@host pfexec zfs recv slavepool
```

This operation only succeeds if the file system on the slave machine has not been modified at all. You cannot apply the incremental changes to a destination file system that has changed. In the example above, the `ls` command would cause problems by changing the metadata, such as the last access time for files or directories.

To prevent changes on the slave file system, set the file system on the slave to be read-only:

```bash
root-shell> zfs set readonly=on slavepool
```

Setting `readonly` means that you cannot change the file system on the slave by normal means, including the file system metadata. Operations that would normally update metadata (like our `ls`) silently perform their function without attempting to update the file system state.

In essence, the slave file system is nothing but a static copy of the original file system. However, even when configured to be read-only, a file system can have snapshots applied to it. With the file system set to read only, re-run the initial copy:

```bash
root-shell> zfs send scratchpool@snap1 | ssh id@host pfexec zfs recv slavepool
```
16.5.2 Configuring MySQL for ZFS Replication

Configuring MySQL on the source file system is a case of creating the data on the file system that you intend to replicate. The configuration file in the example below has been updated to use /scratchpool/mysql-data as the data directory, and now you can initialize the tables:

```
root-shell> mysql_install_db --defaults-file=/etc/mysql/5.5/my.cnf --user=mysql
```

To synchronize the initial information, perform a new snapshot and then send an incremental snapshot to the slave using `zfs send`:

```
root-shell> zfs snapshot scratchpool@snap2
root-shell> zfs send -i scratchpool@snap1 scratchpool@snap2 | ssh id@host pfexec zfs recv slavepool
```

Doublecheck that the slave has the data by looking at the MySQL data directory on the `slavepool`:

```
root-shell> ls -al /slavepool/mysql-data/
```

Now you can start up MySQL, create some data, and then replicate the changes using `zfs send/ zfs recv` to the slave to synchronize the changes.

The rate at which you perform the synchronization depends on your application and environment. The limitation is the speed required to perform the snapshot and then to send the changes over the network.

To automate the process, create a script that performs the snapshot, send, and receive operation, and use `cron` to synchronize the changes at set times or intervals.

16.5.3 Handling MySQL Recovery with ZFS

When using ZFS replication to provide a constant copy of your data, ensure that you can recover your tables, either manually or automatically, in the event of a failure of the original system.

In the event of a failure, follow this sequence:

1. Stop the script on the master, if it is still up and running.
2. Set the slave file system to be read/write:

   ```
   root-shell> zfs set readonly=off slavepool
   ```

3. Start up `mysqld` on the slave. If you are using `InnoDB`, you get auto-recovery, if it is needed, to make sure the table data is correct, as shown here when I started up from our mid-INSERT snapshot:

   ```
   InnoDB: The log sequence number in ibdata files does not match
   InnoDB: the log sequence number in the ib_logfiles!
   081109 15:59:59  InnoDB: Database was not shut down normally!
   InnoDB: Starting crash recovery.
   InnoDB: Reading tablespace information from the .ibd files...
   InnoDB: Restoring possible half-written data pages from the doublewrite
   InnoDB: buffer...
   081109 16:00:03  InnoDB: Started; log sequence number 0 1142807951
   ```
16.6 Using MySQL with memcached

memcached is a simple, highly scalable key-based cache that stores data and objects wherever dedicated or spare RAM is available for quick access by applications, without going through layers of parsing or disk I/O. To use, you run the memcached command on one or more hosts and then use the shared cache to store objects. For more usage instructions, see Section 16.6.2, “Using memcached”.

Benefits of using memcached include:

- Because all information is stored in RAM, the access speed is faster than loading the information each time from disk.
- Because the “value” portion of the key-value pair does not have any data type restrictions, you can cache data such as complex structures, documents, images, or a mixture of such things.
- If you use the in-memory cache to hold transient information, or as a read-only cache for information also stored in a database, the failure of any memcached server is not critical. For persistent data, you can fall back to an alternative lookup method using database queries, and reload the data into RAM on a different server.

The typical usage environment is to modify your application so that information is read from the cache provided by memcached. If the information is not in memcached, then the data is loaded from the MySQL database and written into the cache so that future requests for the same object benefit from the cached data.

For a typical deployment layout, see Figure 16.4, “memcached Architecture Overview”.

Figure 16.4 memcached Architecture Overview

In the example structure, any of the clients can contact one of the memcached servers to request a given key. Each client is configured to talk to all of the servers shown in the illustration. Within the client, when the request is made to store the information, the key used to reference the data is hashed and this hash is then used to select one of the memcached servers. The selection of the memcached server takes place on the client before the server is contacted, keeping the process lightweight.
The same algorithm is used again when a client requests the same key. The same key generates the same hash, and the same memcached server is selected as the source for the data. Using this method, the cached data is spread among all of the memcached servers, and the cached information is accessible from any client. The result is a distributed, memory-based, cache that can return information, particularly complex data and structures, much faster than natively reading the information from the database.

The data held within a traditional memcached server is never stored on disk (only in RAM, which means there is no persistence of data), and the RAM cache is always populated from the backing store (a MySQL database). If a memcached server fails, the data can always be recovered from the MySQL database.

### 16.6.1 Installing memcached

You can build and install memcached from the source code directly, or you can use an existing operating system package or installation.

#### Installing memcached from a Binary Distribution

To install memcached on a Red Hat, or Fedora host, use yum:

```
root-shell> yum install memcached
```

**Note**

On CentOS, you may be able to obtain a suitable RPM from another source, or use the source tarball.

To install memcached on a Debian or Ubuntu host, use apt-get:

```
root-shell> apt-get install memcached
```

To install memcached on a Gentoo host, use emerge:

```
root-shell> emerge install memcached
```

#### Building memcached from Source

On other Unix-based platforms, including Solaris, AIX, HP-UX and Mac OS X, and Linux distributions not mentioned already, you must install from source. For Linux, make sure you have a 2.6-based kernel, which includes the improved epoll interface. For all platforms, ensure that you have libevent 1.1 or higher installed. You can obtain libevent from libevent web page.

You can obtain the source for memcached from memcached Web site.

To build memcached, follow these steps:

1. Extract the memcached source package:

   ```
   shell> gunzip -c memcached-1.2.5.tar.gz | tar xf -
   ```

2. Change to the memcached-1.2.5 directory:

   ```
   shell> cd memcached-1.2.5
   ```

3. Run configure
Using **memcached**

Shell> ./configure

Some additional options you might specify to the `configure`:

- **--prefix**
  
  To specify a different installation directory, use the **--prefix** option:

  Shell> ./configure --prefix=/opt

  The default is to use the **/usr/local** directory.

- **--with-libevent**
  
  If you have installed **libevent** and `configure` cannot find the library, use the **--with-libevent** option to specify the location of the installed library.

- **--enable-64bit**
  
  To build a 64-bit version of **memcached** (which enables you to use a single instance with a large RAM allocation), use **--enable-64bit**.

- **--enable-threads**
  
  To enable multi-threading support in **memcached**, which improves the response times on servers with a heavy load, use **--enable-threads**. You must have support for the POSIX threads within your operating system to enable thread support. For more information on the threading support, see Section 16.6.2.7, "**memcached** Thread Support".

- **--enable-dtrace**
  
  **memcached** includes a range of DTrace threads that can be used to monitor and benchmark a **memcached** instance. For more information, see Section 16.6.2.5, "Using **memcached** and DTrace".

4. Run **make** to build **memcached**:

    Shell> make

5. Run **make install** to install **memcached**:

    Shell> make install

**16.6.2 Using **memcached****

To start using **memcached**, start the **memcached** service on one or more servers. Running **memcached** sets up the server, allocates the memory and starts listening for connections from clients.

Note

You do not need to be a privileged user (**root**) to run **memcached** except to listen on one of the privileged TCP/IP ports (below 1024). You must, however, use a user that has not had their memory limits restricted using **setrlimit** or similar.

To start the server, run **memcached** as a nonprivileged (that is, non-**root**) user:

Shell> memcached
By default, `memcached` uses the following settings:

- Memory allocation of 64MB
- Listens for connections on all network interfaces, using port 11211
- Supports a maximum of 1024 simultaneous connections

Typically, you would specify the full combination of options that you want when starting `memcached`, and normally provide a startup script to handle the initialization of `memcached`. For example, the following line starts `memcached` with a maximum of 1024MB RAM for the cache, listening on port 11211 on the IP address 192.168.0.110, running as a background daemon:

```shell
shell> memcached -d -m 1024 -p 11211 -l 192.168.0.110
```

To ensure that `memcached` is started up on boot, check the init script and configuration parameters.

`memcached` supports the following options:

- `-u user`

  If you start `memcached` as `root`, use the `-u` option to specify the user for executing `memcached`:

  ```shell
  shell> memcached -u memcache
  ```

- `-m memory`

  Set the amount of memory allocated to `memcached` for object storage. Default is 64MB.

  To increase the amount of memory allocated for the cache, use the `-m` option to specify the amount of RAM to be allocated (in megabytes). The more RAM you allocate, the more data you can store and therefore the more effective your cache is.

  **Warning**

  Do not specify a memory allocation larger than your available RAM. If you specify too large a value, then some RAM allocated for `memcached` uses swap space, and not physical RAM. This may lead to delays when storing and retrieving values, because data is swapped to disk, instead of storing the data directly in RAM.

  You can use the output of the `vmstat` command to get the free memory, as shown in `free` column:

  ```shell
  shell> vmstat
  kthr memory page disk faults cpu
   r b w swap free re mf pi po fr de sr s1 s2 -- -- in sy cs us sy id
  0 0 0 5170504 3450392 2 7 2 0 0 4 0 0 0 0 296 54 199 0 0 100
  ```

  For example, to allocate 3GB of RAM:

  ```shell
  shell> memcached -m 3072
  ```

  On 32-bit x86 systems where you are using PAE to access memory above the 4GB limit, you cannot allocate RAM beyond the maximum process size. You can get around this by running multiple instances of `memcached`, each listening on a different port:
Using **memcached**

```shell
shell> memcached -m 1024 -p11211
shell> memcached -m 1024 -p11212
shell> memcached -m 1024 -p11213
```

**Note**

On all systems, particularly 32-bit, ensure that you leave enough room for both **memcached** application in addition to the memory setting. For example, if you have a dedicated **memcached** host with 4GB of RAM, do not set the memory size above 3500MB. Failure to do this may cause either a crash or severe performance issues.

- **-l interface**

  Specify a network interface/address to listen for connections. The default is to listen on all available address (**INADDR_ANY**).

  ```shell
  shell> memcached -l 192.168.0.110
  ```

  Support for IPv6 address support was added in **memcached** 1.2.5.

- **-p port**

  Specify the TCP port to use for connections. Default is 18080.

  ```shell
  shell> memcached -p 18080
  ```

- **-U port**

  Specify the UDP port to use for connections. Default is 11211, 0 switches UDP off.

  ```shell
  shell> memcached -U 18080
  ```

- **-s socket**

  Specify a Unix socket to listen on.

  If you are running **memcached** on the same server as the clients, you can disable the network interface and use a local Unix socket using the **-s** option:

  ```shell
  shell> memcached -s /tmp/memcached
  ```

  Using a Unix socket automatically disables network support, and saves network ports (allowing more ports to be used by your web server or other process).

- **-a mask**

  Specify the access mask to be used for the Unix socket, in octal. Default is 0700.

- **-c connections**

  Specify the maximum number of simultaneous connections to the **memcached** service. The default is 1024.
Using `memcached`

shell> memcached -c 2048

Use this option, either to reduce the number of connections (to prevent overloading `memcached` service) or to increase the number to make more effective use of the server running `memcached` server.

- **-t threads**

  Specify the number of threads to use when processing incoming requests.

  By default, `memcached` is configured to use 4 concurrent threads. The threading improves the performance of storing and retrieving data in the cache, using a locking system to prevent different threads overwriting or updating the same values. To increase or decrease the number of threads, use the `-t` option:

  shell> memcached -t 8

- **-d**

  Run `memcached` as a daemon (background) process:

  shell> memcached -d

- **-r**

  Maximize the size of the core file limit. In the event of a failure, this attempts to dump the entire memory space to disk as a core file, up to any limits imposed by `setrlimit`.

- **-M**

  Return an error to the client when the memory has been exhausted. This replaces the normal behavior of removing older items from the cache to make way for new items.

- **-k**

  Lock down all paged memory. This reserves the memory before use, instead of allocating new slabs of memory as new items are stored in the cache.

  **Note**

  There is a user-level limit on how much memory you can lock. Trying to allocate more than the available memory fails. You can set the limit for the user you started the daemon with (not for the `-u user` user) within the shell by using `ulimit -S -l NUM_KB`

- **-v**

  Verbose mode. Prints errors and warnings while executing the main event loop.

- **-vv**

  Very verbose mode. In addition to information printed by `-v`, also prints each client command and the response.

- **-vvv**

  Extremely verbose mode. In addition to information printed by `-vv`, also show the internal state transitions.
Using `memcached`

- **-h**
  
  Print the help message and exit.

- **-i**
  
  Print the `memcached` and `libevent` license.

- **-I mem**
  
  Specify the maximum size permitted for storing an object within the `memcached` instance. The size supports a unit postfix (k for kilobytes, m for megabytes). For example, to increase the maximum supported object size to 32MB:

  ```shell
  shell> memcached -I 32m
  ```

  The maximum object size you can specify is 128MB, the default remains at 1MB.

  This option was added in 1.4.2.

- **-b**
  
  Set the backlog queue limit. The backlog queue configures how many network connections can be waiting to be processed by `memcached`. Increasing this limit may reduce errors received by the client that it is not able to connect to the `memcached` instance, but does not improve the performance of the server. The default is 1024.

- **-P pidfile**
  
  Save the process ID of the `memcached` instance into `file`.

- **-f**
  
  Set the chunk size growth factor. When allocating new memory chunks, the allocated size of new chunks is determined by multiplying the default slab size by this factor.

  To see the effects of this option without extensive testing, use the `-vv` command-line option to show the calculated slab sizes. For more information, see Section 16.6.2.8, “`memcached` Logs”.

- **-n bytes**
  
  The minimum space allocated for the key+value+flags information. The default is 48 bytes.

- **-L**
  
  On systems that support large memory pages, enables large memory page use. Using large memory pages enables `memcached` to allocate the item cache in one large chunk, which can improve the performance by reducing the number misses when accessing memory.

- **-C**
  
  Disable the use of compare and swap (CAS) operations.

  This option was added in `memcached` 1.3.x.

- **-D char**
Set the default character to be used as a delimiter between the key prefixes and IDs. This is used for the per-prefix statistics reporting (see Section 16.6.4, “Getting memcached Statistics”). The default is the colon (:) If this option is used, statistics collection is turned on automatically. If not used, you can enable stats collection by sending the stats detail on command to the server.

This option was added in memcached 1.3.x.

• -R num

Sets the maximum number of requests per event process. The default is 20.

• -B protocol

Set the binding protocol, that is, the default memcached protocol support for client connections. Options are ascii, binary or auto. Automatic (auto) is the default.

This option was added in memcached 1.4.0.

16.6.2.1 memcached Deployment

When using memcached you can use a number of different potential deployment strategies and topologies. The exact strategy to use depends on your application and environment. When developing a system for deploying memcached within your system, keep in mind the following points:

• memcached is only a caching mechanism. It shouldn't be used to store information that you cannot otherwise afford to lose and then load from a different location.

• There is no security built into the memcached protocol. At a minimum, make sure that the servers running memcached are only accessible from inside your network, and that the network ports being used are blocked (using a firewall or similar). If the information on the memcached servers that is being stored is any sensitive, then encrypt the information before storing it in memcached.

• memcached does not provide any sort of failover. Because there is no communication between different memcached instances. If an instance fails, your application must capable of removing it from the list, reloading the data and then writing data to another memcached instance.

• Latency between the clients and the memcached can be a problem if you are using different physical machines for these tasks. If you find that the latency is a problem, move the memcached instances to be on the clients.

• Key length is determined by the memcached server. The default maximum key size is 250 bytes.

• Try to use at least two memcached instances, especially for multiple clients, to avoid having a single point of failure. Ideally, create as many memcached nodes as possible. When adding and removing memcached instances from a pool, the hashing and distribution of key/value pairs may be affected. For information on how to avoid problems, see Section 16.6.2.4, “memcached Hashing/Distribution Types”.

16.6.2.2 Using Namespaces

The memcached cache is a very simple massive key/value storage system, and as such there is no way of compartmentalizing data automatically into different sections. For example, if you are storing information by the unique ID returned from a MySQL database, then storing the data from two different tables could run into issues because the same ID might be valid in both tables.

Some interfaces provide an automated mechanism for creating namespaces when storing information into the cache. In practice, these namespaces are merely a prefix before a given ID that is applied every time a value is stored or retrieve from the cache.
You can implement the same basic principle by using keys that describe the object and the unique identifier within the key that you supply when the object is stored. For example, when storing user data, prefix the ID of the user with `user:` or `user-`.

**Note**

Using namespaces or prefixes only controls the keys stored/retrieved. There is no security within `memcached`, and therefore no way to enforce that a particular client only accesses keys with a particular namespace. Namespaces are only useful as a method of identifying data and preventing corruption of key/value pairs.

### 16.6.2.3 Data Expiry

There are two types of data expiry within a `memcached` instance. The first type is applied at the point when you store a new key/value pair into the `memcached` instance. If there is not enough space within a suitable slab to store the value, then an existing least recently used (LRU) object is removed (evicted) from the cache to make room for the new item.

The LRU algorithm ensures that the object that is removed is one that is either no longer in active use or that was used so long ago that its data is potentially out of date or of little value. However, in a system where the memory allocated to `memcached` is smaller than the number of regularly used objects required in the cache, a lot of expired items could be removed from the cache even though they are in active use. You use the statistics mechanism to get a better idea of the level of evictions (expired objects). For more information, see Section 16.6.4, “Getting `memcached` Statistics”.

You can change this eviction behavior by setting the `-M` command-line option when starting `memcached`. This option forces an error to be returned when the memory has been exhausted, instead of automatically evicting older data.

The second type of expiry system is an explicit mechanism that you can set when a key/value pair is inserted into the cache, or when deleting an item from the cache. Using an expiration time can be a useful way of ensuring that the data in the cache is up to date and in line with your application needs and requirements.

A typical scenario for explicitly setting the expiry time might include caching session data for a user when accessing a Web site. `memcached` uses a lazy expiry mechanism where the explicit expiry time that has been set is compared with the current time when the object is requested. Only objects that have not expired are returned.

You can also set the expiry time when explicitly deleting an object from the cache. In this case, the expiry time is really a timeout and indicates the period when any attempts to set the value for a given key are rejected.

### 16.6.2.4 `memcached` Hashing/Distribution Types

The `memcached` client interface supports a number of different distribution algorithms that are used in multi-server configurations to determine which host should be used when setting or getting data from a given `memcached` instance. When you get or set a value, a hash is constructed from the supplied key and then used to select a host from the list of configured servers. Because the hashing mechanism uses the supplied key as the basis for the hash, the same server is selected during both set and get operations.

You can think of this process as follows. Given an array of servers (a, b, and c), the client uses a hashing algorithm that returns an integer based on the key being stored or retrieved. The resulting value is then used to select a server from the list of servers configured in the client. Most standard client hashing within `memcache` clients uses a simple modulus calculation on the value against the number of configured `memcached` servers. You can summarize the process in pseudocode as:
Using `memcached`

```perl
@memcservers = ['a.memc','b.memc','c.memc'];
$value = hash($key);
$chosen = $value % length(@memcservers);
```

Replacing the above with values:

```perl
@memcservers = ['a.memc','b.memc','c.memc'];
$value = hash('myid');
$chosen = 7009 % 3;
```

In the above example, the client hashing algorithm chooses the server at index 1 (7009 % 3 = 1), and store or retrieve the key and value with that server.

**Note**

This selection and hashing process is handled automatically by the `memcached` client you are using; you need only provide the list of `memcached` servers to use.

You can see a graphical representation of this below in Figure 16.5, "memcached Hash Selection".

**Figure 16.5 memcached Hash Selection**

![Graphical representation of memcached hash selection](image)

The same hashing and selection process takes place during any operation on the specified key within the `memcached` client.

Using this method provides a number of advantages:

- The hashing and selection of the server to contact is handled entirely within the client. This eliminates the need to perform network communication to determine the right machine to contact.

- Because the determination of the `memcached` server occurs entirely within the client, the server can be selected automatically regardless of the operation being executed (set, get, increment, etc.).

- Because the determination is handled within the client, the hashing algorithm returns the same value for a given key; values are not affected or reset by differences in the server environment.

- Selection is very fast. The hashing algorithm on the key value is quick and the resulting selection of the server is from a simple array of available machines.

- Using client-side hashing simplifies the distribution of data over each `memcached` server. Natural distribution of the values returned by the hashing algorithm means that keys are automatically spread over the available servers.
Using memcached

Providing that the list of servers configured within the client remains the same, the same stored key returns the same value, and therefore selects the same server.

However, if you do not use the same hashing mechanism then the same data may be recorded on different servers by different interfaces, both wasting space on your memcached and leading to potential differences in the information.

**Note**

One way to use a multi-interface compatible hashing mechanism is to use the libmemcached library and the associated interfaces. Because the interfaces for the different languages (including C, Ruby, Perl and Python) use the same client library interface, they always generate the same hash code from the ID.

The problem with client-side selection of the server is that the list of the servers (including their sequential order) must remain consistent on each client using the memcached servers, and the servers must be available. If you try to perform an operation on a key when:

- A new memcached instance has been added to the list of available instances
- A memcached instance has been removed from the list of available instances
- The order of the memcached instances has changed

When the hashing algorithm is used on the given key, but with a different list of servers, the hash calculation may choose a different server from the list.

If a new memcached instance is added into the list of servers, as new.memc is in the example below, then a GET operation using the same key, myid, can result in a cache-miss. This is because the same value is computed from the key, which selects the same index from the array of servers, but index 2 now points to the new server, not the server c.memc where the data was originally stored. This would result in a cache miss, even though the key exists within the cache on another memcached instance.

**Figure 16.6 memcached Hash Selection with New memcached instance**

![Diagram showing hash selection with new memcached instance](image)

This means that servers c.memc and new.memc both contain the information for key myid, but the information stored against the key in each server may be different in each instance. A more significant problem is a much higher number of cache-misses when retrieving data, as the addition of a new server changes the distribution of keys, and this in turn requires rebuilding the cached data on the memcached instances, causing an increase in database reads.

The same effect can occur if you actively manage the list of servers configured in your clients, adding and removing the configured memcached instances as each instance is identified as being available. For example, removing a memcached instance when the client notices that the instance can no longer be contacted can cause the server selection to fail as described here.
To prevent this causing significant problems and invalidating your cache, you can select the hashing algorithm used to select the server. There are two common types of hashing algorithms, consistent and modula.

With consistent hashing algorithms, the same key when applied to a list of servers always uses the same server to store or retrieve the keys, even if the list of configured servers changes. This means that you can add and remove servers from the configure list and always use the same server for a given key. There are two types of consistent hashing algorithms available, Ketama and Wheel. Both types are supported by libmemcached, and implementations are available for PHP and Java.

Any consistent hashing algorithm has some limitations. When you add servers to an existing list of configured servers, keys are distributed to the new servers as part of the normal distribution. When you remove servers from the list, the keys are re-allocated to another server within the list, meaning that the cache needs to be re-populated with the information. Also, a consistent hashing algorithm does not resolve the issue where you want consistent selection of a server across multiple clients, but where each client contains a different list of servers. The consistency is enforced only within a single client.

With a modula hashing algorithm, the client selects a server by first computing the hash and then choosing a server from the list of configured servers. As the list of servers changes, so the server selected when using a modula hashing algorithm also changes. The result is the behavior described above; changes to the list of servers mean that different servers are selected when retrieving data, leading to cache misses and increase in database load as the cache is re-seeded with information.

If you use only a single memcached instance for each client, or your list of memcached servers configured for a client never changes, then the selection of a hashing algorithm is irrelevant, as it has no noticeable effect.

If you change your servers regularly, or you use a common set of servers that are shared among a large number of clients, then using a consistent hashing algorithm should help to ensure that your cache data is not duplicated and the data is evenly distributed.

### 16.6.2.5 Using memcached and DTrace

memcached includes a number of different DTrace probes that can be used to monitor the operation of the server. The probes included can monitor individual connections, slab allocations, and modifications to the hash table when a key/value pair is added, updated, or removed.

For more information on DTrace and writing DTrace scripts, read the [DTrace User Guide](#).

Support for DTrace probes was added to memcached 1.2.6 includes a number of DTrace probes that can be used to help monitor your application. DTrace is supported on Solaris 10, OpenSolaris, Mac OS X 10.5 and FreeBSD. To enable the DTrace probes in memcached, build from source and use the `--enable-dtrace` option. For more information, see Section 16.6.1, "Installing memcached".

The probes supported by memcached are:

- **conn-allocate(connid)**
  - Fired when a connection object is allocated from the connection pool.
  - **connid**: The connection ID.

- **conn-release(connid)**
  - Fired when a connection object is released back to the connection pool.

Arguments:
Using memcached

- **connid**: The connection ID.

- **conn-create(ptr)**

  Fired when a new connection object is being created (that is, there are no free connection objects in the connection pool).

  Arguments:
  - **ptr**: A pointer to the connection object

- **conn-destroy(ptr)**

  Fired when a connection object is being destroyed.

  Arguments:
  - **ptr**: A pointer to the connection object.

- **conn-dispatch(connid, threadid)**

  Fired when a connection is dispatched from the main or connection-management thread to a worker thread.

  Arguments:
  - **connid**: The connection ID.
  - **threadid**: The thread ID.

- **slabs-allocate(size, slabclass, slabsize, ptr)**

  Allocate memory from the slab allocator.

  Arguments:
  - **size**: The requested size.
  - **slabclass**: The allocation is fulfilled in this class.
  - **slabsize**: The size of each item in this class.
  - **ptr**: A pointer to allocated memory.

- **slabs-allocate-failed(size, slabclass)**

  Failed to allocate memory (out of memory).

  Arguments:
  - **size**: The requested size.
  - **slabclass**: The class that failed to fulfill the request.

- **slabs-slabclass-allocate(slabclass)**

  Fired when a slab class needs more space.
Arguments:

- **slabclass**: The class that needs more memory.

- **slabs-slabclass-allocate-failed(slabclass)**
  Failed to allocate memory (out of memory).
  Arguments:
  - **slabclass**: The class that failed to grab more memory.

- **slabs-free(size, slabclass, ptr)**
  Release memory.
  Arguments:
  - **size**: The amount of memory to release, in bytes.
  - **slabclass**: The class the memory belongs to.
  - **ptr**: A pointer to the memory to release.

- **assoc-find(key, depth)**
  Fired when we have searched the hash table for a named key. These two elements provide an insight into how well the hash function operates. Traversals are a sign of a less optimal function, wasting CPU capacity.
  Arguments:
  - **key**: The key searched for.
  - **depth**: The depth in the list of hash table.

- **assoc-insert(key, nokeys)**
  Fired when a new item has been inserted.
  Arguments:
  - **key**: The key just inserted.
  - **nokeys**: The total number of keys currently being stored, including the key for which insert was called.

- **assoc-delete(key, nokeys)**
  Fired when a new item has been removed.
  Arguments:
  - **key**: The key just deleted.
  - **nokeys**: The total number of keys currently being stored, excluding the key for which delete was called.

- **item-link(key, size)**
Using memcached

Fired when an item is being linked in the cache.

Arguments:

- **key**: The item's key.
- **size**: The size of the data.

**item-unlink(key, size)**

Fired when an item is being deleted.

Arguments:

- **key**: The item's key.
- **size**: The size of the data.

**item-remove(key, size)**

Fired when the refcount for an item is reduced.

Arguments:

- **key**: The item's key.
- **size**: The size of the data.

**item-update(key, size)**

Fired when the "last referenced" time is updated.

Arguments:

- **key**: The item's key.
- **size**: The size of the data.

**item-replace(oldkey, oldsize, newkey, newsize)**

Fired when an item is being replaced with another item.

Arguments:

- **oldkey**: The key of the item to replace.
- **oldsize**: The size of the old item.
- **newkey**: The key of the new item.
- **newsize**: The size of the new item.

**process-command-start(connid, request, size)**

Fired when the processing of a command starts.

Arguments:
Using *memcached*

- **connid**: The connection ID.
- **request**: The incoming request.
- **size**: The size of the request.

**process-command-end(connid, response, size)**

Fired when the processing of a command is done.

Arguments:
- **connid**: The connection ID.
- **response**: The response to send back to the client.
- **size**: The size of the response.

**command-get(connid, key, size)**

Fired for a `get` command.

Arguments:
- **connid**: The connection ID.
- **key**: The requested key.
- **size**: The size of the key's data (or -1 if not found).

**command-gets(connid, key, size, casid)**

Fired for a `gets` command.

Arguments:
- **connid**: The connection ID.
- **key**: The requested key.
- **size**: The size of the key's data (or -1 if not found).
- **casid**: The casid for the item.

**command-add(connid, key, size)**

Fired for a `add` command.

Arguments:
- **connid**: The connection ID.
- **key**: The requested key.
- **size**: The new size of the key's data (or -1 if not found).

**command-set(connid, key, size)**
Fired for a `set` command.

Arguments:
- **connid**: The connection ID.
- **key**: The requested key.
- **size**: The new size of the key's data (or -1 if not found).
- **command-replace(connid, key, size)**

Fired for a `replace` command.

Arguments:
- **connid**: The connection ID.
- **key**: The requested key.
- **size**: The new size of the key's data (or -1 if not found).
- **command-prepend(connid, key, size)**

Fired for a `prepend` command.

Arguments:
- **connid**: The connection ID.
- **key**: The requested key.
- **size**: The new size of the key's data (or -1 if not found).
- **command-append(connid, key, size)**

Fired for a `append` command.

Arguments:
- **connid**: The connection ID.
- **key**: The requested key.
- **size**: The new size of the key's data (or -1 if not found).
- **command-cas(connid, key, size, casid)**

Fired for a `cas` command.

Arguments:
- **connid**: The connection ID.
- **key**: The requested key.
- **size**: The size of the key's data (or -1 if not found).
Using \texttt{memcached}

- \texttt{casid}: The cas ID requested.

- \texttt{command-incr(connid, key, val)}
  Fired for \texttt{incr} command.
  Arguments:
  - \texttt{connid}: The connection ID.
  - \texttt{key}: The requested key.
  - \texttt{val}: The new value.

- \texttt{command-decr(connid, key, val)}
  Fired for \texttt{decr} command.
  Arguments:
  - \texttt{connid}: The connection ID.
  - \texttt{key}: The requested key.
  - \texttt{val}: The new value.

- \texttt{command-delete(connid, key, exptime)}
  Fired for a \texttt{delete} command.
  Arguments:
  - \texttt{connid}: The connection ID.
  - \texttt{key}: The requested key.
  - \texttt{exptime}: The expiry time.

16.6.2.6 Memory Allocation within \texttt{memcached}

When you first start \texttt{memcached}, the memory that you have configured is not automatically allocated. Instead, \texttt{memcached} only starts allocating and reserving physical memory once you start saving information into the cache.

When you start to store data into the cache, \texttt{memcached} does not allocate the memory for the data on an item by item basis. Instead, a slab allocation is used to optimize memory usage and prevent memory fragmentation when information expires from the cache.

With slab allocation, memory is reserved in blocks of 1MB. The slab is divided up into a number of blocks of equal size. When you try to store a value into the cache, \texttt{memcached} checks the size of the value that you are adding to the cache and determines which slab contains the right size allocation for the item. If a slab with the item size already exists, the item is written to the block within the slab.

If the new item is bigger than the size of any existing blocks, then a new slab is created, divided up into blocks of a suitable size. If an existing slab with the right block size already exists, but there are no free blocks, a new slab is created. If you update an existing item with data that is larger than the existing block allocation for that key, then the key is re-allocated into a suitable slab.
Using memcached

For example, the default size for the smallest block is 88 bytes (40 bytes of value, and the default 48 bytes for the key and flag data). If the size of the first item you store into the cache is less than 40 bytes, then a slab with a block size of 88 bytes is created and the value stored.

If the size of the data that you intend to store is larger than this value, then the block size is increased by the chunk size factor until a block size large enough to hold the value is determined. The block size is always a function of the scale factor, rounded up to a block size which is exactly divisible into the chunk size.

For a sample of the structure, see Figure 16.7, “Memory Allocation in memcached”.

Figure 16.7 Memory Allocation in memcached

The result is that you have multiple pages allocated within the range of memory allocated to memcached. Each page is 1MB in size (by default), and is split into a different number of chunks, according to the chunk size required to store the key/value pairs. Each instance has multiple pages allocated, and a page is always created when a new item needs to be created requiring a chunk of a particular size. A slab may consist of multiple pages, and each page within a slab contains an equal number of chunks.

The chunk size of a new slab is determined by the base chunk size combined with the chunk size growth factor. For example, if the initial chunks are 104 bytes in size, and the default chunk size growth factor is used (1.25), then the next chunk size allocated would be the best power of 2 fit for $104 \times 1.25$, or 136 bytes.

Allocating the pages in this way ensures that memory does not get fragmented. However, depending on the distribution of the objects that you store, it may lead to an inefficient distribution of the slabs and chunks if you have significantly different sized items. For example, having a relatively small number of items within each chunk size may waste a lot of memory with just few chunks in each allocated page.

You can tune the growth factor to reduce this effect by using the -f command line option, which adapts the growth factor applied to make more effective use of the chunks and slabs allocated. For information on how to determine the current slab allocation statistics, see Section 16.6.4.2, “memcached Slabs Statistics”.

If your operating system supports it, you can also start memcached with the -L command line option. This option preallocates all the memory during startup using large memory pages. This can improve performance by reducing the number of misses in the CPU memory cache.

16.6.2.7 memcached Thread Support

If you enable the thread implementation within when building memcached from source, then memcached uses multiple threads in addition to the libevent system to handle requests.

When enabled, the threading implementation operates as follows:

- Threading is handled by wrapping functions within the code to provide basic protection from updating the same global structures at the same time.
• Each thread uses its own instance of the libevent to help improve performance.

• TCP/IP connections are handled with a single thread listening on the TCP/IP socket. Each connection is then distributed to one of the active threads on a simple round-robin basis. Each connection then operates solely within this thread while the connection remains open.

• For UDP connections, all the threads listen to a single UDP socket for incoming requests. Threads that are not currently dealing with another request ignore the incoming packet. One of the remaining, nonbusy, threads reads the request and sends the response. This implementation can lead to increased CPU load as threads wake from sleep to potentially process the request.

Using threads can increase the performance on servers that have multiple CPU cores available, as the requests to update the hash table can be spread between the individual threads. To minimize overhead from the locking mechanism employed, experiment with different thread values to achieve the best performance based on the number and type of requests within your given workload.

16.6.2.8 memcached Logs

If you enable verbose mode, using the -v, -vv, or -vvv options, then the information output by memcached includes details of the operations being performed.

Without the verbose options, memcached normally produces no output during normal operating.

• Output when using -v

The lowest verbosity level shows you:

• Errors and warnings

• Transient errors

• Protocol and socket errors, including exhausting available connections

• Each registered client connection, including the socket descriptor number and the protocol used.

For example:

32: Client using the ascii protocol
33: Client using the ascii protocol

Note that the socket descriptor is only valid while the client remains connected. Non-persistent connections may not be effectively represented.

Examples of the error messages output at this level include:

<%d send buffer was %d, now %d
Can't listen for events on fd %d
Can't read from libevent pipe
Catastrophic: event fd doesn't match conn fd!
Couldn't build response
Couldn't realloc input buffer
Couldn't update event
Failed to build UDP headers
Failed to read, and not due to blocking
Too many open connections
Unexpected state %d

• Output when using -vvv
When using the second level of verbosity, you get more detailed information about protocol operations, keys updated, chunk and network operations and details.

During the initial start-up of `memcached` with this level of verbosity, you are shown the sizes of the individual slab classes, the chunk sizes, and the number of entries per slab. These do not show the allocation of the slabs, just the slabs that would be created when data is added. You are also given information about the listen queues and buffers used to send information. A sample of the output generated for a TCP/IP based system with the default memory and growth factors is given below:

```
shell> memcached -vv
slab class  1: chunk size     80 perslab 13107
slab class  2: chunk size    104 perslab 10082
slab class  3: chunk size    136 perslab  7710
slab class  4: chunk size    176 perslab  5957
slab class  5: chunk size    224 perslab  4681
slab class  6: chunk size    280 perslab  3744
slab class  7: chunk size    352 perslab  2978
slab class  8: chunk size    440 perslab  2383
slab class  9: chunk size    552 perslab  1899
slab class 10: chunk size    696 perslab  1506
slab class 11: chunk size    872 perslab  1202
slab class 12: chunk size    1096 perslab   956
slab class 13: chunk size    1376 perslab   762
slab class 14: chunk size    1720 perslab   609
slab class 15: chunk size    2152 perslab   487
slab class 16: chunk size    2696 perslab   388
slab class 17: chunk size    3376 perslab   310
slab class 18: chunk size    4224 perslab   248
slab class 19: chunk size    5280 perslab   198
slab class 20: chunk size    6600 perslab   158
slab class 21: chunk size    8256 perslab   127
slab class 22: chunk size   10320 perslab   101
slab class 23: chunk size   12904 perslab    81
slab class 24: chunk size   16136 perslab    64
slab class 25: chunk size   20176 perslab    51
slab class 26: chunk size   25224 perslab    41
slab class 27: chunk size   31536 perslab    33
slab class 28: chunk size   39424 perslab    26
slab class 29: chunk size   49280 perslab    21
slab class 30: chunk size   61600 perslab    17
slab class 31: chunk size   77000 perslab    13
slab class 32: chunk size   96256 perslab    10
slab class 33: chunk size  120320 perslab     8
slab class 34: chunk size  150400 perslab     6
slab class 35: chunk size  188000 perslab     5
slab class 36: chunk size  235000 perslab     4
slab class 37: chunk size  293752 perslab     3
slab class 38: chunk size  367192 perslab     2
slab class 39: chunk size  458992 perslab     2
<26 server listening (auto-negotiate)
<29 server listening (auto-negotiate)
<30 send buffer was 57344, now 2097152
<31 send buffer was 57344, now 2097152
```

1874
Using **memcached**

Using this verbosity level can be a useful way to check the effects of the growth factor used on slabs with different memory allocations, which in turn can be used to better tune the growth factor to suit the data you are storing in the cache. For example, if you set the growth factor to 4 (quadrupling the size of each slab):

```
shell> memcached -f 4 -m 1g -vv
slab class 1: chunk size  80 perslab 13107
slab class 2: chunk size  320 perslab  3276
slab class 3: chunk size 1280 perslab  819
slab class 4: chunk size  5120 perslab  204
slab class 5: chunk size 20480 perslab  51
slab class 6: chunk size 81920 perslab  12
slab class 7: chunk size 327680 perslab   3
...
```

During use of the cache, this verbosity level also prints out detailed information on the storage and recovery of keys and other information. An example of the output during a typical set/get and increment/decrement operation is shown below.

```
32: Client using the ascii protocol
<32 set my_key 0 0 10
>32 STORED
<32 set object_key 1 0 36
>32 STORED
<32 get my_key
>32 sending key my_key
>32 END
<32 get object_key
>32 sending key object_key
>32 END
<32 set key 0 0 6
>32 STORED
<32 incr key 1
>32 789544
<32 decr key 1
>32 789543
<32 incr key 2
>32 789545
<32 set my_key 0 0 10
>32 STORED
<32 set object_key 1 0 36
>32 STORED
<32 get my_key
>32 sending key my_key
>32 END
<32 get object_key
>32 sending key object_key 1 36
>32 END
<32 set key 0 0 6
>32 STORED
<32 incr key 1
>32 789544
<32 decr key 1
>32 789543
<32 incr key 2
>32 789545
```

During client communication, for each line, the initial character shows the direction of flow of the information. The < for communication from the client to the **memcached** server and > for communication back to the client. The number is the numeric socket descriptor for the connection.
• Output when using \(-vvv\)

This level of verbosity includes the transitions of connections between different states in the event library while reading and writing content to/from the clients. It should be used to diagnose and identify issues in client communication. For example, you can use this information to determine if \texttt{memcached} is taking a long time to return information to the client, during the read of the client operation or before returning and completing the operation. An example of the typical sequence for a set operation is provided below:

```
<32 new auto-negotiating client connection
32: going from conn_new_cmd to conn_waiting
32: going from conn_waiting to conn_read
32: going from conn_read to conn_parse_cmd
32: Client using the ascii protocol
<32 set my_key 0 0 10
32: going from conn_parse_cmd to conn_nread
> NOT FOUND my_key
>32 STORED
32: going from conn_nread to conn_write
32: going from conn_write to conn_new_cmd
32: going from conn_new_cmd to conn_waiting
32: going from conn_waiting to conn_read
32: going from conn_read to conn_closing
<32 connection closed.
```

All of the verbosity levels in \texttt{memcached} are designed to be used during debugging or examination of issues. The quantity of information generated, particularly when using \(-vvv\), is significant, particularly on a busy server. Also be aware that writing the error information out, especially to disk, may negate some of the performance gains you achieve by using \texttt{memcached}. Therefore, use in production or deployment environments is not recommended.

16.6.3 Developing a \texttt{memcached} Application

A number of language interfaces let applications store and retrieve information with \texttt{memcached} servers. You can write \texttt{memcached} applications in popular languages such as Perl, PHP, Python, Ruby, C, and Java.

Data stored into a \texttt{memcached} server is referred to by a single string (the key), with storage into the cache and retrieval from the cache using the key as the reference. The cache therefore operates like a large associative array or hash table. It is not possible to structure or otherwise organize the information stored in the cache. To emulate database notions such as multiple tables or composite key values, you must encode the extra information into the strings used as keys. For example, to store or look up the address corresponding to a specific latitude and longitude, you might turn those two numeric values into a single comma-separated string to use as a key.

16.6.3.1 Basic \texttt{memcached} Operations

The interface to \texttt{memcached} supports the following methods for storing and retrieving information in the cache, and these are consistent across all the different APIs, although the language specific mechanics might be different:

• \texttt{get(key)}: Retrieves information from the cache. Returns the value associated with the key if the specified key exists. Returns \texttt{NULL}, \texttt{nil}, \texttt{undefined}, or the closest equivalent in the corresponding language, if the specified key does not exist.

• \texttt{set(key, value [, expiry])}: Sets the item associated with a key in the cache to the specified value. Note that this either updates an existing item if the key already exists, or adds a new key/value pair if the key doesn't exist. If the expiry time is specified, then the item expires (and is deleted) when
Developing a `memcached` Application

the expiry time is reached. The time is specified in seconds, and is taken as a relative time if the value is less than 30 days (30*24*60*60), or an absolute time (epoch) if larger than this value.

- `add(key, value [, expiry])`: Adds the key and associated value to the cache, if the specified key does not already exist.

- `replace(key, value [, expiry])`: Replaces the item associated with the specified `key`, only if the key already exists. The new value is given by the `value` parameter.

- `delete(key [, time])`: Deletes the `key` and its associated item from the cache. If you supply a `time`, then adding another item with the specified `key` is blocked for the specified period.

- `incr(key, value)`: Increments the item associated with the `key` by the specified `value`.

- `decr(key, value)`: Decrements the item associated with the `key` by the specified `value`.

- `flush_all`: Invalidates (or expires) all the current items in the cache. Technically they still exist (they are not deleted), but they are silently destroyed the next time you try to access them.

In all implementations, most or all of these functions are duplicated through the corresponding native language interface.

When practical, use `memcached` to store full items, rather than caching a single column value from the database. For example, when displaying a record about an object (invoice, user history, or blog post), load all the data for the associated entry from the database, and compile it into the internal structure that would normally be required by the application. Save the complete object in the cache.

Complex data structures cannot be stored directly. Most interfaces serialize the data for you, that is, put it in a textual form that can reconstruct the original pointers and nesting. Perl uses `Storable`, PHP uses `serialize`, Python uses `cPickle` (or `Pickle`) and Java uses the `Serializable` interface. In most cases, the serialization interface used is customizable. To share data stored in `memcached` instances between different language interfaces, consider using a common serialization solution such as JSON (Javascript Object Notation).

16.6.3.2 Using `memcached` as a MySQL Caching Layer

When using `memcached` to cache MySQL data, your application must retrieve data from the database and load the appropriate key-value pairs into the cache. Then, subsequent lookups can be done directly from the cache.

Because MySQL has its own in-memory caching mechanisms for queried data, such as the InnoDB buffer pool and the MySQL query cache, look for opportunities beyond loading individual column values or rows into the cache. Prefer to cache composite values, such as those retrieved from multiple tables through a join query, or result sets assembled from multiple rows.

**Caution**

Limit the information in the cache to non-sensitive data, because there is no security required to access or update the information within a `memcached` instance. Anybody with access to the machine has the ability to read, view and potentially update the information. To keep the data secure, encrypt the information before caching it. To restrict the users capable of connecting to the server, either disable network access, or use IPTables or similar techniques to restrict access to the `memcached` ports to a select set of hosts.

You can introduce `memcached` to an existing application, even if caching was not part of the original design. In many languages and environments the changes to the application will be just a few lines, first
Developing a memcached Application

to attempt to read from the cache when loading data, fall back to the old method if the information is not cached, and to update the cache with information once the data has been read.

The general sequence for using memcached in any language as a caching solution for MySQL is as follows:

1. Request the item from the cache.
2. If the item exists, use the item data.
3. If the item does not exist, load the data from MySQL, and store the value into the cache. This means the value is available to the next client that requests it from the cache.

For a flow diagram of this sequence, see Figure 16.8, “Typical memcached Application Flowchart”.

Figure 16.8 Typical memcached Application Flowchart

Adapting Database Best Practices to memcached Applications

The most direct way to cache MySQL data is to use a 2-column table, where the first column is a primary key. Because of the uniqueness requirements for memcached keys, make sure your database schema makes appropriate use of primary keys and unique constraints.

If you combine multiple column values into a single memcached item value, choose data types to make it easy to parse the value back into its components, for example by using a separator character between numeric values.

The queries that map most easily to memcached lookups are those with a single WHERE clause, using an = or IN operator. For complicated WHERE clauses, or those using operators such as <, >, BETWEEN, or LIKE, memcached does not provide a simple or efficient way to scan through or filter the keys or associated values, so typically you perform those operations as SQL queries on the underlying database.
16.6.3.3 Using **libmemcached** with C and C++

The **libmemcached** library provides both C and C++ interfaces to **memcached** and is also the basis for a number of different additional API implementations, including Perl, Python and Ruby. Understanding the core **libmemcached** functions can help when using these other interfaces.

The C library is the most comprehensive interface library for **memcached** and provides functions and operational systems not always exposed in interfaces not based on the **libmemcached** library.

The different functions can be divided up according to their basic operation. In addition to functions that interface to the core API, a number of utility functions provide extended functionality, such as appending and prepending data.

To build and install **libmemcached**, download the **libmemcached** package, run **configure**, and then build and install:

```
shell> tar xjf libmemcached-0.21.tar.gz
shell> cd libmemcached-0.21
shell> ./configure
shell> make
shell> make install
```

On many Linux operating systems, you can install the corresponding **libmemcached** package through the usual **yum**, **apt-get**, or similar commands.

To build an application that uses the library, first set the list of servers. Either directly manipulate the servers configured within the main **memcached_st** structure, or separately populate a list of servers, and then add this list to the **memcached_st** structure. The latter method is used in the following example. Once the server list has been set, you can call the functions to store or retrieve data. A simple application for setting a preset value to **localhost** is provided here:

```c
#include <stdio.h>
#include <string.h>
#include <unistd.h>
#include <libmemcached/memcached.h>

int main(int argc, char *argv[]) {
    memcached_server_st *servers = NULL;
    memcached_st *memc;
    memcached_return rc;
    char *key= "keystring";
    char *value= "keyvalue";
    memcached_server_st *memcached_servers_parse (char *server_strings);
    memc= memcached_create(NULL);
    servers= memcached_server_list_append(servers, "localhost", 11211, &rc);
    rc= memcached_server_push(memc, servers);
    if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr,"Added server successfully\n");
    else
        fprintf(stderr,"Could't add server: %s\n",memcached_strerror(memc, rc));
    rc= memcached_set(memc, key, strlen(key), value, strlen(value), (time_t)0, (uint32_t)0);
    if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr,"Key stored successfully\n");
    else
```
Developing a memcached Application

```c
fprintf(stderr,"Couldn't store key: %s\n",memcached_strerror(memc, rc));
return 0;
```

To test the success of an operation, use the return value, or populated result code, for a given function. The value is always set to MEMCACHED_SUCCESS if the operation succeeded. In the event of a failure, use the memcached_strerror() function to translate the result code into a printable string.

To build the application, specify the memcached library:

```shell
shell> gcc -o memc_basic memc_basic.c -lmemcached
```

Running the above sample application, after starting a memcached server, should return a success message:

```shell
shell> memc_basic
Added server successfully
Key stored successfully
```

**libmemcached Base Functions**

The base libmemcached functions let you create, destroy and clone the main memcached_st structure that is used to interface with the memcached servers. The main functions are defined below:

```c
memcached_st *memcached_create (memcached_st *ptr);
```

Creates a new memcached_st structure for use with the other libmemcached API functions. You can supply an existing, static, memcached_st structure, or NULL to have a new structured allocated. Returns a pointer to the created structure, or NULL on failure.

```c
void memcached_free (memcached_st *ptr);
```

Frees the structure and memory allocated to a previously created memcached_st structure.

```c
memcached_st *memcached_clone(memcached_st *clone, memcached_st *source);
```

Clones an existing memcached structure from the specified source, copying the defaults and list of servers defined in the structure.

**libmemcached Server Functions**

The libmemcached API uses a list of servers, stored within the memcached_server_st structure, to act as the list of servers used by the rest of the functions. To use memcached, you first create the server list, and then apply the list of servers to a valid libmemcached object.

Because the list of servers, and the list of servers within an active libmemcached object can be manipulated separately, you can update and manage server lists while an active libmemcached interface is running.

The functions for manipulating the list of servers within a memcached_st structure are:
Developing a `memcached` Application

```c
char *hostname,
unsigned int port);
```

Adds a server, using the given `hostname` and `port` into the `memcached_st` structure given in `ptr`.

```c
memcached_return
  memcached_server_add_unix_socket (memcached_st *ptr,
                                 char *socket);
```

Adds a Unix socket to the list of servers configured in the `memcached_st` structure.

```c
unsigned int memcached_server_count (memcached_st *ptr);
```

Returns a count of the number of configured servers within the `memcached_st` structure.

```c
memcached_server_st *
  memcached_server_list (memcached_st *ptr);
```

Returns an array of all the defined hosts within a `memcached_st` structure.

```c
memcached_return
  memcached_server_push (memcached_st *ptr,
                       memcached_server_st *list);
```

Pushes an existing list of servers onto list of servers configured for a current `memcached_st` structure. This adds servers to the end of the existing list, and duplicates are not checked.

The `memcached_server_st` structure can be used to create a list of `memcached` servers which can then be applied individually to `memcached_st` structures.

```c
memcached_server_st *
  memcached_server_list_append (memcached_server_st *ptr,
                              char *hostname,
                              unsigned int port,
                              memcached_return *error);
```

Adds a server, with `hostname` and `port`, to the server list in `ptr`. The result code is handled by the `error` argument, which should point to an existing `memcached_return` variable. The function returns a pointer to the returned list.

```c
unsigned int memcached_server_list_count (memcached_server_st *ptr);
```

Returns the number of the servers in the server list.

```c
void memcached_server_list_free (memcached_server_st *ptr);
```

Frees the memory associated with a server list.

```c
memcached_server_st *memcached_servers_parse (char *server_strings);
```

Parses a string containing a list of servers, where individual servers are separated by a comma, space, or both, and where individual servers are of the form `server[:port]`. The return value is a server list structure.
Developing a memcached Application

**libmemcached Set Functions**

The set-related functions within libmemcached provide the same functionality as the core functions supported by the memcached protocol. The full definition for the different functions is the same for all the base functions (add, replace, prepend, append). For example, the function definition for `memcached_set()` is:

```c
memcached_return
    memcached_set (memcached_st *ptr,
                 const char *key,
                 size_t key_length,
                 const char *value,
                 size_t value_length,
                 time_t expiration,
                 uint32_t flags);
```

The `ptr` is the `memcached_st` structure. The `key` and `key_length` define the key name and length, and `value` and `value_length` the corresponding value and length. You can also set the expiration and optional flags. For more information, see Controlling libmemcached Behaviors.

This table outlines the remainder of the set-related libmemcached functions and the equivalent core functions supported by the memcached protocol.

<table>
<thead>
<tr>
<th>libmemcached Function</th>
<th>Equivalent Core Function</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>memcached_set(memc, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Generic <code>set()</code> operation.</td>
</tr>
<tr>
<td><code>memcached_add(memc, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Generic <code>add()</code> function.</td>
</tr>
<tr>
<td><code>memcached_replace(memc, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Generic <code>replace()</code>.</td>
</tr>
<tr>
<td><code>memcached_prepend(memc, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Prepends the specified <code>value</code> before the current value of the specified <code>key</code>.</td>
</tr>
<tr>
<td><code>memcached_append(memc, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Appends the specified <code>value</code> after the current value of the specified <code>key</code>.</td>
</tr>
<tr>
<td><code>memcached_cas(memc, key, key_length, value, value_length, expiration, flags, cas)</code></td>
<td>Overwrites the data for a given key as long as the corresponding <code>cas</code> value is still the same within the server.</td>
</tr>
<tr>
<td><code>memcached_set_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Similar to the generic <code>set()</code>, but has the option of an additional master key that can be used to identify an individual server.</td>
</tr>
<tr>
<td><code>memcached_add_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Similar to the generic <code>add()</code>, but has the option of an additional master key that can be used to identify an individual server.</td>
</tr>
<tr>
<td><code>memcached_replace_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code></td>
<td>Similar to the generic <code>replace()</code>, but has the option of an additional master key that can be used to identify an individual server.</td>
</tr>
</tbody>
</table>
Developing a `memcached` Application

<table>
<thead>
<tr>
<th><strong>libmemcached Function</strong></th>
<th><strong>Equivalent Core Function</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>key_length, value, value_length, expiration, flags)</td>
<td></td>
</tr>
<tr>
<td><code>memcached_prepend_by_key</code> (memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</td>
<td>Similar to the <code>memcached_prepend()</code>, but has the option of an additional master key that can be used to identify an individual server.</td>
</tr>
<tr>
<td><code>memcached_append_by_key</code> (memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</td>
<td>Similar to the <code>memcached_append()</code>, but has the option of an additional master key that can be used to identify an individual server.</td>
</tr>
<tr>
<td><code>memcached_cas_by_key</code> (memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</td>
<td>Similar to the <code>memcached_cas()</code>, but has the option of an additional master key that can be used to identify an individual server.</td>
</tr>
</tbody>
</table>

The *by_key* methods add two further arguments that define the master key, to be used and applied during the hashing stage for selecting the servers. You can see this in the following definition:

```c
libmemcached_return
memcached_set_by_key (memcached_st *ptr,
const char *master_key,
size_t master_key_length,
const char *key,
size_t key_length,
const char *value,
size_t value_length,
time_t expiration,
uint32_t flags);
```

All the functions return a value of type `memcached_return`, which you can compare against the `MEMCACHED_SUCCESS` constant.

**libmemcached Get Functions**

The `libmemcached` functions provide both direct access to a single item, and a multiple-key request mechanism that provides much faster responses when fetching a large number of keys simultaneously.

The main get-style function, which is equivalent to the generic `get()` is `memcached_get()`. This function returns a string pointer, pointing to the value associated with the specified key.

```c
char *memcached_get (memcached_st *ptr,
const char *key, size_t key_length,
size_t *value_length,
unsigned int32_t *flags,
memcached_return *error);
```

A multi-key get, `memcached_mget()`, is also available. Using a multiple key get operation is much quicker to do in one block than retrieving the key values with individual calls to `memcached_get()`. To start the multi-key get, call `memcached_mget()`:

```c
memcached_return
memcached_mget (memcached_st *ptr,
char **keys, size_t *key_length,
unsigned int number_of_keys);
```
The return value is the success of the operation. The **keys** parameter should be an array of strings containing the keys, and **key_length** an array containing the length of each corresponding key. **number_of_keys** is the number of keys supplied in the array.

To fetch the individual values, use **memcached_fetch()** to get each corresponding value.

```c
char *memcached_fetch (memcached_st *ptr,
    const char *key, size_t *key_length,
    size_t *value_length,
    uint32_t *flags,
    memcached_return *error);
```

The function returns the key value, with the **key**, **key_length** and **value_length** parameters being populated with the corresponding key and length information. The function returns **NULL** when there are no more values to be returned. A full example, including the populating of the key data and the return of the information is provided here.

```c
#include <stdio.h>
#include <string.h>
#include <unistd.h>
#include <libmemcached/memcached.h>

int main(int argc, char *argv[]) {
    memcached_server_st *servers = NULL;
    memcached_st *memc;
    memcached_return rc;
    char *keys[] = {"huey", "dewey", "louie"};
    size_t key_length[3];
    char *values[] = {"red", "blue", "green"};
    size_t value_length[3];
    unsigned int x;
    uint32_t flags;
    char return_key[MEMCACHED_MAX_KEY];
    size_t return_key_length;
    char *return_value;
    size_t return_value_length;
    memc= memcached_create(NULL);
    servers= memcached_server_list_append(servers, "localhost", 11211, &rc);
    rc= memcached_server_push(memc, servers);
    if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr,"Added server successfully\n");
    else
        fprintf(stderr,"Couldn't add server: %s\n",memcached_strerror(memc, rc));
    for(x= 0; x < 3; x++)
        { 
            key_length[x] = strlen(keys[x]);
            value_length[x] = strlen(values[x]);
            rc= memcached_set(memc, keys[x], key_length[x], values[x],
            value_length[x], (time_t)0, (uint32_t)0);
            if (rc == MEMCACHED_SUCCESS)
                fprintf(stderr,"Key %s stored successfully\n",keys[x]);
            else
                fprintf(stderr,"Couldn't store key: %s\n",memcached_strerror(memc, rc));
        }
    rc= memcached_mget(memc, keys, key_length, 3);
}
```
Developing a memcached Application

```c
if (rc == MEMCACHED_SUCCESS)
{
    while ((return_value= memcached_fetch(memc, return_key, &return_key_length, 
                                &return_value_length, &flags, &rc)) != NULL)
    {
        if (rc == MEMCACHED_SUCCESS)
        {
            fprintf(stderr,"Key %s returned %s\n",return_key, return_value);
        }
    }
}
return 0;
}
```

Running the above application produces the following output:

```
shell> memc_multi_fetch
Added server successfully
Key huey stored successfully
Key dewey stored successfully
Key louie stored successfully
Key huey returned red
Key dewey returned blue
Key louie returned green
```

Controlling **libmemcached** Behaviors

The behavior of **libmemcached** can be modified by setting one or more behavior flags. These can either be set globally, or they can be applied during the call to individual functions. Some behaviors also accept an additional setting, such as the hashing mechanism used when selecting servers.

To set global behaviors:

```c
memcached_return
    memcached_behavior_set (memcached_st *ptr, 
                           memcached_behavior flag, 
                           uint64_t data);
```

To get the current behavior setting:

```c
uint64_t
    memcached_behavior_get (memcached_st *ptr, 
                           memcached_behavior flag);
```

The following table describes **libmemcached** behavior flags.

<table>
<thead>
<tr>
<th>Behavior</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MEMCACHED_BEHAVIOR_NO_BLOCK</td>
<td>Caused <strong>libmemcached</strong> to use asynchronous I/O.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_TCP_NODELAY</td>
<td>Turns on no-delay for network sockets.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_HASH</td>
<td>Without a value, sets the default hashing algorithm for keys to use MD5. Other valid values include MEMCACHED_HASH_DEFAULT, MEMCACHED_HASH_MD5, MEMCACHED_HASH_CRC, MEMCACHED_HASH_FNV1_64, MEMCACHED_HASH_FNV1A_64, MEMCACHED_HASH_FNV1_32, and MEMCACHED_HASH_FNV1A_32.</td>
</tr>
<tr>
<td>MEMCACHED_BEHAVIOR_DISTRIBUTION</td>
<td>Changes the method of selecting the server used to store a given value. The default method</td>
</tr>
</tbody>
</table>
Developing a **memcached** Application

<table>
<thead>
<tr>
<th>Behavior</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>is <code>MEMCACHED_DISTRIBUTION_MODULA</code>. You can enable consistent hashing by setting <code>MEMCACHED_DISTRIBUTION_CONSISTENT</code>. <code>MEMCACHED_DISTRIBUTION_CONSISTENT</code> is an alias for the value <code>MEMCACHED_DISTRIBUTION_CONSISTENT_KETAMA</code>.</td>
</tr>
<tr>
<td><code>MEMCACHED_BEHAVIOR_CACHE_LOOKUPS</code></td>
<td>Cache the lookups made to the DNS service. This can improve the performance if you are using names instead of IP addresses for individual hosts.</td>
</tr>
<tr>
<td><code>MEMCACHED_BEHAVIOR_SUPPORT_CAS</code></td>
<td>Support CAS operations. By default, this is disabled because it imposes a performance penalty.</td>
</tr>
<tr>
<td><code>MEMCACHED_BEHAVIOR_KETAMA</code></td>
<td>Sets the default distribution to <code>MEMCACHED_DISTRIBUTION_CONSISTENT_KETAMA</code> and the hash to <code>MEMCACHED_HASH_MD5</code>.</td>
</tr>
<tr>
<td><code>MEMCACHED_BEHAVIOR_POLL_TIMEOUT</code></td>
<td>Modify the timeout value used by <code>poll()</code>. Supply a signed int pointer for the timeout value.</td>
</tr>
<tr>
<td><code>MEMCACHED_BEHAVIOR_BUFFER_REQUESTS</code></td>
<td>Buffers IO requests instead of them being sent. A get operation, or closing the connection causes the data to be flushed.</td>
</tr>
<tr>
<td><code>MEMCACHED_BEHAVIOR_VERIFY_KEY</code></td>
<td>Forces <code>libmemcached</code> to verify that a specified key is valid.</td>
</tr>
<tr>
<td><code>MEMCACHED_BEHAVIOR_SORT_HOSTS</code></td>
<td>If set, hosts added to the list of configured hosts for a <code>memcached_st</code> structure are placed into the host list in sorted order. This breaks consistent hashing if that behavior has been enabled.</td>
</tr>
<tr>
<td><code>MEMCACHED_BEHAVIOR_CONNECT_TIMEOUT</code></td>
<td>In nonblocking mode this changes the value of the timeout during socket connection.</td>
</tr>
</tbody>
</table>

**libmemcached** Command-Line Utilities

In addition to the main C library interface, `libmemcached` also includes a number of command-line utilities that can be useful when working with and debugging `memcached` applications.

All of the command-line tools accept a number of arguments, the most critical of which is `servers`, which specifies the list of servers to connect to when returning information.

The main tools are:

- **memcat**: Display the value for each ID given on the command line:
  ```shell
  shell> memcat --servers=localhost hwkey
  Hello world
  ```

- **memcp**: Copy the contents of a file into the cache, using the file name as the key:
  ```shell
  shell> echo "Hello World" > hwkey
  shell> memcp --servers=localhost hwkey
  shell> memcat --servers=localhost hwkey
  Hello world
  ```

- **memrm**: Remove an item from the cache:
  ```shell
  ```
Developing a **memcached** Application

- **memslap**: Test the load on one or more **memcached** servers, simulating get/set and multiple client operations. For example, you can simulate the load of 100 clients performing get operations:

  ```shell
  shell> memslap --servers=localhost --concurrency=100 --flush --test=get
  memslap --servers=localhost --concurrency=100 --flush --test=get Threads connecting to servers 100
  Took 13.571 seconds to read data
  ```

- **memflush**: Flush (empty) the contents of the **memcached** cache.

  ```shell
  shell> memflush --servers=localhost
  ```

### 16.6.3.4 Using MySQL and **memcached** with Perl

The **Cache::Memcached** module provides a native interface to the Memcache protocol, and provides support for the core functions offered by **memcached**. Install the module using your operating system's package management system, or using CPAN:

```perl
root-shell> perl -MCPAN -e 'install Cache::Memcached'
```

To use **memcached** from Perl through the **Cache::Memcached** module, first create a new **Cache::Memcached** object that defines the list of servers and other parameters for the connection. The only argument is a hash containing the options for the cache interface. For example, to create a new instance that uses three **memcached** servers:

```perl
use Cache::Memcached;
my $cache = new Cache::Memcached {
    'servers' => [
        '192.168.0.100:11211',
        '192.168.0.101:11211',
        '192.168.0.102:11211',
    ],
};
```

#### Note

When using the **Cache::Memcached** interface with multiple servers, the API automatically performs certain operations across all the servers in the group. For example, getting statistical information through **Cache::Memcached** returns a hash that contains data on a host-by-host basis, as well as generalized statistics for all the servers in the group.

You can set additional properties on the cache object instance when it is created by specifying the option as part of the option hash. Alternatively, you can use a corresponding method on the instance:

- **servers** or method **set_servers()**: Specifies the list of the servers to be used. The servers list should be a reference to an array of servers, with each element as the address and port number combination (separated by a colon). You can also specify a local connection through a Unix socket (for example `/tmp/sock/memcached`). To specify the server with a weight (indicating how much more frequently the server should be used during hashing), specify an array reference with the **memcached** server instance and a weight number. Higher numbers give higher priority.
• **compress_threshold** or method **set_compress_threshold()**: Specifies the threshold when values are compressed. Values larger than the specified number are automatically compressed (using **zlib**) during storage and retrieval.

• **no_rehash** or method **set_norehash()**: Disables finding a new server if the original choice is unavailable.

• **readonly** or method **set_readonly()**: Disables writes to the **memcached** servers.

Once the **Cache::Memcached** object instance has been configured, you can use the **set()** and **get()** methods to store and retrieve information from the **memcached** servers. Objects stored in the cache are automatically serialized and deserialized using the **Storable** module.

The **Cache::Memcached** interface supports the following methods for storing/retrieving data, and relate to the generic methods as shown in the table.

<table>
<thead>
<tr>
<th>Cache::Memcached Function</th>
<th>Equivalent Generic Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>get()</td>
<td>Generic get().</td>
</tr>
<tr>
<td>get_multi(keys)</td>
<td>Gets multiple keys from memcache using just one query. Returns a hash reference of key/value pairs.</td>
</tr>
<tr>
<td>set()</td>
<td>Generic set().</td>
</tr>
<tr>
<td>add()</td>
<td>Generic add().</td>
</tr>
<tr>
<td>replace()</td>
<td>Generic replace().</td>
</tr>
<tr>
<td>delete()</td>
<td>Generic delete().</td>
</tr>
<tr>
<td>incr()</td>
<td>Generic incr().</td>
</tr>
<tr>
<td>decr()</td>
<td>Generic decr().</td>
</tr>
</tbody>
</table>

Below is a complete example for using **memcached** with Perl and the **Cache::Memcached** module:

```perl
#!/usr/bin/perl
use Cache::Memcached;
use DBI;
use Data::Dumper;

# Configure the memcached server
my $cache = new Cache::Memcached {
    'servers' => [
        'localhost:11211',
    ],
};

# Get the film name from the command line
# memcached keys must not contain spaces, so create
# a key name by replacing spaces with underscores
my $filmname = shift or die "Must specify the film name\n";
my $filmkey = $filmname;
$filmkey =~ s/ /_/;

# Load the data from the cache
my $filmdata = $cache->get($filmkey);

# If the data wasn't in the cache, then we load it from the database
```
if (!defined($filmdata))
{
    $filmdata = load_filmdata($filmname);
    if (defined($filmdata))
    {
        # Set the data into the cache, using the key
        if ($cache->set($filmkey,$filmdata))
        {
            print STDERR "Film data loaded from database and cached\n";
        }
        else
        {
            print STDERR "Couldn't store to cache\n";
        }
    }
    else
    {
        die "Couldn't find $filmname\n";
    }
}
else
{
    print STDERR "Film data loaded from Memcached\n";
}

sub load_filmdata
{
    my ($filename) = @_;
    my $dsn = "DBI:mysql:database=sakila;host=localhost;port=3306";
    $dbh = DBI->connect($dsn, 'sakila','password');
    my ($filmbase) = $dbh->selectrow_hashref(sprintf('select * from film where title = %s', $dbh->quote($filmname)));
    if (!defined($filmname))
    {
        return (undef);
    }
    $filmbase->{stars} = $dbh->selectall_arrayref(sprintf('select concat(first_name," ",last_name) from film_actor left join (actor) on (film_actor.actor_id = actor.actor_id) where film_id=%s', $dbh->quote($filmbase->{film_id})));
    return($filmbase);
}

The example uses the Sakila database, obtaining film data from the database and writing a composite record of the film and actors to memcached. When calling it for a film does not exist, you get this result:

shell> memcached-sakila.pl "ROCK INSTINCT"
Film data loaded from database and cached

When accessing a film that has already been added to the cache:

shell> memcached-sakila.pl "ROCK INSTINCT"
Film data loaded from Memcached
16.6.3.5 Using MySQL and memcached with Python

The Python memcache module interfaces to memcached servers, and is written in pure Python (that is, without using one of the C APIs). You can download and install a copy from Python Memcached.

To install, download the package and then run the Python installer:

```bash
python setup.py install
running install
running bdist_egg
running egg_info
creating python_memcached.egg-info
...
removing 'build/bdist.linux-x86_64/egg' (and everything under it)
Processing python_memcached-1.43-py2.4.egg
creating /usr/lib64/python2.4/site-packages/python_memcached-1.43-py2.4.egg
Extracting python_memcached-1.43-py2.4.egg to /usr/lib64/python2.4/site-packages
Adding python-memcached 1.43 to easy-install.pth file

Installed /usr/lib64/python2.4/site-packages/python_memcached-1.43-py2.4.egg
Processing dependencies for python-memcached==1.43
Finished processing dependencies for python-memcached==1.43
```

Once installed, the memcache module provides a class-based interface to your memcached servers. When you store Python data structures as memcached items, they are automatically serialized (turned into string values) using the Python cPickle or pickle modules.

To create a new memcache interface, import the memcache module and create a new instance of the memcache.Client class. For example, if the memcached daemon is running on localhost using the default port:

```python
import memcache
memc = memcache.Client(['127.0.0.1:11211'])
```

The first argument is an array of strings containing the server and port number for each memcached instance to use. To enable debugging, set the optional debug parameter to 1.

By default, the hashing mechanism used to divide the items among multiple servers is crc32. To change the function used, set the value of memcache.serverHashFunction to the alternate function to use. For example:

```python
from zlib import adler32
memcache.serverHashFunction = adler32
```

Once you have defined the servers to use within the memcache instance, the core functions provide the same functionality as in the generic interface specification. The following table provides a summary of the supported functions:

<table>
<thead>
<tr>
<th>Python memcache Function</th>
<th>Equivalent Generic Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>get()</td>
<td>Generic get().</td>
</tr>
<tr>
<td>get_multi(keys)</td>
<td>Gets multiple values from the supplied array of keys. Returns a hash reference of key/value pairs.</td>
</tr>
<tr>
<td>set()</td>
<td>Generic set().</td>
</tr>
<tr>
<td>set_multi(dict[, expiry [, key_prefix]])</td>
<td>Sets multiple key/value pairs from the supplied dict.</td>
</tr>
<tr>
<td>add()</td>
<td>Generic add().</td>
</tr>
</tbody>
</table>
Developing a `memcached` Application

<table>
<thead>
<tr>
<th>Python <code>memcache</code> Function</th>
<th>Equivalent Generic Function</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>replace()</code></td>
<td>Generic <code>replace()</code></td>
</tr>
<tr>
<td><code>prepend(key, value [, expiry])</code></td>
<td>Prepends the supplied <code>value</code> to the value of the existing <code>key</code>.</td>
</tr>
<tr>
<td><code>append(key, value [, expiry][])</code></td>
<td>Appends the supplied <code>value</code> to the value of the existing <code>key</code>.</td>
</tr>
<tr>
<td><code>delete()</code></td>
<td>Generic <code>delete()</code></td>
</tr>
<tr>
<td><code>delete_multi(keys [, expiry [key_prefix]])</code></td>
<td>Deletes all the keys from the hash matching each string in the array <code>keys</code>.</td>
</tr>
<tr>
<td><code>incr()</code></td>
<td>Generic <code>incr()</code></td>
</tr>
<tr>
<td><code>decr()</code></td>
<td>Generic <code>decr()</code></td>
</tr>
</tbody>
</table>

**Note**

Within the Python `memcache` module, all the *_multi()* functions support an optional `key_prefix` parameter. If supplied, then the string is used as a prefix to all key lookups. For example, if you call:

```python
memc.get_multi(['a','b'], key_prefix='users:')
```

The function retrieves the keys `users:a` and `users:b` from the servers.

Here is an example showing the storage and retrieval of information to a `memcache` instance, loading the raw data from MySQL:

```python
import sys
import MySQLdb
import memcache

memc = memcache.Client(['127.0.0.1:11211'], debug=1);

try:
    conn = MySQLdb.connect (host = "localhost",
                        user = "sakila",
                        passwd = "password",
                        db = "sakila")
except MySQLdb.Error, e:
    print "Error %d: %s" % (e.args[0], e.args[1])
    sys.exit (1)

popularfilms = memc.get('top5films')
if not popularfilms:
    cursor = conn.cursor()
    cursor.execute('select film_id,title from film order by rental_rate desc limit 5')
    rows = cursor.fetchall()
    memc.set('top5films', rows, 60)
    print "Updated memcached with MySQL data"
else:
    print "Loaded data from memcached"
    for row in popularfilms:
        print "%s, %s" % (row[0], row[1])
```

When executed for the first time, the data is loaded from the MySQL database and stored to the `memcached` server.
Developing a **memcached** Application

Because the data is automatically serialized using **cPickle/pickle**, when you load the data back from **memcached**, you can use the object directly. In the example above, the information stored to **memcached** is in the form of rows from a Python DB cursor. When accessing the information (within the 60 second expiry time), the data is loaded from **memcached** and dumped:

```
shell> python memc_python.py
Updated memcached with MySQL data
```

```
shell> python memc_python.py
2, ACE GOLDFINGER
7, AIRPLANE SIERRA
8, AIRPORT POLLOCK
10, ALADDIN CALENDAR
13, ALI FOREVER
```

The serialization and deserialization happens automatically. Because serialization of Python data may be incompatible with other interfaces and languages, you can change the serialization module used during initialization. For example, you might use JSON format when you store complex data structures using a script written in one language, and access them in a script written in a different language.

### 16.6.3.6 Using MySQL and **memcached** with PHP

PHP provides support for the Memcache functions through a PECL extension. To enable the PHP **memcache** extensions, build PHP using the `--enable-memcache` option to **configure** when building from source.

If you are installing on a Red Hat-based server, you can install the **php-pecl-memcache** RPM:

```
root-shell> yum --install php-pecl-memcache
```

On Debian-based distributions, use the **php-memcache** package.

To set global runtime configuration options, specify the configuration option values within your **php.ini** file. The following table provides the name, default value, and a description for each global runtime configuration option.

<table>
<thead>
<tr>
<th>Configuration option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>memcache.allow_failover</code></td>
<td>1</td>
<td>Specifies whether another server in the list should be queried if the first server selected fails.</td>
</tr>
<tr>
<td><code>memcache.max_failover_attempts</code></td>
<td>20</td>
<td>Specifies the number of servers to try before returning a failure.</td>
</tr>
<tr>
<td><code>memcache.chunk_size</code></td>
<td>8192</td>
<td>Defines the size of network chunks used to exchange data with the <strong>memcached</strong> server.</td>
</tr>
<tr>
<td><code>memcache.default_port</code></td>
<td>11211</td>
<td>Defines the default port to use when communicating with the <strong>memcached</strong> servers.</td>
</tr>
<tr>
<td><code>memcache.hash_strategy</code></td>
<td>standard</td>
<td>Specifies which hash strategy to use. Set to <strong>consistent</strong> to enable servers to be added or removed from the pool without causing the keys to be remapped to other servers. When set to <strong>standard</strong>, an older (modula) strategy is used that potentially uses different servers for storage.</td>
</tr>
</tbody>
</table>
Developing a **memcached** Application

<table>
<thead>
<tr>
<th>Configuration option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>memcache.hash_function</code></td>
<td><code>crc32</code></td>
<td>Specifies which function to use when mapping keys to servers. <code>crc32</code> uses the standard CRC32 hash. <code>fnv</code> uses the FNV-1a hashing algorithm.</td>
</tr>
</tbody>
</table>

To create a connection to a **memcached** server, create a new **Memcache** object and then specify the connection options. For example:

```php
<?php
    $cache = new Memcache;
    $cache->connect('localhost',11211);
?>
```

This opens an immediate connection to the specified server.

To use multiple **memcached** servers, you need to add servers to the memcache object using `addServer()`:

```php
bool Memcache::addServer ( string $host [, int $port [, bool $persistent [, int $timeout [, int $retry_interval [, bool $status [, callback $failure_callback ]]]]]]])
```

The server management mechanism within the **php-memcache** module is a critical part of the interface as it controls the main interface to the **memcached** instances and how the different instances are selected through the hashing mechanism.

To create a simple connection to two **memcached** instances:

```php
<?php
    $cache = new Memcache;
    $cache->addServer('192.168.0.100',11211);
    $cache->addServer('192.168.0.101',11211);
?>
```

In this scenario, the instance connection is not explicitly opened, but only opened when you try to store or retrieve a value. To enable persistent connections to **memcached** instances, set the `$persistent` argument to true. This is the default setting, and causes the connections to remain open.

To help control the distribution of keys to different instances, use the global `memcache.hash_strategy` setting. This sets the hashing mechanism used to select. You can also add another weight to each server, which effectively increases the number of times the instance entry appears in the instance list, therefore increasing the likelihood of the instance being chosen over other instances. To set the weight, set the value of the `$weight` argument to more than one.

The functions for setting and retrieving information are identical to the generic functional interface offered by **memcached**, as shown in this table:

<table>
<thead>
<tr>
<th>PECL <strong>memcache</strong> Function</th>
<th>Generic Function</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>get()</code></td>
<td>Generic <code>get()</code></td>
</tr>
<tr>
<td><code>set()</code></td>
<td>Generic <code>set()</code></td>
</tr>
<tr>
<td><code>add()</code></td>
<td>Generic <code>add()</code></td>
</tr>
<tr>
<td><code>replace()</code></td>
<td>Generic <code>replace()</code></td>
</tr>
</tbody>
</table>
Developing a **memcached** Application

<table>
<thead>
<tr>
<th>PECL <strong>memcache</strong> Function</th>
<th>Generic Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>delete()</td>
<td>Generic delete().</td>
</tr>
<tr>
<td>increment()</td>
<td>Generic incr().</td>
</tr>
<tr>
<td>decrement()</td>
<td>Generic decr().</td>
</tr>
</tbody>
</table>

A full example of the PECL **memcache** interface is provided below. The code loads film data from the Sakila database when the user provides a film name. The data stored into the **memcached** instance is recorded as a **mysqli** result row, and the API automatically serializes the information for you.

```php
<?php
$memc = new Memcache;
$memc->addServer('localhost','11211');
if(!empty($_POST['film'])) {
    <html xmlns="http://www.w3.org/1999/xhtml" xml:lang="en" lang="en">
        <head>
            <meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
            <title>Simple Memcache Lookup</title>
        </head>
        <body>
            <form method="post">
                <p><b>Film</b>: <input type="text" size="20" name="film"></p>
                <input type="submit">
            </form>
            <hr/>
        </body>
    </html>
} else {
    echo "Loading data...\n";
    $film = htmlspecialchars($_POST['film'], ENT_QUOTES, 'UTF-8');
    $mfilms = $memc->get($film);
    if ($mfilms) {
        printf("<p>Film data for %s loaded from memcache</p>" , $mfilms['title']);
        foreach(array_keys($mfilms) as $key) {
            printf("<p><b>%s</b>: %s</p>" , $key, $mfilms[$key]);
        }
    } else {
        $mysqli = mysqli('localhost','sakila','password','sakila');
        if (mysqli_connect_error()) {
            sprintf("Database error: (%d) %s", mysqli_connect_errno(), mysqli_connect_error());
        }
        $sql = sprintf('SELECT * FROM film WHERE title="%s"', $mysqli->real_escape_string($film));
        $result = $mysqli->query($sql);
        if (!$result) {
            sprintf("Database error: (%d) %s", $mysqli->errno, $mysqli->error);
            exit;
        }
    }
```
Developing a `memcached` Application

```php
$row = $result->fetch_assoc();
$memc->set($row['title'], $row);
printf("<p>Loaded (%s) from MySQL</p>", htmlspecialchars($row['title'], ENT_QUOTES, 'UTF-8');
```

With PHP, the connections to the `memcached` instances are kept open as long as the PHP and associated Apache instance remain running. When adding or removing servers from the list in a running instance (for example, when starting another script that mentions additional servers), the connections are shared, but the script only selects among the instances explicitly configured within the script.

To ensure that changes to the server list within a script do not cause problems, make sure to use the consistent hashing mechanism.

### 16.6.3.7 Using MySQL and `memcached` with Ruby

There are a number of different modules for interfacing to `memcached` within Ruby. The `Ruby-MemCache` client library provides a native interface to `memcached` that does not require any external libraries, such as `libmemcached`. You can obtain the installer package from [http://www.deveiate.org/projects/RMemCache](http://www.deveiate.org/projects/RMemCache).

To install, extract the package and then run `install.rb`:

```bash
shell> install.rb
```

If you have RubyGems, you can install the `Ruby-MemCache` gem:

```bash
shell> gem install Ruby-MemCache
```

Bulk updating Gem source index for: http://gems.rubyforge.org
Install required dependency io-reactor? [Yn]  y
Successfully installed Ruby-MemCache-0.0.1
Successfully installed io-reactor-0.05
Installing ri documentation for io-reactor-0.05...
Installing RDoc documentation for io-reactor-0.05...

To use a `memcached` instance from within Ruby, create a new instance of the `MemCache` object.

```ruby
require 'memcache'
memc = MemCache::new '192.168.0.100:11211'
```

You can add a weight to each server to increase the likelihood of the server being selected during hashing by appending the weight count to the server host name/port string:

```ruby
require 'memcache'
memc = MemCache::new '192.168.0.100:11211:3'
```

To add servers to an existing list, you can append them directly to the `MemCache` object:

```ruby
memc += ['192.168.0.101:12111']
```

To set data into the cache, you can just assign a value to a key within the new cache object, which works just like a standard Ruby hash object:

```ruby
memc['key'] = "value"
```
Developing a memcached Application

Or to retrieve the value:

```ruby
print memc["key"]
```

For more explicit actions, you can use the method interface, which mimics the main memcached API functions, as summarized in the following table:

<table>
<thead>
<tr>
<th>Ruby MemCache Method</th>
<th>Equivalent memcached API Functions</th>
</tr>
</thead>
<tbody>
<tr>
<td>get()</td>
<td>Generic get().</td>
</tr>
<tr>
<td>get_hash(keys)</td>
<td>Get the values of multiple keys, returning the information as a hash of the keys and their values.</td>
</tr>
<tr>

</tr>
<tr>
<td>decr()</td>
<td>Generic decr().</td>
</tr>
</tbody>
</table>

16.6.3.8 Using MySQL and memcached with Java

The `com.danga.MemCached` class within Java provides a native interface to memcached instances. You can obtain the client from https://github.com/gwhalin/Memcached-Java-Client/downloads. The Java class uses hashes that are compatible with libmemcached, so you can mix and match Java and libmemcached applications accessing the same memcached instances. The serialization between Java and other interfaces are not compatible. If this is a problem, use JSON or a similar nonbinary serialization format.

On most systems, you can download the package and use the jar directly.

To use the `com.danga.MemCached` interface, you create a `MemCachedClient` instance and then configure the list of servers by configuring the `SockIOPool`. Through the pool specification you set up the server list, weighting, and the connection parameters to optimized the connections between your client and the memcached instances that you configure.

Generally, you can configure the memcached interface once within a single class, then use this interface throughout the rest of your application.

For example, to create a basic interface, first configure the `MemCachedClient` and base `SockIOPool` settings:

```java
public class MyClass {

    protected static MemCachedClient mcc = new MemCachedClient();

    static {
        String[] servers = {
            "localhost:11211",
        };

        Integer[] weights = { 1 };
    }
```
SockIOPool pool = SockIOPool.getInstance();
pool.setServers( servers );
pool.setWeights( weights );

In the above sample, the list of servers is configured by creating an array of the memcached instances to use. You can then configure individual weights for each server.

The remainder of the properties for the connection are optional, but you can set the connection numbers (initial connections, minimum connections, maximum connections, and the idle timeout) by setting the pool parameters:

pool.setInitConn( 5 );
pool.setMinConn( 5 );
pool.setMaxConn( 250 );
pool.setMaxIdle( 1000 * 60 * 60 * 6 )

Once the parameters have been configured, initialize the connection pool:

pool.initialize();

The pool, and the connection to your memcached instances should now be ready to use.

To set the hashing algorithm used to select the server used when storing a given key, use pool.setHashingAlg():

pool.setHashingAlg( SockIOPool.NEW_COMPAT_HASH );

Valid values are NEW_COMPAT_HASH, OLD_COMPAT_HASH and NATIVE_HASH are also basic modula hashing algorithms. For a consistent hashing algorithm, use CONSISTENT_HASH. These constants are equivalent to the corresponding hash settings within libmemcached.

The following table outlines the Java com.danga.MemCached methods and the equivalent generic methods in the memcached interface specification.

<table>
<thead>
<tr>
<th>Java com.danga.MemCached Method</th>
<th>Equivalent Generic Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>get()</td>
<td>Generic get().</td>
</tr>
<tr>
<td>getMulti(keys)</td>

<td>Generic incr().</td>
</tr>
<tr>
<td>decr()</td>
<td>Generic decr().</td>
</tr>
</tbody>
</table>

16.6.3.9 Using the memcached TCP Text Protocol

Communicating with a memcached server can be achieved through either the TCP or UDP protocols. When using the TCP protocol, you can use a simple text based interface for the exchange of information.
Developing a memcached Application

When communicating with memcached, you can connect to the server using the port configured for the server. You can open a connection with the server without requiring authorization or login. As soon as you have connected, you can start to send commands to the server. When you have finished, you can terminate the connection without sending any specific disconnection command. Clients are encouraged to keep their connections open to decrease latency and improve performance.

Data is sent to the memcached server in two forms:

- Text lines, which are used to send commands to the server, and receive responses from the server.
- Unstructured data, which is used to receive or send the value information for a given key. Data is returned to the client in exactly the format it was provided.

Both text lines (commands and responses) and unstructured data are always terminated with the string \r \n. Because the data being stored may contain this sequence, the length of the data (returned by the client before the unstructured data is transmitted should be used to determine the end of the data.

Commands to the server are structured according to their operation:

- **Storage commands:** set, add, replace, append, prepend, cas

  Storage commands to the server take the form:

  ```
  command key [flags] [exptime] length [noreply]
  ```

  Or when using compare and swap (cas):

  ```
  cas key [flags] [exptime] length [casunique] [noreply]
  ```

  Where:

  - **command:** The command name.
    - **set:** Store value against key
    - **add:** Store this value against key if the key does not already exist
    - **replace:** Store this value against key if the key already exists
    - **append:** Append the supplied value to the end of the value for the specified key. The flags and exptime arguments should not be used.
    - **prepend:** Append value currently in the cache to the end of the supplied value for the specified key. The flags and exptime arguments should not be used.
    - **cas:** Set the specified key to the supplied value, only if the supplied casunique matches. This is effectively the equivalent of change the information if nobody has updated it since I last fetched it.
    - **key:** The key. All data is stored using a the specific key. The key cannot contain control characters or whitespace, and can be up to 250 characters in size.
    - **flags:** The flags for the operation (as an integer). Flags in memcached are transparent. The memcached server ignores the contents of the flags. They can be used by the client to indicate any type of information. In memcached 1.2.0 and lower the value is a 16-bit integer value. In memcached 1.2.1 and higher the value is a 32-bit integer.
    - **exptime:** The expiry time, or zero for no expiry.
Developing a *memcached* Application

- **length**: The length of the supplied value block in bytes, excluding the terminating `\r\n` characters.
- **casunique**: A unique 64-bit value of an existing entry. This is used to compare against the existing value. Use the value returned by the `gets` command when issuing `cas` updates.
- **noreply**: Tells the server not to reply to the command.

For example, to store the value `abcdef` into the key `xyzkey`, you would use:

```
set xyzkey 0 0 6
abcdef
```

The return value from the server is one line, specifying the status or error information. For more information, see Table 16.3, "*memcached* Protocol Responses".

- **Retrieval commands**: `get`, `gets`

  Retrieval commands take the form:

  ```
  get key1 [key2 .... keyn]
  gets key1 [key2 ... keyn]
  ```

  You can supply multiple keys to the commands, with each requested key separated by whitespace.

  The server responds with an information line of the form:

  ```
  VALUE key flags bytes [casunique]
  ```

  Where:

  - **key**: The key name.
  - **flags**: The value of the flag integer supplied to the *memcached* server when the value was stored.
  - **bytes**: The size (excluding the terminating `\r\n` character sequence) of the stored value.
  - **casunique**: The unique 64-bit integer that identifies the item.

  The information line is immediately followed by the value data block. For example:

  ```
  get xyzkey
  VALUE xyzkey 0 6
  abcdef
  ```

  If you have requested multiple keys, an information line and data block is returned for each key found. If a requested key does not exist in the cache, no information is returned.

- **Delete commands**: `delete`

  Deletion commands take the form:

  ```
  delete key [time] [noreply]
  ```

  Where:

  - **key**: The key name.
Developing a memcached Application

• **time**: The time in seconds (or a specific Unix time) for which the client wishes the server to refuse add or replace commands on this key. All add, replace, get, and gets commands fail during this period. set operations succeed. After this period, the key is deleted permanently and all commands are accepted.

If not supplied, the value is assumed to be zero (delete immediately).

• **noreply**: Tells the server not to reply to the command.

Responses to the command are either **DELETED** to indicate that the key was successfully removed, or **NOT_FOUND** to indicate that the specified key could not be found.

• **Increment/Decrement**: incr, decr

The increment and decrement commands change the value of a key within the server without performing a separate get/set sequence. The operations assume that the currently stored value is a 64-bit integer. If the stored value is not a 64-bit integer, then the value is assumed to be zero before the increment or decrement operation is applied.

Increment and decrement commands take the form:

```
incr key value [noreply]
deincr key value [noreply]
```

Where:

• **key**: The key name.

• **value**: An integer to be used as the increment or decrement value.

• **noreply**: Tells the server not to reply to the command.

The response is:

• **NOT_FOUND**: The specified key could not be located.

• **value**: The new value associated with the specified key.

Values are assumed to be unsigned. For **decr** operations, the value is never decremented below 0. For **incr** operations, the value wraps around the 64-bit maximum.

• **Statistics commands**: stats

The **stats** command provides detailed statistical information about the current status of the memcached instance and the data it is storing.

Statistics commands take the form:

```
STAT [name] [value]
```

Where:

• **name**: The optional name of the statistics to return. If not specified, the general statistics are returned.

• **value**: A specific value to be used when performing certain statistics operations.
Developing a `memcached` Application

The return value is a list of statistics data, formatted as follows:

```
STAT name value
```

The statistics are terminated with a single line, `END`.

For more information, see Section 16.6.4, “Getting `memcached` Statistics”.

For reference, a list of the different commands supported and their formats is provided below.

**Table 16.2 `memcached` Command Reference**

<table>
<thead>
<tr>
<th>Command</th>
<th>Command Formats</th>
</tr>
</thead>
<tbody>
<tr>
<td>set</td>
<td>set key flags exptime length, set key flags exptime length noreply</td>
</tr>
<tr>
<td>add</td>
<td>add key flags exptime length, add key flags exptime length noreply</td>
</tr>
<tr>
<td>replace</td>
<td>replace key flags exptime length, replace key flags exptime length noreply</td>
</tr>
<tr>
<td>append</td>
<td>append key length, append key length noreply</td>
</tr>
<tr>
<td>prepend</td>
<td>prepend key length, prepend key length noreply</td>
</tr>
<tr>
<td>cas</td>
<td>cas key flags exptime length casunique, cas key flags exptime length casunique noreply</td>
</tr>
<tr>
<td>get</td>
<td>get key1 [key2 ... keyn]</td>
</tr>
<tr>
<td>gets</td>
<td></td>
</tr>
<tr>
<td>delete</td>
<td>delete key, delete key noreply, delete key expiry, delete key expiry noreply</td>
</tr>
<tr>
<td>incr</td>
<td>incr key, incr key noreply, incr key value, incr key value noreply</td>
</tr>

<td>decr</td>
<td>decr key, decr key noreply, decr key value, decr key value noreply</td>
</tr>
<tr>
<td>stat</td>
<td>stat, stat name, stat name value</td>
</tr>
</tbody>
</table>

When sending a command to the server, the response from the server is one of the settings in the following table. All response values from the server are terminated by `\r\n`:

**Table 16.3 `memcached` Protocol Responses**

<table>
<thead>
<tr>
<th>String</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>STORED</td>
<td>Value has successfully been stored.</td>
</tr>
<tr>
<td>NOT_STORED</td>
<td>The value was not stored, but not because of an error. For commands where you are adding a or updating a value if it exists (such as <code>add</code> and <code>replace</code>), or where the item has already been set to be deleted.</td>
</tr>
<tr>
<td>EXISTS</td>
<td>When using a <code>cas</code> command, the item you are trying to store already exists and has been modified since you last checked it.</td>
</tr>
<tr>
<td>NOT_FOUND</td>
<td>The item you are trying to store, update or delete does not exist or has already been deleted.</td>
</tr>
<tr>
<td>ERROR</td>
<td>You submitted a nonexistent command name.</td>
</tr>
</tbody>
</table>
### 16.6.4 Getting `memcached` Statistics

The `memcached` system has a built-in statistics system that collects information about the data being stored into the cache, cache hit ratios, and detailed information on the memory usage and distribution of information through the slab allocation used to store individual items. Statistics are provided at both a basic level that provide the core statistics, and more specific statistics for specific areas of the `memcached` server.

This information can be useful to ensure that you are getting the correct level of cache and memory usage, and that your slab allocation and configuration properties are set at an optimal level.

The stats interface is available through the standard `memcached` protocol, so the reports can be accessed by using `telnet` to connect to the `memcached`. The supplied `memcached-tool` includes support for obtaining the Section 16.6.4.2, “memcached Slabs Statistics” and Section 16.6.4.1, “memcached General Statistics” information. For more information, see Section 16.6.4.6, “Using `memcached-tool`”.

Alternatively, most of the language API interfaces provide a function for obtaining the statistics from the server.

For example, to get the basic stats using `telnet`:

```
shell> telnet localhost 11211
Trying ::1...
Connected to localhost.
Escape character is '\\]'.
stats
STAT pid 23599
STAT uptime 675
STAT time 1211439587
STAT version 1.2.5
STAT pointer_size 32
STAT rusage_user 1.404992
STAT rusage_system 4.694685
STAT curr_items 32
STAT cmd_get 113482
STAT cmd_set 80519
STAT get_hits 78926
STAT get_misses 34556
STAT evictions 0
STAT bytes_read 6379783
```
When using Perl and the `Cache::Memcached` module, the `stats()` function returns information about all the servers currently configured in the connection object, and total statistics for all the `memcached` servers as a whole.

For example, the following Perl script obtains the stats and dumps the hash reference that is returned:

```perl
use Cache::Memcached;
use Data::Dumper;
my $memc = new Cache::Memcached;
$memc->set_servers(@ARGV);
print Dumper($memc->stats());
```

When executed on the same `memcached` as used in the `Telnet` example above we get a hash reference with the host by host and total statistics:

```
$VAR1 = {
   'hosts' => {
      'localhost:11211' => {
         'misc' => {
            'bytes' => '2421',
            'curr_connections' => '3',
            'connection_structures' => '56',
            'pointer_size' => '32',
            'time' => '1211440166',
            'total_items' => '410956',
            'cmd_set' => '588167',
            'bytes_written' => '35715151',
            'evictions' => '0',
            'curr_items' => '31',
            'pid' => '23599',
            'limit_maxbytes' => '67108864',
            'uptime' => '1254',
            'rusage_user' => '9.857805',
            'cmd_get' => '838451',
            'rusage_system' => '34.096988',
            'version' => '1.2.5',
            'get_hits' => '581511',
            'bytes_read' => '46665716',
            'threads' => '1',
            'total_connections' => '3104',
            'get_misses' => '256940'
         },
         'sizes' => {
            '128' => '16',
            '64' => '15'
         }
      }
   }
   'self' => {},
   'total' => {
      'cmd_get' => 838451,
      'bytes' => 2421,
      'get_hits' => 581511,
      'connection_structures' => 56,
      'bytes_read' => 46665716,
      'total_items' => 410956,
      'total_connections' => 3104,
   }
};
```
Getting `memcached` Statistics

The statistics are divided up into a number of distinct sections, and then can be requested by adding the type to the `stats` command. Each statistics output is covered in more detail in the following sections.

- General statistics, see Section 16.6.4.1, "memcached General Statistics".
- Slab statistics (`slabs`), see Section 16.6.4.2, "memcached Slabs Statistics".
- Item statistics (`items`), see Section 16.6.4.3, "memcached Item Statistics".
- Size statistics (`sizes`), see Section 16.6.4.4, "memcached Size Statistics".
- Detailed status (`detail`), see Section 16.6.4.5, "memcached Detail Statistics".

### 16.6.4.1 memcached General Statistics

The output of the general statistics provides an overview of the performance and use of the `memcached` instance. The statistics returned by the command and their meaning is shown in the following table.

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Data type</th>
<th>Description</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pid</code></td>
<td>32u</td>
<td>Process ID of the <code>memcached</code> instance.</td>
<td></td>
</tr>
<tr>
<td><code>uptime</code></td>
<td>32u</td>
<td>Uptime (in seconds) for this <code>memcached</code> instance.</td>
<td></td>
</tr>
<tr>
<td><code>time</code></td>
<td>32u</td>
<td>Current time (as epoch).</td>
<td></td>
</tr>
<tr>
<td><code>version</code></td>
<td>string</td>
<td>Version string of this instance.</td>
<td></td>
</tr>
<tr>
<td><code>pointer_size</code></td>
<td>string</td>
<td>Size of pointers for this host specified in bits (32 or 64).</td>
<td></td>
</tr>
<tr>
<td><code>rusage_user</code></td>
<td>32u:32u</td>
<td>Total user time for this instance (seconds:microseconds).</td>
<td></td>
</tr>
<tr>
<td><code>rusage_system</code></td>
<td>32u:32u</td>
<td>Total system time for this instance (seconds:microseconds).</td>
<td></td>
</tr>
<tr>
<td><code>curr_items</code></td>
<td>32u</td>
<td>Current number of items stored by this instance.</td>
<td></td>
</tr>
<tr>
<td><code>total_items</code></td>
<td>32u</td>
<td>Total number of items stored during the life of this instance.</td>
<td></td>
</tr>
<tr>
<td><code>bytes</code></td>
<td>64u</td>
<td>Current number of bytes used by this server to store items.</td>
<td></td>
</tr>
<tr>
<td><code>curr_connections</code></td>
<td>32u</td>
<td>Current number of open connections.</td>
<td></td>
</tr>
<tr>
<td><code>total_connections</code></td>
<td>32u</td>
<td>Total number of connections opened since the server started running.</td>
<td></td>
</tr>
<tr>
<td><code>connection_structures</code></td>
<td>32u</td>
<td>Number of connection structures allocated by the server.</td>
<td></td>
</tr>
</tbody>
</table>
## Getting memcached Statistics

<table>
<thead>
<tr>

<td>Number of items that have been compared and swapped and not found.</td>
<td>1.3.x</td>
</tr>
<tr>
<td>cas_badvalue</td>
<td>64u</td>
<td>Number of keys that have been compared and swapped, but the comparison (original) value did not match the supplied value.</td>
<td>1.3.x</td>
</tr>
<tr>
<td>evictions</td>
<td>64u</td>
<td>Number of valid items removed from cache to free memory for new items.</td>
<td></td>
</tr>
<tr>
<td>bytes_read</td>
<td>64u</td>
<td>Total number of bytes read by this server from network.</td>
<td></td>
</tr>
<tr>
<td>byte_written</td>
<td>64u</td>
<td>Total number of bytes sent by this server to network.</td>
<td></td>
</tr>
<tr>
<td>limit_maxbytes</td>
<td>32u</td>
<td>Number of bytes this server is permitted to use for storage.</td>
<td></td>
</tr>
<tr>
<td>threads</td>
<td>32u</td>
<td>Number of worker threads requested.</td>
<td></td>
</tr>
<tr>
<td>conn_yields</td>
<td>64u</td>
<td>Number of yields for connections (related to the -R option).</td>
<td>1.4.0</td>
</tr>
</tbody>
</table>

The most useful statistics from those given here are the number of cache hits, misses, and evictions.

A large number of `get_misses` may just be an indication that the cache is still being populated with information. The number should, over time, decrease in comparison to the number of cache `get_hits`. If, however, you have a large number of cache misses compared to cache hits after an extended period of execution, it may be an indication that the size of the cache is too small and you either need to increase the total memory size, or increase the number of the memcached instances to improve the hit ratio.

A large number of `evictions` from the cache, particularly in comparison to the number of items stored is a sign that your cache is too small to hold the amount of information that you regularly want to keep cached. Instead of items being retained in the cache, items are being evicted to make way for new items keeping the turnover of items in the cache high, reducing the efficiency of the cache.
### 16.6.4.2 memcached Slabs Statistics

To get the slabs statistics, use the `stats slabs` command, or the API equivalent.

The slab statistics provide you with information about the slabs that have created and allocated for storing information within the cache. You get information both on each individual slab-class and total statistics for the whole slab.

```
STAT 1:chunk_size 104
STAT 1:chunks_per_page 10082
STAT 1:total_pages 1
STAT 1:total_chunks 10082
STAT 1:used_chunks 10081
STAT 1:free_chunks 1
STAT 1:free_chunks_end 10079
STAT 9:chunk_size 696
STAT 9:chunks_per_page 1506
STAT 9:total_pages 63
STAT 9:total_chunks 94878
STAT 9:used_chunks 94878
STAT 9:free_chunks 0
STAT 9:free_chunks_end 0
STAT active_slabs 2
STAT total_malloced 67083616
END
```

Individual stats for each slab class are prefixed with the slab ID. A unique ID is given to each allocated slab from the smallest size up to the largest. The prefix number indicates the slab class number in relation to the calculated chunk from the specified growth factor. Hence in the example, 1 is the first chunk size and 9 is the 9th chunk allocated size.

The parameters returned for each chunk size and a description of each parameter are provided in the following table.

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>chunk_size</td>
<td>Space allocated to each chunk within this slab class.</td>
<td></td>
</tr>
<tr>
<td>chunks_per_page</td>
<td>Number of chunks within a single page for this slab class.</td>
<td></td>
</tr>
<tr>
<td>total_pages</td>
<td>Number of pages allocated to this slab class.</td>
<td></td>
</tr>
<tr>
<td>total_chunks</td>
<td>Number of chunks allocated to the slab class.</td>
<td></td>
</tr>
<tr>
<td>used_chunks</td>
<td>Number of chunks allocated to an item..</td>
<td></td>
</tr>
<tr>
<td>free_chunks</td>
<td>Number of chunks not yet allocated to items.</td>
<td></td>
</tr>
<tr>
<td>free_chunks_end</td>
<td>Number of free chunks at the end of the last allocated page.</td>
<td></td>
</tr>
<tr>
<td>get_hits</td>
<td>Number of get hits to this chunk</td>
<td>1.3.x</td>
</tr>
<tr>
<td>cmd_set</td>
<td>Number of set commands on this chunk</td>
<td>1.3.x</td>
</tr>
<tr>
<td>delete_hits</td>
<td>Number of delete hits to this chunk</td>
<td>1.3.x</td>
</tr>
<tr>
<td>incr_hits</td>
<td>Number of increment hits to this chunk</td>
<td>1.3.x</td>
</tr>
<tr>
<td>decr_hits</td>
<td>Number of decrement hits to this chunk</td>
<td>1.3.x</td>
</tr>
<tr>
<td>cas_hits</td>
<td>Number of CAS hits to this chunk</td>
<td>1.3.x</td>
</tr>
<tr>
<td>cas_badval</td>
<td>Number of CAS hits on this chunk where the existing value did not match</td>
<td>1.3.x</td>
</tr>
<tr>
<td>mem_requested</td>
<td>The true amount of memory of memory requested within this chunk</td>
<td>1.4.x</td>
</tr>
</tbody>
</table>
The following additional statistics cover the information for the entire server, rather than on a chunk by chunk basis:

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>active_slabs</td>
<td>Total number of slab classes allocated.</td>
<td></td>
</tr>
<tr>
<td>total_malloced</td>
<td>Total amount of memory allocated to slab pages.</td>
<td></td>
</tr>
</tbody>
</table>

The key values in the slab statistics are the chunk_size, and the corresponding total_chunks and used_chunks parameters. These given an indication of the size usage of the chunks within the system. Remember that one key/value pair is placed into a chunk of a suitable size.

From these stats, you can get an idea of your size and chunk allocation and distribution. If you store many items with a number of largely different sizes, consider adjusting the chunk size growth factor to increase in larger steps to prevent chunk and memory wastage. A good indication of a bad growth factor is a high number of different slab classes, but with relatively few chunks actually in use within each slab. Increasing the growth factor creates fewer slab classes and therefore makes better use of the allocated pages.

16.6.4.3 memcached Item Statistics

To get the items statistics, use the stats items command, or the API equivalent.

The items statistics give information about the individual items allocated within a given slab class.

```
STAT items:2:number 1
STAT items:2:age 452
STAT items:2:evicted 0
STAT items:2:evicted_nonzero 0
STAT items:2:evicted_time 2
STAT items:2:outofmemory 0
STAT items:2:tailrepairs 0
...
STAT items:27:number 1
STAT items:27:age 452
STAT items:27:evicted 0
STAT items:27:evicted_nonzero 0
STAT items:27:evicted_time 2
STAT items:27:outofmemory 0
STAT items:27:tailrepairs 0
```

The prefix number against each statistics relates to the corresponding chunk size, as returned by the stats slabs statistics. The result is a display of the number of items stored within each chunk within each slab size, and specific statistics about their age, eviction counts, and out of memory counts. A summary of the statistics is given in the following table.

<table>
<thead>
<tr>
<th>Statistic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>number</td>
<td>The number of items currently stored in this slab class.</td>
</tr>
<tr>
<td>age</td>
<td>The age of the oldest item within the slab class, in seconds.</td>
</tr>
<tr>
<td>evicted</td>
<td>The number of items evicted to make way for new entries.</td>
</tr>
<tr>
<td>evicted_time</td>
<td>The time of the last evicted entry</td>
</tr>
<tr>
<td>evicted_nonzero</td>
<td>The time of the last evicted non-zero entry</td>
</tr>
<tr>
<td>outofmemory</td>
<td>The number of items for this slab class that have triggered an out of memory error (only value when the -M command line option is in effect).</td>
</tr>
<tr>
<td>tailrepairs</td>
<td>Number of times the entries for a particular ID need repairing</td>
</tr>
</tbody>
</table>
Item level statistics can be used to determine how many items are stored within a given slab and their freshness and recycle rate. You can use this to help identify whether there are certain slab classes that are triggering a much larger number of evictions that others.

16.6.4.4 memcached Size Statistics

To get size statistics, use the `stats sizes` command, or the API equivalent.

The size statistics provide information about the sizes and number of items of each size within the cache. The information is returned as two columns, the first column is the size of the item (rounded up to the nearest 32 byte boundary), and the second column is the count of the number of items of that size within the cache:

<table>
<thead>
<tr>
<th>Size</th>
<th>Count</th>
</tr>
</thead>
<tbody>
<tr>
<td>96</td>
<td>35</td>
</tr>
<tr>
<td>128</td>
<td>38</td>
</tr>
<tr>
<td>160</td>
<td>807</td>
</tr>
<tr>
<td>192</td>
<td>804</td>
</tr>
<tr>
<td>224</td>
<td>410</td>
</tr>
<tr>
<td>256</td>
<td>222</td>
</tr>
<tr>
<td>288</td>
<td>83</td>
</tr>
<tr>
<td>320</td>
<td>39</td>
</tr>
<tr>
<td>352</td>
<td>53</td>
</tr>
<tr>
<td>384</td>
<td>33</td>
</tr>
<tr>
<td>416</td>
<td>64</td>
</tr>
<tr>
<td>448</td>
<td>51</td>
</tr>
<tr>
<td>480</td>
<td>30</td>
</tr>
<tr>
<td>512</td>
<td>54</td>
</tr>
<tr>
<td>544</td>
<td>39</td>
</tr>
<tr>
<td>576</td>
<td>10065</td>
</tr>
</tbody>
</table>

Caution
Running this statistic locks up your cache as each item is read from the cache and its size calculated. On a large cache, this may take some time and prevent any set or get operations until the process completes.

The item size statistics are useful only to determine the sizes of the objects you are storing. Since the actual memory allocation is relevant only in terms of the chunk size and page size, the information is only useful during a careful debugging or diagnostic session.

16.6.4.5 memcached Detail Statistics

For memcached 1.3.x and higher, you can enable and obtain detailed statistics about the get, set, and del operations on the individual keys stored in the cache, and determine whether the attempts hit (found) a particular key. These operations are only recorded while the detailed stats analysis is turned on.

To enable detailed statistics, you must send the `stats detail on` command to the memcached server:

```bash
$ telnet localhost 11211
Trying 127.0.0.1...
Connected to tiger.
Escape character is '^]'.
stats detail on
OK
```

Individual statistics are recorded for every `get`, `set` and `del` operation on a key, including keys that are not currently stored in the server. For example, if an attempt is made to obtain the value of key `abckey` and it does not exist, the `get` operating on the specified key are recorded while detailed statistics are in
Getting memcached Statistics

effect, even if the key is not currently stored. The **hits**, that is, the number of **get** or **del** operations for a key that exists in the server are also counted.

To turn detailed statistics off, send the **stats detail off** command to the **memcached** server:

```
$ telnet localhost 11211
Trying 127.0.0.1...
Connected to tiger.
Escape character is '^]'.
stats detail on
OK
```

To obtain the detailed statistics recorded during the process, send the **stats detail dump** command to the **memcached** server:

```
stats detail dump
PREFIX hykkey get 0 hit 0 set 1 del 0
PREFIX xyzkey get 0 hit 0 set 1 del 0
PREFIX yukkey get 1 hit 0 set 0 del 0
PREFIX abckey get 3 hit 3 set 1 del 0
END
```

You can use the detailed statistics information to determine whether your **memcached** clients are using a large number of keys that do not exist in the server by comparing the **hit** and **get** or **del** counts. Because the information is recorded by key, you can also determine whether the failures or operations are clustered around specific keys.

16.6.4.6 Using **memcached-tool**

The **memcached-tool**, located within the **scripts** directory within the **memcached** source directory. The tool provides convenient access to some reports and statistics from any **memcached** instance.

The basic format of the command is:

```
shell> ./memcached-tool hostname:port [command]
```

The default output produces a list of the slab allocations and usage. For example:

```
shell> memcached-tool localhost:11211 display
 # Item_Size Max_age Pages Count Full? Evicted Evict_Time OOM
   1      80B   93s   1   20   no   0      0      0
   2     104B   93s   1   16   no   0      0      0
   3     136B  1335s  1   28   no   0      0      0
   4     176B  1335s  1   24   no   0      0      0
   5     224B  1335s  1   32   no   0      0      0
   6     280B  1335s  1   34   no   0      0      0
   7     352B  1335s  1   36   no   0      0      0
   8     440B  1335s  1   46   no   0      0      0
   9     552B  1335s  1   58   no   0      0      0
  10     696B  1335s  1   66   no   0      0      0
  11     872B  1335s  1   89   no   0      0      0
  12     1.1K  1335s  1  112   no   0      0      0
  13     1.3K  1335s  1  145   no   0      0      0
  14     1.7K  1335s  1  123   no   0      0      0
  15     2.1K  1335s  1  198   no   0      0      0
  16     2.6K  1335s  1  199   no   0      0      0
  17     3.3K  1335s  1  229   no   0      0      0
  18     4.1K  1335s  1  248   yes  36     2      0
  19     5.2K  1335s  2  328   no   0      0      0
  20     6.4K  1335s  2  316   yes  387    1      0
```
Getting `memcached` Statistics

<table>
<thead>
<tr>
<th></th>
<th>Item Size</th>
<th>Max_age</th>
<th>Pages</th>
<th>Count</th>
<th>Full?</th>
<th>Evicted</th>
<th>Evict_Time</th>
<th>OOM</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>80B</td>
<td>93s</td>
<td>1</td>
<td>20</td>
<td>no</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>104B</td>
<td>93s</td>
<td>1</td>
<td>16</td>
<td>no</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

This output is the same if you specify the command as `display`:

```
shell> memcached-tool localhost:11211 display
```

The output shows a summarized version of the output from the `slabs` statistics. The columns provided in the output are shown below:

- **#:** The slab number
- **Item_Size:** The size of the slab
- **Max_age:** The age of the oldest item in the slab
- **Pages:** The number of pages allocated to the slab
- **Count:** The number of items in this slab
- **Full?:** Whether the slab is fully populated
- **Evicted:** The number of objects evicted from this slab
- **Evict_Time:** The time (in seconds) since the last eviction
- **OOM:** The number of items that have triggered an out of memory error

You can also obtain a dump of the general statistics for the server using the `stats` command:

```
shell> memcached-tool localhost:11211 stats
```

16.6.5 memcached FAQ

Questions

• 17.6.5.1: [1912] Can memcached be run on a Windows environment?

• 17.6.5.2: [1912] What is the maximum size of an object you can store in memcached? Is that configurable?

• 17.6.5.3: [1912] Is it true memcached will be much more effective with db-read-intensive applications than with db-write-intensive applications?

• 17.6.5.4: [1912] Is there any overhead in not using persistent connections? If persistent is always recommended, what are the downsides (for example, locking up)?

• 17.6.5.5: [1912] How is an event such as a crash of one of the memcached servers handled by the memcached client?

• 17.6.5.6: [1912] What is a recommended hardware configuration for a memcached server?

• 17.6.5.7: [1913] Is memcached more effective for video and audio as opposed to textual read/writes?

• 17.6.5.8: [1913] Can memcached work with ASPX?

• 17.6.5.9: [1913] How expensive is it to establish a memcache connection? Should those connections be pooled?

• 17.6.5.10: [1913] How is the data handled when the memcached server is down?

• 17.6.5.11: [1913] How are auto-increment columns in the MySQL database coordinated across multiple instances of memcached?

• 17.6.5.12: [1913] Is compression available?

• 17.6.5.13: [1914] Can we implement different types of memcached as different nodes in the same server, so can there be deterministic and non-deterministic in the same server?

• 17.6.5.14: [1914] What are best practices for testing an implementation, to ensure that it improves performance, and to measure the impact of memcached configuration changes? And would you recommend keeping the configuration very simple to start?
Questions and Answers

17.6.5.1: Can memcached be run on a Windows environment?

No. Currently memcached is available only on the Unix/Linux platform. There is an unofficial port available, see http://www.codeplex.com/memcachedproviders.

17.6.5.2: What is the maximum size of an object you can store in memcached? Is that configurable?

The default maximum object size is 1MB. In memcached 1.4.2 and later, you can change the maximum size of an object using the \(-I\) command line option.

For versions before this, to increase this size, you have to re-compile memcached. You can modify the value of the POWER_BLOCK within the slabs.c file within the source.

In memcached 1.4.2 and higher, you can configure the maximum supported object size by using the \(-I\) command-line option. For example, to increase the maximum object size to 5MB:

```
$ memcached -I 5m
```

If an object is larger than the maximum object size, you must manually split it. memcached is very simple: you give it a key and some data, it tries to cache it in RAM. If you try to store more than the default maximum size, the value is just truncated for speed reasons.

17.6.5.3: Is it true memcached will be much more effective with db-read-intensive applications than with db-write-intensive applications?

Yes. memcached plays no role in database writes, it is a method of caching data already read from the database in RAM.

17.6.5.4: Is there any overhead in not using persistent connections? If persistent is always recommended, what are the downsides (for example, locking up)?

If you don't use persistent connections when communicating with memcached, there will be a small increase in the latency of opening the connection each time. The effect is comparable to use nonpersistent connections with MySQL.

In general, the chance of locking or other issues with persistent connections is minimal, because there is very little locking within memcached. If there is a problem, eventually your request will time out and return no result, so your application will need to load from MySQL again.

17.6.5.5: How is an event such as a crash of one of the memcached servers handled by the memcached client?

There is no automatic handling of this. If your client fails to get a response from a server, code a fallback mechanism to load the data from the MySQL database.

The client APIs all provide the ability to add and remove memcached instances on the fly. If within your application you notice that memcached server is no longer responding, you can remove the server from the list of servers, and keys will automatically be redistributed to another memcached server in the list. If retaining the cache content on all your servers is important, make sure you use an API that supports a consistent hashing algorithm. For more information, see Section 16.6.2.4, “memcached Hashing/Distribution Types”.

17.6.5.6: What is a recommended hardware configuration for a memcached server?
**memcached FAQ**

**memcached** has a very low processing overhead. All that is required is spare physical RAM capacity. A **memcached** server does not require a dedicated machine. If you have web, application, or database servers that have spare RAM capacity, then use them with **memcached**.

To build and deploy a dedicated **memcached** server, use a relatively low-power CPU, lots of RAM, and one or more Gigabit Ethernet interfaces.

**17.6.5.7: Is **memcached** more effective for video and audio as opposed to textual read/writes?**

**memcached** works equally well for all kinds of data. To **memcached**, any value you store is just a stream of data. Remember, though, that the maximum size of an object you can store in **memcached** is 1MB, but can be configured to be larger by using the **-I** option in **memcached** 1.4.2 and later, or by modifying the source in versions before 1.4.2. If you plan on using **memcached** with audio and video content, you will probably want to increase the maximum object size. Also remember that **memcached** is a solution for caching information for reading. It shouldn't be used for writes, except when updating the information in the cache.

**17.6.5.8: Can **memcached** work with ASPX?**

There are ports and interfaces for many languages and environments. ASPX relies on an underlying language such as C# or VisualBasic, and if you are using ASP.NET then there is a C# **memcached** library. For more information, see https://sourceforge.net/projects/memcacheddotnet/.

**17.6.5.9: How expensive is it to establish a memcache connection? Should those connections be pooled?**

Opening the connection is relatively inexpensive, because there is no security, authentication or other handshake taking place before you can start sending requests and getting results. Most APIs support a persistent connection to a **memcached** instance to reduce the latency. Connection pooling would depend on the API you are using, but if you are communicating directly over TCP/IP, then connection pooling would provide some small performance benefit.

**17.6.5.10: How is the data handled when the **memcached** server is down?**

The behavior is entirely application dependent. Most applications fall back to loading the data from the database (just as if they were updating the **memcached** information). If you are using multiple **memcached** servers, you might also remove a downed server from the list to prevent it from affecting performance. Otherwise, the client will still attempt to communicate with the **memcached** server that corresponds to the key you are trying to load.

**17.6.5.11: How are auto-increment columns in the MySQL database coordinated across multiple instances of **memcached**?**

They aren't. There is no relationship between MySQL and **memcached** unless your application (or, if you are using the MySQL UDFs for **memcached**, your database definition) creates one.

If you are storing information based on an auto-increment key into multiple instances of **memcached**, the information is only stored on one of the **memcached** instances anyway. The client uses the key value to determine which **memcached** instance to store the information. It doesn't store the same information across all the instances, as that would be a waste of cache memory.

**17.6.5.12: Is compression available?**

Yes. Most of the client APIs support some sort of compression, and some even allow you to specify the threshold at which a value is deemed appropriate for compression during storage.
17.6.5.13: Can we implement different types of memcached as different nodes in the same server, so can there be deterministic and non-deterministic in the same server?

Yes. You can run multiple instances of memcached on a single server, and in your client configuration you choose the list of servers you want to use.

17.6.5.14: What are best practices for testing an implementation, to ensure that it improves performance, and to measure the impact of memcached configuration changes? And would you recommend keeping the configuration very simple to start?

The best way to test the performance is to start up a memcached instance. First, modify your application so that it stores the data just before the data is about to be used or displayed into memcached. Since the APIs handle the serialization of the data, it should just be a one-line modification to your code. Then, modify the start of the process that would normally load that information from MySQL with the code that requests the data from memcached. If the data cannot be loaded from memcached, default to the MySQL process.

All of the changes required will probably amount to just a few lines of code. To get the best benefit, make sure you cache entire objects (for example, all the components of a web page, blog post, discussion thread, and so on), rather than using memcached as a simple cache of individual rows of MySQL tables.

Keeping the configuration simple at the start, or even over the long term, is easy with memcached. Once you have the basic structure up and running, often the only ongoing change is to add more servers into the list of servers used by your applications. You don’t need to manage the memcached servers, and there is no complex configuration; just add more servers to the list and let the client API and the memcached servers make the decisions.

16.7 MySQL Proxy

The MySQL Proxy is an application that communicates over the network using the MySQL network protocol and provides communication between one or more MySQL servers and one or more MySQL clients. Because MySQL Proxy uses the MySQL network protocol, it can be used without modification with any MySQL-compatible client that uses the protocol. This includes the mysql command-line client, any clients that uses the MySQL client libraries, and any connector that supports the MySQL network protocol.

In the most basic configuration, MySQL Proxy simply interposes itself between the server and clients, passing queries from the clients to the MySQL Server and returning the responses from the MySQL Server to the appropriate client. In more advanced configurations, the MySQL Proxy can also monitor and alter the communication between the client and the server. Query interception enables you to add profiling, and interception of the exchanges is scriptable using the Lua scripting language.

By intercepting the queries from the client, the proxy can insert additional queries into the list of queries sent to the server, and remove the additional results when they are returned by the server. Using this functionality you can return the results from the original query to the client while adding informational statements to each query, for example, to monitor their execution time or progress, and separately log the results.

The proxy enables you to perform additional monitoring, filtering, or manipulation of queries without requiring you to make any modifications to the client and without the client even being aware that it is communicating with anything but a genuine MySQL server.

This documentation covers MySQL Proxy 0.8.2. And MySQL Proxy contains third-party code. For license information on third-party code, see Appendix E, Licenses for Third-Party Components.

Warning

MySQL Proxy is currently an Alpha release and should not be used within production environments.
16.7.1 MySQL Proxy Supported Platforms

MySQL Proxy is currently available as a precompiled binary for the following platforms:

- Linux (including Red Hat, Fedora, Debian, SuSE) and derivatives
- Mac OS X
- FreeBSD
- IBM AIX
- Sun Solaris

**Note**

You must have the .NET Framework 1.1 or higher installed.

Other Unix/Linux platforms not listed should be compatible by using the source package and building MySQL Proxy locally.

System requirements for the MySQL Proxy application are the same as the main MySQL server. Currently MySQL Proxy is compatible only with MySQL 5.0.1 and later. MySQL Proxy is provided as a standalone, statically linked binary. You need not have MySQL or Lua installed.

16.7.2 Installing MySQL Proxy

You have three choices for installing MySQL Proxy:

- Precompiled binaries are available for a number of different platforms. See Section 16.7.2.1, “Installing MySQL Proxy from a Binary Distribution”.
- You can install from the source code to build on an environment not supported by the binary distributions. See Section 16.7.2.2, “Installing MySQL Proxy from a Source Distribution”.
- The latest version of the MySQL Proxy source code is available through a development repository is the best way to stay up to date with the latest fixes and revisions. See Section 16.7.2.3, “Installing MySQL Proxy from the Bazaar Repository”.

16.7.2.1 Installing MySQL Proxy from a Binary Distribution

If you download a binary package, you must extract and copy the package contents to your desired installation directory. The package contains files required by MySQL Proxy, including additional Lua scripts and other components required for execution.

To install, unpack the archive into the desired directory, then modify your PATH environment variable so that you can use the mysql-proxy command directly:
Installing MySQL Proxy

shell> cd /usr/local
shell> tar zxf mysql-proxy-0.8.2-platform.tar.gz
shell> PATH=$PATH:/usr/local/mysql-proxy-0.8.2-platform/sbin

To update the path globally on a system, you might need administrator privileges to modify the appropriate /etc/profile, /etc/bashrc, or other system configuration file.

On Windows, you can update the PATH environment variable using this procedure:

1. On the Windows desktop, right-click the My Computer icon, and select Properties.
2. Next select the Advanced tab from the System Properties menu that appears, and click the Environment Variables button.
3. Under System Variables, select Path, then click the Edit button. The Edit System Variable dialogue should appear.

The Microsoft Visual C++ runtime libraries are a requirement for running MySQL Proxy as of version 0.8.2. Users that do not have these libraries must download and install the Microsoft Visual C++ 2008 Service Pack 1 Redistributable Package MFC Security Update. Use the following link to obtain the package:

16.7.2.2 Installing MySQL Proxy from a Source Distribution

You can download a source package and compile the MySQL Proxy yourself. To build from source, you must have the following prerequisite components installed:

- **libevent** 1.x or higher (1.3b or later is preferred).
- **lua** 5.1.x or higher.
- **glib2** 2.6.0 or higher.
- **pkg-config**.
- **libtool** 1.5 or higher.
- MySQL 5.0.x or higher developer files.

**Note**

On some operating systems, you might need to manually build the required components to get the latest version. If you have trouble compiling MySQL Proxy, consider using a binary distributions instead.

After verifying that the prerequisite components are installed, configure and build MySQL Proxy:

shell> tar zxf mysql-proxy-0.8.2.tar.gz
shell> cd mysql-proxy-0.8.2
shell> ./configure
shell> make

To test the build, use the **check** target to **make**:
Installing MySQL Proxy

```
shell> make check
```

The tests try to connect to localhost using the root user. To provide a password, set the `MYSQL_PASSWORD` environment variable:

```
shell> MYSQL_PASSWORD=root_pwd make check
```

You can install using the install target:

```
shell> make install
```

By default, mysql-proxy is installed into `/usr/local/sbin/mysql-proxy`. The Lua example scripts are installed into `/usr/local/share`.

### 16.7.2.3 Installing MySQL Proxy from the Bazaar Repository

The MySQL Proxy source is available through a public Bazaar repository and is the quickest way to get the latest releases and fixes.

A build from the Bazaar repository requires that the following prerequisite components be installed:

- Bazaar 1.10.0 or later.
- `libtool` 1.5 or higher.
- `autoconf` 2.56 or higher.
- `automake` 1.10 or higher.
- `libevent` 1.x or higher (1.3b or later is preferred).
- `lua` 5.1.x or higher.
- `glib2` 2.4.0 or higher.
- `pkg-config`.
- MySQL 5.0.x or higher developer files.

The `mysql-proxy` source is hosted on Launchpad. To check out a local copy of the Bazaar repository, use `bzr`:

```
shell> bzr branch lp:mysql-proxy
```

The preceding command downloads a complete version of the Bazaar repository for `mysql-proxy`. The main source files are located within the `trunk` subdirectory. The configuration scripts must be generated before you can configure and build `mysql-proxy`. The `autogen.sh` script generates the required configuration scripts for you:

```
shell> sh ./autogen.sh
```

The `autogen.sh` script creates the standard `configure` script, which you then use to configure and build with `make`:
To create a standalone source distribution, identical to the source distribution available for download, use this command:

```
shell> make distcheck
```

The preceding command creates the file `mysql-proxy-0.8.2.tar.gz` (with the corresponding current version) within the current directory.

### 16.7.2.4 Setting Up MySQL Proxy as a Windows Service

The MySQL distribution on Windows includes the `mysql-proxy-svc.exe` command that enables a MySQL Proxy instance to be managed by the Windows service control manager. You can control the service, including automatically starting and stopping it during boot, reboot and shutdown, without separately running the MySQL Proxy application.

To set up a MySQL Proxy service, use the `sc` command to create a new service using the MySQL Proxy service command. Specify the MySQL Proxy options on the `sc` command line, and identify the service with a unique name. For example, to configure a new MySQL Proxy instance that will automatically start when your system boots, redirecting queries to the local MySQL server:

```
C:\> sc create "Proxy" DisplayName= "MySQL Proxy" start= "auto" »
     binPath= "C:\Program Files\MySQL\mysql-proxy-0.8.2\bin\mysql-proxy-svc.exe »
        --proxy-backend-addresses=127.0.0.1:3306"
```

**Note**
The space following the equal sign after each property is required; failure to include it results in an error.

The preceding command creates a new service called `Proxy`. You can start and stop the service using the `net start|stop` command with the service name. The service is not automatically started after it is created. To start the service:

```
C:\> net start proxy
The MySQL Proxy service is starting.
The MySQL Proxy service was started successfully.
```

You can specify additional command-line options to the `sc` command. You can also set up multiple MySQL Proxy services on the same machine (provided they are configured to listen on different ports and/or IP addresses.

You can delete a service that you have created:

```
C:\> sc delete proxy
```

For more information on creating services using `sc`, see How to create a Windows service by using `Sc.exe`.

### 16.7.3 MySQL Proxy Command Options

To start MySQL Proxy, you can run it directly from the command line:
For most situations, you specify at least the host name or address and the port number of the backend MySQL server to which the MySQL Proxy should pass queries.

You can specify options to `mysql-proxy` either on the command line, or by using a configuration file and the `--defaults-file` command-line option to specify the file location.

If you use a configuration file, format it as follows:

- Specify the options within a `[mysql-proxy]` configuration group. For example:

```
[mysql-proxy]
admin-address = host:port
```

- Specify all configuration options in the form of a configuration name and the value to set.

- For options that are a simple toggle on the command line (for example, `--proxy-skip-profiling`), use `true` or `false`. For example, the following is invalid:

```
[mysql-proxy]
proxy-skip-profiling
```

But this is valid:

```
[mysql-proxy]
proxy-skip-profiling = true
```

- Give the configuration file Unix permissions of `0660` (readable and writable by user and group, no access for others).

Failure to adhere to any of these requirements causes `mysql-proxy` to generate an error during startup.

The following tables list the supported configuration file and command-line options.

**Table 16.4 `mysql-proxy` Help Options**

<table>
<thead>
<tr>
<th>Format</th>
<th>Option File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--help</code></td>

<tr>
<td>--plugins=plugin,...</td>
<td>plugins=plugin,...</td>
<td>List of plugins to load</td>
</tr>
<tr>
<td>--user=user_name</td>
<td>user=user_name</td>
<td>The user to use when running mysql-proxy</td>
</tr>
<tr>
<td>--version</td>
<td></td>
<td>Show version information</td>
</tr>
</tbody>
</table>

Except as noted in the following details, all of the options can be used within the configuration file by supplying the option and the corresponding value. For example:

```
[mysql-proxy]
log-file = /var/log/mysql-proxy.log
log-level = message
```

- 
  **--help, -h**

  Command-Line Format
  
<table>
<thead>
<tr>
<th>Command-Line Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>--help</td>
</tr>
<tr>
<td>-h</td>
</tr>
</tbody>
</table>

  Show available help options.

- 
  **--help-admin**

  Command-Line Format
  
<table>
<thead>
<tr>
<th>Command-Line Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>--help-admin</td>
</tr>
</tbody>
</table>

  Show options for the admin module.

- 
  **--help-all**

  Command-Line Format
  
<table>
<thead>
<tr>
<th>Command-Line Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>--help-all</td>
</tr>
</tbody>
</table>

  Show all help options.

- 
  **--help-proxy**

  Command-Line Format
  
<table>
<thead>
<tr>
<th>Command-Line Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>--help-proxy</td>
</tr>
</tbody>
</table>

  Show options for the proxy module.

- 
  **--admin-address=host:port**

  Command-Line Format
  
<table>
<thead>
<tr>
<th>Command-Line Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>--admin-address=host:port</td>
</tr>
</tbody>
</table>

  Option-File Format
  
<table>

MySQL Proxy Command Options

<table>
<thead>
<tr>
<th>Option-File Format</th>
<th>admin-lua-script=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>file_name</td>
</tr>
<tr>
<td>Default</td>
<td></td>
</tr>
</tbody>
</table>

The script to use for the proxy administration module.

- **--admin-password=password**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--admin-password=password</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>admin-password=password</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>root</td>
</tr>
</tbody>
</table>

The password to use to authenticate users wanting to connect to the MySQL Proxy administration module. This module uses the MySQL protocol to request a user name and password for connections.

- **--admin-username=user_name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--admin-username=user_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>admin-username=user_name</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>root</td>
</tr>
</tbody>
</table>

The user name to use to authenticate users wanting to connect to the MySQL Proxy administration module. This module uses the MySQL protocol to request a user name and password for connections. The default user name is root.

- **--basedir=dir_name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--basedir=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>basedir=dir_name</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>directory name</td>
</tr>
</tbody>
</table>

The base directory to use as a prefix for all other file name configuration options. The base name should be an absolute (not relative) directory. If you specify a relative directory, mysql-proxy generates an error during startup.

- **--daemon**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--daemon</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>daemon</td>
</tr>
</tbody>
</table>

Starts the proxy in daemon mode.

- **--defaults-file=file_name**
### MySQL Proxy Command Options

**Command-Line Format**

```markdown
--defaults-file=file_name
```

The file to read for configuration options. If not specified, MySQL Proxy takes options only from the command line.

- **--event-threads=count**

```markdown
Command-Line Format  --event-threads=count
Option-File Format    event-threads=count
```

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
</tr>
<tr>
<td><strong>Default</strong></td>
</tr>
</tbody>
</table>

The number of event threads to reserve to handle incoming requests.

- **--keepalive**

```markdown
Command-Line Format  --keepalive
Option-File Format    keepalive
```

Create a process surrounding the main `mysql-proxy` process that attempts to restart the main `mysql-proxy` process in the event of a crash or other failure.

**Note**

The `--keepalive` option is not available on Microsoft Windows. When running as a service, `mysql-proxy` automatically restarts.

- **--log-backtrace-on-crash**

```markdown
Command-Line Format  --log-backtrace-on-crash
Option-File Format    log-backtrace-on-crash
```

Log a backtrace to the error log and try to initialize the debugger in the event of a failure.

- **--log-file=file_name**

```markdown
Command-Line Format  --log-file=file_name
Option-File Format    log-file=file_name
```

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
</tr>
</tbody>
</table>

The file to use to record log information. If this option is not given, `mysql-proxy` logs to the standard error output.

- **--log-level=level**

```markdown
Command-Line Format  --log-level=level
Option-File Format    log-level=level
```

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
</tr>
</tbody>
</table>

The level of log output to use.
The log level to use when outputting error messages. Messages with that level (or lower) are output. For example, `message` level also outputs message with `info`, `warning`, and `error` levels.

- **--log-use-syslog**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--log-use-syslog</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>log-use-syslog</td>
</tr>
</tbody>
</table>

Log errors to the syslog (Unix/Linux only).

- **--lua-cpath=dir_name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--lua-cpath=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>lua-cpath=dir_name</td>
</tr>
</tbody>
</table>

The `LUA_CPATH` to use when loading compiled modules or libraries for Lua scripts.

- **--lua-path=dir_name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--lua-path=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>lua-path=dir_name</td>
</tr>
</tbody>
</table>

The `LUA_CPATH` to use when loading modules for Lua.

- **--max-open-files=count**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max-open-files=count</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>max-open-files=count</td>
</tr>
</tbody>
</table>

The maximum number of open files and sockets supported by the `mysql-proxy` process. Certain scripts might require a higher value.

- **--no-proxy**
MySQL Proxy Command Options

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--no-proxy</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>no-proxy</td>
</tr>
</tbody>
</table>

Disable the proxy module.

• **--plugin-dir=dir_name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--plugin-dir=dir_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>plugin-dir=dir_name</td>
</tr>
</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>directory name</td>
</tr>
</tbody>
</table>

The directory to use when loading plugins for `mysql-proxy`.

• **--plugins=plugin**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--plugins=plugin,...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>plugins=plugin,...</td>
</tr>
</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td></td>
</tr>
</tbody>
</table>

Loads a plugin.

When using this option on the command line, you can specify the option multiple times to specify multiple plugins. For example:

```
shell> mysql-proxy --plugins=proxy --plugins=admin
```

When using the option within the configuration file, you should separate multiple plugins by commas. The equivalent of the preceding example would be:

```
... plugins=proxy,admin
```

• **--proxy-address=host:port, P host:port**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--proxy-address=host:port</th>
</tr>
</thead>
<tbody>
<tr>
<td>-P host:port</td>
<td></td>
</tr>
<tr>
<td>Option-File Format</td>
<td>proxy-address=host:port</td>
</tr>
</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td></td>
</tr>
<tr>
<td>Default</td>
<td>:4040</td>
</tr>
</tbody>
</table>

The listening host name (or IP address) and port of the proxy server. The default is **:4040** (all IPs on port 4040).

• **--proxy-read-only-backend-addresses=host:port, r host:port**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--proxy-read-only-backend-addresses=host:port</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### MySQL Proxy Command Options

#### -r host:port

**Option-File Format**

| proxy-read-only-backend-addresses=host:port |

**Permitted Values**

| Type | string |

The listening host name (or IP address) and port of the proxy server for read-only connections. The default is for this information not to be set.

**Note**

Setting this value only configures the servers within the corresponding internal structure (see `proxy.global.backends [1933]`). You can determine the backend type by checking the `type` field for each connection.

You should therefore only use this option in combination with a script designed to make use of the different backend types.

When using this option on the command line, you can specify the option and the server multiple times to specify multiple backends. For example:

```shell
shell> mysql-proxy --proxy-read-only-backend-addresses=192.168.0.1:3306 --proxy-read-only-backend-addresses=192.168.0.2:3306
```

When using the option within the configuration file, you should separate multiple servers by commas. The equivalent of the preceding example would be:

```shell
... proxy-read-only-backend-addresses = 192.168.0.1:3306,192.168.0.2:3306
```

#### --proxy-backend-addresses=host:port

**Command-Line Format**

| --proxy-backend-addresses=host:port |

| -b host:port |

**Option-File Format**

| proxy-backend-addresses=host:port |

**Permitted Values**

| Type | string |

The host name (or IP address) and port of the MySQL server to connect to. You can specify multiple backend servers by supplying multiple options. Clients are connected to each backend server in round-robin fashion. For example, if you specify two servers A and B, the first client connection will go to server A; the second client connection to server B and the third client connection to server A.

When using this option on the command line, you can specify the option and the server multiple times to specify multiple backends. For example:

```shell
shell> mysql-proxy --proxy-backend-addresses 192.168.0.1:3306 --proxy-backend-addresses 192.168.0.2:3306
```

When using the option within the configuration file, you should separate multiple servers by commas. The equivalent of the preceding example would be:
MySQL Proxy Command Options

- **--proxy-backend-addresses**

  proxy-backend-addresses = 192.168.0.1:3306,192.168.0.2:3306

- **--proxy-pool-no-change-user**

  **Command-Line Format**  
  --proxy-pool-no-change-user

  **Option-File Format**  
  proxy-pool-no-change-user

  Disable use of the MySQL protocol CHANGE_USER command when reusing a connection from the pool of connections specified by the proxy-backend-addresses list.

- **--proxy-skip-profiling**

  **Command-Line Format**  
  --proxy-skip-profiling

  **Option-File Format**  
  proxy-skip-profiling

  Disable query profiling (statistics time tracking). The default is for tracking to be enabled.

- **--proxy-fix-bug-25371**

  **Removed**  
  0.8.1

  **Command-Line Format**  
  --proxy-fix-bug-25371

  **Option-File Format**  
  proxy-fix-bug-25371

  Enable a workaround for an issue when connecting to a MySQL server later than 5.1.12 when using a MySQL client library of any earlier version.

  This option was removed in mysql-proxy 0.8.1. Now, mysql-proxy returns an error message at the protocol level if it sees a COM_CHANGE_USER being sent to a server that has a version from 5.1.14 to 5.1.17.

- **--proxy-lua-script=file_name, -s file_name**

  **Command-Line Format**  
  --proxy-lua-script=file_name  
  -s file_name

  **Option-File Format**  
  proxy-lua-script=file_name

  **Permitted Values**

  **Type**  
  file name

  The Lua script file to be loaded. Note that the script file is not physically loaded and parsed until a connection is made. Also note that the specified Lua script is reloaded for each connection; if the content of the Lua script changes while mysql-proxy is running, the updated content is automatically used when a new connection is made.

- **--pid-file=file_name**

  **Command-Line Format**  
  --pid-file=file_name

  **Option-File Format**  
  pid-file=file_name

  **Permitted Values**

  **Type**  
  file name
The name of the file in which to store the process ID.

- **--user=user_name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--user=user_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>user=user_name</td>
</tr>
</tbody>
</table>

**Permitted Values**

- **Type**: string

Run `mysql-proxy` as the specified user.

- **--version, -V**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--version</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-V</td>
</tr>
</tbody>
</table>

Show the version number.

The most common usage is as a simple proxy service (that is, without additional scripting). For basic proxy operation, you must specify at least one `proxy-backend-addresses` option to specify the MySQL server to connect to by default:

```
shell> mysql-proxy --proxy-backend-addresses=MySQL.example.com:3306
```

The default proxy port is **4040**, so you can connect to your MySQL server through the proxy by specifying the host name and port details:

```
shell> mysql --host=localhost --port=4040
```

If your server requires authentication information, this will be passed through natively without alteration by `mysql-proxy`, so you must also specify the required authentication information:

```
shell> mysql --host=localhost --port=4040 --user=user_name --password=password
```

You can also connect to a read-only port (which filters out UPDATE and INSERT queries) by connecting to the read-only port. By default the host name is the default, and the port is **4042**, but you can alter the host/port information by using the `--proxy-read-only-backend-addresses` command-line option.

For more detailed information on how to use these command-line options, and `mysql-proxy` in general in combination with Lua scripts, see Section 16.7.5, "Using MySQL Proxy".

### 16.7.4 MySQL Proxy Scripting

You can control how MySQL Proxy manipulates and works with the queries and results that are passed on to the MySQL server through the use of the embedded Lua scripting language. You can find out more about the Lua programming language from the Lua Web site.

The following diagram shows an overview of the classes exposed by MySQL Proxy.
The primary interaction between MySQL Proxy and the server is provided by defining one or more functions through an Lua script. A number of functions are supported, according to different events and operations in the communication sequence between a client and one or more backend MySQL servers:

- **connect_server()**: This function is called each time a connection is made to MySQL Proxy from a client. You can use this function during load-balancing to intercept the original connection and decide which server the client should ultimately be attached to. If you do not define a special solution, a simple round-robin style distribution is used by default.

- **read_handshake()**: This function is called when the initial handshake information is returned by the server. You can capture the handshake information returned and provide additional checks before the authorization exchange takes place.

- **read_auth()**: This function is called when the authorization packet (user name, password, default database) are submitted by the client to the server for authentication.

- **read_auth_result()**: This function is called when the server returns an authorization packet to the client indicating whether the authorization succeeded.

- **read_query()**: This function is called each time a query is sent by the client to the server. You can use this to edit and manipulate the original query, including adding new queries before and after the original statement. You can also use this function to return information directly to the client, bypassing the server, which can be useful to filter unwanted queries or queries that exceed known limits.

- **read_query_result()**: This function is called each time a result is returned from the server, providing you have manually injected queries into the query queue. If you have not explicitly injected queries within the **read_query()** function, this function is not triggered. You can use this to edit the result set, or to remove or filter the result sets generated from additional queries you injected into the queue when using **read_query()**.

The following table lists MySQL proxy and server communication functions, the supplied information, and the direction of information flow when the function is triggered.

<table>
<thead>
<tr>
<th>Function</th>
<th>Supplied Information</th>
<th>Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>connect_server()</td>
<td>None</td>
<td>Client to Server</td>
</tr>
<tr>
<td>read_handshake()</td>
<td>None</td>
<td>Server to Client</td>
</tr>
<tr>
<td>read_auth()</td>
<td>None</td>
<td>Client to Server</td>
</tr>
<tr>
<td>read_auth_result()</td>
<td>None</td>
<td>Server to Client</td>
</tr>
<tr>
<td>read_query()</td>
<td>Query</td>
<td>Client to Server</td>
</tr>
<tr>
<td>read_query_result()</td>
<td>Query result</td>
<td>Server to Client</td>
</tr>
</tbody>
</table>

By default, all functions return a result that indicates whether the data should be passed on to the client or server (depending on the direction of the information being transferred). This return value can be overridden by explicitly returning a constant indicating that a particular response should be sent. For example, it is possible to construct result set information by hand within **read_query()** and to return the result set directly to the client without ever sending the original query to the server.

In addition to these functions, a number of built-in structures provide control over how MySQL Proxy forwards queries and returns the results by providing a simplified interface to elements such as the list of queries and the groups of result sets that are returned.

### 16.7.4.1 Proxy Scripting Sequence During Query Injection

The following figure gives an example of how the proxy might be used when injecting queries into the query queue. Because the proxy sits between the client and MySQL server, what the proxy sends to the
server, and the information that the proxy ultimately returns to the client, need not match or correlate. Once the client has connected to the proxy, the sequence shown in the following diagram occurs for each individual query sent by the client.

1. When the client submits one query to the proxy, the read_query() function within the proxy is triggered. The function adds the query to the query queue.

2. Once manipulation by read_query() has completed, the queries are submitted, sequentially, to the MySQL server.

3. The MySQL server returns the results from each query, one result set for each query submitted. The read_query_result() function is triggered for each result set, and each invocation can decide which result set to return to the client.

For example, you can queue additional queries into the global query queue to be processed by the server. This can be used to add statistical information by adding queries before and after the original query, changing the original query:

```sql
SELECT * FROM City;
```
Into a sequence of queries:

```
SELECT NOW();
SELECT * FROM City;
SELECT NOW();
```

You can also modify the original statement; for example, to add `EXPLAIN` to each statement executed to get information on how the statement was processed, again altering our original SQL statement into a number of statements:

```
SELECT * FROM City;
EXPLAIN SELECT * FROM City;
```

In both of these examples, the client would have received more result sets than expected. Regardless of how you manipulate the incoming query and the returned result, the number of queries returned by the proxy must match the number of original queries sent by the client.

You could adjust the client to handle the multiple result sets sent by the proxy, but in most cases you will want the existence of the proxy to remain transparent. To ensure that the number of queries and result sets match, you can use the MySQL Proxy `read_query_result()` to extract the additional result set information and return only the result set the client originally requested back to the client. You can achieve this by giving each query that you add to the query queue a unique ID, then filter out queries that do not match the original query ID when processing them with `read_query_result()`.

### 16.7.4.2 Internal Structures

There are a number of internal structures within the scripting element of MySQL Proxy. The primary structure is `proxy` and this provides an interface to the many common structures used throughout the script, such as connection lists and configured backend servers. Other structures, such as the incoming packet from the client and result sets are only available within the context of one of the scriptable functions.

The following table describes common attributes of the MySQL `proxy` scripting element.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>connection</td>
<td>A structure containing the active client connections. For a list of attributes, see <code>proxy.connection[1932]</code>.</td>
</tr>
<tr>
<td>servers</td>
<td>A structure containing the list of configured backend servers. For a list of attributes, see <code>proxy.global.backends[1933]</code>.</td>
</tr>
<tr>
<td>queries</td>
<td>A structure containing the queue of queries that will be sent to the server during a single client query. For a list of attributes, see <code>proxy.queries[1934]</code>.</td>
</tr>
<tr>
<td>PROXY_VERSION</td>
<td>The version number of MySQL Proxy, encoded in hex. You can use this to check that the version number supports a particular option from within the Lua script. Note that the value is encoded as a hex value, so to check the version is at least 0.5.1 you compare against <code>0x00501</code>.</td>
</tr>
</tbody>
</table>

**proxy.connection**

The `proxy.connection` object is read only, and provides information about the current connection, and is split into a `client` and `server` tables. This enables you to examine information about both the incoming client connections to the proxy (`client`), and to the backend servers (`server`).

The following table describes the client and server attributes of the `proxy.connection` object.
MySQL Proxy Scripting

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>client.default_db</td>
<td>Default database requested by the client</td>
</tr>
<tr>
<td>client.username</td>
<td>User name used to authenticate</td>
</tr>
<tr>
<td>client.scrambled_password</td>
<td>The scrambled version of the password used to authenticate</td>
</tr>
<tr>
<td>client.dst.name</td>
<td>The combined address:port of the Proxy port used by this client (should match the <code>--proxy-address</code> configuration parameter)</td>
</tr>
<tr>
<td>client.dst.address</td>
<td>The IP address of the of the Proxy port used by this client</td>
</tr>
<tr>
<td>client.src.port</td>
<td>The port number of the of the Proxy port used by this client</td>
</tr>
<tr>
<td>client.src.name</td>
<td>The combined address:port of the client (originating) TCP/IP endpoint</td>
</tr>
<tr>
<td>client.src.address</td>
<td>The IP address of the client (originating) TCP/IP port</td>
</tr>
<tr>
<td>client.src.port</td>
<td>The port of the client (originating) TCP/IP endpoint</td>
</tr>
<tr>
<td>server.scramble_buffer</td>
<td>The scramble buffer used to scramble the password</td>
</tr>
<tr>
<td>server.mysqld_version</td>
<td>The MySQL version number of the server</td>
</tr>
<tr>
<td>server.thread_id</td>
<td>The ID of the thread handling the connection to the current server</td>
</tr>
<tr>
<td>server.dst.name</td>
<td>The combined address:port for the backend server for the current connection (i.e. the connection to the MySQL server)</td>
</tr>
<tr>
<td>server.dst.address</td>
<td>The address for the backend server</td>
</tr>
<tr>
<td>server.dst.port</td>
<td>The port for the backend server</td>
</tr>
<tr>
<td>server.src.name</td>
<td>The combined address:port for the TCP/IP endpoint used by the Proxy to connect to the backend server</td>
</tr>
<tr>
<td>server.src.address</td>
<td>The address of the endpoint for the proxy-side connection to the MySQL server</td>
</tr>
<tr>
<td>server.src.port</td>
<td>The port of the endpoint for the proxy-side connection to the MySQL server</td>
</tr>
</tbody>
</table>

**proxy.global.backends**

The `proxy.global.backends` table is partially writable and contains an array of all the configured backend servers and the server metadata (IP address, status, etc.). You can determine the array index of the current connection using `proxy.connection['backend_ndx']` which is the index into this table of the backend server being used by the active connection.

The attributes for each entry within the `proxy.global.backends` table are shown in the following table.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dst.name</td>
<td>The combined address:port of the backend server.</td>
</tr>
<tr>
<td>dst.address</td>
<td>The IP address of the backend server.</td>
</tr>
<tr>
<td>dst.port</td>
<td>The port of the backend server.</td>
</tr>
<tr>
<td>connected_clients</td>
<td>The number of clients currently connected.</td>
</tr>
<tr>
<td>state</td>
<td>The status of the backend server. See Backend State/Type Constants [1937].</td>
</tr>
<tr>
<td>type</td>
<td>The type of the backend server. You can use this to identify whether the backed was configured as a standard read/write backend, or a read-only backend. You can compare this value to the <code>proxy.BACKEND_TYPE_RW</code> and <code>proxy.BACKEND_TYPE_RO</code>.</td>
</tr>
</tbody>
</table>
**proxy.queries**

The `proxy.queries` object is a queue representing the list of queries to be sent to the server. The queue is not populated automatically, but if you do not explicitly populate the queue, queries are passed on to the backend server verbatim. Also, if you do not populate the query queue by hand, the `read_query_result()` function is not triggered.

The following functions are supported for populating the `proxy.queries` object.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>append(id,packet, [options])</code></td>
<td>Appends a query to the end of the query queue. The <code>id</code> is an integer identifier that you can use to recognize the query results when they are returned by the server. The packet should be a properly formatted query packet. The optional <code>options</code> should be a table containing the options specific to this packet.</td>
</tr>
<tr>
<td><code>prepend(id,packet)</code></td>
<td>Prepends a query to the query queue. The <code>id</code> is an identifier that you can use to recognize the query results when they are returned by the server. The packet should be a properly formatted query packet.</td>
</tr>
<tr>
<td><code>reset()</code></td>
<td>Empties the query queue.</td>
</tr>
<tr>
<td><code>len()</code></td>
<td>Returns the number of query packets in the queue.</td>
</tr>
</tbody>
</table>

For example, you could append a query packet to the `proxy.queries` queue by using the `append()`:

```
proxy.queries:append(1,p Packet)
```

The optional third argument to `append()` should contain the options for the packet. To have access to the result set through the `read_query_result()` function, set the `resultset_is_needed` flag to `true`:

```
proxy.queries:append(1,p Packet, {resultset_is_needed = true})
```

If that flag is `false` (the default), proxy will:

- Send the result set to the client as soon as it is received
- Reduce memory usage (because the result set is not stored internally for processing)
- Reduce latency of returning results to the client
- Pass data from server to client unaltered

The default mode is therefore quicker and useful if you only want to monitor the queries sent, and the basic statistics.

To perform any kind of manipulation on the returned data, you must set the flag to `true`, which will:

- Store the result set so that it can be processed.
- Enable modification of the result set before it is returned to the client.
- Enable you to discard the result set instead of returning it to the client.

**proxy.response**

The `proxy.response` structure is used when you want to return your own MySQL response, instead of forwarding a packet that you have received a backend server. The structure holds the response type information, an optional error message, and the result set (rows/columns) to return.
The following table describes the attributes of the `proxy.response` structure.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>The type of the response. The type must be either <code>MYSQLD_PACKET_OK</code> or <code>MYSQLD_PACKET_ERR</code>. If the <code>MYSQLD_PACKET_ERR</code>, you should set the value of the <code>mysql.response.errmsg</code> with a suitable error message.</td>
</tr>
<tr>
<td>errmsg</td>
<td>A string containing the error message that will be returned to the client.</td>
</tr>
<tr>
<td>resultset</td>
<td>A structure containing the result set information (columns and rows), identical to what would be returned when returning a results from a <code>SELECT</code> query.</td>
</tr>
</tbody>
</table>

When using `proxy.response` you either set `proxy.response.type` to `proxy.MYSQLD_PACKET_OK` and then build `resultset` to contain the results to return, or set `proxy.response.type` to `proxy.MYSQLD_PACKET_ERR` and set the `proxy.response.errmsg` to a string with the error message. To send the completed result set or error message, you should return the `proxy.PROXY_SEND_RESULT` to trigger the return of the packet information.

An example of this can be seen in the `tutorial-resultset.lua` script within the MySQL Proxy package:

```lua
if string.lower(command) == "show" and string.lower(option) == "querycounter" then
   ---
   -- proxy.PROXY_SEND_RESULT requires
   --
   -- proxy.response.type to be either
   -- * proxy.MYSQLD_PACKET_OK or
   -- * proxy.MYSQLD_PACKET_ERR
   --
   -- for proxy.MYSQLD_PACKET_OK you need a resultset
   -- * fields
   -- * rows
   --
   -- for proxy.MYSQLD_PACKET_ERR
   -- * errmsg
   proxy.response.type = proxy.MYSQLD_PACKET_OK
   proxy.response.resultset = {
      fields = {
         { type = proxy.MYSQL_TYPE_LONG, name = "global_query_counter", },
         { type = proxy.MYSQL_TYPE_LONG, name = "query_counter", },
      },
      rows = {
         { proxy.global.query_counter, query_counter }
      }
   }
   -- we have our result, send it back
   return proxy.PROXY_SEND_RESULT
elseif string.lower(command) == "show" and string.lower(option) == "myerror" then
   proxy.response.type = proxy.MYSQLD_PACKET_ERR
   proxy.response.errmsg = "my first error"
   return proxy.PROXY_SEND_RESULT
proxy.response.resultset
```

**proxy.response.resultset**

The `proxy.response.resultset` structure should be populated with the rows and columns of data to return. The structure contains the information about the entire result set, with the individual elements of the data shown in the following table.
The following table describes the attributes of the `proxy.response.resultset` structure.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fields</td>
<td>The definition of the columns being returned. This should be a dictionary structure with the <code>type</code> specifying the MySQL data type, and the <code>name</code> specifying the column name. Columns should be listed in the order of the column data that will be returned.</td>
</tr>
<tr>
<td>flags</td>
<td>A number of flags related to the result set. Valid flags include <code>auto_commit</code> (whether an automatic commit was triggered), <code>no_good_index_used</code> (the query executed without using an appropriate index), and <code>no_index_used</code> (the query executed without using any index).</td>
</tr>
<tr>
<td>rows</td>
<td>The actual row data. The information should be returned as an array of arrays. Each inner array should contain the column data, with the outer array making up the entire result set.</td>
</tr>
<tr>
<td>warning_count</td>
<td>The number of warnings for this result set.</td>
</tr>
<tr>
<td>affected_rows</td>
<td>The number of rows affected by the original statement.</td>
</tr>
<tr>
<td>insert_id</td>
<td>The last insert ID for an auto-incremented column in a table.</td>
</tr>
<tr>
<td>query_status</td>
<td>The status of the query operation. You can use the <code>MYSQLD_PACKET_OK</code> or <code>MYSQLD_PACKET_ERR</code> constants to populate this parameter.</td>
</tr>
</tbody>
</table>

For an example showing how to use this structure, see `proxy.response` [1934].

**Proxy Return State Constants**

The following constants are used internally by the proxy to specify the response to send to the client or server. All constants are exposed as values within the main `proxy` table.

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROXY_SEND_QUERY</td>
<td>Causes the proxy to send the current contents of the queries queue to the server.</td>
</tr>
<tr>
<td>PROXY_SEND_RESULT</td>
<td>Causes the proxy to send a result set back to the client.</td>
</tr>
<tr>
<td>PROXY_IGNORE_RESULT</td>
<td>Causes the proxy to drop the result set (nothing is returned to the client).</td>
</tr>
</tbody>
</table>

As constants, these entities are available without qualification in the Lua scripts. For example, at the end of the `read_query_result()` you might return `PROXY_IGNORE_RESULT`:

```lua
return proxy.PROXY_IGNORE_RESULT
```

**Packet State Constants**

The following states describe the status of a network packet. These items are entries within the main `proxy` table.

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MYSQLD_PACKET_OK</td>
<td>The packet is OK</td>
</tr>
<tr>
<td>MYSQLD_PACKET_ERR</td>
<td>The packet contains error information</td>
</tr>
<tr>
<td>MYSQLD_PACKET_RAW</td>
<td>The packet contains raw data</td>
</tr>
</tbody>
</table>
## Backend State/Type Constants

The following constants are used either to define the status or type of the backend MySQL server to which the proxy is connected. These items are entries within the main `proxy` table.

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BACKEND_STATE_UNKNOWN</td>
<td>The current status is unknown</td>
</tr>
<tr>
<td>BACKEND_STATE_UP</td>
<td>The backend is known to be up (available)</td>
</tr>
<tr>
<td>BACKEND_STATE_DOWN</td>
<td>The backend is known to be down (unavailable)</td>
</tr>
<tr>
<td>BACKEND_TYPE_UNKNOWN</td>
<td>Backend type is unknown</td>
</tr>
<tr>
<td>BACKEND_TYPE_RW</td>
<td>Backend is available for read/write</td>
</tr>
<tr>
<td>BACKEND_TYPE_RO</td>
<td>Backend is available only for read-only use</td>
</tr>
</tbody>
</table>

## Server Command Constants

The values described in the table below are used in the packets exchanged between the client and server to identify the information in the rest of the packet. These items are entries within the main `proxy` table. The packet type is defined as the first character in the sent packet. For example, when intercepting packets from the client to edit or monitor a query, you would check that the first byte of the packet was of type `proxy.COM_QUERY`.

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COM_SLEEP</td>
<td>Sleep</td>
</tr>
<tr>
<td>COM_QUIT</td>
<td>Quit</td>
</tr>
<tr>
<td>COM_INIT_DB</td>
<td>Initialize database</td>
</tr>
<tr>
<td>COM_QUERY</td>
<td>Query</td>
</tr>
<tr>
<td>COM_FIELD_LIST</td>
<td>Field List</td>
</tr>
<tr>
<td>COM_CREATE_DB</td>
<td>Create database</td>
</tr>
<tr>
<td>COM_DROP_DB</td>
<td>Drop database</td>
</tr>
<tr>
<td>COM_REFRESH</td>
<td>Refresh</td>
</tr>
<tr>
<td>COM_SHUTDOWN</td>
<td>Shutdown</td>
</tr>
<tr>
<td>COM_STATISTICS</td>
<td>Statistics</td>
</tr>
<tr>
<td>COM_PROCESS_INFO</td>
<td>Process List</td>
</tr>
<tr>
<td>COM_CONNECT</td>
<td>Connect</td>
</tr>
<tr>
<td>COM_PROCESS_KILL</td>
<td>Kill</td>
</tr>
<tr>
<td>COM_DEBUG</td>
<td>Debug</td>
</tr>
<tr>
<td>COM_PING</td>
<td>Ping</td>
</tr>
<tr>
<td>COM_TIME</td>
<td>Time</td>
</tr>
<tr>
<td>COM_DELAYED_INSERT</td>
<td>Delayed insert</td>
</tr>
<tr>
<td>COM_CHANGE_USER</td>
<td>Change user</td>
</tr>
<tr>
<td>COM_BINLOG_DUMP</td>
<td>Binlog dump</td>
</tr>
<tr>
<td>COM_TABLE_DUMP</td>
<td>Table dump</td>
</tr>
<tr>
<td>COM_CONNECT_OUT</td>
<td>Connect out</td>
</tr>
<tr>
<td>COM_REGISTER_SLAVE</td>
<td>Register slave</td>
</tr>
</tbody>
</table>
## MySQL Proxy Scripting

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COM_STMT_PREPARE</td>
<td>Prepare server-side statement</td>
</tr>
<tr>
<td>COM_STMT_EXECUTE</td>
<td>Execute server-side statement</td>
</tr>
<tr>
<td>COM_STMT_SEND_LONG_DATA</td>
<td>Long data</td>
</tr>
<tr>
<td>COM_STMT_CLOSE</td>
<td>Close server-side statement</td>
</tr>
<tr>
<td>COM_STMT_RESET</td>
<td>Reset statement</td>
</tr>
<tr>
<td>COM_SET_OPTION</td>
<td>Set option</td>
</tr>
<tr>
<td>COM_STMT_FETCH</td>
<td>Fetch statement</td>
</tr>
<tr>
<td>COM_DAEMON</td>
<td>Daemon (MySQL 5.1 only)</td>
</tr>
<tr>
<td>COM_ERROR</td>
<td>Error</td>
</tr>
</tbody>
</table>

### MySQL Type Constants

These constants are used to identify the field types in the query result data returned to clients from the result of a query. These items are entries within the main proxy table.

<table>
<thead>
<tr>
<th>Constant</th>
<th>Field Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>MYSQL_TYPE_DECIMAL</td>
<td>Decimal</td>
</tr>
<tr>
<td>MYSQL_TYPE_NEWDECIMAL</td>
<td>Decimal (MySQL 5.0 or later)</td>
</tr>
<tr>
<td>MYSQL_TYPE_TINY</td>
<td>Tiny</td>
</tr>
<tr>
<td>MYSQL_TYPE_SHORT</td>
<td>Short</td>
</tr>
<tr>
<td>MYSQL_TYPE_LONG</td>
<td>Long</td>
</tr>
<tr>
<td>MYSQL_TYPE_FLOAT</td>
<td>Float</td>
</tr>
<tr>
<td>MYSQL_TYPE_DOUBLE</td>
<td>Double</td>
</tr>
<tr>
<td>MYSQL_TYPE_NULL</td>
<td>Null</td>
</tr>
<tr>
<td>MYSQL_TYPE_TIMESTAMP</td>
<td>Timestamp</td>
</tr>
<tr>
<td>MYSQL_TYPE_LONGLONG</td>
<td>Long long</td>
</tr>
<tr>
<td>MYSQL_TYPE_INT24</td>
<td>Integer</td>
</tr>
<tr>
<td>MYSQL_TYPE_DATE</td>
<td>Date</td>
</tr>
<tr>
<td>MYSQL_TYPE_TIME</td>
<td>Time</td>
</tr>
<tr>
<td>MYSQL_TYPE_DATETIME</td>
<td>Datetime</td>
</tr>
<tr>
<td>MYSQL_TYPE_YEAR</td>
<td>Year</td>
</tr>
<tr>
<td>MYSQL_TYPE_NEWDATE</td>
<td>Date (MySQL 5.0 or later)</td>
</tr>
<tr>
<td>MYSQL_TYPE_ENUM</td>
<td>Enumeration</td>
</tr>
<tr>
<td>MYSQL_TYPE_SET</td>
<td>Set</td>
</tr>
<tr>
<td>MYSQL_TYPE_TINY_BLOB</td>
<td>Tiny Blob</td>
</tr>
<tr>
<td>MYSQL_TYPE_MEDIUM_BLOB</td>
<td>Medium Blob</td>
</tr>
<tr>
<td>MYSQL_TYPE_LONG_BLOB</td>
<td>Long Blob</td>
</tr>
<tr>
<td>MYSQL_TYPE_BLOB</td>
<td>Blob</td>
</tr>
<tr>
<td>MYSQL_TYPE_VAR_STRING</td>
<td>Varstring</td>
</tr>
<tr>
<td>MYSQL_TYPE_STRING</td>
<td>String</td>
</tr>
</tbody>
</table>
16.7.4.3 Capturing a Connection with `connect_server()`

When the proxy accepts a connection from a MySQL client, the `connect_server()` function is called.

There are no arguments to the function, but you can use and if necessary manipulate the information in the `proxy.connection` table, which is unique to each client session.

For example, if you have multiple backend servers, you can specify which server that connection should use by setting the value of `proxy.connection.backend_ndx` to a valid server number. The following code chooses between two servers based on whether the current time in minutes is odd or even:

```lua
function connect_server()
    print("--> a client really wants to talk to a server")
    if (tonumber(os.date("%M")) % 2 == 0) then
        proxy.connection.backend_ndx = 2
        print("Choosing backend 2")
    else
        proxy.connection.backend_ndx = 1
        print("Choosing backend 1")
    end
    print("Using " .. proxy.global.backends[proxy.connection.backend_ndx].dst.name)
end
```

This example also displays the IP address/port combination by accessing the information from the internal `proxy.global.backends` table.

16.7.4.4 Examining the Handshake with `read_handshake()`

Handshake information is sent by the server to the client after the initial connection (through `connect_server()`) has been made. The handshake information contains details about the MySQL version, the ID of the thread that will handle the connection information, and the IP address of the client and server. This information is exposed through the `proxy.connection` structure.

- `proxy.connection.server.mysqld_version`: The version of the MySQL server.
- `proxy.connection.server.thread_id`: The thread ID.
- `proxy.connection.server.scramble_buffer`: The password scramble buffer.
- `proxy.connection.server.dst.name`: The IP address of the server.
- `proxy.connection.client.src.name`: The IP address of the client.

For example, you can print out the handshake data and refuse clients by IP address with the following function:

```lua
function read_handshake()
    print("<-- let's send him some information about us")
    print("  mysqld-version: " .. proxy.connection.server.mysqld_version)
    print("    thread-id     : " .. proxy.connection.server.thread_id)
```
MySQL Proxy Scripting

print("    scramble-buf  : " .. string.format("%q",proxy.connection.server.scramble_buffer))
print("    server-addr   : " .. proxy.connection.server.dst.name)
print("    client-addr   : " .. proxy.connection.client.dst.name)

if not proxy.connection.client.src.name:match("^127.0.0.1:" then
    proxy.response.type = proxy.MYSQLD_PACKET_ERR
    proxy.response.errmsg = "only local connects are allowed"
    print("we don't like this client");
    return proxy.PROXY_SEND_RESULT
end

Note that you must return an error packet to the client by using `proxy.PROXY_SEND_RESULT`.

16.7.4.5 Examining the Authentication Credentials with `read_auth()`

The `read_auth()` function is triggered when an authentication handshake is initiated by the client. In the execution sequence, `read_auth()` occurs immediately after `read_handshake()`, so the server selection has already been made, but the connection and authorization information has not yet been provided to the backend server.

You can obtain the authentication information by examining the `proxy.connection.client` structure. For more information, see `proxy.connection` [1932].

For example, you can print the user name and password supplied during authorization using:

```lua
function read_auth()
    print("    username      : " .. proxy.connection.client.username)
    print("    password      : " .. string.format("%q", proxy.connection.client.scrambled_password))
end
```

You can interrupt the authentication process within this function and return an error packet back to the client by constructing a new packet and returning `proxy.PROXY_SEND_RESULT`:

```lua
proxy.response.type = proxy.MYSQLD_PACKET_ERR
proxy.response.errmsg = "Logins are not allowed"
return proxy.PROXY_SEND_RESULT
```

16.7.4.6 Accessing Authentication Information with `read_auth_result()`

The return packet from the server during authentication is captured by `read_auth_result()` function. The only argument to this function is the authentication packet returned by the server. As the packet is a raw MySQL network protocol packet, you must access the first byte to identify the packet type and contents. The `MYSQLD_PACKET_ERR` and `MYSQLD_PACKET_OK` constants can be used to identify whether the authentication was successful:

```lua
function read_auth_result(auth)
    local state = auth.packet:byte()
    if state == proxy.MYSQLD_PACKET_OK then
        print("<-- auth ok");
    elseif state == proxy.MYSQLD_PACKET_ERR then
        print("<-- auth failed");
    else
        print("<-- auth ... don't know: " .. string.format("%q", auth.packet));
    end
end
```
If a long-password capable client tries to authenticate to a server that supports long passwords, but the user password provided is actually short, `read_auth_result()` will be called twice. The first time, `auth.packet:byte()` will equal 254, indicating that the client should try again using the old password protocol. The second time `read_auth_result()` is called, `auth.packet:byte()` will indicate whether the authentication actually succeeded.

### 16.7.4.7 Manipulating Queries with `read_query()`

The `read_query()` function is called once for each query submitted by the client and accepts a single argument, the query packet that was provided. To access the content of the packet, you must parse the packet contents manually.

For example, you can intercept a query packet and print out the contents using the following function definition:

```plaintext
function read_query( packet )
    if packet:byte() == proxy.COM_QUERY then
        print("we got a normal query: " .. packet:sub(2))
    end
end
```

This example checks the first byte of the packet to determine the type. If the type is `COM_QUERY` (see Server Command Constants [1937]), we extract the query from the packet and print it. The structure of the packet type supplied is important. In the case of a `COM_QUERY` packet, the remaining contents of the packet are the text of the query string. In this example, no changes have been made to the query or the list of queries that will ultimately be sent to the MySQL server.

To modify a query, or add new queries, you must populate the query queue (`proxy.queries`), then execute the queries that you have placed into the queue. If you do not modify the original query or the queue, the query received from the client is sent to the MySQL server verbatim.

When adding queries to the queue, you should follow these guidelines:

- The packets inserted into the queue must be valid query packets. For each packet, you must set the initial byte to the packet type. If you are appending a query, you can append the query statement to the rest of the packet.

- Once you add a query to the queue, the queue is used as the source for queries sent to the server. If you add a query to the queue to add more information, you must also add the original query to the queue or it will not be executed.

- Once the queue has been populated, you must set the return value from `read_query()` to indicate whether the query queue should be sent to the server.

- When you add queries to the queue, you should add an ID. The ID you specify is returned with the result set so that you identify each query and corresponding result set. The ID has no other purpose than as an identifier for correlating the query and result set. When operating in a passive mode, during profiling for example, you identify the original query and the corresponding result set so that the results expected by the client can be returned correctly.

- Unless your client is designed to cope with more result sets than queries, you should ensure that the number of queries from the client match the number of result sets returned to the client. Using the unique ID and removing result sets you inserted will help.

Normally, the `read_query()` and `read_query_result()` function are used in conjunction with each other to inject additional queries and remove the additional result sets. However, `read_query_result()` is only called if you populate the query queue within `read_query()`.
16.7.4.8 Manipulating Results with `read_query_result()`

The `read_query_result()` is called for each result set returned by the server only if you have manually injected queries into the query queue. If you have not manipulated the query queue, this function is not called. The function supports a single argument, the result packet, which provides a number of properties:

- **id**: The ID of the result set, which corresponds to the ID that was set when the query packet was submitted to the server when using `append(id)` on the query queue. You must have set the `resultset_is_needed` flag to `append` to intercept the result set before it is returned to the client. See `proxy.queries` [1934].

- **query**: The text of the original query.

- **query_time**: The number of microseconds required to receive the first row of a result set since the query was sent to the server.

- **response_time**: The number of microseconds required to receive the last row of the result set since the query was sent to the server.

- **resultset**: The content of the result set data.

By accessing the result information from the MySQL server, you can extract the results that match the queries that you injected, return different result sets (for example, from a modified query), and even create your own result sets.

The following Lua script, for example, will output the query, followed by the query time and response time (that is, the time to execute the query and the time to return the data for the query) for each query sent to the server:

```lua
function read_query( packet )
    if packet:byte() == proxy.COM_QUERY then
        print("we got a normal query: " .. packet:sub(2))
        proxy.queries:append(1, packet )
        return proxy.PROXY_SEND_QUERY
    end
end

function read_query_result(inj)
    print("query-time: " .. (inj.query_time / 1000) .. "ms")
    print("response-time: " .. (inj.response_time / 1000) .. "ms")
end
```

You can access the rows of returned results from the result set by accessing the `rows` property of the `resultset` property of the result that is exposed through `read_query_result()`. For example, you can iterate over the results showing the first column from each row using this Lua fragment:

```lua
for row in inj.resultset.rows do
    print("injected query returned: " .. row[1])
end
```

Just like `read_query()`, `read_query_result()` can return different values for each result according to the result returned. If you have injected additional queries into the query queue, for example, remove the results returned from those additional queries and return only the results from the query originally submitted by the client.

The following example injects additional `SELECT NOW()` statements into the query queue, giving them a different ID to the ID of the original query. Within `read_query_result()`, if the ID for the injected
queries is identified, we display the result row, and return the `proxy.PROXY_IGNORE_RESULT` from the function so that the result is not returned to the client. If the result is from any other query, we print out the query time information for the query and return the default, which passes on the result set unchanged. We could also have explicitly returned `proxy.PROXY_IGNORE_RESULT` to the MySQL client.

```lua
function read_query(packet)
    if packet:byte() == proxy.COM_QUERY then
        proxy.queries:append(2, string.char(proxy.COM_QUERY) .. "SELECT NOW()"); {resultset_is_needed = true}
        proxy.queries:append(1, packet, {resultset_is_needed = true})
        proxy.queries:append(2, string.char(proxy.COM_QUERY) .. "SELECT NOW()"); {resultset_is_needed = true}
        return proxy.PROXY_SEND_QUERY
    end
end

function read_query_result(inj)
    if inj.id == 2 then
        for row in inj.resultset.rows do
            print("injected query returned: " .. row[1])
        end
        return proxy.PROXY_IGNORE_RESULT
    else
        print("query-time: " .. (inj.query_time / 1000) .. "ms")
        print("response-time: " .. (inj.response_time / 1000) .. "ms")
    end
end
```

For further examples, see Section 16.7.5, "Using MySQL Proxy".

### 16.7.5 Using MySQL Proxy

There are a number of different ways to use MySQL Proxy. At the most basic level, you can allow MySQL Proxy to pass queries from clients to a single server. To use MySQL Proxy in this mode, you just have to specify on the command line the backend server to which the proxy should connect:

```shell
shell> mysql-proxy --proxy-backend-addresses=sakila:3306
```

If you specify multiple backend MySQL servers, the proxy connects each client to each server in a round-robin fashion. Suppose that you have two MySQL servers, A and B. The first client to connect is connected to server A, the second to server B, the third to server A. For example:

```shell
shell> mysql-proxy \
    --proxy-backend-addresses=narcissus:3306 \
    --proxy-backend-addresses=nostromo:3306
```

When you specify multiple servers in this way, the proxy automatically identifies when a MySQL server has become unavailable and marks it accordingly. New connections are automatically attached to a server that is available, and a warning is reported to the standard output from `mysql-proxy`:

```network-mysqld.c.367: connect(nostromo:3306) failed: Connection refused
network-mysqld-proxy.c.2405: connecting to backend (nostromo:3306) failed, marking it as down for ...
```

Lua scripts enable a finer level of control, both over the connections and their distribution and how queries and result sets are processed. When using an Lua script, you must specify the name of the script on the command line using the `--proxy-lua-script` option:

```shell
shell> mysql-proxy --proxy-lua-script=mc.lua --proxy-backend-addresses=sakila:3306
```
When you specify a script, the script is not executed until a connection is made. This means that faults with the script are not raised until the script is executed. Script faults will not affect the distribution of queries to backend MySQL servers.

**Note**
Because a script is not read until the connection is made, you can modify the contents of the Lua script file while the proxy is still running and the modified script is automatically used for the next connection. This ensures that MySQL Proxy remains available because it need not be restarted for the changes to take effect.

### 16.7.5.1 Using the Administration Interface

The `mysql-proxy` administration interface can be accessed using any MySQL client using the standard protocols. You can use the administration interface to gain information about the proxy server as a whole - standard connections to the proxy are isolated to operate as if you were connected directly to the backend MySQL server.

In `mysql-proxy` 0.8.0 and earlier, a rudimentary interface was built into the proxy. In later versions this was replaced so that you must specify an administration script to be used when users connect to the administration interface.

To use the administration interface, specify the user name and password required to connect to the admin service, using the `--admin-username` and `--admin-password` options. You must also specify the Lua script to be used as the interface to the administration service by using the `admin-lua-script` script option to point to a Lua script.

For example, you can create a basic interface to the internal components of the `mysql-proxy` system using the following script, written by Diego Medina:

```lua
function set_error(errmsg)

    Copyright 2008, 2010, Oracle and/or its affiliates. All rights reserved.

--]]

function set_error(errmsg)
```
proxy.response = {  
  type = proxy.MYSQLD_PACKET_ERR,  
  errmsg = errmsg or "error"
}
end

function read_query(packet)  
  if packet:byte() ~= proxy.COM_QUERY then  
    set_error("[admin] we only handle text-based queries (COM_QUERY)")  
    return proxy.PROXY_SEND_RESULT
  end

  local query = packet:sub(2)  
  local rows = { }  
  local fields = { }

  -- try to match the string up to the first non-alphanum  
  local f_s, f_e, command = string.find(packet, "^%s*(%w+)%", 2)  
  local option

  if f_e then  
    -- if that match, take the next sub-string as option  
    f_s, f_e, option = string.find(packet, "^%s+(%w+)%", f_e + 1)
  end

  -- we got our commands, execute it  
  if command == "show" and option == "querycounter" then  
    ---  
    --- proxy.PROXY_SEND_RESULT requires  
    ---  
    --- proxy.response.type to be either  
    --- * proxy.MYSQLD_PACKET_OK or  
    --- * proxy.MYSQLD_PACKET_ERR  
    ---  
    --- for proxy.MYSQLD_PACKET_OK you need a resultset  
    --- * fields  
    --- * rows  
    ---  
    --- for proxy.MYSQLD_PACKET_ERR  
    --- * errmsg  
    proxy.response.type = proxy.MYSQLD_PACKET_OK  
    proxy.response.resultset = {  
      fields = {  
        { type = proxy.MYSQL_TYPE_LONG, name = "query_counter", },
      },  
      rows = {  
        { proxy.global.query_counter }  
      }
    }
  
  -- we have our result, send it back  
  return proxy.PROXY_SEND_RESULT
  elseif command == "show" and option == "myerror" then
    proxy.response.type = proxy.MYSQLD_PACKET_ERR  
    proxy.response.errmsg = "my first error"
    return proxy.PROXY_SEND_RESULT
  elseif string.sub(packet, 2):lower() == 'select help' then
    return show_process_help()
  elseif string.sub(packet, 2):lower() == 'show proxy processlist' then
    return show_process_table()
  elseif query == "SELECT * FROM backends" then
    fields = {  
      { name = "backend_ndx",  
    }
Using MySQL Proxy

```plaintext
for i = 1, #proxy.global.backends do
  local b = proxy.global.backends[i]
  rows[#rows + 1] = {
    i, b.dst.name, b.state, b.type
  }
end
else
  set_error()
  return proxy.PROXY_SEND_RESULT
end

proxy.response = {
  type = proxy.MYSQLD_PACKET_OK,
  resultset = {
    fields = fields,
    rows = rows
  }
}
return proxy.PROXY_SEND_RESULT

function make_dataset (header, dataset)
  proxy.response.type = proxy.MYSQLD_PACKET_OK
  proxy.response.resultset = {
    fields = {},
    rows = {}
  }
  for i,v in pairs (header) do
    table.insert(proxy.response.resultset.fields, {type = proxy.MYSQL_TYPE_STRING, name = v})
  end
  for i,v in pairs (dataset) do
    table.insert(proxy.response.resultset.rows, v)
  end
  return proxy.PROXY_SEND_RESULT
end

function show_process_table()
  local dataset = {}
  local header = { 'Id', 'IP Address', 'Time' }
  local rows = {}
  for t_i, t_v in pairs (proxy.global.process) do
    for s_i, s_v in pairs (t_v) do
      table.insert(rows, { t_i, s_v.ip, os.date('%c',s_v.ts) })
    end
  end
  return make_dataset(header,rows)
end

function show_process_help()
  local dataset = {}
  local header = { 'command', 'description' }
  local rows = {
    {'SELECT HELP',     'This command.'},
    {'SHOW PROXY PROCESSLIST', 'Show all connections and their true IP Address.'},
  }
  return make_dataset(header,rows)
end
```
Using MySQL Proxy

```lua
} return make_dataset(header,rows) end

function dump_process_table()
    proxy.global.initialize_process_table()
    print('current contents of process table')
    for t_i, t_v in pairs (proxy.global.process) do
        print ('session id: ', t_i)
        for s_i, s_v in pairs ( t_v ) do
            print ('\t', s_i, s_v.ip, s_v.ts )
        end
    end
    print ('---END PROCESS TABLE---')
end

--[[ Help

along with this program; if not, write to the Free Software
Foundation, Inc., 51 Franklin Street, Fifth Floor, Boston, MA 02110-1301 USA
--]]
-- reporter.lua

--[[
See http://www.chriscalender.com/?p=41
(Thanks to Chris Calender)
See http://datacharmer.blogspot.com/2009/01/mysql-proxy-is-back.html
(Thanks Giuseppe Maxia)
--]]
```
function proxy.global.initialize_process_table()
    if proxy.global.process == nil then
        proxy.global.process = {}  
    end
    if proxy.global.process[proxy.connection.server.thread_id] == nil then
        proxy.global.process[proxy.connection.server.thread_id] = {}
    end
end

function read_auth_result( auth )
    local state = auth.packet:byte()
    if state == proxy.MYSQLD_PACKET_OK then
        proxy.global.initialize_process_table()
        table.insert( proxy.global.process[proxy.connection.server.thread_id],
                      { ip = proxy.connection.client.src.name, ts = os.time() } )
    end
end

function disconnect_client()
    local connection_id = proxy.connection.server.thread_id
    if connection_id then
        -- client has disconnected, set this to nil
        proxy.global.process[connection_id] = nil
    end
end

---
-- read_query() can return a resultset
--
-- You can use read_query() to return a result-set.
--
-- @param packet the mysql-packet sent by the client
--
-- @return
--   * nothing to pass on the packet as is,
--   * proxy.PROXY_SEND_QUERY to send the queries from the proxy.queries queue
--   * proxy.PROXY_SEND_RESULT to send your own result-set
--
function read_query( packet )
    -- a new query came in this connection
    -- using proxy.global.* to make it available to the admin plugin
    proxy.global.query_counter = proxy.global.query_counter + 1
end

To use the script, save the first script to a file (admin.lua in the following example) and the other to reporter.lua, then run mysql-proxy specifying the admin script and a backend MySQL server:

```
shell> mysql-proxy --admin-lua-script=admin.lua --admin-password=password \ 
    "--admin-username=root --proxy-backend-addresses=127.0.0.1:3306 --proxy-lua-script=reporter.lua"
```

In a different window, connect to the MySQL server through the proxy:

```
shell> mysql --user=root --password=password --port=4040
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 1798669
Server version: 5.0.70-1og Gentoo Linux mysql-5.0.70-r1
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
mysql>
```
In another different window, connect to the `mysql-proxy` admin service using the specified user name and password:

```
shell> mysql --user=root --password=password --port=4041 --host=localhost
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 1
Server version: 5.0.99-agent-admin
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
mysql>
```

To monitor the status of the proxy, ask for a list of the current active processes:

```
mysql> show proxy processlist;
+---------+---------------------+--------------------------+
| Id      | IP Address          | Time                     |
+---------+---------------------+--------------------------+
| 1798669 | 192.168.0.112:52592 | Wed Jan 20 16:58:00 2010 |
+---------+---------------------+--------------------------+
1 row in set (0.00 sec)
mysql>
```

For more information on the example, see MySQL Proxy Admin Example.

### 16.7.6 MySQL Proxy FAQ

#### Questions

- **17.7.6.1**: In load balancing, how can I separate reads from writes?
- **17.7.6.2**: How do I use a socket with MySQL Proxy? Proxy change logs mention that support for UNIX sockets has been added.
- **17.7.6.3**: Can I use MySQL Proxy with all versions of MySQL?
- **17.7.6.4**: Can I run MySQL Proxy as a daemon?
- **17.7.6.5**: Do proxy applications run on a separate server? If not, what is the overhead incurred by Proxy on the DB server side?
- **17.7.6.6**: With load balancing, what happens to transactions? Are all queries sent to the same server?
- **17.7.6.7**: Is it possible to use MySQL Proxy with updating a Lucene index (or Solr) by making TCP calls to that server to update?
- **17.7.6.8**: Is the system context switch expensive, how much overhead does the Lua script add?
- **17.7.6.9**: How much latency does a proxy add to a connection?
- **17.7.6.10**: Do you have to make one large script and call it at proxy startup, can I change scripts without stopping and restarting (interrupting) the proxy?
- **17.7.6.11**: If MySQL Proxy has to live on same machine as MySQL, are there any tuning considerations to ensure both perform optimally?
- **17.7.6.12**: I currently use SQL Relay for efficient connection pooling with a number of Apache processes connecting to a MySQL server. Can MySQL Proxy currently accomplish this? My goal is to minimize connection latency while keeping temporary tables available.
MySQL Proxy FAQ

- **17.7.6.13**: [1952] Are these reserved function names (for example, `error_result()` ) that get automatically called?

- **17.7.6.14**: [1952] As the script is re-read by MySQL Proxy, does it cache this or is it looking at the file system with each request?

- **17.7.6.15**: [1952] Given that there is a `connect_server()` function, can a Lua script link up with multiple servers?

- **17.7.6.16**: [1952] Is the MySQL Proxy an API?

- **17.7.6.17**: [1952] The global namespace variable example with quotas does not persist after a reboot, is that correct?

- **17.7.6.18**: [1952] Can MySQL Proxy handle SSL connections?

- **17.7.6.19**: [1952] Could MySQL Proxy be used to capture passwords?

- **17.7.6.20**: [1952] Are there tools for isolating problems? How can someone figure out whether a problem is in the client, the database, or the proxy?

- **17.7.6.21**: [1952] Is MySQL Proxy similar to what is provided by Java connection pools?

- **17.7.6.22**: [1953] So authentication with connection pooling has to be done at every connection? What is the authentication latency?

- **17.7.6.23**: [1953] If you have multiple databases on the same box, can you use proxy to connect to databases on default port 3306?

- **17.7.6.24**: [1953] What about caching the authorization information so clients connecting are given back-end connections that were established with identical authorization information, thus saving a few more round trips?

- **17.7.6.25**: [1953] Is there any big web site using MySQL Proxy? For what purpose and what transaction rate have they achieved?

- **17.7.6.26**: [1953] How does MySQL Proxy compare to DBSLayer?

- **17.7.6.27**: [1953] I tried using MySQL Proxy without any Lua script to try a round-robin type load balancing. In this case, if the first database in the list is down, MySQL Proxy would not connect the client to the second database in the list.

- **17.7.6.28**: [1953] Is it “safe” to use LuaSocket with proxy scripts?

- **17.7.6.29**: [1953] How different is MySQL Proxy from DBCP (Database connection pooling) for Apache in terms of connection pooling?

- **17.7.6.30**: [1953] MySQL Proxy can handle about 5000 connections, what is the limit on a MySQL server?

- **17.7.6.31**: [1953] Would the Java-only connection pooling solution work for multiple web servers? With this, I would assume that you can pool across many web servers at once?

**Questions and Answers**

17.7.6.1: **In load balancing, how can I separate reads from writes?**

There is no automatic separation of queries that perform reads or writes to the different backend servers. However, you can specify to `mysql-proxy` that one or more of the “backend” MySQL servers are read only.
17.7.6.2: How do I use a socket with MySQL Proxy? Proxy change logs mention that support for
UNIX sockets has been added.

Specify the path to the socket:

```
--proxy-backend-addresses=/path/to/socket
```

17.7.6.3: Can I use MySQL Proxy with all versions of MySQL?

MySQL Proxy is designed to work with MySQL 5.0 or higher, and supports the MySQL network protocol for
5.0 and higher.

17.7.6.4: Can I run MySQL Proxy as a daemon?

Use the `--daemon` option. To keep track of the process ID, the daemon can be started with the `--pid-
file=file` option to save the PID to a known file name. On version 0.5.x, the Proxy cannot be started
natively as a daemon.

17.7.6.5: Do proxy applications run on a separate server? If not, what is the overhead incurred by
Proxy on the DB server side?

You can run the proxy on the application server, on its own box, or on the DB-server depending on the use
case.

17.7.6.6: With load balancing, what happens to transactions? Are all queries sent to the same
server?

Without any special customization the whole connection is sent to the same server. That keeps the whole
connection state intact.

17.7.6.7: Is it possible to use MySQL Proxy with updating a Lucene index (or Solr) by making TCP
calls to that server to update?

Yes, but it is not advised for now.

17.7.6.8: Is the system context switch expensive, how much overhead does the Lua script add?

Lua is fast and the overhead should be small enough for most applications. The raw packet overhead is
around 400 microseconds.

17.7.6.9: How much latency does a proxy add to a connection?

In the range of 400 microseconds per request.

17.7.6.10: Do you have to make one large script and call it at proxy startup, can I change scripts
without stopping and restarting (interrupting) the proxy?

You can just change the script and the proxy will reload it when a client connects.

17.7.6.11: If MySQL Proxy has to live on same machine as MySQL, are there any tuning
considerations to ensure both perform optimally?
MySQL Proxy FAQ

MySQL Proxy can live on any box: application, database, or its own box. MySQL Proxy uses comparatively little CPU or RAM, with negligible additional requirements or overhead.

17.7.6.12: I currently use SQL Relay for efficient connection pooling with a number of Apache processes connecting to a MySQL server. Can MySQL Proxy currently accomplish this? My goal is to minimize connection latency while keeping temporary tables available.

Yes.

17.7.6.13: Are these reserved function names (for example, `error_result()`) that get automatically called?

Only functions and values starting with `proxy.*` are provided by the proxy. All others are user provided.

17.7.6.14: As the script is re-read by MySQL Proxy, does it cache this or is it looking at the file system with each request?

It looks for the script at client-connect and reads it if it has changed, otherwise it uses the cached version.

17.7.6.15: Given that there is a `connect_server()` function, can a Lua script link up with multiple servers?

MySQL Proxy provides some tutorials in the source package; one is `examples/tutorial-keepalive.lua`.

17.7.6.16: Is the MySQL Proxy an API?

No. MySQL Proxy is an application that forwards packets from a client to a server using the MySQL network protocol. The MySQL Proxy provides a API allowing you to change its behavior.

17.7.6.17: The global namespace variable example with quotas does not persist after a reboot, is that correct?

Yes. If you restart the proxy, you lose the results, unless you save them in a file.

17.7.6.18: Can MySQL Proxy handle SSL connections?

No, being the man-in-the-middle, Proxy cannot handle encrypted sessions because it cannot share the SSL information.

17.7.6.19: Could MySQL Proxy be used to capture passwords?

The MySQL network protocol does not allow passwords to be sent in cleartext, all you could capture is the encrypted version.

17.7.6.20: Are there tools for isolating problems? How can someone figure out whether a problem is in the client, the database, or the proxy?

You can set a debug script in the proxy, which is an exceptionally good tool for this purpose. You can see very clearly which component is causing the problem, if you set the right breakpoints.

17.7.6.21: Is MySQL Proxy similar to what is provided by Java connection pools?

Yes and no. Java connection pools are specific to Java applications, MySQL Proxy works with any client API that talks the MySQL network protocol. Also, connection pools do not provide any functionality for intelligently examining the network packets and modifying the contents.
17.7.6.22: So authentication with connection pooling has to be done at every connection? What is the authentication latency?

You can skip the round-trip and use the connection as it was added to the pool. As long as the application cleans up the temporary tables it used. The overhead is (as always) around 400 microseconds.

17.7.6.23: If you have multiple databases on the same box, can you use proxy to connect to databases on default port 3306?

Yes, MySQL Proxy can listen on any port, provided that none of the MySQL servers are listening on the same port.

17.7.6.24: What about caching the authorization information so clients connecting are given backend connections that were established with identical authorization information, thus saving a few more round trips?

There is an --proxy-pool-no-change-user option that provides this functionality.

17.7.6.25: Is there any big web site using MySQL Proxy? For what purpose and what transaction rate have they achieved?

Yes, gaiaonline. They have tested MySQL Proxy and seen it handle 2400 queries per second through the proxy.

17.7.6.26: How does MySQL Proxy compare to DBSlayer?

DBSlayer is a REST->MySQL tool, MySQL Proxy is transparent to your application. No change to the application is needed.

17.7.6.27: I tried using MySQL Proxy without any Lua script to try a round-robin type load balancing. In this case, if the first database in the list is down, MySQL Proxy would not connect the client to the second database in the list.

This issue is fixed in version 0.7.0.

17.7.6.28: Is it “safe” to use LuaSocket with proxy scripts?

You can, but it is not advised because it may block.

17.7.6.29: How different is MySQL Proxy from DBCP (Database connection pooling) for Apache in terms of connection pooling?

Connection Pooling is just one use case of the MySQL Proxy. You can use it for a lot more and it works in cases where you cannot use DBCP (for example, if you do not have Java).

17.7.6.30: MySQL Proxy can handle about 5000 connections, what is the limit on a MySQL server?

The server limit is given by the value of the max_connections system variable. The default value is version dependent.

17.7.6.31: Would the Java-only connection pooling solution work for multiple web servers? With this, I would assume that you can pool across many web servers at once?

Yes. But you can also start one proxy on each application server to get a similar behavior as you have it already.
Replication enables data from one MySQL database server (the master) to be replicated to one or more MySQL database servers (the slaves). Replication is asynchronous by default, therefore slaves do not need to be connected permanently to receive updates from the master. This means that updates can occur over long-distance connections and even over temporary or intermittent connections such as a dial-up service. Depending on the configuration, you can replicate all databases, selected databases, or even selected tables within a database.

For answers to some questions often asked by those who are new to MySQL Replication, see Section A.13, “MySQL 5.5 FAQ: Replication”.

Advantages of replication in MySQL include:

- Scale-out solutions - spreading the load among multiple slaves to improve performance. In this environment, all writes and updates must take place on the master server. Reads, however, may take place on one or more slaves. This model can improve the performance of writes (since the master is dedicated to updates), while dramatically increasing read speed across an increasing number of slaves.

- Data security - because data is replicated to the slave, and the slave can pause the replication process, it is possible to run backup services on the slave without corrupting the corresponding master data.

- Analytics - live data can be created on the master, while the analysis of the information can take place on the slave without affecting the performance of the master.
• Long-distance data distribution - if a branch office would like to work with a copy of your main data, you can use replication to create a local copy of the data for their use without requiring permanent access to the master.

Replication in MySQL features support for one-way, asynchronous replication, in which one server acts as the master, while one or more other servers act as slaves. This is in contrast to the synchronous replication which is a characteristic of MySQL Cluster (see Chapter 18, MySQL Cluster NDB 7.2). In MySQL 5.5, an interface to semisynchronous replication is supported in addition to the built-in asynchronous replication. With semisynchronous replication, a commit performed on the master side blocks before returning to the session that performed the transaction until at least one slave acknowledges that it has received and logged the events for the transaction. See Section 17.3.8, “Semisynchronous Replication”

There are a number of solutions available for setting up replication between two servers, but the best method to use depends on the presence of data and the engine types you are using. For more information on the available options, see Section 17.1.1, “How to Set Up Replication”.

There are two core types of replication format, Statement Based Replication (SBR), which replicates entire SQL statements, and Row Based Replication (RBR), which replicates only the changed rows. You may also use a third variety, Mixed Based Replication (MBR). For more information on the different replication formats, see Section 17.1.2, “Replication Formats”. In MySQL 5.5, statement-based format is the default.

Replication is controlled through a number of different options and variables. These control the core operation of the replication, timeouts, and the databases and filters that can be applied on databases and tables. For more information on the available options, see Section 17.1.3, “Replication and Binary Logging Options and Variables”.

You can use replication to solve a number of different problems, including problems with performance, supporting the backup of different databases, and as part of a larger solution to alleviate system failures. For information on how to address these issues, see Section 17.3, “Replication Solutions”.

For notes and tips on how different data types and statements are treated during replication, including details of replication features, version compatibility, upgrades, and problems and their resolution, including an FAQ, see Section 17.4, “Replication Notes and Tips”.

For detailed information on the implementation of replication, how replication works, the process and contents of the binary log, background threads and the rules used to decide how statements are recorded and replication, see Section 17.2, “Replication Implementation”.

17.1 Replication Configuration

Replication between servers in MySQL is based on the binary logging mechanism. The MySQL instance operating as the master (the source of the database changes) writes updates and changes as “events” to the binary log. The information in the binary log is stored in different logging formats according to the database changes being recorded. Slaves are configured to read the binary log from the master and to execute the events in the binary log on the slave's local database.

The master is “dumb” in this scenario. Once binary logging has been enabled, all statements are recorded in the binary log. Each slave receives a copy of the entire contents of the binary log. It is the responsibility of the slave to decide which statements in the binary log should be executed; you cannot configure the master to log only certain events. If you do not specify otherwise, all events in the master binary log are executed on the slave. If required, you can configure the slave to process only events that apply to particular databases or tables.

Each slave keeps a record of the binary log coordinates: The file name and position within the file that it has read and processed from the master. This means that multiple slaves can be connected to the master and executing different parts of the same binary log. Because the slaves control this process, individual slaves can be connected and disconnected from the server without affecting the master's operation.
Also, because each slave remembers the position within the binary log, it is possible for slaves to be disconnected, reconnect and then “catch up” by continuing from the recorded position.

Both the master and each slave must be configured with a unique ID (using the `server-id` option). In addition, each slave must be configured with information about the master host name, log file name, and position within that file. These details can be controlled from within a MySQL session using the `CHANGE MASTER TO` statement on the slave. The details are stored within the slave's `master.info` file.

This section describes the setup and configuration required for a replication environment, including step-by-step instructions for creating a new replication environment. The major components of this section are:

- For a guide to setting up two or more servers for replication, Section 17.1.1, “How to Set Up Replication”, deals with the configuration of the systems and provides methods for copying data between the master and slaves.

- Events in the binary log are recorded using a number of formats. These are referred to as statement-based replication (SBR) or row-based replication (RBR). A third type, mixed-format replication (MIXED), uses SBR or RBR replication automatically to take advantage of the benefits of both SBR and RBR formats when appropriate. The different formats are discussed in Section 17.1.2, “Replication Formats”.

- Detailed information on the different configuration options and variables that apply to replication is provided in Section 17.1.3, “Replication and Binary Logging Options and Variables”.

- Once started, the replication process should require little administration or monitoring. However, for advice on common tasks that you may want to execute, see Section 17.1.4, “Common Replication Administration Tasks”.

### 17.1.1 How to Set Up Replication

This section describes how to set up complete replication of a MySQL server. There are a number of different methods for setting up replication, and the exact method to use depends on how you are setting up replication, and whether you already have data within your master database.

There are some generic tasks that are common to all replication setups:

- On the master, you must enable binary logging and configure a unique server ID. This might require a server restart. See Section 17.1.1.1, “Setting the Replication Master Configuration”.

- On each slave that you want to connect to the master, you must configure a unique server ID. This might require a server restart. See Section 17.1.1.2, “Setting the Replication Slave Configuration”.

- You may want to create a separate user that will be used by your slaves to authenticate with the master to read the binary log for replication. The step is optional. See Section 17.1.1.3, “Creating a User for Replication”.

- Before creating a data snapshot or starting the replication process, you should record the position of the binary log on the master. You will need this information when configuring the slave so that the slave knows where within the binary log to start executing events. See Section 17.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”.

- If you already have data on your master and you want to use it to synchronize your slave, you will need to create a data snapshot. You can create a snapshot using `mysqldump` (see Section 17.1.1.5, “Creating a Data Snapshot Using `mysqldump`”) or by copying the data files directly (see Section 17.1.1.6, “Creating a Data Snapshot Using Raw Data Files”).

- You will need to configure the slave with settings for connecting to the master, such as the host name, login credentials, and binary log file name and position. See Section 17.1.1.10, “Setting the Master Configuration on the Slave”.

1957
Once you have configured the basic options, you will need to follow the instructions for your replication setup. A number of alternatives are provided:

- If you are establishing a new MySQL master and one or more slaves, you need only set up the configuration, as you have no data to exchange. For guidance on setting up replication in this situation, see Section 17.1.1.7, “Setting Up Replication with New Master and Slaves”.

- If you are already running a MySQL server, and therefore already have data that must be transferred to your slaves before replication starts, have not previously configured the binary log and are able to shut down your MySQL server for a short period during the process, see Section 17.1.1.8, “Setting Up Replication with Existing Data”.

- If you are adding slaves to an existing replication environment, you can set up the slaves without affecting the master. See Section 17.1.1.9, “Introducing Additional Slaves to an Existing Replication Environment”.

If you will be administering MySQL replication servers, we suggest that you read this entire chapter through and try all statements mentioned in Section 13.4.1, “SQL Statements for Controlling Master Servers”, and Section 13.4.2, “SQL Statements for Controlling Slave Servers”. You should also familiarize yourself with the replication startup options described in Section 17.1.3, “Replication and Binary Logging Options and Variables”.

Note

Note that certain steps within the setup process require the SUPER privilege. If you do not have this privilege, it might not be possible to enable replication.

17.1.1.1 Setting the Replication Master Configuration

On a replication master, you must enable binary logging and establish a unique server ID. If this has not already been done, this part of master setup requires a server restart.

Binary logging must be enabled on the master because the binary log is the basis for sending data changes from the master to its slaves. If binary logging is not enabled, replication will not be possible.

Each server within a replication group must be configured with a unique server ID. This ID is used to identify individual servers within the group, and must be a positive integer between 1 and \((2^{32})–1\). How you organize and select the numbers is entirely up to you.

To configure the binary log and server ID options, you will need to shut down your MySQL server and edit the my.cnf or my.ini file. Add the following options to the configuration file within the [mysqld] section. If these options already exist, but are commented out, uncomment the options and alter them according to your needs. For example, to enable binary logging using a log file name prefix of mysql-bin, and configure a server ID of 1, use these lines:

```plaintext
[mysqld]
log-bin=mysql-bin
server-id=1
```

After making the changes, restart the server.

Note

If you omit server-id [1974] (or set it explicitly to its default value of 0), a master refuses connections from all slaves.
How to Set Up Replication

Note
For the greatest possible durability and consistency in a replication setup using InnoDB with transactions, you should use `innodb_flush_log_at_trx_commit=1` and `sync_binlog=1` in the master `my.cnf` file.

Note
Ensure that the `skip-networking` option is not enabled on your replication master. If networking has been disabled, your slave will not able to communicate with the master and replication will fail.

17.1.1.2 Setting the Replication Slave Configuration

On a replication slave, you must establish a unique server ID. If this has not already been done, this part of slave setup requires a server restart.

If the slave server ID is not already set, or the current value conflicts with the value that you have chosen for the master server, you should shut down your slave server and edit the configuration to specify a unique server ID. For example:

```ini
[mysqld]
server-id=2
```

After making the changes, restart the server.

If you are setting up multiple slaves, each one must have a unique `server-id` value that differs from that of the master and from each of the other slaves. Think of `server-id` values as something similar to IP addresses: These IDs uniquely identify each server instance in the community of replication partners.

Note
If you omit `server-id` (or set it explicitly to its default value of 0), a slave refuses to connect to a master.

You do not have to enable binary logging on the slave for replication to be enabled. However, if you enable binary logging on the slave, you can use the binary log for data backups and crash recovery on the slave, and also use the slave as part of a more complex replication topology (for example, where the slave acts as a master to other slaves).

17.1.1.3 Creating a User for Replication

Each slave must connect to the master using a MySQL user name and password, so there must be a user account on the master that the slave can use to connect. Any account can be used for this operation, providing it has been granted the `REPLICATION SLAVE` privilege. You may wish to create a different account for each slave, or connect to the master using the same account for each slave.

You need not create an account specifically for replication. However, you should be aware that the user name and password will be stored in plain text within the `master.info` file (see Section 17.2.2.2, “Slave Status Logs”). Therefore, you may want to create a separate account that has privileges only for the replication process, to minimize the possibility of compromise to other accounts.

To create a new account, use `CREATE USER`. To grant this account the privileges required for replication, use the `GRANT` statement. If you create an account solely for the purposes of replication, that account
needs only the `REPLICATION SLAVE` privilege. For example, to set up a new user, `repl`, that can connect for replication from any host within the `mydomain.com` domain, issue these statements on the master:

```sql
mysql> CREATE USER 'repl'@'%.mydomain.com' IDENTIFIED BY 'slavepass';
mysql> GRANT REPLICATION SLAVE ON *.* TO 'repl'@'%.mydomain.com';
```

See Section 13.7.1, “Account Management Statements”, for more information on statements for manipulation of user accounts.

### 17.1.1.4 Obtaining the Replication Master Binary Log Coordinates

To configure replication on the slave you must determine the master's current coordinates within its binary log. You will need this information so that when the slave starts the replication process, it is able to start processing events from the binary log at the correct point.

If you have existing data on your master that you want to synchronize on your slaves before starting the replication process, you must stop processing statements on the master, and then obtain its current binary log coordinates and dump its data, before permitting the master to continue executing statements. If you do not stop the execution of statements, the data dump and the master status information that you use will not match and you will end up with inconsistent or corrupted databases on the slaves.

To obtain the master binary log coordinates, follow these steps:

1. Start a session on the master by connecting to it with the command-line client, and flush all tables and block write statements by executing the `FLUSH TABLES WITH READ LOCK` statement:

   ```sql
   mysql> FLUSH TABLES WITH READ LOCK;
   ```

   For InnoDB tables, note that `FLUSH TABLES WITH READ LOCK` also blocks `COMMIT` operations.

   **Warning**

   Leave the client from which you issued the `FLUSH TABLES` statement running so that the read lock remains in effect. If you exit the client, the lock is released.

2. In a different session on the master, use the `SHOW MASTER STATUS` statement to determine the current binary log file name and position:

   ```sql
   mysql > SHOW MASTER STATUS;
   +------------------+----------+--------------+------------------+
   | File             | Position | Binlog_Do_DB | Binlog_Ignore_DB |
   +------------------+----------+--------------+------------------+
   | mysql-bin.000003 | 73       | test         | manual,mysql     |
   +------------------+----------+--------------+------------------+
   ```

   The `File` column shows the name of the log file and `Position` shows the position within the file. In this example, the binary log file is `mysql-bin.000003` and the position is 73. Record these values. You need them later when you are setting up the slave. They represent the replication coordinates at which the slave should begin processing new updates from the master.

   If the master has been running previously without binary logging enabled, the log file name and position values displayed by `SHOW MASTER STATUS` or `mysqldump --master-data` will be empty. In that case, the values that you need to use later when specifying the slave's log file and position are the empty string ('') and 4.
How to Set Up Replication

You now have the information you need to enable the slave to start reading from the binary log in the correct place to start replication.

If you have existing data that needs be synchronized with the slave before you start replication, leave the client running so that the lock remains in place and then proceed to Section 17.1.1.5, “Creating a Data Snapshot Using \texttt{mysqldump}”, or Section 17.1.1.6, “Creating a Data Snapshot Using Raw Data Files”. The idea here is to prevent any further changes so that the data copied to the slaves is in synchrony with the master.

If you are setting up a brand new master and slave replication group, you can exit the first session to release the read lock.

17.1.1.5 Creating a Data Snapshot Using \texttt{mysqldump}

One way to create a snapshot of the data in an existing master database is to use the \texttt{mysqldump} tool to create a dump of all the databases you want to replicate. Once the data dump has been completed, you then import this data into the slave before starting the replication process.

The example shown here dumps all databases to a file named \texttt{dbdump.db}, and includes the \texttt{--master-data} option which automatically appends the \texttt{CHANGE MASTER TO} statement required on the slave to start the replication process:

\begin{verbatim}
shell> mysqldump --all-databases --master-data > dbdump.db
\end{verbatim}

If you do not use \texttt{--master-data}, then it is necessary to lock all tables in a separate session manually (using \texttt{FLUSH TABLES WITH READ LOCK}) prior to running \texttt{mysqldump}, then exiting or running \texttt{UNLOCK TABLES} from the second session to release the locks. You must also obtain binary log position information matching the snapshot, using \texttt{SHOW MASTER STATUS}, and use this to issue the appropriate \texttt{CHANGE MASTER TO} statement when starting the slave.

When choosing databases to include in the dump, remember that you need to filter out databases on each slave that you do not want to include in the replication process.

To import the data, either copy the dump file to the slave, or access the file from the master when connecting remotely to the slave.

17.1.1.6 Creating a Data Snapshot Using Raw Data Files

If your database is large, copying the raw data files can be more efficient than using \texttt{mysqldump} and importing the file on each slave. This technique skips the overhead of updating indexes as the \texttt{INSERT} statements are replayed.

Using this method with tables in storage engines with complex caching or logging algorithms requires extra steps to produce a perfect “point in time” snapshot: the initial copy command might leave out cache information and logging updates, even if you have acquired a global read lock. How the storage engine responds to this depends on its crash recovery abilities.

This method also does not work reliably if the master and slave have different values for \texttt{ft_stopword_file}, \texttt{ft_min_word_len}, or \texttt{ft_max_word_len} and you are copying tables having full-text indexes.

If you use InnoDB tables, you can use the \texttt{mysqlbackup} command from the MySQL Enterprise Backup component to produce a consistent snapshot. This command records the log name and offset corresponding to the snapshot to be later used on the slave. MySQL Enterprise Backup is a commercial
How to Set Up Replication

product that is included as part of a MySQL Enterprise subscription. See Section 25.2, “MySQL Enterprise Backup” for detailed information.

Otherwise, use the cold backup technique to obtain a reliable binary snapshot of InnoDB tables: copy all data files after doing a slow shutdown of the MySQL Server.

To create a raw data snapshot of MyISAM tables, you can use standard copy tools such as cp or copy, a remote copy tool such as scp or rsync, an archiving tool such as zip or tar, or a file system snapshot tool such as dump, providing that your MySQL data files exist on a single file system. If you are replicating only certain databases, copy only those files that relate to those tables. (For InnoDB, all tables in all databases are stored in the system tablespace files, unless you have the innodb_file_per_table option enabled.)

You might want to specifically exclude the following files from your archive:

• Files relating to the mysql database.
• The master.info file.
• The master’s binary log files.
• Any relay log files.

To get the most consistent results with a raw data snapshot, shut down the master server during the process, as follows:

1. Acquire a read lock and get the master's status. See Section 17.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”.

2. In a separate session, shut down the master server:

```
shell> mysqladmin shutdown
```

3. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

```
shell> tar cf /tmp/db.tar ./data
shell> zip -r /tmp/db.zip ./data
shell> rsync --recursive ./data /tmp/dbdata
```

4. Restart the master server.

If you are not using InnoDB tables, you can get a snapshot of the system from a master without shutting down the server as described in the following steps:

1. Acquire a read lock and get the master's status. See Section 17.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”.

2. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

```
shell> tar cf /tmp/db.tar ./data
shell> zip -r /tmp/db.zip ./data
shell> rsync --recursive ./data /tmp/dbdata
```

3. In the client where you acquired the read lock, release the lock:
Once you have created the archive or copy of the database, copy the files to each slave before starting the slave replication process.

### 17.1.1.7 Setting Up Replication with New Master and Slaves

The easiest and most straightforward method for setting up replication is to use new master and slave servers.

You can also use this method if you are setting up new servers but have an existing dump of the databases from a different server that you want to load into your replication configuration. By loading the data into a new master, the data will be automatically replicated to the slaves.

To set up replication between a new master and slave:

1. Configure the MySQL master with the necessary configuration properties. See Section 17.1.1.1, “Setting the Replication Master Configuration”.
2. Start up the MySQL master.
3. Set up a user. See Section 17.1.1.3, “Creating a User for Replication”.
4. Obtain the master status information. See Section 17.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”.
5. On the master, release the read lock:

   ```
   mysql> UNLOCK TABLES;
   ```

6. On the slave, edit the MySQL configuration. See Section 17.1.1.2, “Setting the Replication Slave Configuration”.
7. Start up the MySQL slave.
8. Execute a `CHANGE MASTER TO` statement to set the master replication server configuration. See Section 17.1.1.10, “Setting the Master Configuration on the Slave”.

Perform the slave setup steps on each slave.

Because there is no data to load or exchange on a new server configuration you do not need to copy or import any information.

If you are setting up a new replication environment using the data from a different existing database server, you will now need to run the dump file generated from that server on the new master. The database updates will automatically be propagated to the slaves:

```shell
shell> mysql -h master < fulldb.dump
```

### 17.1.1.8 Setting Up Replication with Existing Data

When setting up replication with existing data, you will need to decide how best to get the data from the master to the slave before starting the replication service.

The basic process for setting up replication with existing data is as follows:

1. With the MySQL master running, create a user to be used by the slave when connecting to the master during replication. See Section 17.1.1.3, “Creating a User for Replication”.

2. If you have not already configured the `server-id` and enabled binary logging on the master server, you will need to shut it down to configure these options. See Section 17.1.1.1, “Setting the Replication Master Configuration”.

If you have to shut down your master server, this is a good opportunity to take a snapshot of its databases. You should obtain the master status (see Section 17.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”) before taking down the master, updating the configuration and taking a snapshot. For information on how to create a snapshot using raw data files, see Section 17.1.1.6, “Creating a Data Snapshot Using Raw Data Files”.

3. If your master server is already correctly configured, obtain its status (see Section 17.1.1.4, “Obtaining the Replication Master Binary Log Coordinates”) and then use `mysqldump` to take a snapshot (see Section 17.1.1.5, “Creating a Data Snapshot Using `mysqldump`”) or take a raw snapshot of the live server using the guide in Section 17.1.1.6, “Creating a Data Snapshot Using Raw Data Files”.

4. Update the configuration of the slave. See Section 17.1.1.2, “Setting the Replication Slave Configuration”.

5. The next step depends on how you created the snapshot of data on the master.
   
   If you used `mysqldump`:
   a. Start the slave, using the `--skip-slave-start` option so that replication does not start.
   b. Import the dump file:
      
      ```
      shell> mysql < fulldb.dump
      ```

   If you created a snapshot using the raw data files:
   a. Extract the data files into your slave data directory. For example:
      
      ```
      shell> tar xvf dbdump.tar
      ```
      
      You may need to set permissions and ownership on the files so that the slave server can access and modify them.
   b. Start the slave, using the `--skip-slave-start` option so that replication does not start.

6. Configure the slave with the replication coordinates from the master. This tells the slave the binary log file and position within the file where replication needs to start. Also, configure the slave with the login credentials and host name of the master. For more information on the `CHANGE MASTER TO` statement required, see Section 17.1.1.10, “Setting the Master Configuration on the Slave”.

7. Start the slave threads:
   
   ```
   mysql> START SLAVE;
   ```

After you have performed this procedure, the slave should connect to the master and catch up on any updates that have occurred since the snapshot was taken.

If you have forgotten to set the `server-id` option for the master, slaves cannot connect to it.

If you have forgotten to set the `server-id` option for the slave, you get the following error in the slave’s error log:
Warning: You should set server-id to a non-0 value if master_host is set; we will force server id to 2, but this MySQL server will not act as a slave.

You also find error messages in the slave's error log if it is not able to replicate for any other reason.

Once a slave is replicating, you can find in its data directory one file named `master.info` and another named `relay-log.info`. The slave uses these two files to keep track of how much of the master's binary log it has processed. Do not remove or edit these files unless you know exactly what you are doing and fully understand the implications. Even in that case, it is preferred that you use the `CHANGE MASTER TO` statement to change replication parameters. The slave will use the values specified in the statement to update the status files automatically.

Note

The content of `master.info` overrides some of the server options specified on the command line or in `my.cnf`. See Section 17.1.3, “Replication and Binary Logging Options and Variables”, for more details.

A single snapshot of the master suffices for multiple slaves. To set up additional slaves, use the same master snapshot and follow the slave portion of the procedure just described.

### 17.1.1.9 Introducing Additional Slaves to an Existing Replication Environment

To add another slave to an existing replication configuration, you can do so without stopping the master. Instead, set up the new slave by making a copy of an existing slave, except that you configure the new slave with a different `server-id` value.

To duplicate an existing slave:

1. Shut down the existing slave:

   ```shell
   mysqladmin shutdown
   ```

2. Copy the data directory from the existing slave to the new slave. You can do this by creating an archive using `tar` or `WinZip`, or by performing a direct copy using a tool such as `cp` or `rsync`. Ensure that you also copy the log files and relay log files.

   A common problem that is encountered when adding new replication slaves is that the new slave fails with a series of warning and error messages like these:

   ```
   071118 16:44:10 [Warning] Neither --relay-log nor --relay-log-index were used; so replication may break when this MySQL server acts as a slave and has his hostname changed!! Please use '--relay-log=new_slave_hostname-relay-bin' to avoid this problem.
   071118 16:44:10 [ERROR] Failed to open the relay log './old_slave_hostname-relay-bin.003525' (relay_log_pos 22940879)
   071118 16:44:10 [ERROR] Could not find target log during relay log initialization
   071118 16:44:10 [ERROR] Failed to initialize the master info structure
   ```

   This is due to the fact that, if the `--relay-log` option is not specified, the relay log files contain the host name as part of their file names. (This is also true of the relay log index file if the `--relay-log-index` option is not used. See Section 17.1.3, “Replication and Binary Logging Options and Variables”, for more information about these options.)

   To avoid this problem, use the same value for `--relay-log` on the new slave that was used on the existing slave. (If this option was not set explicitly on the existing slave, use `existing_slave_hostname-relay-bin`.) If this is not feasible, copy the existing slave's relay
log index file to the new slave and set the `--relay-log-index` option on the new slave to match what was used on the existing slave. (If this option was not set explicitly on the existing slave, use `existing_slave_hostname-relay-bin.index`.) Alternatively—if you have already tried to start the new slave (after following the remaining steps in this section) and have encountered errors like those described previously—then perform the following steps:

a. If you have not already done so, issue a `STOP SLAVE` on the new slave.

   If you have already started the existing slave again, issue a `STOP SLAVE` on the existing slave as well.

b. Copy the contents of the existing slave's relay log index file into the new slave's relay log index file, making sure to overwrite any content already in the file.

c. Proceed with the remaining steps in this section.

3. Copy the `master.info` and `relay-log.info` files from the existing slave to the new slave if they were not located in the data directory. These files hold the current log coordinates for the master's binary log and the slave's relay log.

4. Start the existing slave.

5. On the new slave, edit the configuration and give the new slave a unique `server-id` [1974] not used by the master or any of the existing slaves.

6. Start the new slave. The slave will use the information in its `master.info` file to start the replication process.

17.1.10 Setting the Master Configuration on the Slave

To set up the slave to communicate with the master for replication, you must tell the slave the necessary connection information. To do this, execute the following statement on the slave, replacing the option values with the actual values relevant to your system:

```sql
mysql> CHANGE MASTER TO
   -> MASTER_HOST='master_host_name',
   -> MASTER_USER='replication_user_name',
   -> MASTER_PASSWORD='replication_password',
   -> MASTER_LOG_FILE='recorded_log_file_name',
   -> MASTER_LOG_POS=recorded_log_position;
```

Note

Replication cannot use Unix socket files. You must be able to connect to the master MySQL server using TCP/IP.

The `CHANGE MASTER TO` statement has other options as well. For example, it is possible to set up secure replication using SSL. For a full list of options, and information about the maximum permissible length for the string-valued options, see Section 13.4.2.1, "CHANGE MASTER TO Syntax".

17.1.2 Replication Formats

Replication works because events written to the binary log are read from the master and then processed on the slave. The events are recorded within the binary log in different formats according to the type of event. The different replication formats used correspond to the binary logging format used when the events were recorded in the master's binary log. The correlation between binary logging formats and the terms used during replication are:
Replication Formats

- Replication capabilities in MySQL originally were based on propagation of SQL statements from master to slave. This is called statement-based replication (often abbreviated as SBR), which corresponds to the standard statement-based binary logging format. In older versions of MySQL (5.1.4 and earlier), binary logging and replication used this format exclusively.

- Row-based binary logging logs changes in individual table rows. When used with MySQL replication, this is known as row-based replication (often abbreviated as RBR). In row-based replication, the master writes events to the binary log that indicate how individual table rows are changed.

- The server can change the binary logging format in real time according to the type of event using mixed-format logging.

  When the mixed format is in effect, statement-based logging is used by default, but automatically switches to row-based logging in particular cases as described later. Replication using the mixed format is often referred to as mixed-based replication or mixed-format replication. For more information, see Section 5.2.4.3, “Mixed Binary Logging Format”.

In MySQL 5.5, statement-based format is the default.

MySQL Cluster. The default binary logging format in all MySQL Cluster NDB 7.2 releases, beginning with MySQL Cluster NDB 7.2.1, is STATEMENT. (This is a change from previous versions of MySQL Cluster.) You should note that MySQL Cluster Replication always uses row-based replication, and that the NDB storage engine is incompatible with statement-based replication. This means that you must manually set the format to ROW prior to enabling MySQL Cluster Replication. See Section 18.6.2, “General Requirements for MySQL Cluster Replication”, for more information.

When using MIXED format, the binary logging format is determined in part by the storage engine being used and the statement being executed. For more information on mixed-format logging and the rules governing the support of different logging formats, see Section 5.2.4.3, “Mixed Binary Logging Format”.

The logging format in a running MySQL server is controlled by setting the binlog_format server system variable. This variable can be set with session or global scope. The rules governing when and how the new setting takes effect are the same as for other MySQL server system variables—setting the variable for the current session lasts only until the end of that session, and the change is not visible to other sessions; setting the variable globally requires a restart of the server to take effect. For more information, see Section 13.7.4, “SET Syntax”.

There are conditions under which you cannot change the binary logging format at runtime or doing so causes replication to fail. See Section 5.2.4.2, “Setting The Binary Log Format”.

You must have the SUPER privilege to set either the global or session binlog_format value.

The statement-based and row-based replication formats have different issues and limitations. For a comparison of their relative advantages and disadvantages, see Section 17.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

With statement-based replication, you may encounter issues with replicating stored routines or triggers. You can avoid these issues by using row-based replication instead. For more information, see Section 20.7, “Binary Logging of Stored Programs”.

17.1.2.1 Advantages and Disadvantages of Statement-Based and Row-Based Replication

Each binary logging format has advantages and disadvantages. For most users, the mixed replication format should provide the best combination of data integrity and performance. If, however, you want to take advantage of the features specific to the statement-based or row-based replication format when performing certain tasks, you can use the information in this section, which provides a summary of their relative advantages and disadvantages, to determine which is best for your needs.
Advantages of statement-based replication

- Proven technology that has existed in MySQL since 3.23.
- Less data written to log files. When updates or deletes affect many rows, this results in much less storage space required for log files. This also means that taking and restoring from backups can be accomplished more quickly.
- Log files contain all statements that made any changes, so they can be used to audit the database.

Disadvantages of statement-based replication

- Statements that are unsafe for SBR.
  Not all statements which modify data (such as `INSERT`, `DELETE`, `UPDATE`, and `REPLACE` statements) can be replicated using statement-based replication. Any nondeterministic behavior is difficult to replicate when using statement-based replication. Examples of such DML (Data Modification Language) statements include the following:
  - A statement that depends on a UDF or stored program that is nondeterministic, since the value returned by such a UDF or stored program or depends on factors other than the parameters supplied to it. (Row-based replication, however, simply replicates the value returned by the UDF or stored program, so its effect on table rows and data is the same on both the master and slave.) See Section 17.4.1.11, “Replication of Invoked Features”, for more information.
  - `DELETE` and `UPDATE` statements that use a `LIMIT` clause without an `ORDER BY` are nondeterministic. See Section 17.4.1.15, “Replication and LIMIT”.
  - Statements using any of the following functions cannot be replicated properly using statement-based replication:
    - `LOAD_FILE`
    - `UUID`, `UUID_SHORT`
    - `USER`
    - `FOUND_ROWS`
    - `SYSDATE` (unless both the master and the slave are started with the `--sysdate-is-now` option)
    - `GET_LOCK`
    - `IS_FREE_LOCK`
    - `IS_USED_LOCK`
    - `MASTER_POS_WAIT`
    - `RAND`
    - `RELEASE_LOCK`
• SLEEP()
• VERSION()

However, all other functions are replicated correctly using statement-based replication, including NOW() and so forth.

For more information, see Section 17.4.1.14, “Replication and System Functions”.

Statements that cannot be replicated correctly using statement-based replication are logged with a warning like the one shown here:

[Warning] Statement is not safe to log in statement format.

A similar warning is also issued to the client in such cases. The client can display it using SHOW WARNINGS.

• INSERT ... SELECT requires a greater number of row-level locks than with row-based replication.
• UPDATE statements that require a table scan (because no index is used in the WHERE clause) must lock a greater number of rows than with row-based replication.
• For InnoDB: An INSERT statement that uses AUTO_INCREMENT blocks other nonconflicting INSERT statements.
• For complex statements, the statement must be evaluated and executed on the slave before the rows are updated or inserted. With row-based replication, the slave only has to modify the affected rows, not execute the full statement.
• If there is an error in evaluation on the slave, particularly when executing complex statements, statement-based replication may slowly increase the margin of error across the affected rows over time. See Section 17.4.1.27, “Slave Errors During Replication”.
• Stored functions execute with the same NOW() value as the calling statement. However, this is not true of stored procedures.
• Deterministic UDFs must be applied on the slaves.
• Table definitions must be (nearly) identical on master and slave. See Section 17.4.1.9, “Replication with Differing Table Definitions on Master and Slave”, for more information.

Advantages of row-based replication

• All changes can be replicated. This is the safest form of replication.

The mysql database is not replicated. The mysql database is instead seen as a node-specific database. Row-based replication is not supported on tables in this database. Instead, statements that would normally update this information—such as GRANT, REVOKE and the manipulation of triggers, stored routines (including stored procedures), and views—are all replicated to slaves using statement-based replication.

For statements such as CREATE TABLE ... SELECT, a CREATE statement is generated from the table definition and replicated using statement-based format, while the row insertions are replicated using row-based format.

• The technology is the same as in most other database management systems; knowledge about other systems transfers to MySQL.
Replication Formats

- Fewer row locks are required on the master, which thus achieves higher concurrency, for the following types of statements:
  - INSERT ... SELECT
  - INSERT statements with AUTO_INCREMENT
  - UPDATE or DELETE statements with WHERE clauses that do not use keys or do not change most of the examined rows.
- Fewer row locks are required on the slave for any INSERT, UPDATE, or DELETE statement.

Disadvantages of row-based replication

- RBR tends to generate more data that must be logged. To replicate a DML statement (such as an UPDATE or DELETE statement), statement-based replication writes only the statement to the binary log. By contrast, row-based replication writes each changed row to the binary log. If the statement changes many rows, row-based replication may write significantly more data to the binary log; this is true even for statements that are rolled back. This also means that taking and restoring from backup can require more time. In addition, the binary log is locked for a longer time to write the data, which may cause concurrency problems.

- Deterministic UDFs that generate large BLOB values take longer to replicate with row-based replication than with statement-based replication. This is because the BLOB column value is logged, rather than the statement generating the data.

- You cannot examine the logs to see what statements were executed, nor can you see on the slave what statements were received from the master and executed.

However, you can see what data was changed using `mysqlbinlog` with the options `--base64-output=DECODE-ROWS` and `--verbose`.

- For tables using the MyISAM storage engine, a stronger lock is required on the slave for INSERT statements when applying them as row-based events to the binary log than when applying them as statements. This means that concurrent inserts on MyISAM tables are not supported when using row-based replication.

17.1.2.2 Usage of Row-Based Logging and Replication

Major changes in the replication environment and in the behavior of applications can result from using row-based logging (RBL) or row-based replication (RBR) rather than statement-based logging or replication. This section describes a number of issues known to exist when using row-based logging or replication, and discusses some best practices for taking advantage of row-based logging and replication.

For additional information, see Section 17.1.2, “Replication Formats”, and Section 17.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.

For information about issues specific to MySQL Cluster Replication (which depends on row-based replication), see Section 18.6.3, “Known Issues in MySQL Cluster Replication”.

- **RBL, RBR, and temporary tables.** As noted in Section 17.4.1.22, “Replication and Temporary Tables”, temporary tables are not replicated when using row-based format. When mixed format is in effect, “safe” statements involving temporary tables are logged using statement-based format. For more information, see Section 17.1.2.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”.
Temporary tables are not replicated when using row-based format because there is no need. In addition, because temporary tables can be read only from the thread which created them, there is seldom if ever any benefit obtained from replicating them, even when using statement-based format.

Beginning with MySQL 5.5.5, you can switch from statement-based to row-based binary logging mode even when temporary tables have been created. However, while using the row-based format, the MySQL server cannot determine the logging mode that was in effect when a given temporary table was created. For this reason, the server in such cases logs a `DROP TEMPORARY TABLE IF EXISTS` statement for each temporary table that still exists for a given client session when that session ends. (Bug #11760229, Bug #11762267) While this means that it is possible that an unnecessary `DROP TEMPORARY TABLE` statement might be logged in some cases, the statement is harmless, and does not cause an error even if the table does not exist, due to the presence of the `IF NOT EXISTS` option.

• **RBL and synchronization of nontransactional tables.** When many rows are affected, the set of changes is split into several events; when the statement commits, all of these events are written to the binary log. When executing on the slave, a table lock is taken on all tables involved, and then the rows are applied in batch mode. (This may or may not be effective, depending on the engine used for the slave's copy of the table.)

• **Latency and binary log size.** Because RBL writes changes for each row to the binary log, its size can increase quite rapidly. In a replication environment, this can significantly increase the time required to make changes on the slave that match those on the master. You should be aware of the potential for this delay in your applications.

• **Reading the binary log.** `mysqlbinlog` displays row-based events in the binary log using the `BINLOG` statement (see Section 13.7.6.1, "BINLOG Syntax"). This statement displays an event in printable form, but as a base 64-encoded string the meaning of which is not evident. When invoked with the `--base64-output=DECODE-ROWS` and `--verbose` options, `mysqlbinlog` formats the contents of the binary log in a manner that is easily human readable. This is helpful when binary log events were written in row-based format if you want to read or recover from a replication or database failure using the contents of the binary log. For more information, see Section 4.6.7.2, "mysqlbinlog Row Event Display".

• **Binary log execution errors and slave_exec_mode.** If `slave_exec_mode` is IDEMPOTENT, a failure to apply changes from RBL because the original row cannot be found does not trigger an error or cause replication to fail. This means that it is possible that updates are not applied on the slave, so that the master and slave are no longer synchronized. Latency issues and use of nontransactional tables with RBR when `slave_exec_mode` is IDEMPOTENT can cause the master and slave to diverge even further. For more information about `slave_exec_mode`, see Section 5.1.4, "Server System Variables".

  Note

  `slave_exec_mode=IDEMPOTENT` is generally useful only for circular replication or multi-master replication with MySQL Cluster, for which IDEMPOTENT is the default value (see Section 18.6, "MySQL Cluster Replication").

  For other scenarios, setting `slave_exec_mode` to STRICT is normally sufficient; this is the default value for storage engines other than NDB.

• **Lack of binary log checksums.** RBL uses no checksums. This means that network, disk, and other errors may not be identified when processing the binary log. To ensure that data is transmitted without network corruption, you may want to consider using SSL, which adds another layer of checksumming, for replication connections. The `CHANGE MASTER TO` statement has options to enable replication over SSL. See also Section 13.4.2.1, "CHANGE MASTER TO Syntax", for general information about setting up MySQL with SSL.
• **Filtering based on server ID not supported.** A common practice is to filter out changes on some slaves by using a `WHERE` clause that includes the relation `@@server_id <> id_value` clause with `UPDATE` and `DELETE` statements, a simple example of such a clause being `WHERE @@server_id <> 1`. However, this does not work correctly with row-based logging. If you must use the `server_id` system variable for statement filtering, you must also use `--binlog_format=STATEMENT`.

In MySQL 5.5, you can do filtering based on server ID by using the `IGNORE_SERVER_ID` option for the `CHANGE MASTER TO` statement. This option works with the statement-based and row-based logging formats.

• **Database-level replication options.** The effects of the `--replicate-do-db`, `--replicate-ignore-db`, and `--replicate-rewrite-db` options differ considerably depending on whether row-based or statement-based logging is used. Because of this, it is recommended to avoid database-level options and instead use table-level options such as `--replicate-do-table` and `--replicate-ignore-table`. For more information about these options and the impact that your choice of replication format has on how they operate, see Section 17.1.3, “Replication and Binary Logging Options and Variables”.

• **RBL, nontransactional tables, and stopped slaves.** When using row-based logging, if the slave server is stopped while a slave thread is updating a nontransactional table, the slave database may reach an inconsistent state. For this reason, it is recommended that you use a transactional storage engine such as `InnoDB` for all tables replicated using the row-based format.

Use of `STOP_SLAVE` (or `STOP_SLAVE SQL_THREAD` in MySQL 5.5.9 and later) prior to shutting down the slave MySQL server helps prevent such issues from occurring, and is always recommended regardless of the logging format or storage engines employed.

### 17.1.2.3 Determination of Safe and Unsafe Statements in Binary Logging

When speaking of the “safeness” of a statement in MySQL Replication, we are referring to whether a statement and its effects can be replicated correctly using statement-based format. If this is true of the statement, we refer to the statement as safe; otherwise, we refer to it as unsafe.

In general, a statement is safe if it deterministic, and unsafe if it is not. However, certain nondeterministic functions are not considered unsafe (see Nondeterministic functions not considered unsafe, later in this section). In addition, statements using results from floating-point math functions—which are hardware-dependent—are always considered unsafe (see Section 17.4.1.12, “Replication and Floating-Point Values”).

**Handling of safe and unsafe statements.** A statement is treated differently depending on whether the statement is considered safe, and with respect to the binary logging format (that is, the current value of `binlog_format`).

• No distinction is made in the treatment of safe and unsafe statements when the binary logging mode is `ROW`.

• If the binary logging format is `MIXED`, statements flagged as unsafe are logged using the row-based format; statements regarded as safe are logged using the statement-based format.

• If the binary logging format is `STATEMENT`, statements flagged as being unsafe generate a warning to this effect. (Safe statements are logged normally.)

Each statement flagged as unsafe generates a warning. Formerly, in cases where a great many such statements were executed on the master, this could lead to very large error log files, sometimes even filling up an entire disk unexpectedly. To guard against this, MySQL 5.5.27 introduced a warning suppression mechanism, which behaves as follows: Whenever the 50 most recent `ER_BINLOG_UNSAFE_STATEMENT` warnings have been generated more than 50 times in any 50-second period, warning suppression is
enabled. When activated, this causes such warnings not to be written to the error log; instead, for each 50 warnings of this type, a note \textit{The last warning was repeated $N$ times in last $S$ seconds} is written to the error log. This continues as long as the 50 most recent such warnings were issued in 50 seconds or less; once the rate has decreased below this threshold, the warnings are once again logged normally. Warning suppression has no effect on how the safety of statements for statement-based logging is determined, nor on how warnings are sent to the client (MySQL clients still receive one warning for each such statement).

For more information, see Section 17.1.2, “Replication Formats”.

Statements considered unsafe.
Statements having the following characteristics are considered unsafe:

- **Statements containing system functions that may return a different value on slave.**
  These functions include \texttt{FOUND_ROWS()}, \texttt{GET_LOCK()}, \texttt{IS_FREE_LOCK()}, \texttt{IS_USED_LOCK()}, \texttt{LOAD_FILE()}, \texttt{MASTER_POS_WAIT()}, \texttt{RAND()}, \texttt{RELEASE_LOCK()}, \texttt{ROW_COUNT()}, \texttt{SESSION_USER()}, \texttt{SLEEP()}, \texttt{SYSDATE()}, \texttt{SYSTEM_USER()}, \texttt{USER()}, \texttt{UUID()} and \texttt{UUID_SHORT()}.

- **Nondeterministic functions not considered unsafe.** Although these functions are not deterministic, they are treated as safe for purposes of logging and replication: \texttt{CONNECTION_ID()}, \texttt{CURDATE()}, \texttt{CURRENT_DATE()}, \texttt{CURRENT_TIME()}, \texttt{CURRENT_TIMESTAMP()}, \texttt{CURTIME()}, \texttt{LOCALTIME()}, \texttt{LOCALTIMESTAMP()}, \texttt{NOW()}, \texttt{UNIX_TIMESTAMP()}, \texttt{UTC_DATE()}, \texttt{UTC_TIME()}, \texttt{UTC_TIMESTAMP()} and \texttt{LAST_INSERT_ID()}.

- **References to system variables.** Most system variables are not replicated correctly using the statement-based format. For exceptions, see Section 5.2.4.3, “Mixed Binary Logging Format”.

- **UDFs.** Since we have no control over what a UDF does, we must assume that it is executing unsafe statements.

- **Updates a table having an \texttt{AUTO_INCREMENT} column.** Prior to MySQL 5.5.3, all such statements were always considered unsafe because the order in which the rows are updated could differ on the master and the slave. In MySQL 5.3.3 and later, these statements are unsafe only when they are executed by a trigger or stored program (Bug #50192, Bug #11758052).

  An \texttt{INSERT} into a table that has a composite primary key containing an \texttt{AUTO_INCREMENT} column that is not the first column of this composite key is unsafe.

  For more information, see Section 17.4.1.1, “Replication and \texttt{AUTO_INCREMENT}”.

- **\texttt{INSERT DELAYED} statement.** This statement is considered unsafe because the insertion of the rows may interleave with concurrently executing statements.

- **\texttt{INSERT \ldots ON DUPLICATE KEY UPDATE} statements on tables with multiple primary or unique keys.** When executed against a table that contains more than one primary or unique key, this statement is considered unsafe, being sensitive to the order in which the storage engine checks the keys, which is not deterministic, and on which the choice of rows updated by the MySQL Server depends.

  An \texttt{INSERT \ldots ON DUPLICATE KEY UPDATE} statement against a table having more than one unique or primary key is marked as unsafe for statement-based replication beginning with MySQL 5.5.24. (Bug #11765650, Bug #58637)

- **Updates using \texttt{LIMIT}.** The order in which rows are retrieved is not specified.
See Section 17.4.1.15, “Replication and LIMIT”.

- **Accesses or references log tables.** The contents of the system log table may differ between master and slave.

- **Nontransactional operations after transactional operations.** Within a transaction, allowing any nontransactional reads or writes to execute after any transactional reads or writes is considered unsafe. For more information, see Section 17.4.1.33, “Replication and Transactions”.

- **Accesses or references self-logging tables.** All reads and writes to self-logging tables are considered unsafe. Within a transaction, any statement following a read or write to self-logging tables is also considered unsafe.

- **LOAD DATA INFILE statements.** Beginning with MySQL 5.5.6, LOAD DATA INFILE is considered unsafe, it causes a warning in statement-based mode, and a switch to row-based format when using mixed-format logging. See Section 17.4.1.16, “Replication and LOAD DATA INFILE”.

For additional information, see Section 17.4.1, “Replication Features and Issues”.

### 17.1.3 Replication and Binary Logging Options and Variables

The next few sections contain information about *mysqld* options and server variables that are used in replication and for controlling the binary log. Options and variables for use on replication masters and replication slaves are covered separately, as are options and variables relating to binary logging. A set of quick-reference tables providing basic information about these options and variables is also included (in the next section following this one).

Of particular importance is the `--server-id` option.

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--server-id=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>server-id</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>server_id</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 .. 4294967295</td>
</tr>
</tbody>
</table>

This option is common to both master and slave replication servers, and is used in replication to enable master and slave servers to identify themselves uniquely. For additional information, see Section 17.1.3.2, “Replication Master Options and Variables”, and Section 17.1.3.3, “Replication Slave Options and Variables”.

On the master and each slave, you must use the `--server-id` option to establish a unique replication ID in the range from 1 to $2^{32} - 1$. “Unique”, means that each ID must be different from every other ID in use by any other replication master or slave. Example: `server-id=3`.

If you omit `--server-id`, the default ID is 0, in which case the master refuses connections from all slaves, and slaves refuse to connect to the master. In MySQL 5.5, whether the server ID is set to 0 explicitly or the default is allowed to be used, the server sets the `server_id` system variable to 1; this is a known issue that is fixed in MySQL 5.7.
For more information, see Section 17.1.2, “Setting the Replication Slave Configuration”.

### 17.1.3.1 Replication and Binary Logging Option and Variable Reference

The following tables list basic information about the MySQL command-line options and system variables applicable to replication and the binary log.

**Table 17.1 Replication Options and Variables: MySQL 5.5**

<table>
<thead>
<tr>

## 17.1.3.4, “Binary Log Options and Variables”

For information about the `sql_log_bin` and `sql_log_off` variables, see Section 5.1.4, “Server System Variables”.

For a table showing all command-line options, system and status variables used with `mysqld`, see Section 5.1.1, “Server Option and Variable Reference”.

### 17.1.3.2 Replication Master Options and Variables

This section describes the server options and system variables that you can use on replication master servers. You can specify the options either on the command line or in an option file. You can specify system variable values using `SET`.

On the master and each slave, you must use the `server-id` [1974] option to establish a unique replication ID. For each server, you should pick a unique positive integer in the range from 1 to $2^{32} - 1$, and each ID must be different from every other ID in use by any other replication master or slave. Example: `server-id=3`.

Section 17.1.3.4, “Binary Log Options and Variables”, provides more detailed information about options and variables relating to binary logging. For additional general information about the binary log, see Section 5.2.4, “The Binary Log”.

---

1981
Replication and Binary Logging Options and Variables

For options used on the master for controlling binary logging, see Section 17.1.3.4, “Binary Log Options and Variables”.

System Variables Used on Replication Masters

The following system variables are used in controlling replication masters:

- `auto_increment_increment`

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>auto_increment_increment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Range</td>
<td>1 .. 65535</td>
</tr>
</tbody>
</table>

`auto_increment_increment` and `auto_increment_offset` are intended for use with master-to-master replication, and can be used to control the operation of `AUTO_INCREMENT` columns. Both variables have global and session values, and each can assume an integer value between 1 and 65,535 inclusive. Setting the value of either of these two variables to 0 causes its value to be set to 1 instead. Attempting to set the value of either of these two variables to an integer greater than 65,535 or less than 0 causes its value to be set to 65,535 instead. Attempting to set the value of `auto_increment_increment` or `auto_increment_offset` to a noninteger value gives rise to an error, and the actual value of the variable remains unchanged.

Note

`auto_increment_increment` is also supported for use with NDB tables.

These two variables affect `AUTO_INCREMENT` column behavior as follows:

- `auto_increment_increment` controls the interval between successive column values. For example:

```sql
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 1     |
| auto_increment_offset    | 1     |
+--------------------------+-------+
2 rows in set (0.00 sec)
mysql> CREATE TABLE autoinc1
    -> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.04 sec)
mysql> SET @auto_increment_increment=10;
Query OK, 0 rows affected (0.00 sec)
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 10    |
+--------------------------+-------+
```
| auto_increment_offset | 1     |
+-----------------------+-------+
2 rows in set (0.01 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
| col  |
+-----+
|  1   |
|  11  |
|  21  |
|  31  |
+-----+
4 rows in set (0.00 sec)

- auto_increment_offset determines the starting point for the AUTO_INCREMENT column value.

Consider the following, assuming that these statements are executed during the same session as the example given in the description for auto_increment_increment:

mysql> SET @@auto_increment_offset=5;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 10    |
| auto_increment_offset    | 5     |
+--------------------------+-------+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc2
    -> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO autoinc2 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc2;
+-----+
| col  |
+-----+
|  5   |
|  15  |
|  25  |
|  35  |
+-----+
4 rows in set (0.02 sec)

If the value of auto_increment_offset is greater than that of auto_increment_increment, the value of auto_increment_offset is ignored.

Should one or both of these variables be changed and then new rows inserted into a table containing an AUTO_INCREMENT column, the results may seem counterintuitive because the series of AUTO_INCREMENT values is calculated without regard to any values already present in the column, and the next value inserted is the least value in the series that is greater than the maximum existing value in the AUTO_INCREMENT column. In other words, the series is calculated like so:
auto_increment_offset + \( N \times \) auto_increment_increment

where \( N \) is a positive integer value in the series [1, 2, 3, ...]. For example:

```sql
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| auto_increment_increment | 10    |

+-----+
8 rows in set (0.00 sec)
```

The values shown for `auto_increment_increment` and `auto_increment_offset` generate the series \( 5 + N \times 10 \), that is, [5, 15, 25, 35, 45, ...]. The greatest value present in the `col` column prior to the `INSERT` is 31, and the next available value in the `AUTO_INCREMENT` series is 35, so the inserted values for `col` begin at that point and the results are as shown for the `SELECT` query.

It is not possible to confine the effects of these two variables to a single table, and thus they do not take the place of the sequences offered by some other database management systems; these variables control the behavior of all `AUTO_INCREMENT` columns in all tables on the MySQL server. If the global value of either variable is set, its effects persist until the global value is changed or overridden by setting the session value, or until `mysqld` is restarted. If the local value is set, the new value affects `AUTO_INCREMENT` columns for all tables into which new rows are inserted by the current user for the duration of the session, unless the values are changed during that session.

The default value of `auto_increment_increment` is 1. See Section 17.4.1.1, “Replication and `AUTO_INCREMENT`”.

- `auto_increment_offset`
<table>
<thead>
<tr>
<th>System Variable Name</th>
<th>auto_increment_offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>1</td>
</tr>
<tr>
<td>Range</td>
<td>1 .. 65535</td>
</tr>
</tbody>
</table>

This variable has a default value of 1. For particulars, see the description for `auto_increment_increment`.

Note

`auto_increment_offset` is also supported for use with NDB tables.

17.1.3.3 Replication Slave Options and Variables

Startup Options for Replication Slaves

Obsolete Replication Slave Options

System Variables Used on Replication Slaves

This section describes the server options and system variables that apply to slave replication servers. You can specify the options either on the command line or in an option file. Many of the options can be set while the server is running by using the `CHANGE MASTER TO` statement. You can specify system variable values using `SET`.

**Server ID.** On the master and each slave, you must use the `server-id` option to establish a unique replication ID in the range from 1 to $2^{32} - 1$. “Unique” means that each ID must be different from every other ID in use by any other replication master or slave. Example `my.cnf` file:

```
[mysqld]
server-id=3
```

Startup Options for Replication Slaves

The following list describes startup options for controlling replication slave servers. Many of these options can be set while the server is running by using the `CHANGE MASTER TO` statement. Others, such as the `--replicate-*` options, can be set only when the slave server starts. Replication-related system variables are discussed later in this section.

- `--abort-slave-event-count`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--abort-slave-event-count=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>abort-slave-event-count</code></td>

</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Min Value</th>
<th>0</th>
</tr>
</thead>
</table>

When this option is set to some positive integer value other than 0 (the default) it affects replication behavior as follows: After the slave SQL thread has started, value log events are permitted to be executed; after that, the slave SQL thread does not receive any more events, just as if the network connection from the master were cut. The slave thread continues to run, and the output from SHOW SLAVE STATUS displays Yes in both the Slave_IO_Running and the Slave_SQL_Running columns, but no further events are read from the relay log.

This option is used internally by the MySQL test suite for replication testing and debugging. It is not intended for use in a production setting.

- **--disconnect-slave-event-count**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--disconnect-slave-event-count=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>disconnect-slave-event-count</td>
</tr>

</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Default</td>
</tr>
</tbody>
</table>

Normally, a slave does not log to its own binary log any updates that are received from a master server. This option tells the slave to log the updates performed by its SQL thread to its own binary log. For this option to have any effect, the slave must also be started with the --log-bin option to enable binary logging. Prior to MySQL 5.5, the server would not start when using the --log-slave-updates option without also starting the server with the --log-bin option, and would fail with an error; in MySQL 5.5, only a warning is generated. (Bug #44663) --log-slave-updates is used when you want to chain replication servers. For example, you might want to set up replication servers using this arrangement:

A -> B -> C

Here, A serves as the master for the slave B, and B serves as the master for the slave C. For this to work, B must be both a master and a slave. You must start both A and B with --log-bin to enable binary logging, and B with the --log-slave-updates option so that updates received from A are logged by B to its binary log.

- **--log-slow-slave-statements**
When the slow query log is enabled, this option enables logging for queries that have taken more than long_query_time seconds to execute on the slave.

- `--log-warnings[=level]`

This option causes a server to print more messages to the error log about what it is doing. With respect to replication, the server generates warnings that it succeeded in reconnecting after a network/connection failure, and informs you as to how each slave thread started. This option is enabled (1) by default; to disable it, use `--log-warnings=0`. If the value is greater than 1, aborted connections are written to the error log, and access-denied errors for new connection attempts are written. See Section B.5.2.11, “Communication Errors and Aborted Connections”.

Note that the effects of this option are not limited to replication. It produces warnings across a spectrum of server activities.

- `--master-info-file=file_name`
### Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file name</td>
<td>The name to use for the file in which the slave records information about the master. The default name is <code>master.info</code> in the data directory. For information about the format of this file, see Section 17.2.2.2, “Slave Status Logs”.</td>
</tr>
</tbody>
</table>

- `--master-retry-count=count`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--master-retry-count=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>master-retry-count</code></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Platform</th>
<th>Bit Size</th>
<th>Type</th>
<th>Default</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>32</td>
<td>numeric</td>
<td>0 .. 4294967295</td>
</tr>
<tr>
<td></td>
<td></td>
<td>64</td>
<td>numeric</td>
<td>0 .. 18446744073709551615</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
</table>

The number of times that the slave tries to connect to the master before giving up. Reconnects are attempted at intervals set by the `MASTER_CONNECT_RETRY` option of the `CHANGE MASTER TO` statement (default 60). Reconnects are triggered when data reads by the slave time out according to the `--slave-net-timeout` option. The default value is 86400. A value of 0 means “infinite”; the slave attempts to connect forever.

- `slave-max-allowed-packet=bytes`

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.5.26</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave-max-allowed-packet=#</code></td>
</tr>
<tr>
<td>Option-File Format</td>
<td><code>slave-max-allowed-packet</code></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
</table>

In MySQL 5.5.26 and later, this option sets the maximum packet size in bytes for the slave SQL and I/O threads, so that large updates using row-based replication do not cause replication to fail because an update exceeded `max_allowed_packet`. (Bug #12400221, Bug #60926)

The corresponding server variable `slave_max_allowed_packet` always has a value that is a positive integer multiple of 1024; if you set it to some value that is not such a multiple, the value is automatically rounded down to the next highest multiple of 1024. (For example, if you start the server with `--slave-`
max_allowed_packet=10000, the value used is 9216; setting 0 as the value causes 1024 to be used.) A truncation warning is issued in such cases.

The maximum (and default) value is 1073741824 (1 GB); the minimum is 1024.

- `--max-relay-log-size=size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max_relay_log_size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>max_relay_log_size</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>max_relay_log_size</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 .. 1073741824</td>
</tr>
</tbody>
</table>

The size at which the server rotates relay log files automatically. If this value is nonzero, the relay log is rotated automatically when its size exceeds this value. If this value is zero (the default), the size at which relay log rotation occurs is determined by the value of `max_binlog_size`. For more information, see Section 17.2.2.1, “The Slave Relay Log”.

- `--read-only`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--read-only</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>read_only</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>read_only</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
</tbody>
</table>

Cause the slave to permit no updates except from slave threads or from users having the `SUPER` privilege. On a slave server, this can be useful to ensure that the slave accepts updates only from its master server and not from clients. This variable does not apply to `TEMPORARY` tables.

- `--relay-log=file_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--relay-log=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>relay-log</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>relay_log</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>file_name</td>
</tr>
</tbody>
</table>
The basename for the relay log. The default basename is `host_name-relay-bin`. The server writes the file in the data directory unless the basename is given with a leading absolute path name to specify a different directory. The server creates relay log files in sequence by adding a numeric suffix to the basename.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; *the default basename is used only if the option is not actually specified*. If you use the `--relay-log` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see Section 4.2.3, “Specifying Program Options”.

If you specify this option, the value specified is also used as the basename for the relay log index file. You can override this behavior by specifying a different relay log index file basename using the `--relay-log-index` option.

Starting with MySQL 5.5.20, when the server reads an entry from the index file, it checks whether the entry contains a relative path. If it does, the relative part of the path is replaced with the absolute path set using the `--relay-log` option. An absolute path remains unchanged; in such a case, the index must be edited manually to enable the new path or paths to be used. Prior to MySQL 5.5.20, manual intervention was required whenever relocating the binary log or relay log files. (Bug #11745230, Bug #12133)

You may find the `--relay-log` option useful in performing the following tasks:

- Creating relay logs whose names are independent of host names.
- If you need to put the relay logs in some area other than the data directory because your relay logs tend to be very large and you do not want to decrease `max_relay_log_size`.
- To increase speed by using load-balancing between disks.
- `--relay-log-index=file_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--relay-log-index=name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>relay-log-index</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>relay_log_index</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td></td>
<td>Permitted Values</td>
</tr>
<tr>
<td>Type</td>
<td>file name</td>
</tr>
</tbody>
</table>

The name to use for the relay log index file. The default name is `host_name-relay-bin.index` in the data directory, where `host_name` is the name of the slave server.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; *the default basename is used only if the option is not actually specified*. If you use the `--relay-log-index` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see Section 4.2.3, “Specifying Program Options”.

1990
If you specify this option, the value specified is also used as the basename for the relay logs. You can override this behavior by specifying a different relay log file basename using the `--relay-log` option.

- **--relay-log-info-file=file_name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--relay-log-info-file=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>relay-log-info-file</td>
</tr>
</tbody>
</table>

Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>file name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>relay-log.info</td>
</tr>
</tbody>
</table>

The name to use for the file in which the slave records information about the relay logs. The default name is `relay-log.info` in the data directory. For information about the format of this file, see Section 17.2.2.2, “Slave Status Logs”.

- **--relay-log-purge={0|1}**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--relay_log_purge</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>relay_log_purge</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>relay_log_purge</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>TRUE</td>
</tr>
</tbody>
</table>

Disable or enable automatic purging of relay logs as soon as they are no longer needed. The default value is 1 (enabled). This is a global variable that can be changed dynamically with `SET GLOBAL relay_log_purge = N`.

- **--relay-log-recovery={0|1}**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--relay-log-recovery</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>relay-log-recovery</td>
</tr>
</tbody>
</table>

Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
<th>boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Enables automatic relay log recovery immediately following server startup, which means that the replication slave discards all unprocessed relay logs and retrieves them from the replication master. This should be used following a crash on the replication slave to ensure that no possibly corrupted relay logs are processed. The default value is 0 (disabled).

- **--relay-log-space-limit=size**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--relay_log_space_limit=##</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>relay_log_space_limit</td>
</tr>
</tbody>
</table>

The size of the relay log file. The default value is the size of the `relay-log.info` file.
This option places an upper limit on the total size in bytes of all relay logs on the slave. A value of 0 means “no limit.” This is useful for a slave server host that has limited disk space. When the limit is reached, the I/O thread stops reading binary log events from the master server until the SQL thread has caught up and deleted some unused relay logs. Note that this limit is not absolute: There are cases where the SQL thread needs more events before it can delete relay logs. In that case, the I/O thread exceeds the limit until it becomes possible for the SQL thread to delete some relay logs because not doing so would cause a deadlock. You should not set `--relay-log-space-limit` to less than twice the value of `--max-relay-log-size` (or `--max-binlog-size` if `--max-relay-log-size` is 0). In that case, there is a chance that the I/O thread waits for free space because `--relay-log-space-limit` is exceeded, but the SQL thread has no relay log to purge and is unable to satisfy the I/O thread. This forces the I/O thread to ignore `--relay-log-space-limit` temporarily.

- `--replicate-do-db=db_name`

The effects of this option depend on whether statement-based or row-based replication is in use.

**Statement-based replication.** Tell the slave SQL thread to restrict replication to statements where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database; however, doing so does not replicate cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` while a different database (or no database) is selected.

**Warning**

To specify multiple databases you must use multiple instances of this option. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.
An example of what does not work as you might expect when using statement-based replication: If the slave is started with `--replicate-do-db=sales` and you issue the following statements on the master, the `UPDATE` statement is not replicated:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “check just the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

**Row-based replication.** Tells the slave SQL thread to restrict replication to database `db_name`. Only tables belonging to `db_name` are changed; the current database has no effect on this. Suppose that the slave is started with `--replicate-do-db=sales` and row-based replication is in effect, and then the following statements are run on the master:

```
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The February table in the Sales database on the slave is changed in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, issuing the following statements on the master has no effect on the slave when using row-based replication and `--replicate-do-db=sales`:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the statement `USE prices` were changed to `USE sales`, the `UPDATE` statement’s effects would still not be replicated.

Another important difference in how `--replicate-do-db` is handled in statement-based replication as opposed to row-based replication occurs with regard to statements that refer to multiple databases. Suppose that the slave is started with `--replicate-do-db=db1`, and the following statements are executed on the master:

```
USE db1;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

If you are using statement-based replication, then both tables are updated on the slave. However, when using row-based replication, only `table1` is affected on the slave; since `table2` is in a different database, `table2` on the slave is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

In this case, the `UPDATE` statement would have no effect on the slave when using statement-based replication. However, if you are using row-based replication, the `UPDATE` would change `table1` on the slave, but not `table2`—in other words, only tables in the database named by `--replicate-do-db` are changed, and the choice of default database has no effect on this behavior.
If you need cross-database updates to work, use `--replicate-wild-do-table=db_name.%` instead. See Section 17.2.3, “How Servers Evaluate Replication Filtering Rules”.

**Note**

This option affects replication in the same manner that `--binlog-do-db` affects binary logging, and the effects of the replication format on how `--replicate-do-db` affects replication behavior are the same as those of the logging format on the behavior of `--binlog-do-db`.

This option has no effect on `BEGIN, COMMIT, or ROLLBACK` statements.

- `--replicate-ignore-db=db_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--replicate-ignore-db=name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>replicate-ignore-db</code></td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td><code>string</code></td>
</tr>
</tbody>
</table>

As with `--replicate-do-db`, the effects of this option depend on whether statement-based or row-based replication is in use.

**Statement-based replication.** Tells the slave SQL thread not to replicate any statement where the default database (that is, the one selected by `USE`) is `db_name`.

**Row-based replication.** Tells the slave SQL thread not to update any tables in the database `db_name`. The default database has no effect.

When using statement-based replication, the following example does not work as you might expect. Suppose that the slave is started with `--replicate-ignore-db=sales` and you issue the following statements on the master:

```sql
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement is replicated in such a case because `--replicate-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based replication, the `UPDATE` statement's effects are not propagated to the slave, and the slave's copy of the `sales.january` table is unchanged; in this instance, `--replicate-ignore-db=sales` causes all changes made to tables in the master's copy of the `sales` database to be ignored by the slave.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

You should not use this option if you are using cross-database updates and you do not want these updates to be replicated. See Section 17.2.3, “How Servers Evaluate Replication Filtering Rules”.

If you need cross-database updates to work, use `--replicate-wild-ignore-table=db_name.%` instead. See Section 17.2.3, “How Servers Evaluate Replication Filtering Rules”.
Replication and Binary Logging Options and Variables

Note

This option affects replication in the same manner that `--binlog-ignore-db` affects binary logging, and the effects of the replication format on how `--replicate-ignore-db` affects replication behavior are the same as those of the logging format on the behavior of `--binlog-ignore-db`.

This option has no effect on `BEGIN`, `COMMIT`, or `ROLLBACK` statements.

• `--replicate-do-table=db_name.tbl_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--replicate-do-table=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>replicate-do-table</td>
</tr>
</tbody>
</table>

Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
</tr>
</tbody>
</table>

Tells the slave SQL thread to restrict replication to the specified table. To specify more than one table, use this option multiple times, once for each table. This works for both cross-database updates and default database updates, in contrast to `--replicate-do-db`. See Section 17.2.3, “How Servers Evaluate Replication Filtering Rules”.

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*-db` options.

• `--replicate-ignore-table=db_name.tbl_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--replicate-ignore-table=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>replicate-ignore-table</td>
</tr>
</tbody>
</table>

Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
</tr>
</tbody>
</table>

Tells the slave SQL thread not to replicate any statement that updates the specified table, even if any other tables might be updated by the same statement. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates, in contrast to `--replicate-ignore-db`. See Section 17.2.3, “How Servers Evaluate Replication Filtering Rules”.

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*-db` options.

• `--replicate-rewrite-db=from_name->to_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--replicate-rewrite-db=old_name-&gt;new_name</th>
</tr>
</thead>
<tbody>
<tr>

<td>replicate-rewrite-db</td>
</tr>
</tbody>
</table>

Permitted Values

<table>
<thead>
<tr>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
</tr>
</tbody>
</table>

Tells the slave to translate the default database (that is, the one selected by `USE`) to `to_name` if it was `from_name` on the master. Only statements involving tables are affected (not statements such as `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`), and only if `from_name` is the default...
database on the master. To specify multiple rewrites, use this option multiple times. The server uses the first one with a `from_name` value that matches. The database name translation is done before the `--replicate-*` rules are tested.

Statements in which table names are qualified with database names when using this option do not work with table-level replication filtering options such as `--replicate-do-table`. Suppose we have a database named `a` on the master, one named `b` on the slave, each containing a table `t`, and have started the master with `--replicate-rewrite-db='a->b'`. At a later point in time, we execute `DELETE FROM a.t`. In this case, no relevant filtering rule works, for the reasons shown here:

1. `--replicate-do-table=a.t` does not work because the slave has table `t` in database `b`.
2. `--replicate-do-table=b.t` does not match the original statement and so is ignored.
3. `--replicate-do-table=*.t` is handled identically to `--replicate-do-table=a.t`, and thus does not work, either.

Similarly, the `--replication-rewrite-db` option does not work with cross-database updates.

If you use this option on the command line and the `"` character is special to your command interpreter, quote the option value. For example:

```shell
mysqld --replicate-rewrite-db="olddb->newdb"
```

- **--replicate-same-server-id**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--replicate-same-server-id</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>replicate-same-server-id</code></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Default</td>
</tr>
</tbody>
</table>

To be used on slave servers. Usually you should use the default setting of 0, to prevent infinite loops caused by circular replication. If set to 1, the slave does not skip events having its own server ID. Normally, this is useful only in rare configurations. Cannot be set to 1 if `--log-slave-updates` is used. By default, the slave I/O thread does not write binary log events to the relay log if they have the slave’s server ID (this optimization helps save disk usage). If you want to use `--replicate-same-server-id`, be sure to start the slave with this option before you make the slave read its own events that you want the slave SQL thread to execute.

- **--replicate-wild-do-table=db_name.tbl_name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--replicate-wild-do-table=name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>replicate-wild-do-table</code></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
</tbody>
</table>

Tells the slave thread to restrict replication to statements where any of the updated tables match the specified database and table name patterns. Patterns can contain the “%” and “_” wildcard characters, which have the same meaning as for the `LIKE` pattern-matching operator. To specify more than one table, use this option multiple times, once for each table. This works for cross-database updates. See Section 17.2.3, “How Servers Evaluate Replication Filtering Rules”.

---

1996
This option applies to tables, views, and triggers. It does not apply to stored procedures and functions, or events. To filter statements operating on the latter objects, use one or more of the `--replicate-*_db` options.

Example: `--replicate-wild-do-table=foo%.bar%` replicates only updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

If the table name pattern is `%`, it matches any table name and the option also applies to database-level statements (CREATE DATABASE, DROP DATABASE, and ALTER DATABASE). For example, if you use `--replicate-wild-do-table=foo%.%`, database-level statements are replicated if the database name matches the pattern `foo`.

To include literal wildcard characters in the database or table name patterns, escape them with a backslash. For example, to replicate all tables of a database that is named `my_own%db`, but not replicate tables from the `my1ownAABCdb` database, you should escape the `_` and `%` characters like this: `--replicate-wild-do-table=my\_own\%db`. If you use the option on the command line, you might need to double the backslashes or quote the option value, depending on your command interpreter. For example, with the `bash` shell, you would need to type `--replicate-wild-do-table=my\_own\\%db`.

• `--replicate-wild-ignore-table=db_name.tbl_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--replicate-wild-ignore-table=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>replicate-wild-ignore-table</td>
</tr>
</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
</tr>
</tbody>
</table>

Tells the slave thread not to replicate a statement where any table matches the given wildcard pattern. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates. See Section 17.2.3, “How Servers Evaluate Replication Filtering Rules”.

Example: `--replicate-wild-ignore-table=foo%.bar%` does not replicate updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

For information about how matching works, see the description of the `--replicate-wild-do-table` option. The rules for including literal wildcard characters in the option value are the same as for `--replicate-wild-ignore-table` as well.

• `--report-host=host_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--report-host=host_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>report-host</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>report_host</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
</tr>
</tbody>
</table>

The host name or IP address of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server. Leave the value unset if you do not want the slave to register itself with the master. Note that it is not sufficient for the master to
simply read the IP address of the slave from the TCP/IP socket after the slave connects. Due to NAT and other routing issues, that IP may not be valid for connecting to the slave from the master or other hosts.

- **--report-password=password**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--report-password=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>report-password</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>report_password</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>string</td>
</tr>
</tbody>
</table>

The account password of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the `--show-slave-auth-info` option is given.

Although the name of this option might imply otherwise, `--report-password` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the password for the MySQL replication user account.

- **--report-port=slave_port_num**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--report-port=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>report-port</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>report_port</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values (&gt;= 5.5.23)</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>numeric</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Range</td>
<td>0 .. 65535</td>
</tr>
</tbody>
</table>

The TCP/IP port number for connecting to the slave, to be reported to the master during slave registration. Set this only if the slave is listening on a nondefault port or if you have a special tunnel from the master or other clients to the slave. If you are not sure, do not use this option.

Prior to MySQL 5.5.23, the default value for this option was 3306. In MySQL 5.5.23 and later, the value shown is the port number actually used by the slave (Bug #13333431). This change also affects the default value displayed by `SHOW SLAVE HOSTS`.

- **--report-user=user_name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--report-user=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>report-user</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>report_user</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td></td>
<td>1998</td>
</tr>
</tbody>
</table>
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Dynamic Variable</th>
<th>No</th>
</tr>
</thead>
<tbody>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>string</td>
</tr>
</tbody>
</table>

The account user name of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the `--show-slave-auth-info` option is given.

Although the name of this option might imply otherwise, `--report-user` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the name of the MySQL replication user account.

- `--show-slave-auth-info`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--show-slave-auth-info</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>show-slave-auth-info</code></td>
</tr>
</tbody>
</table>

Display slave user names and passwords in the output of `SHOW SLAVE HOSTS` on the master server for slaves started with the `--report-user` and `--report-password` options.

- `--skip-slave-start`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--skip-slave-start</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>skip-slave-start</code></td>
</tr>
</tbody>
</table>

Tells the slave server not to start the slave threads when the server starts. To start the threads later, use a `START SLAVE` statement.

- `--slave_compressed_protocol={0|1}`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--slave_compressed_protocol</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>slave_compressed_protocol</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>slave_compressed_protocol</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Default</td>
</tr>
</tbody>
</table>

If this option is set to 1, use compression for the slave/master protocol if both the slave and the master support it. The default is 0 (no compression).
Replication and Binary Logging Options and Variables

- **--slave-load-tmpdir=file_name**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--slave-load-tmpdir=path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>slave-load-tmpdir</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>slave_load_tmpdir</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>directory name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>/tmp</td>
</tr>
</tbody>
</table>

The name of the directory where the slave creates temporary files. This option is by default equal to the value of the tmpdir system variable. When the slave SQL thread replicates a LOAD DATA INFILE statement, it extracts the file to be loaded from the relay log into temporary files, and then loads these into the table. If the file loaded on the master is huge, the temporary files on the slave are huge, too. Therefore, it might be advisable to use this option to tell the slave to put temporary files in a directory located in some file system that has a lot of available space. In that case, the relay logs are huge as well, so you might also want to use the --relay-log option to place the relay logs in that file system.

The directory specified by this option should be located in a disk-based file system (not a memory-based file system) because the temporary files used to replicate LOAD DATA INFILE must survive machine restarts. The directory also should not be one that is cleared by the operating system during the system startup process.

- **--slave-net-timeout=seconds**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--slave-net-timeout=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>slave-net-timeout</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>slave_net_timeout</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>3600</td>
</tr>
<tr>
<td>Min Value</td>
<td>1</td>
</tr>
</tbody>
</table>

The number of seconds to wait for more data from the master before the slave considers the connection broken, aborts the read, and tries to reconnect. The first retry occurs immediately after the timeout. The interval between retries is controlled by the MASTER_CONNECT_RETRY option for the CHANGE MASTER TO statement, and the number of reconnection attempts is limited by the --master-retry-count option. The default is 3600 seconds (one hour).

- **--slave-skip-errors=[err_code1, err_code2,...|all]**

(MySQL Cluster NDB 7.2.6 and later): **--slave-skip-errors=[err_code1, err_code2,...|all|ddl_exist_errors]**

| Command-Line Format | --slave-skip-errors=name |

2000
REPlication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Option-File Format</th>
<th>slave-skip-errors</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable Name</td>
<td>slave_skip_errors</td>

</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Default</td>
</tr>
<tr>
<td>Valid Values</td>
</tr>
</tbody>
</table>

Normally, replication stops when an error occurs on the slave. This gives you the opportunity to resolve the inconsistency in the data manually. This option tells the slave SQL thread to continue replication when a statement returns any of the errors listed in the option value.

Do not use this option unless you fully understand why you are getting errors. If there are no bugs in your replication setup and client programs, and no bugs in MySQL itself, an error that stops replication should never occur. Indiscriminate use of this option results in slaves becoming hopelessly out of synchrony with the master, with you having no idea why this has occurred.

For error codes, you should use the numbers provided by the error message in your slave error log and in the output of `SHOW SLAVE STATUS`. Appendix B, *Errors, Error Codes, and Common Problems*, lists server error codes.

You can also (but should not) use the very nonrecommended value of `all` to cause the slave to ignore all error messages and keeps going regardless of what happens. Needless to say, if you use `all`, there are no guarantees regarding the integrity of your data. Please do not complain (or file bug reports) in this case if the slave's data is not anywhere close to what it is on the master. *You have been warned.*

MySQL Cluster NDB 7.2.6 and later support an additional shorthand value `ddl_exist_errors` for use with the enhanced failover mechanism which is implemented beginning with that version of MySQL Cluster. This value is equivalent to the error code list `1007,1008,1050,1051,1054,1060,1061,1068,1094,1146`. This value is not supported by the `mysqld` binary included with the MySQL Server 5.5 distribution. (Bug #11762277, Bug #54854) For more information, see Section 18.6.8, “Implementing Failover with MySQL Cluster Replication”.

Examples:

```
--slave-skip-errors=1062,1053
--slave-skip-errors=all
--slave-skip-errors=ddl_exist_errors
```

### Obsolete Replication Slave Options

The following options are removed in MySQL 5.5. If you attempt to start `mysqld` with any of these options in MySQL 5.5, the server aborts with an unknown variable error. To set the replication parameters formerly associated with these options, you must use the `CHANGE MASTER TO ...` statement (see Section 13.4.2.1, “CHANGE MASTER TO Syntax”).

The options affected are shown in this list:

```sql
--slave-skip-errors=1062,1053
--slave-skip-errors=all
--slave-skip-errors=ddl_exist_errors
```
Replication and Binary Logging Options and Variables

- `--master-host`
- `--master-user`
- `--master-password`
- `--master-port`
- `--master-connect-retry`
- `--master-ssl`
- `--master-ssl-ca`
- `--master-ssl-capath`
- `--master-ssl-cert`
- `--master-ssl-cipher`
- `--master-ssl-key`

System Variables Used on Replication Slaves

The following list describes system variables for controlling replication slave servers. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used with replication slaves are listed earlier in this section.

- `init_slave`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--init-slave=name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>init_slave</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>init_slave</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>string</td>
</tr>
</tbody>
</table>

This variable is similar to `init_connect`, but is a string to be executed by a slave server each time the SQL thread starts. The format of the string is the same as for the `init_connect` variable.

**Note**

The SQL thread sends an acknowledgment to the client before it executes `init_slave`. Therefore, it is not guaranteed that `init_slave` has been executed when `START SLAVE` returns. See Section 13.4.2.5, "START SLAVE Syntax", for more information.

- `relay_log`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--relay-log=name</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>relay-log</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>relay_log</code></td>
</tr>
</tbody>
</table>
## Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Variable Scope</th>
<th>Global</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>file name</td>
</tr>
</tbody>
</table>

The name of the relay log file.

- **relay_log_index**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--relay-log-index</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>relay_log_index</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>relay_log_index</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>file name</td>
</tr>
<tr>
<td>Default</td>
<td><em>host_name</em>-relay-bin.index</td>
</tr>
</tbody>
</table>

The name of the relay log index file. The default name is *host_name*-relay-bin.index in the data directory, where *host_name* is the name of the slave server.

- **relay_log_info_file**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--relay-log-info-file=file_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>relay_log_info_file</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>relay_log_info_file</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>file name</td>
</tr>
<tr>
<td>Default</td>
<td>relay-log.info</td>
</tr>
</tbody>
</table>

The name of the file in which the slave records information about the relay logs. The default name is relay-log.info in the data directory.

- **relay_log_recovery**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--relay-log-recovery</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>relay_log_recovery</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>relay_log_recovery</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>FALSE</td>
</tr>
</tbody>
</table>
Enables automatic relay log recovery immediately following server startup, which means that the replication slave discards all unprocessed relay logs and retrieves them from the replication master. This should be used following a crash on the replication slave to ensure that no possibly corrupted relay logs are processed. The default value is 0 (disabled). This global variable can be changed dynamically, or by starting the slave with the --relay-log-recovery option.

• rpl_recovery_rank

This variable is unused, and is removed in MySQL 5.6.

• slave_compressed_protocol

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--slave_compressed_protocol</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>slave_compressed_protocol</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>slave_compressed_protocol</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>boolean</td>
</tr>
<tr>
<td>Default</td>
<td>OFF</td>
</tr>
</tbody>
</table>

Whether to use compression of the slave/master protocol if both the slave and the master support it.

• slave_exec_mode

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--slave-exec-mode=mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>slave_exec_mode</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>slave_exec_mode</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>enumeration</td>
</tr>
<tr>
<td>Default</td>
<td>STRICT (ALL)</td>
</tr>
<tr>
<td>Default</td>
<td>IDEMPOTENT (NDB)</td>
</tr>
<tr>
<td>Valid Values</td>
<td>IDEMPOTENT</td>
</tr>
<tr>
<td></td>
<td>STRICT</td>
</tr>
</tbody>
</table>

Controls whether IDEMPOTENT or STRICT mode is used in replication conflict resolution and error checking. IDEMPOTENT mode causes suppression of duplicate-key and no-key-found errors.

This mode is needed for multi-master replication, circular replication, and some other special replication scenarios for MySQL Cluster Replication. (See Section 18.6.10, “MySQL Cluster Replication: Multi-Master and Circular Replication”, and Section 18.6.11, “MySQL Cluster Replication Conflict Resolution”, for more information.) The mysql supplied with MySQL Cluster ignores any value explicitly set for slave_exec_mode, and always treats it as IDEMPOTENT.

In MySQL Server 5.5, STRICT mode is the default value. This should not be changed; currently, IDEMPOTENT mode is supported only by NDB.
Replication and Binary Logging Options and Variables

- **slave_load_tmpdir**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--slave-load-tmpdir=path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>slave-load-tmpdir</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>slave_load_tmpdir</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

**Permitted Values**

- **Type**: directory name
- **Default**: /tmp

The name of the directory where the slave creates temporary files for replicating `LOAD DATA INFILE` statements.

- **slave_max_allowed_packet**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.5.26</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable Name</td>
<td>slave_max_allowed_packet</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Permitted Values**

- **Type**: numeric
- **Default**: 1073741824
- **Range**: 1024 .. 1073741824

In MySQL 5.5.26 and later, this variable sets the maximum packet size for the slave SQL and I/O threads, so that large updates using row-based replication do not cause replication to fail because an update exceeded `max_allowed_packet`.

This global variable always has a value that is a positive integer multiple of 1024; if you set it to some value that is not, the value is rounded down to the next highest multiple of 1024 for it is stored or used; setting `slave_max_allowed_packet` to 0 causes 1024 to be used. (A truncation warning is issued in all such cases.) The default and maximum value is 1073741824 (1 GB); the minimum is 1024.

`slave_max_allowed_packet` can also be set at startup, using the `--slave-max-allowed-packet` option.

- **slave_net_timeout**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--slave-net-timeout=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>slave-net-timeout</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>slave_net_timeout</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Permitted Values**

- **Type**: numeric

slave_net_timeout can also be set at startup, using the `--slave-net-timeout` option.
The number of seconds to wait for more data from a master/slave connection before aborting the read.

- **slave_skip_errors**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--slave-skip-errors=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>slave-skip-errors</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>slave_skip_errors</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>string</td>
</tr>
<tr>
<td>Default</td>
<td>OFF</td>
</tr>
<tr>
<td>Valid Values</td>
<td></td>
</tr>
<tr>
<td>Valid Values</td>
<td>[list of error codes]</td>
</tr>
<tr>
<td></td>
<td>all</td>
</tr>
<tr>
<td></td>
<td>ddl_exist_errors</td>
</tr>
</tbody>
</table>

Normally, replication stops when an error occurs on the slave. This gives you the opportunity to resolve the inconsistency in the data manually. This variable tells the slave SQL thread to continue replication when a statement returns any of the errors listed in the variable value.

- **slave_transaction_retries**

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--slave_transaction_retries=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>slave_transaction_retries</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>slave_transaction_retries</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Platform Bit Size</td>
</tr>
<tr>
<td></td>
<td>32</td>
</tr>
<tr>
<td></td>
<td>Type</td>
</tr>
<tr>
<td></td>
<td>Default</td>
</tr>
<tr>
<td></td>
<td>Range</td>
</tr>
<tr>
<td>Permitted Values</td>
<td>Platform Bit Size</td>
</tr>
<tr>
<td></td>
<td>64</td>
</tr>
<tr>
<td></td>
<td>Type</td>
</tr>
<tr>
<td></td>
<td>Default</td>
</tr>
<tr>
<td></td>
<td>Range</td>
</tr>
</tbody>
</table>
If a replication slave SQL thread fails to execute a transaction because of an InnoDB deadlock or because the transaction’s execution time exceeded InnoDB’s `innodb_lock_wait_timeout` or NDBCLUSTER’s `TransactionDeadlockDetectionTimeout` or `TransactionInactiveTimeout`, it automatically retries `slave_transaction_retries` times before stopping with an error. The default value is 10.

- **slave_type_conversions**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.5.3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--slave_type_conversions=set</code></td>
</tr>
<tr>
<td>Option-File Format</td>
<td><code>slave_type_conversions</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>slave_type_conversions</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Default</td>
</tr>
<tr>
<td>Valid Values</td>
</tr>
</tbody>
</table>

Controls the type conversion mode in effect on the slave when using row-based replication, including MySQL Cluster Replication. Its value is a comma-delimited set of zero or more elements from the list: ALL_LOSSY, ALL_NON_LOSSY. Set this variable to an empty string to disallow type conversions between the master and the slave. Changes require a restart of the slave to take effect.

For additional information on type conversion modes applicable to attribute promotion and demotion in row-based replication, see [Row-based replication: attribute promotion and demotion](#).

This variable was added in MySQL 5.5.3.

- **sql_slave_skip_counter**

<table>
<thead>
<tr>
<th>System Variable Name</th>
<th><code>sql_slave_skip_counter</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
</tbody>
</table>

The number of events from the master that a slave server should skip.

⚠️ **Important**

If skipping the number of events specified by setting this variable would cause the slave to begin in the middle of an event group, the slave continues to skip until it finds the beginning of the next event group and begins from that point. For more information, see Section 13.4.2.4, "SET GLOBAL sql_slave_skip_counter Syntax".

- **sync_master_info**
If the value of this variable is greater than 0, a replication slave synchronizes its `master.info` file to disk (using `fdatasync()`) after every `sync_master_info` events. The default value is 0 (recommended in most situations), which does not force any synchronization to disk by the MySQL server; in this case, the server relies on the operating system to flush the `master.info` file's contents from time to time as for any other file.

- `sync_relay_log`
Replication and Binary Logging Options and Variables

| Range | 0 .. 18446744073709547520 |

If the value of this variable is greater than 0, the MySQL server synchronizes its relay log to disk (using `fdatasync()`) after every `sync_relay_log` events are written to the relay log.

The default value of `sync_relay_log` is 0, which does no synchronizing to disk; in this case, the server relies on the operating system to flush the relay log's contents from time to time as for any other file.

A value of 1 is the safest choice because in the event of a crash you lose at most one event from the relay log. However, it is also the slowest choice (unless the disk has a battery-backed cache, which makes synchronization very fast).

- `sync_relay_log_info`

| Command-Line Format | `--sync-relay-log-info=#` |
| Option-File Format  | `sync_relay_log_info` |
| System Variable Name| `sync_relay_log_info` |
| Variable Scope      | Global |
| Dynamic Variable    | Yes |
| **Permitted Values**| |
| Platform Bit Size   | 32 |
| Type                | numeric |
| Default             | 0 |
| Range               | 0 .. 4294967295 |

If the value of this variable is greater than 0, a replication slave synchronizes its `relay-log.info` file to disk (using `fdatasync()`) after every `sync_relay_log_info` transactions. A value of 1 is the generally the best choice. The default value of `sync_relay_log_info` is 0, which does not force any synchronization to disk by the MySQL server—in this case, the server relies on the operating system to flush the `relay-log.info` file's contents from time to time as for any other file.

17.1.3.4 Binary Log Options and Variables

Startup Options Used with Binary Logging

System Variables Used with Binary Logging

You can use the `mysqld` options and system variables that are described in this section to affect the operation of the binary log as well as to control which statements are written to the binary log. For additional information about the binary log, see Section 5.2.4, “The Binary Log”. For additional information about using MySQL server options and system variables, see Section 5.1.3, “Server Command Options”, and Section 5.1.4, “Server System Variables”.

2009
Start up Options Used with Binary Logging

The following list describes start up options for enabling and configuring the binary log. System variables used with binary logging are discussed later in this section.

- \texttt{--binlog-row-event-max-size=N}

\begin{tabular}{|l|l|}
\hline
\textbf{Command-Line Format} & \texttt{--binlog-row-event-max-size=#} \\
\textbf{Option-File Format} & \texttt{binlog-row-event-max-size} \\
\hline
\textbf{Permitted Values} & \\
\textbf{Platform} & 32 \\
\textbf{Bit Size} & \\
\textbf{Type} & numeric \\
\textbf{Default} & 1024 \\
\textbf{Range} & 256 .. 4294967295 \\
\hline
\textbf{Permitted Values} & \\
\textbf{Platform} & 64 \\
\textbf{Bit Size} & \\
\textbf{Type} & numeric \\
\textbf{Default} & 1024 \\
\textbf{Range} & 256 .. 18446744073709551615 \\
\hline
\end{tabular}

Specify the maximum size of a row-based binary log event, in bytes. Rows are grouped into events smaller than this size if possible. The value should be a multiple of 256. The default is 1024. See Section 17.1.2, “Replication Formats”.

- \texttt{--log-bin[=base_name]}

\begin{tabular}{|l|l|l|l|}
\hline
\textbf{Command-Line Format} & \texttt{--log-bin} \\
\textbf{Option-File Format} & \texttt{log-bin} \\
\textbf{System Variable Name} & \texttt{log_bin} \\
\textbf{Variable Scope} & Global \\
\textbf{Dynamic Variable} & No \\
\hline
\textbf{Permitted Values} & \\
\textbf{Type} & file name \\
\hline
\end{tabular}

Enable binary logging. The server logs all statements that change data to the binary log, which is used for backup and replication. See Section 5.2.4, “The Binary Log”.

The option value, if given, is the basename for the log sequence. The server creates binary log files in sequence by adding a numeric suffix to the basename. It is recommended that you specify a basename (see Section B.5.8, “Known Issues in MySQL”, for the reason). Otherwise, MySQL uses host_name-bin as the basename.

In MySQL 5.5.20 and later, when the server reads an entry from the index file, it checks whether the entry contains a relative path, and if it does, the relative part of the path in replaced with the absolute path set using the \texttt{--log-bin} option. An absolute path remains unchanged; in such a case, the index must be edited manually to enable the new path or paths to be used. Previous to MySQL 5.5.20, manual
Replication and Binary Logging Options and Variables

intervention was required whenever relocating the binary log or relay log files. (Bug #11745230, Bug #12133)

Setting this option causes the \texttt{log\_bin} system variable to be set to \texttt{ON} (or \texttt{1}), and not to the basename. This is a known issue; see Bug #19614 for more information.

• \texttt{--log-bin-index[=file\_name]}

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>\texttt{--log-bin-index=name}</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>\texttt{log-bin-index}</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>\texttt{file name}</td>
</tr>
</tbody>
</table>

The index file for binary log file names. See Section 5.2.4, “The Binary Log”. If you omit the file name, and if you did not specify one with \texttt{--log-bin}, MySQL uses \texttt{host\_name-bin.index} as the file name.

• \texttt{--log-bin-trust-function-creators[={0|1}]}

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>\texttt{--log-bin-trust-function-creators}</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>\texttt{log-bin-trust-function-creators}</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>\texttt{log_bin_trust_function_creators}</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>\texttt{boolean}</td>
</tr>
<tr>
<td>Default</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

This option sets the corresponding \texttt{log\_bin\_trust\_function\_creators} system variable. If no argument is given, the option sets the variable to 1. \texttt{log\_bin\_trust\_function\_creators} affects how MySQL enforces restrictions on stored function and trigger creation. See Section 20.7, “Binary Logging of Stored Programs”.

• \texttt{--log-bin-use-v1-row-events[={0|1}]}

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.5.15-ndb-7.2.1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>\texttt{--log-bin-use-v1-row-events[={0</td>
</tr>
<tr>
<td>Option-File Format</td>
<td>\texttt{log-bin-use-v1-row-events}</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>\texttt{log_bin_use_v1_row_events}</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>No</td>
</tr>
<tr>
<td>Permitted Values</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>\texttt{boolean}</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
</tbody>
</table>

Version 2 binary log row events are used by default beginning with MySQL Cluster NDB 7.2.1; however, Version 2 events cannot be read by previous MySQL Cluster releases. Setting \texttt{--log-bin-use-v1-row-events} to 1 causes \texttt{mysqld} to write the binary log using Version 1 logging events, which is the
only version of binary log events used in previous releases, and thus produce binary logs that can be read by older slaves.

The value used for this option can be obtained from the read-only log_bin_use_v1_row_events system variable.

`--log-bin-use-v1-row-events` is chiefly of interest when setting up replication conflict detection and resolution using NDB$EPOCH_TRANS() as the conflict detection function, which requires Version 2 binary log row events. Thus, this option and `--ndb-log-transaction-id` are not compatible.

**Note**

Version 2 binary log row events are also available in MySQL Cluster NDB 7.0.27 and MySQL Cluster NDB 7.1.6 and later MySQL Cluster NDB 7.0 and 7.1 releases. However, prior to MySQL Cluster NDB 7.2.1, Version 1 events are the default (and so the default value for this option is 1 in those versions). You should keep this in mind when planning upgrades for setups using MySQL Cluster Replication.

`--log-bin-use-v1-row-events` is not supported in mainline MySQL Server 5.5 releases.

For more information, see Section 18.6.11, “MySQL Cluster Replication Conflict Resolution”.

• `--log-short-format`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--log-short-format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>log-short-format</td>
</tr>
</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

Log less information to the binary log and slow query log, if they have been activated.

**Statement selection options.** The options in the following list affect which statements are written to the binary log, and thus sent by a replication master server to its slaves. There are also options for slave servers that control which statements received from the master should be executed or ignored. For details, see Section 17.1.3.3, “Replication Slave Options and Variables”.

• `--binlog-do-db=db_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--binlog-do-db=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>binlog-do-db</td>
</tr>
</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>string</th>
</tr>
</thead>
</table>

This option affects binary logging in a manner similar to the way that `--replicate-do-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-do-db` depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as CREATE TABLE and ALTER TABLE are always logged as statements, without
regard to the logging format in effect, so the following statement-based rules for `--binlog-do-db` always apply in determining whether or not the statement is logged.

**Statement-based logging.** Only those statements are written to the binary log where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database; however, doing so does not cause cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` to be logged while a different database (or no database) is selected.

**Warning**
To specify multiple databases you must use multiple instances of this option. Because database names can contain commas, the list will be treated as the name of a single database if you supply a comma-separated list.

An example of what does not work as you might expect when using statement-based logging: If the server is started with `--binlog-do-db=sales` and you issue the following statements, the `UPDATE` statement is not logged:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “just check the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

Another case which may not be self-evident occurs when a given database is replicated even though it was not specified when setting the option. If the server is started with `--binlog-do-db=sales`, the following `UPDATE` statement is logged even though `prices` was not included when setting `--binlog-do-db`:

```
USE sales;
UPDATE prices.discounts SET percentage = percentage + 10;
```

Because `sales` is the default database when the `UPDATE` statement is issued, the `UPDATE` is logged.

**Row-based logging.** Logging is restricted to database `db_name`. Only changes to tables belonging to `db_name` are logged; the default database has no effect on this. Suppose that the server is started with `--binlog-do-db=sales` and row-based logging is in effect, and then the following statements are executed:

```
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The changes to the `february` table in the `sales` database are logged in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, when using the row-based logging format and `--binlog-do-db=sales`, changes made by the following `UPDATE` are not logged:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```
Even if the `USE prices` statement were changed to `USE sales`, the `UPDATE` statement's effects would still not be written to the binary log.

Another important difference in `--binlog-do-db` handling for statement-based logging as opposed to the row-based logging occurs with regard to statements that refer to multiple databases. Suppose that the server is started with `--binlog-do-db=db1`, and the following statements are executed:

```
USE db1;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

If you are using statement-based logging, the updates to both tables are written to the binary log. However, when using the row-based format, only the changes to `table1` are logged; `table2` is in a different database, so it is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

In this case, the `UPDATE` statement is not written to the binary log when using statement-based logging. However, when using row-based logging, the change to `table1` is logged, but not that to `table2`—in other words, only changes to tables in the database named by `--binlog-do-db` are logged, and the choice of default database has no effect on this behavior.

- `--binlog-ignore-db=db_name`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--binlog-ignore-db=name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>binlog-ignore-db</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Permitted Values</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>string</td>
<td></td>
</tr>
</tbody>
</table>

This option affects binary logging in a manner similar to the way that `--replicate-ignore-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-ignore-db` depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for `--binlog-ignore-db` always apply in determining whether or not the statement is logged.

**Statement-based logging.** Tells the server to not log any statement where the default database (that is, the one selected by `USE`) is `db_name`.

Prior to MySQL 5.5.32, this option caused any statements containing fully qualified table names not to be logged if there was no default database specified (that is, when `SELECT DATABASE()` returned `NULL`). In MySQL 5.5.32 and later, when there is no default database, no `--binlog-ignore-db` options are applied, and such statements are always logged. (Bug #11829838, Bug #60188)

**Row-based format.** Tells the server not to log updates to any tables in the database `db_name`. The current database has no effect.
When using statement-based logging, the following example does not work as you might expect. Suppose that the server is started with `--binlog-ignore-db=sales` and you issue the following statements:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement is logged in such a case because `--binlog-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based logging, the `UPDATE` statement’s effects are not written to the binary log, which means that no changes to the `sales.january` table are logged; in this instance, `--binlog-ignore-db=sales` causes all changes made to tables in the master’s copy of the `sales` database to be ignored for purposes of binary logging.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, the list will be treated as the name of a single database if you supply a comma-separated list.

You should not use this option if you are using cross-database updates and you do not want these updates to be logged.

**Testing and debugging options.** The following binary log options are used in replication testing and debugging. They are not intended for use in normal operations.

- `--max-binlog-dump-events=N`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--max-binlog-dump-events=#</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>max-binlog-dump-events</code></td>
</tr>
</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>numeric</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>0</td>
</tr>
</tbody>
</table>

This option is used internally by the MySQL test suite for replication testing and debugging.

- `--sporadic-binlog-dump-fail`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th><code>--sporadic-binlog-dump-fail</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td><code>sporadic-binlog-dump-fail</code></td>
</tr>
</tbody>
</table>

**Permitted Values**

<table>
<thead>
<tr>
<th>Type</th>
<th>boolean</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>FALSE</td>
</tr>
</tbody>
</table>

This option is used internally by the MySQL test suite for replication testing and debugging.

**System Variables Used with Binary Logging**

The following list describes system variables for controlling binary logging. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used to control binary logging are listed earlier in this section. For information about the `sql_log_bin` and `sql_log_off` variables, see Section 5.1.4, “Server System Variables”.

- `binlog_cache_size`
### Replication and Binary Logging Options and Variables

The size of the cache to hold changes to the binary log during a transaction. A binary log cache is allocated for each client if the server supports any transactional storage engines and if the server has the binary log enabled (`--log-bin` option). If you often use large transactions, you can increase this cache size to get better performance. The `Binlog_cache_use` and `Binlog_cache_disk_use` status variables can be useful for tuning the size of this variable. See Section 5.2.4, “The Binary Log”.

In MySQL 5.5.3, a separate binary log cache (the binary log statement cache) was introduced for nontransactional statements and in MySQL 5.5.3 through 5.5.8, this variable sets the size for both caches. This means that, in these MySQL versions, the total memory used for these caches is double the value set for `binlog_cache_size`.

Beginning with MySQL 5.5.9, `binlog_cache_size` sets the size for the transaction cache only, and the size of the statement cache is governed by the `binlog_stmt_cache_size` system variable.

- **`binlog_direct_non_transactional_updates`**

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.5.2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td><code>--binlog_direct_non_transactional_updates[=value]</code></td>
</tr>
<tr>
<td>Option-File Format</td>
<td><code>binlog_direct_non_transactional_updates</code></td>
</tr>
<tr>
<td>System Variable Name</td>
<td><code>binlog_direct_non_transactional_updates</code></td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

#### Permitted Values

<table>
<thead>
<tr>
<th>Platform</th>
<th>Bit Size</th>
<th>Type</th>
<th>Default</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>32</td>
<td>numeric</td>
<td>32768</td>
<td>4096 .. 4294967295</td>
</tr>
<tr>
<td></td>
<td>64</td>
<td>numeric</td>
<td>32768</td>
<td>4096 .. 18446744073709547520</td>
</tr>
</tbody>
</table>
Due to concurrency issues, a slave can become inconsistent when a transaction contains updates to both transactional and nontransactional tables. MySQL tries to preserve causality among these statements by writing nontransactional statements to the transaction cache, which is flushed upon commit. However, problems arise when modifications done to nontransactional tables on behalf of a transaction become immediately visible to other connections because these changes may not be written immediately into the binary log.

Beginning with MySQL 5.5.2, the `binlog_direct_non_transactional_updates` variable offers one possible workaround to this issue. By default, this variable is disabled. Enabling `binlog_direct_non_transactional_updates` causes updates to nontransactional tables to be written directly to the binary log, rather than to the transaction cache.

`binlog_direct_non_transactional_updates` works only for statements that are replicated using the statement-based binary logging format; that is, it works only when the value of `binlog_format` is `STATEMENT`, or when `binlog_format` is `MIXED` and a given statement is being replicated using the statement-based format. This variable has no effect when the binary log format is `ROW`, or when `binlog_format` is set to `MIXED` and a given statement is replicated using the row-based format.

---

**Important**

Before enabling this variable, you must make certain that there are no dependencies between transactional and nontransactional tables; an example of such a dependency would be the statement `INSERT INTO myisam_table SELECT * FROM innodb_table`. Otherwise, such statements are likely to cause the slave to diverge from the master.

Beginning with MySQL 5.5.5, this variable has no effect when the binary log format is `ROW` or `MIXED`. (Bug #51291)

• `binlog_format`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--binlog-format=format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>binlog-format</td>
</tr>
<tr>
<td>System-File Name</td>
<td>binlog_format</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global, Session</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
<tr>
<td><strong>Permitted Values</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td>enumeration</td>
</tr>
<tr>
<td><strong>Default</strong></td>
<td><code>STATEMENT</code></td>
</tr>
<tr>
<td><strong>Valid Values</strong></td>
<td><code>ROW</code></td>
</tr>
<tr>
<td></td>
<td><code>STATEMENT</code></td>
</tr>
<tr>
<td></td>
<td><code>MIXED</code></td>
</tr>
</tbody>
</table>

This variable sets the binary logging format, and can be any one of `STATEMENT`, `ROW`, or `MIXED`. See Section 17.1.2, “Replication Formats”. `binlog_format` is set by the `--binlog-format` option at startup, or by the `binlog_format` system variable at runtime.
Note
While you can change the logging format at runtime, it is not recommended that you change it while replication is ongoing. This is due in part to the fact that slaves do not honor the master's binlog_format setting; a given MySQL Server can change only its own logging format.

In MySQL 5.5, the default format is STATEMENT.

Exception. In MySQL Cluster NDB 7.2.1 through MySQL Cluster NDB 7.2.12, the default for this variable is STATEMENT. In MySQL Cluster NDB 7.2.13 and later, when the NDB storage engine is enabled, the default is MIXED. (Bug #16417224) See also Section 18.6.6, “Starting MySQL Cluster Replication (Single Replication Channel)”, and Section 18.6.7, “Using Two Replication Channels for MySQL Cluster Replication”.

You must have the SUPER privilege to set either the global or session binlog_format value.

The rules governing when changes to this variable take effect and how long the effect lasts are the same as for other MySQL server system variables. See Section 13.7.4, "SET Syntax", for more information.

When MIXED is specified, statement-based replication is used, except for cases where only row-based replication is guaranteed to lead to proper results. For example, this happens when statements contain user-defined functions (UDF) or the UUID() function. An exception to this rule is that MIXED always uses statement-based replication for stored functions and triggers.

There are exceptions when you cannot switch the replication format at runtime:

- From within a stored function or a trigger.
- If the session is currently in row-based replication mode and has open temporary tables.
- Beginning with MySQL 5.5.3, within a transaction. (Bug #47863)

Trying to switch the format in those cases results in an error.

Note
Prior to MySQL Cluster NDB 7.2.1, it was also not possible to change the binary logging format at runtime when the NDBCLUSTER storage engine was enabled. In MySQL Cluster NDB 7.2.1 and later, this restriction is removed.

The binary log format affects the behavior of the following server options:

- --replicate-do-db
- --replicate-ignore-db
- --binlog-do-db
- --binlog-ignore-db

These effects are discussed in detail in the descriptions of the individual options.

Beginning with MySQL 5.5.9, this variable determines the size of the cache for the binary log to hold nontransactional statements issued during a transaction. In MySQL 5.5.3 and later, separate binary log transaction and statement caches are allocated for each client if the server supports any transactional storage engines and if the server has the binary log enabled (\--log-bin\ option). If you often use large nontransactional statements during transactions, you can increase this cache size to get more performance. The Binlog_stmt_cache_use and Binlog_stmt_cache_disk_use status variables can be useful for tuning the size of this variable. See Section 5.2.4, "The Binary Log".

In MySQL 5.5.3 through 5.5.8, the size for both caches is set using binlog_cache_size. This means that, in these MySQL versions, the total memory used for these caches is double the value set for binlog_cache_size. Beginning with MySQL 5.5.9, binlog_cache_size sets the size for the transaction cache only.

Whether the binary log is enabled. If the \--log-bin\ option is used, then the value of this variable is ON; otherwise it is OFF. This variable reports only on the status of binary logging (enabled or disabled); it does not actually report the value to which \--log-bin\ is set.

See Section 5.2.4, "The Binary Log".

- log_bin_use_v1_row_events

<table>
<thead>
<tr>
<th>Introduced</th>
<th>5.5.15-ndb-7.2.1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Command-Line Format</td>
<td>--log-bin-use-v1-row-events={0</td>
</tr>
</tbody>
</table>
The variable `log_bin_use_v1_row_events` shows whether Version 2 binary logging, available beginning with MySQL Cluster NDB 7.2.1, is in use. A value of 1 shows that the server is writing the binary log using Version 1 logging events (the only version of binary log events used in previous releases), and thus producing a binary log that can be read by older slaves. 0 indicates that Version 2 binary log events are in use.

This variable is read-only. To switch between Version 1 and Version 2 binary event binary logging, it is necessary to restart `mysqld` with the `--log-bin-use-v1-row-events` option.

Other than when performing upgrades of MySQL Cluster Replication, `--log-bin-use-v1-row-events` is chiefly of interest when setting up replication conflict detection and resolution using NDB `$EPOCH_TRANS()`, which requires Version 2 binary row event logging. Thus, this option and `--ndb-log-transaction-id` are not compatible.

---

**Note**

MySQL Cluster NDB 7.2.1 and later use Version 2 binary log row events by default (and so the default value for this variable changes to 0 in those versions). You should keep this mind when planning upgrades for setups using MySQL Cluster Replication.

This variable is not supported in mainline MySQL Server 5.5.

For more information, see Section 18.6.11, “MySQL Cluster Replication Conflict Resolution”.

- `log_slave_updates`
Replication and Binary Logging Options and Variables

<table>
<thead>
<tr>
<th>Option-File Format</th>
<th>max_binlog_cache_size</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Variable Name</td>
<td>max_binlog_cache_size</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Permitted Values**

- **Type**: numeric
- **Default**: 18446744073709547520
- **Range**: 4096 .. 18446744073709547520

If a transaction requires more than this many bytes of memory, the server generates a Multi-statement transaction required more than 'max_binlog_cache_size' bytes of storage error. The minimum value is 4096. The maximum possible value is 16EB (exabytes). The maximum recommended value is 4GB; this is due to the fact that MySQL currently cannot work with binary log positions greater than 4GB.

**Note**

Prior to MySQL 5.5.28, 64-bit Windows platforms truncated the stored value for this variable to 4G, even when it was set to a greater value (Bug #13961678).

In MySQL 5.5.3, a separate binary log cache (the binary log statement cache) was introduced for nontransactional statements and in MySQL 5.5.3 through 5.5.8, this variable sets the upper limit for both caches. This means that, in these MySQL versions, the effective maximum for these caches is double the value set for `max_binlog_cache_size`.

Beginning with MySQL 5.5.9, `max_binlog_cache_size` sets the size for the transaction cache only, and the upper limit for the statement cache is governed by the `max_binlog_stmt_cache_size` system variable.

Also beginning with MySQL 5.5.9, the session visibility of the `max_binlog_cache_size` system variable matches that of the `binlog_cache_size` system variable: In MySQL 5.5.8 and earlier releases, a change in `max_binlog_cache_size` took immediate effect; in MySQL 5.5.9 and later, a change in `max_binlog_cache_size` takes effect only for new sessions that started after the value is changed.

- `max_binlog_size`

<table>
<thead>
<tr>
<th>Command-Line Format</th>
<th>--max_binlog_size=#</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option-File Format</td>
<td>max_binlog_size</td>
</tr>
<tr>
<td>System Variable Name</td>
<td>max_binlog_size</td>
</tr>
<tr>
<td>Variable Scope</td>
<td>Global</td>
</tr>
<tr>
<td>Dynamic Variable</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Permitted Values**

- **Type**: numeric
- **Default**: 1073741824
- **Range**: 4096 .. 1073741824

2021
If a write to the binary log causes the current log file size to exceed the value of this variable, the server rotates the binary logs (closes the current file and opens the next one). The minimum value is 4096 bytes. The maximum and default value is 1GB.

A transaction is written in one chunk to the binary log, so it is never split between several binary logs. Therefore, if you have big transactions, you might see binary log files larger than `max_binlog_size`.

If `max_relay_log_size` is 0, the value of `max_binlog_size` applies to relay logs as well.

- `max_binlog_stmt_cache_size`
Once replication has been started it should execute without requiring much regular administration. Depending on your replication environment, you will want to check the replication status of each slave periodically, daily, or even more frequently.

### 17.1.4.1 Checking Replication Status

The most common task when managing a replication process is to ensure that replication is taking place and that there have been no errors between the slave and the master. The primary statement for this is `SHOW SLAVE STATUS`, which you must execute on each slave:

```
mysql> SHOW SLAVE STATUS\G
*************************** 1. row ***************************
Slave_IO_State: Waiting for master to send event
    Master_Host: master1
    Master_User: root
    Master_Port: 3306
    Connect_Retry: 60
    Master_Log_File: mysql-bin.000004
    Read_Master_Log_Pos: 931
    Relay_Log_File: slave1-relay-bin.000056
    Relay_Log_Pos: 950
    Relay_Master_Log_File: mysql-bin.000004
    Slave_IO_Running: Yes
    Slave_SQL_Running: Yes
    Replicate_Do_DB:
    Replicate_Ignore_DB:
    Replicate_Do_Table:
    Replicate_Ignore_Table:
    Replicate_Wild_Do_Table:
    Replicate_Wild_Ignore_Table:
    Last_Errno: 0
    Last_Error:
```
The key fields from the status report to examine are:

- **Slave_IO_State**: The current status of the slave. See Section 8.12.5.6, “Replication Slave I/O Thread States”, and Section 8.12.5.7, “Replication Slave SQL Thread States”, for more information.

- **Slave_IO_Running**: Whether the I/O thread for reading the master's binary log is running. Normally, you want this to be **Yes** unless you have not yet started replication or have explicitly stopped it with **STOP SLAVE**.

- **Slave_SQL_Running**: Whether the SQL thread for executing events in the relay log is running. As with the I/O thread, this should normally be **Yes**.

- **Last_IO_Error, Last_SQL_Error**: The last errors registered by the I/O and SQL threads when processing the relay log. Ideally these should be blank, indicating no errors.

- **Seconds_Behind_Master**: The number of seconds that the slave SQL thread is behind processing the master binary log. A high number (or an increasing one) can indicate that the slave is unable to handle events from the master in a timely fashion.

  A value of 0 for **Seconds_Behind_Master** can usually be interpreted as meaning that the slave has caught up with the master, but there are some cases where this is not strictly true. For example, this can occur if the network connection between master and slave is broken but the slave I/O thread has not yet noticed this—that is, **slave_net_timeout** has not yet elapsed.

  It is also possible that transient values for **Seconds_Behind_Master** may not reflect the situation accurately. When the slave SQL thread has caught up on I/O, **Seconds_Behind_Master** displays 0; but when the slave I/O thread is still queuing up a new event, **Seconds_Behind_Master** may show a large value until the SQL thread finishes executing the new event. This is especially likely when the events have old timestamps; in such cases, if you execute **SHOW SLAVE STATUS** several times in a relatively short period, you may see this value change back and forth repeatedly between 0 and a relatively large value.

Several pairs of fields provide information about the progress of the slave in reading events from the master binary log and processing them in the relay log:

- **(Master_Log_file, Read_Master_Log_Pos)**: Coordinates in the master binary log indicating how far the slave I/O thread has read events from that log.

- **(Relay_Master_Log_File, Exec_Master_Log_Pos)**: Coordinates in the master binary log indicating how far the slave SQL thread has executed events received from that log.
Common Replication Administration Tasks

• \(\text{Relay\_Log\_File, Relay\_Log\_Pos}\): Coordinates in the slave relay log indicating how far the slave SQL thread has executed the relay log. These correspond to the preceding coordinates, but are expressed in slave relay log coordinates rather than master binary log coordinates.

On the master, you can check the status of connected slaves using \texttt{SHOW PROCESSLIST} to examine the list of running processes. Slave connections have Binlog Dump in the Command field:

```sql
mysql> SHOW PROCESSLIST \G;
*************************** 4. row ***************************
   Id: 10
  User: root
    Host: slave1:58371
      db: NULL
     Command: Binlog Dump
      Time: 777
        State: Has sent all binlog to slave; waiting for binlog to be updated
        Info: NULL
```

Because it is the slave that drives the replication process, very little information is available in this report.

For slaves that were started with the \texttt{--report-host} option and are connected to the master, the \texttt{SHOW SLAVE HOSTS} statement on the master shows basic information about the slaves. The output includes the ID of the slave server, the value of the \texttt{--report-host} option, the connecting port, and master ID:

```sql
mysql> SHOW SLAVE HOSTS;
+-----------+--------+------+-------------------+-----------+
| Server_id | Host   | Port | Rpl_recovery_rank | Master_id |
+-----------+--------+------+-------------------+-----------+
|        10 | slave1 | 3306 |                 0 |         1 |
+-----------+--------+------+-------------------+-----------+
1 row in set (0.00 sec)
```

### 17.1.4.2 Pausing Replication on the Slave

You can stop and start the replication of statements on the slave using the \texttt{STOP SLAVE} and \texttt{START SLAVE} statements.

To stop processing of the binary log from the master, use \texttt{STOP SLAVE}:

```sql
mysql> STOP SLAVE;
```

When replication is stopped, the slave I/O thread stops reading events from the master binary log and writing them to the relay log, and the SQL thread stops reading events from the relay log and executing them. You can pause the I/O or SQL thread individually by specifying the thread type:

```sql
mysql> STOP SLAVE IO_THREAD;
mysql> STOP SLAVE SQL_THREAD;
```

To start execution again, use the \texttt{START SLAVE} statement:

```sql
mysql> START SLAVE;
```

To start a particular thread, specify the thread type:

```sql
mysql> START SLAVE IO_THREAD;
mysql> START SLAVE SQL_THREAD;
```
For a slave that performs updates only by processing events from the master, stopping only the SQL thread can be useful if you want to perform a backup or other task. The I/O thread will continue to read events from the master but they are not executed. This makes it easier for the slave to catch up when you restart the SQL thread.

Stopping only the I/O thread enables the events in the relay log to be executed by the SQL thread up to the point where the relay log ends. This can be useful when you want to pause execution to catch up with events already received from the master, when you want to perform administration on the slave but also ensure that it has processed all updates to a specific point. This method can also be used to pause event receipt on the slave while you conduct administration on the master. Stopping the I/O thread but permitting the SQL thread to run helps ensure that there is not a massive backlog of events to be executed when replication is started again.

17.2 Replication Implementation

Replication is based on the master server keeping track of all changes to its databases (updates, deletes, and so on) in its binary log. The binary log serves as a written record of all events that modify database structure or content (data) from the moment the server was started. Typically, SELECT statements are not recorded because they modify neither database structure nor content.

Each slave that connects to the master requests a copy of the binary log. That is, it pulls the data from the master, rather than the master pushing the data to the slave. The slave also executes the events from the binary log that it receives. This has the effect of repeating the original changes just as they were made on the master. Tables are created or their structure modified, and data is inserted, deleted, and updated according to the changes that were originally made on the master.

Because each slave is independent, the replaying of the changes from the master's binary log occurs independently on each slave that is connected to the master. In addition, because each slave receives a copy of the binary log only by requesting it from the master, the slave is able to read and update the copy of the database at its own pace and can start and stop the replication process at will without affecting the ability to update to the latest database status on either the master or slave side.

For more information on the specifics of the replication implementation, see Section 17.2.1, “Replication Implementation Details”.

Masters and slaves report their status in respect of the replication process regularly so that you can monitor them. See Section 8.12.5, “Examining Thread Information”, for descriptions of all replicated-related states.

The master binary log is written to a local relay log on the slave before it is processed. The slave also records information about the current position with the master's binary log and the local relay log. See Section 17.2.2, “Replication Relay and Status Logs”.

Database changes are filtered on the slave according to a set of rules that are applied according to the various configuration options and variables that control event evaluation. For details on how these rules are applied, see Section 17.2.3, “How Servers Evaluate Replication Filtering Rules”.

17.2.1 Replication Implementation Details

MySQL replication capabilities are implemented using three threads, one on the master server and two on the slave:

- **Binlog dump thread.** The master creates a thread to send the binary log contents to a slave when the slave connects. This thread can be identified in the output of SHOW PROCESSLIST on the master as the Binlog Dump thread.
The binlog dump thread acquires a lock on the master's binary log for reading each event that is to be sent to the slave. As soon as the event has been read, the lock is released, even before the event is sent to the slave.

- **Slave I/O thread.** When a `START SLAVE` statement is issued on a slave server, the slave creates an I/O thread, which connects to the master and asks it to send the updates recorded in its binary logs.

The slave I/O thread reads the updates that the master’s Binlog Dump thread sends (see previous item) and copies them to local files that comprise the slave’s relay log.

The state of this thread is shown as `Slave_IO_running` in the output of `SHOW SLAVE STATUS` or as `Slave_running` in the output of `SHOW STATUS`.

- **Slave SQL thread.** The slave creates an SQL thread to read the relay log that is written by the slave I/O thread and execute the events contained therein.

In the preceding description, there are three threads per master/slave connection. A master that has multiple slaves creates one binlog dump thread for each currently connected slave, and each slave has its own I/O and SQL threads.

A slave uses two threads to separate reading updates from the master and executing them into independent tasks. Thus, the task of reading statements is not slowed down if statement execution is slow. For example, if the slave server has not been running for a while, its I/O thread can quickly fetch all the binary log contents from the master when the slave starts, even if the SQL thread lags far behind. If the slave stops before the SQL thread has executed all the fetched statements, the I/O thread has at least fetched everything so that a safe copy of the statements is stored locally in the slave's relay logs, ready for execution the next time that the slave starts. This enables the master server to purge its binary logs sooner because it no longer needs to wait for the slave to fetch their contents.

The `SHOW PROCESSLIST` statement provides information that tells you what is happening on the master and on the slave regarding replication. For information on master states, see Section 8.12.5.5, “Replication Master Thread States”. For slave states, see Section 8.12.5.6, “Replication Slave I/O Thread States”, and Section 8.12.5.7, “Replication Slave SQL Thread States”.

The following example illustrates how the three threads show up in the output from `SHOW PROCESSLIST`.

On the master server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
*************************** 1. row ***************************
    Id: 2
    User: root
    Host: localhost:32931
    db: NULL
Command: Binlog Dump
    Time: 94
    State: Has sent all binlog to slave; waiting for binlog to be updated
    Info: NULL
```

Here, thread 2 is a Binlog Dump replication thread that services a connected slave. The State information indicates that all outstanding updates have been sent to the slave and that the master is waiting for more updates to occur. If you see no Binlog Dump threads on a master server, this means that replication is not running; that is, no slaves are currently connected.

On a slave server, the output from `SHOW PROCESSLIST` looks like this:
The `SHOW PROCESSLIST` information indicates that thread 10 is the I/O thread that is communicating with the master server, and thread 11 is the SQL thread that is processing the updates stored in the relay logs. At the time that `SHOW PROCESSLIST` was run, both threads were idle, waiting for further updates.

The value in the `Time` column can show how late the slave is compared to the master. See Section A.13, “MySQL 5.5 FAQ: Replication”. If sufficient time elapses on the master side without activity on the `Binlog Dump` thread, the master determines that the slave is no longer connected. As for any other client connection, the timeouts for this depend on the values of `net_write_timeout` and `net_retry_count`; for more information about these, see Section 5.1.4, “Server System Variables”.

The `SHOW SLAVE STATUS` statement provides additional information about replication processing on a slave server. See Section 17.1.4.1, “Checking Replication Status”.

### 17.2.2 Replication Relay and Status Logs

During replication, a slave server creates several logs that hold the binary log events relayed from the master to the slave, and to record information about the current status and location within the relay log. There are three types of logs used in the process, listed here:

- The **relay log** consists of the events read from the binary log of the master and written by the slave I/O thread. Events in the relay log are executed on the slave as part of the SQL thread.

- The **master info log** contains status and current configuration information for the slave's connection to the master. This log holds information on the master host name, login credentials, and coordinates indicating how far the slave has read from the master's binary log.

- The **relay log info log** holds status information about the execution point within the slave's relay log.

#### 17.2.2.1 The Slave Relay Log

The relay log, like the binary log, consists of a set of numbered files containing events that describe database changes, and an index file that contains the names of all used relay log files.

The term “relay log file” generally denotes an individual numbered file containing database events. The term “relay log” collectively denotes the set of numbered relay log files plus the index file.

Relay log files have the same format as binary log files and can be read using `mysqlbinlog` (see Section 4.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”).
By default, relay log file names have the form \textit{host}$_{\text{name}}$-\textit{relay-bin}.$\text{nnnnnn}$ in the data directory, where \textit{host}$_{\text{name}}$ is the name of the slave server host and $\text{nnnnnn}$ is a sequence number. Successive relay log files are created using successive sequence numbers, beginning with 000001. The slave uses an index file to track the relay log files currently in use. The default relay log index file name is \textit{host}$_{\text{name}}$-\textit{relay-bin.index} in the data directory.

The default relay log file and relay log index file names can be overridden with, respectively, the --relay-log and --relay-log-index server options (see Section 17.1.3, “Replication and Binary Logging Options and Variables").

If a slave uses the default host-based relay log file names, changing a slave’s host name after replication has been set up can cause replication to fail with the errors \textit{Failed to open the relay log} and \textit{Could not find target log during relay log initialization}. This is a known issue (see Bug #2122). If you anticipate that a slave’s host name might change in the future (for example, if networking is set up on the slave such that its host name can be modified using DHCP), you can avoid this issue entirely by using the --relay-log and --relay-log-index options to specify relay log file names explicitly when you initially set up the slave. This will make the names independent of server host name changes.

If you encounter the issue after replication has already begun, one way to work around it is to stop the slave server, prepend the contents of the old relay log index file to the new one, and then restart the slave. On a Unix system, this can be done as shown here:

```bash
cat new_relay_log_name.index >> old_relay_log_name.index
mv old_relay_log_name.index new_relay_log_name.index
```

A slave server creates a new relay log file under the following conditions:

- Each time the I/O thread starts.
- When the logs are flushed; for example, with \texttt{FLUSH LOGS} or \texttt{mysqladmin flush-logs}.
- When the size of the current relay log file becomes “too large,” determined as follows:
  - If the value of \texttt{max_relay_log_size} is greater than 0, that is the maximum relay log file size.
  - If the value of \texttt{max_relay_log_size} is 0, \texttt{max_binlog_size} determines the maximum relay log file size.

The SQL thread automatically deletes each relay log file as soon as it has executed all events in the file and no longer needs it. There is no explicit mechanism for deleting relay logs because the SQL thread takes care of doing so. However, \texttt{FLUSH LOGS} rotates relay logs, which influences when the SQL thread deletes them.

### 17.2.2.2 Slave Status Logs

A replication slave server creates two logs. By default, these logs are files named \texttt{master.info} and \texttt{relay-log.info} and created in the data directory. The names and locations of these files can be changed by using the --master-info-file and --relay-log-info-file options, respectively. See Section 17.1.3, “Replication and Binary Logging Options and Variables”.

The two status logs contain information like that shown in the output of the \texttt{SHOW SLAVE STATUS} statement, which is discussed in Section 13.4.2, “SQL Statements for Controlling Slave Servers”. Because the status logs are stored on disk, they survive a slave server's shutdown. The next time the slave starts up, it reads the two logs to determine how far it has proceeded in reading binary logs from the master and in processing its own relay logs.
The master info log should be protected because it contains the password for connecting to the master. See Section 6.1.2.3, “Passwords and Logging”.

The slave I/O thread updates the master info log. The following table shows the correspondence between the lines in the `master.info` file and the columns displayed by `SHOW SLAVE STATUS`.

<table>
<thead>
<tr>
<th>Line in <code>master.info</code></th>
<th><code>SHOW SLAVE STATUS</code> Column</th>
<th>Description</th>

### How Servers Evaluate Replication Filtering Rules

If a master server does not write a statement to its binary log, the statement is not replicated. If the server does log the statement, the statement is sent to all slaves and each slave determines whether to execute it or ignore it.

On the master, you can control which databases to log changes for by using the `--binlog-do-db` and `--binlog-ignore-db` options to control binary logging. For a description of the rules that servers use in evaluating these options, see Section 17.2.3.1, “Evaluation of Database-Level Replication and Binary Logging Options”. You should not use these options to control which databases and tables are replicated. Instead, use filtering on the slave to control the events that are executed on the slave.

On the slave side, decisions about whether to execute or ignore statements received from the master are made according to the `--replicate-*` options that the slave was started with. (See Section 17.1.3, “Replication and Binary Logging Options and Variables”.)

In the simplest case, when there are no `--replicate-*` options, the slave executes all statements that it receives from the master. Otherwise, the result depends on the particular options given.

Database-level options (`--replicate-do-db`, `--replicate-ignore-db`) are checked first; see Section 17.2.3.1, “Evaluation of Database-Level Replication and Binary Logging Options”, for a description of this process. If no database-level options are used, option checking proceeds to any table-level options that may be in use (see Section 17.2.3.2, “Evaluation of Table-Level Replication Options”, for a discussion of these). If one or more database-level options are used but none are matched, the statement is not replicated.

To make it easier to determine what effect an option set will have, it is recommended that you avoid mixing “do” and “ignore” options, or wildcard and nonwildcard options. An example of the latter that may have unintended effects is the use of `--replicate-do-db` and `--replicate-wild-do-table` together, where `--replicate-wild-do-table` uses a pattern for the database name that matches the name given for `--replicate-do-db`. Suppose a replication slave is started with `--replicate-do-db=dbx` `--replicate-wild-do-table=db%.t1`. Then, suppose that on the master, you issue the statement `CREATE DATABASE dbx`. Although you might expect it, this statement is not replicated because it does not reference a table named `t1`.

If any `--replicate-rewrite-db` options were specified, they are applied before the `--replicate-*` filtering rules are tested.
Note
In MySQL 5.5, database-level filtering options are case-sensitive on platforms supporting case sensitivity in filenames, whereas table-level filtering options are not (regardless of platform). This is true regardless of the value of the `lower_case_table_names` system variable.

17.2.3.1 Evaluation of Database-Level Replication and Binary Logging Options

When evaluating replication options, the slave begins by checking to see whether there are any `--replicate-do-db` or `--replicate-ignore-db` options that apply. When using `--binlog-do-db` or `--binlog-ignore-db`, the process is similar, but the options are checked on the master.

With statement-based replication, the default database is checked for a match. With row-based replication, the database where data is to be changed is the database that is checked. Regardless of the binary logging format, checking of database-level options proceeds as shown in the following diagram.

The steps involved are listed here:

1. Are there any `--replicate-do-db` options?
How Servers Evaluate Replication Filtering Rules

- Yes. Do any of them match the database?
- Yes. Execute the statement and exit.
- No. Ignore the statement and exit.
- No. Continue to step 2.

2. Are there any --replicate-ignore-db options?
- Yes. Do any of them match the database?
- Yes. Ignore the statement and exit.
- No. Continue to step 3.
- No. Continue to step 3.

3. Proceed to checking the table-level replication options, if there are any. For a description of how these options are checked, see Section 17.2.3.2, “Evaluation of Table-Level Replication Options”.

Important

A statement that is still permitted at this stage is not yet actually executed. The statement is not executed until all table-level options (if any) have also been checked, and the outcome of that process permits execution of the statement.

For binary logging, the steps involved are listed here:

1. Are there any --binlog-do-db or --binlog-ignore-db options?
- Yes. Continue to step 2.
- No. Log the statement and exit.

2. Is there a default database (has any database been selected by USE)?
- Yes. Continue to step 3.
- No. Ignore the statement and exit.

3. There is a default database. Are there any --binlog-do-db options?
- Yes. Do any of them match the database?
- Yes. Log the statement and exit.
- No. Ignore the statement and exit.
- No. Continue to step 4.

4. Do any of the --binlog-ignore-db options match the database?
- Yes. Ignore the statement and exit.
- No. Log the statement and exit.
Important
For statement-based logging, an exception is made in the rules just given for the CREATE DATABASE, ALTER DATABASE, and DROP DATABASE statements. In those cases, the database being created, altered, or dropped replaces the default database when determining whether to log or ignore updates.

--binlog-do-db can sometimes mean “ignore other databases”. For example, when using statement-based logging, a server running with only --binlog-do-db=sales does not write to the binary log statements for which the default database differs from sales. When using row-based logging with the same option, the server logs only those updates that change data in sales.

17.2.3.2 Evaluation of Table-Level Replication Options
The slave checks for and evaluates table options only if either of the following two conditions is true:

• No matching database options were found.

• One or more database options were found, and were evaluated to arrive at an “execute” condition according to the rules described in the previous section (see Section 17.2.3.1, “Evaluation of Database-Level Replication and Binary Logging Options”).

First, as a preliminary condition, the slave checks whether statement-based replication is enabled. If so, and the statement occurs within a stored function, the slave executes the statement and exits. If row-based replication is enabled, the slave does not know whether a statement occurred within a stored function on the master, so this condition does not apply.

Note
For statement-based replication, replication events represent statements (all changes making up a given event are associated with a single SQL statement); for row-based replication, each event represents a change in a single table row (thus a single statement such as UPDATE mytable SET mycol = 1 may yield many row-based events). When viewed in terms of events, the process of checking table options is the same for both row-based and statement-based replication.

Having reached this point, if there are no table options, the slave simply executes all events. If there are any --replicate-do-table or --replicate-wild-do-table options, the event must match one of these if it is to be executed; otherwise, it is ignored. If there are any --replicate-ignore-table or --replicate-wild-ignore-table options, all events are executed except those that match any of these options. This process is illustrated in the following diagram.
The following steps describe this evaluation in more detail:
1. Are there any table options?
   - Yes. Continue to step 2.
   - No. Execute the event and exit.

2. Are there any `--replicate-do-table` options?
   - Yes. Does the table match any of them?
     - Yes. Execute the event and exit.
     - No. Continue to step 3.
   - No. Continue to step 3.

3. Are there any `--replicate-ignore-table` options?
   - Yes. Does the table match any of them?
     - Yes. Ignore the event and exit.
     - No. Continue to step 4.
   - No. Continue to step 4.

4. Are there any `--replicate-wild-do-table` options?
   - Yes. Does the table match any of them?
     - Yes. Execute the event and exit.
     - No. Continue to step 5.
   - No. Continue to step 5.

5. Are there any `--replicate-wild-ignore-table` options?
   - Yes. Does the table match any of them?
     - Yes. Ignore the event and exit.
     - No. Continue to step 6.
   - No. Continue to step 6.

6. Are there any `--replicate-do-table` or `--replicate-wild-do-table` options?
   - Yes. Ignore the event and exit.
   - No. Execute the event and exit.

### 17.2.3.3 Replication Rule Application

This section provides additional explanation and examples of usage for different combinations of replication filtering options.

Some typical combinations of replication filter rule types are given in the following table:
### Condition (Types of Options) | Outcome
--- | ---
No `--replicate-*` options at all: | The slave executes all events that it receives from the master.
`--replicate-*-db` options, but no table options: | The slave accepts or ignores events using the database options. It executes all events permitted by those options because there are no table restrictions.
`--replicate-*-table` options, but no database options: | All events are accepted at the database-checking stage because there are no database conditions. The slave executes or ignores events based solely on the table options.
A combination of database and table options: | The slave accepts or ignores events using the database options. Then it evaluates all events permitted by those options according to the table options. This can sometimes lead to results that seem counterintuitive, and that may be different depending on whether you are using statement-based or row-based replication; see the text for an example.

A more complex example follows, in which we examine the outcomes for both statement-based and row-based settings.

Suppose that we have two tables `mytbl1` in database `db1` and `mytbl2` in database `db2` on the master, and the slave is running with the following options (and no other replication filtering options):

```plaintext
replicate-ignore-db = db1
replicate-do-table  = db2.tbl2
```

Now we execute the following statements on the master:

```plaintext
USE db1;
INSERT INTO db2.tbl2 VALUES (1);
```

The results on the slave vary considerably depending on the binary log format, and may not match initial expectations in either case.

**Statement-based replication.** The `USE` statement causes `db1` to be the default database. Thus the `--replicate-ignore-db` option matches, and the `INSERT` statement is ignored. The table options are not checked.

**Row-based replication.** The default database has no effect on how the slave reads database options when using row-based replication. Thus, the `USE` statement makes no difference in how the `--replicate-ignore-db` option is handled: the database specified by this option does not match the database where the `INSERT` statement changes data, so the slave proceeds to check the table options. The table specified by `--replicate-do-table` matches the table to be updated, and the row is inserted.

### 17.3 Replication Solutions

Replication can be used in many different environments for a range of purposes. This section provides general notes and advice on using replication for specific solution types.

For information on using replication in a backup environment, including notes on the setup, backup procedure, and files to back up, see Section 17.3.1, “Using Replication for Backups”.

For advice and tips on using different storage engines on the master and slaves, see Section 17.3.2, “Using Replication with Different Master and Slave Storage Engines”.

---

2037
Using replication as a scale-out solution requires some changes in the logic and operation of applications that use the solution. See Section 17.3.3, “Using Replication for Scale-Out”.

For performance or data distribution reasons, you may want to replicate different databases to different replication slaves. See Section 17.3.4, “Replicating Different Databases to Different Slaves”.

As the number of replication slaves increases, the load on the master can increase and lead to reduced performance (because of the need to replicate the binary log to each slave). For tips on improving your replication performance, including using a single secondary server as an replication master, see Section 17.3.5, “Improving Replication Performance”.

For guidance on switching masters, or converting slaves into masters as part of an emergency failover solution, see Section 17.3.6, “Switching Masters During Failover”.

To secure your replication communication, you can use SSL to encrypt the communication channel. For step-by-step instructions, see Section 17.3.7, “Setting Up Replication Using SSL”.

## 17.3.1 Using Replication for Backups

To use replication as a backup solution, replicate data from the master to a slave, and then back up the data slave. The slave can be paused and shut down without affecting the running operation of the master, so you can produce an effective snapshot of “live” data that would otherwise require the master to be shut down.

How you back up a database depends on its size and whether you are backing up only the data, or the data and the replication slave state so that you can rebuild the slave in the event of failure. There are therefore two choices:

- If you are using replication as a solution to enable you to back up the data on the master, and the size of your database is not too large, the `mysqldump` tool may be suitable. See Section 17.3.1.1, “Backing Up a Slave Using `mysqldump`”.

- For larger databases, where `mysqldump` would be impractical or inefficient, you can back up the raw data files instead. Using the raw data files option also means that you can back up the binary and relay logs that will enable you to recreate the slave in the event of a slave failure. For more information, see Section 17.3.1.2, “Backing Up Raw Data from a Slave”.

Another backup strategy, which can be used for either master or slave servers, is to put the server in a read-only state. The backup is performed against the read-only server, which then is changed back to its usual read/write operational status. See Section 17.3.1.3, “Backing Up a Master or Slave by Making It Read Only”.

### 17.3.1.1 Backing Up a Slave Using `mysqldump`

Using `mysqldump` to create a copy of a database enables you to capture all of the data in the database in a format that enables the information to be imported into another instance of MySQL Server (see Section 4.5.4, “`mysqldump — A Database Backup Program`”). Because the format of the information is SQL statements, the file can easily be distributed and applied to running servers in the event that you need access to the data in an emergency. However, if the size of your data set is very large, `mysqldump` may be impractical.

When using `mysqldump`, you should stop replication on the slave before starting the dump process to ensure that the dump contains a consistent set of data:

1. Stop the slave from processing requests. You can stop replication completely on the slave using `mysqladmin`:

   ```bash
   shell> mysqladmin stop-slave
   ```
Alternatively, you can stop only the slave SQL thread to pause event execution:

```shell
mysql -e 'STOP SLAVE SQL_THREAD;
```

This enables the slave to continue to receive data change events from the master's binary log and store them in the relay logs using the I/O thread, but prevents the slave from executing these events and changing its data. Within busy replication environments, permitting the I/O thread to run during backup may speed up the catch-up process when you restart the slave SQL thread.

2. Run `mysqldump` to dump your databases. You may either dump all databases or select databases to be dumped. For example, to dump all databases:

```shell
mysqldump --all-databases > fulldb.dump
```

3. Once the dump has completed, start slave operations again:

```shell
mysqladmin start-slave
```

In the preceding example, you may want to add login credentials (user name, password) to the commands, and bundle the process up into a script that you can run automatically each day.

If you use this approach, make sure you monitor the slave replication process to ensure that the time taken to run the backup does not affect the slave's ability to keep up with events from the master. See Section 17.1.4.1, “Checking Replication Status”. If the slave is unable to keep up, you may want to add another slave and distribute the backup process. For an example of how to configure this scenario, see Section 17.3.4, “Replicating Different Databases to Different Slaves”.

### 17.3.1.2 Backing Up Raw Data from a Slave

To guarantee the integrity of the files that are copied, backing up the raw data files on your MySQL replication slave should take place while your slave server is shut down. If the MySQL server is still running, background tasks may still be updating the database files, particularly those involving storage engines with background processes such as InnoDB. With InnoDB, these problems should be resolved during crash recovery, but since the slave server can be shut down during the backup process without affecting the execution of the master it makes sense to take advantage of this capability.

To shut down the server and back up the files:

1. Shut down the slave MySQL server:

   ```shell
   mysqladmin shutdown
   ```

2. Copy the data files. You can use any suitable copying or archive utility, including `cp`, `tar` or `WinZip`. For example, assuming that the data directory is located under the current directory, you can archive the entire directory as follows:

   ```shell
tar cf /tmp/dbbackup.tar ./data
```

3. Start the MySQL server again. Under Unix:

   ```shell
   mysqld_safe &
   ```

Under Windows:

```C:\> "C:\Program Files\MySQL\MySQL Server 5.5\bin\mysqld"
```

Normally you should back up the entire data directory for the slave MySQL server. If you want to be able to restore the data and operate as a slave (for example, in the event of failure of the slave), then in addition
to the slave's data, you should also back up the slave status files, `master.info` and `relay-log.info`, along with the relay log files. These files are needed to resume replication after you restore the slave's data.

If you lose the relay logs but still have the `relay-log.info` file, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the slave to re-read the binary logs from that point. This requires that the binary logs still exist on the master server.

If your slave is replicating `LOAD DATA INFILE` statements, you should also back up any `SQL_LOAD-*` files that exist in the directory that the slave uses for this purpose. The slave needs these files to resume replication of any interrupted `LOAD DATA INFILE` operations. The location of this directory is the value of the `--slave-load-tmpdir` option. If the server was not started with that option, the directory location is the value of the `tmpdir` system variable.

17.3.1.3 Backing Up a Master or Slave by Making It Read Only

It is possible to back up either master or slave servers in a replication setup by acquiring a global read lock and manipulating the `read_only` system variable to change the read-only state of the server to be backed up:

1. Make the server read-only, so that it processes only retrievals and blocks updates.
2. Perform the backup.
3. Change the server back to its normal read/write state.

**Note**

The instructions in this section place the server to be backed up in a state that is safe for backup methods that get the data from the server, such as `mysqldump` (see Section 4.5.4, “mysqldump — A Database Backup Program”). You should not attempt to use these instructions to make a binary backup by copying files directly because the server may still have modified data cached in memory and not flushed to disk.

The following instructions describe how to do this for a master server and for a slave server. For both scenarios discussed here, suppose that you have the following replication setup:

- A master server M1
- A slave server S1 that has M1 as its master
- A client C1 connected to M1
- A client C2 connected to S1

In either scenario, the statements to acquire the global read lock and manipulate the `read_only` variable are performed on the server to be backed up and do not propagate to any slaves of that server.

**Scenario 1: Backup with a Read-Only Master**

Put the master M1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

While M1 is in a read-only state, the following properties are true:
• Requests for updates sent by C1 to M1 will block because the server is in read-only mode.
• Requests for query results sent by C1 to M1 will succeed.
• Making a backup on M1 is safe.
• Making a backup on S1 is not safe. This server is still running, and might be processing the binary log or update requests coming from client C2

While M1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on M1 completes, restore M1 to its normal operational state by executing these statements:

```sql
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

Although performing the backup on M1 is safe (as far as the backup is concerned), it is not optimal for performance because clients of M1 are blocked from executing updates.

This strategy applies to backing up a master server in a replication setup, but can also be used for a single server in a nonreplication setting.

**Scenario 2: Backup with a Read-Only Slave**

Put the slave S1 in a read-only state by executing these statements on it:

```sql
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

While S1 is in a read-only state, the following properties are true:

• The master M1 will continue to operate, so making a backup on the master is not safe.
• The slave S1 is stopped, so making a backup on the slave S1 is safe.

These properties provide the basis for a popular backup scenario: Having one slave busy performing a backup for a while is not a problem because it does not affect the entire network, and the system is still running during the backup. In particular, clients can still perform updates on the master server, which remains unaffected by backup activity on the slave.

While S1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on S1 completes, restore S1 to its normal operational state by executing these statements:

```sql
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

After the slave is restored to normal operation, it again synchronizes to the master by catching up with any outstanding updates from the binary log of the master.

### 17.3.2 Using Replication with Different Master and Slave Storage Engines

It does not matter for the replication process whether the source table on the master and the replicated table on the slave use different engine types. In fact, the `default_storage_engine` and `storage_engine` system variables are not replicated.
Using Replication with Different Master and Slave Storage Engines

This provides a number of benefits in the replication process in that you can take advantage of different engine types for different replication scenarios. For example, in a typical scale-out scenario (see Section 17.3.3, "Using Replication for Scale-Out"), you want to use InnoDB tables on the master to take advantage of the transactional functionality, but use MyISAM on the slaves where transaction support is not required because the data is only read. When using replication in a data-logging environment you may want to use the Archive storage engine on the slave.

Configuring different engines on the master and slave depends on how you set up the initial replication process:

• If you used mysqldump to create the database snapshot on your master, you could edit the dump file text to change the engine type used on each table.

Another alternative for mysqldump is to disable engine types that you do not want to use on the slave before using the dump to build the data on the slave. For example, you can add the --skip-innodb option on your slave to disable the InnoDB engine. If a specific engine does not exist for a table to be created, MySQL will use the default engine type, usually MyISAM. (This requires that the NO_ENGINE_SUBSTITUTION SQL mode is not enabled.) If you want to disable additional engines in this way, you may want to consider building a special binary to be used on the slave that only supports the engines you want.

• If you are using raw data files (a binary backup) to set up the slave, you will be unable to change the initial table format. Instead, use ALTER TABLE to change the table types after the slave has been started.

• For new master/slave replication setups where there are currently no tables on the master, avoid specifying the engine type when creating new tables.

If you are already running a replication solution and want to convert your existing tables to another engine type, follow these steps:

1. Stop the slave from running replication updates:

   mysql> STOP SLAVE;

   This will enable you to change engine types without interruptions.

2. Execute an ALTER TABLE ... ENGINE='engine_type' for each table to be changed.

3. Start the slave replication process again:

   mysql> START SLAVE;

Although the default_storage_engine variable is not replicated, be aware that CREATE TABLE and ALTER TABLE statements that include the engine specification will be correctly replicated to the slave. For example, if you have a CSV table and you execute:

   mysql> ALTER TABLE csvtable Engine='MyISAM';

The above statement will be replicated to the slave and the engine type on the slave will be converted to MyISAM, even if you have previously changed the table type on the slave to an engine other than CSV. If you want to retain engine differences on the master and slave, you should be careful to use the default_storage_engine variable on the master when creating a new table. For example, instead of:
Using Replication for Scale-Out

mysql> CREATE TABLE tablea (columna int) Engine=MyISAM;

Use this format:

mysql> SET default_storage_engine=MyISAM;
mysql> CREATE TABLE tablea (columna int);

When replicated, the default_storage_engine variable will be ignored, and the CREATE TABLE statement will execute on the slave using the slave’s default engine.

17.3.3 Using Replication for Scale-Out

You can use replication as a scale-out solution; that is, where you want to split up the load of database queries across multiple database servers, within some reasonable limitations.

Because replication works from the distribution of one master to one or more slaves, using replication for scale-out works best in an environment where you have a high number of reads and low number of writes/updates. Most Web sites fit into this category, where users are browsing the Web site, reading articles, posts, or viewing products. Updates only occur during session management, or when making a purchase or adding a comment/message to a forum.

Replication in this situation enables you to distribute the reads over the replication slaves, while still enabling your web servers to communicate with the replication master when a write is required. You can see a sample replication layout for this scenario in Figure 17.1, “Using Replication to Improve Performance During Scale-Out”.

Figure 17.1 Using Replication to Improve Performance During Scale-Out

If the part of your code that is responsible for database access has been properly abstracted/modularized, converting it to run with a replicated setup should be very smooth and easy. Change the implementation of your database access to send all writes to the master, and to send reads to either the master or a slave. If your code does not have this level of abstraction, setting up a replicated system gives you the opportunity and motivation to clean it up. Start by creating a wrapper library or module that implements the following functions:

• safe_writer_connect()
Replicating Different Databases to Different Slaves

- `safe_reader_connect()`
- `safe_reader_statement()`
- `safe_writer_statement()`

`safe_` in each function name means that the function takes care of handling all error conditions. You can use different names for the functions. The important thing is to have a unified interface for connecting for reads, connecting for writes, doing a read, and doing a write.

Then convert your client code to use the wrapper library. This may be a painful and scary process at first, but it pays off in the long run. All applications that use the approach just described are able to take advantage of a master/slave configuration, even one involving multiple slaves. The code is much easier to maintain, and adding troubleshooting options is trivial. You need modify only one or two functions; for example, to log how long each statement took, or which statement among those issued gave you an error.

If you have written a lot of code, you may want to automate the conversion task by using the `replace` utility that comes with standard MySQL distributions, or write your own conversion script. Ideally, your code uses consistent programming style conventions. If not, then you are probably better off rewriting it anyway, or at least going through and manually regularizing it to use a consistent style.

### 17.3.4 Replicating Different Databases to Different Slaves

There may be situations where you have a single master and want to replicate different databases to different slaves. For example, you may want to distribute different sales data to different departments to help spread the load during data analysis. A sample of this layout is shown in Figure 17.2, “Using Replication to Replicate Databases to Separate Replication Slaves”.

**Figure 17.2 Using Replication to Replicate Databases to Separate Replication Slaves**

You can achieve this separation by configuring the master and slaves as normal, and then limiting the binary log statements that each slave processes by using the `--replicate-wild-do-table` configuration option on each slave.

**Important**

You should **not use** `--replicate-do-db` for this purpose when using statement-based replication, since statement-based replication causes this option's affects to vary according to the database that is currently selected. This applies to mixed-format replication as well, since this enables some updates to be replicated using the statement-based format.

However, it should be safe to use `--replicate-do-db` for this purpose if you are using row-based replication only, since in this case the currently selected database has no effect on the option's operation.
For example, to support the separation as shown in Figure 17.2, “Using Replication to Replicate Databases to Separate Replication Slaves”, you should configure each replication slave as follows, before executing `START_SLAVE`:

- Replication slave 1 should use `--replicate-wild-do-table=databaseA.%`.
- Replication slave 2 should use `--replicate-wild-do-table=databaseB.%`.
- Replication slave 3 should use `--replicate-wild-do-table=databaseC.%`.

Each slave in this configuration receives the entire binary log from the master, but executes only those events from the binary log that apply to the databases and tables included by the `--replicate-wild-do-table` option in effect on that slave.

If you have data that must be synchronized to the slaves before replication starts, you have a number of choices:

- Synchronize all the data to each slave, and delete the databases, tables, or both that you do not want to keep.
- Use `mysqldump` to create a separate dump file for each database and load the appropriate dump file on each slave.
- Use a raw data file dump and include only the specific files and databases that you need for each slave.

Note

This does not work with InnoDB databases unless you use `innodb_file_per_table`.

17.3.5 Improving Replication Performance

As the number of slaves connecting to a master increases, the load, although minimal, also increases, as each slave uses a client connection to the master. Also, as each slave must receive a full copy of the master binary log, the network load on the master may also increase and create a bottleneck.

If you are using a large number of slaves connected to one master, and that master is also busy processing requests (for example, as part of a scale-out solution), then you may want to improve the performance of the replication process.

One way to improve the performance of the replication process is to create a deeper replication structure that enables the master to replicate to only one slave, and for the remaining slaves to connect to this primary slave for their individual replication requirements. A sample of this structure is shown in Figure 17.3, “Using an Additional Replication Host to Improve Performance”.

Figure 17.3 Using an Additional Replication Host to Improve Performance
Switching Masters During Failover

For this to work, you must configure the MySQL instances as follows:

- Master 1 is the primary master where all changes and updates are written to the database. Binary logging should be enabled on this machine.

- Master 2 is the slave to the Master 1 that provides the replication functionality to the remainder of the slaves in the replication structure. Master 2 is the only machine permitted to connect to Master 1. Master 2 also has binary logging enabled, and the `--log-slave-updates` option so that replication instructions from Master 1 are also written to Master 2’s binary log so that they can then be replicated to the true slaves.

- Slave 1, Slave 2, and Slave 3 act as slaves to Master 2, and replicate the information from Master 2, which actually consists of the upgrades logged on Master 1.

The above solution reduces the client load and the network interface load on the primary master, which should improve the overall performance of the primary master when used as a direct database solution.

If your slaves are having trouble keeping up with the replication process on the master, there are a number of options available:

- If possible, put the relay logs and the data files on different physical drives. To do this, use the `--relay-log` option to specify the location of the relay log.

- If the slaves are significantly slower than the master, you may want to divide up the responsibility for replicating different databases to different slaves. See Section 17.3.4, “Replicating Different Databases to Different Slaves”.

- If your master makes use of transactions and you are not concerned about transaction support on your slaves, use MyISAM or another nontransactional engine on the slaves. See Section 17.3.2, “Using Replication with Different Master and Slave Storage Engines”.

- If your slaves are not acting as masters, and you have a potential solution in place to ensure that you can bring up a master in the event of failure, then you can switch off `--log-slave-updates`. This prevents “dumb” slaves from also logging events they have executed into their own binary log.

17.3.6 Switching Masters During Failover

There is in MySQL 5.5 no official solution for providing failover between master and slaves in the event of a failure. Instead, you must set up a master and one or more slaves; then, you need to write an application or script that monitors the master to check whether it is up, and instructs the slaves and applications to change master in case of failure. This section discusses some of the issues encountered when setting up failover in this fashion.

**Note**

The MySQL Utilities include a `mysqlfailover` tool that provides failover capability using GTIDs, support for which requires MySQL 5.6 or later. For more information, see `mysqlfailover — Automatic replication health monitoring and failover`, and `Replication with Global Transaction Identifiers`.

You can tell a slave to change to a new master using the `CHANGE MASTER TO` statement. The slave does not check whether the databases on the master are compatible with those on the slave; it simply begins reading and executing events from the specified coordinates in the new master's binary log. In a failover situation, all the servers in the group are typically executing the same events from the same binary log file, so changing the source of the events should not affect the structure or integrity of the database, provided that you exercise care in making the change.
Switching Masters During Failover

Slaves should be run with the `--log-bin` option and without `--log-slave-updates`. In this way, the slave is ready to become a master without restarting the slave `mysql`. Assume that you have the structure shown in Figure 17.4, “Redundancy Using Replication, Initial Structure”.

Remember that you can tell a slave to change its master at any time, using the `CHANGE MASTER TO` statement. The slave will not check whether the databases on the master are compatible with the slave, it will just start reading and executing events from the specified binary log coordinates on the new master. In a failover situation, all the servers in the group are typically executing the same events from the same binary log file, so changing the source of the events should not affect the database structure or integrity providing you are careful.

Run your slaves with the `--log-bin` option and without `--log-slave-updates`. In this way, the slave is ready to become a master as soon as you issue `STOP SLAVE; RESET MASTER, and CHANGE MASTER TO` statement on the other slaves. For example, assume that you have the structure shown in Figure 17.4, “Redundancy Using Replication, Initial Structure”.

**Figure 17.4 Redundancy Using Replication, Initial Structure**

In this diagram, the MySQL Master holds the master database, the MySQL Slave hosts are replication slaves, and the Web Client machines are issuing database reads and writes. Web clients that issue only reads (and would normally be connected to the slaves) are not shown, as they do not need to switch to a new server in the event of failure. For a more detailed example of a read/write scale-out replication structure, see Section 17.3.3, “Using Replication for Scale-Out”.

Each MySQL Slave (Slave 1, Slave 2, and Slave 3) is a slave running with `--log-bin` and without `--log-slave-updates`. Because updates received by a slave from the master are not logged in the binary log unless `--log-slave-updates` is specified, the binary log on each slave is empty initially. If for some reason MySQL Master becomes unavailable, you can pick one of the slaves to become the new master. For example, if you pick Slave 1, all Web Clients should be redirected to Slave 1, which writes the updates to its binary log. Slave 2 and Slave 3 should then replicate from Slave 1.

The reason for running the slave without `--log-slave-updates` is to prevent slaves from receiving updates twice in case you cause one of the slaves to become the new master. If Slave 1 has `--log-slave-updates` enabled, it writes any updates that it receives from Master in its own binary log. This means that, when Slave 2 changes from Master to Slave 1 as its master, it may receive updates from Slave 1 that it has already received from Master.
Make sure that all slaves have processed any statements in their relay log. On each slave, issue `STOP SLAVE IO_THREAD`, then check the output of `SHOW PROCESSLIST` until you see `Has read all relay log`. When this is true for all slaves, they can be reconfigured to the new setup. On the slave `Slave 1` being promoted to become the master, issue `STOP SLAVE` and `RESET MASTER`.

On the other slaves `Slave 2` and `Slave 3`, use `STOP SLAVE` and `CHANGE MASTER TO MASTER_HOST='Slave1'` (where 'Slave1' represents the real host name of `Slave 1`). To use `CHANGE MASTER TO`, add all information about how to connect to `Slave 1` from `Slave 2` or `Slave 3` (user, password, port). When issuing the `CHANGE MASTER TO` statement in this, there is no need to specify the name of the `Slave 1` binary log file or log position to read from, since the first binary log file and position 4, are the defaults. Finally, execute `START SLAVE` on `Slave 2` and `Slave 3`.

Once the new replication setup is in place, you need to tell each `Web Client` to direct its statements to `Slave 1`. From that point on, all updates statements sent by `Web Client` to `Slave 1` are written to the binary log of `Slave 1`, which then contains every update statement sent to `Slave 1` since `Master` died.

The resulting server structure is shown in Figure 17.5, "Redundancy Using Replication, After Master Failure".

**Figure 17.5 Redundancy Using Replication, After Master Failure**

![Diagram showing server structure](image)

When `Master` becomes available again, you should make it a slave of `Slave 1`. To do this, issue on `Master` the same `CHANGE MASTER TO` statement as that issued on `Slave 2` and `Slave 3` previously. `Master` then becomes a slave of `Slave 1` and picks up the `Web Client` writes that it missed while it was offline.

To make `Master` a master again (for example, because it is the most powerful machine), use the preceding procedure as if `Slave 1` was unavailable and `Master` was to be the new master. During this procedure, do not forget to run `RESET MASTER` on `Master` before making `Slave 1`, `Slave 2`, and `Slave 3` slaves of `Master`. If you fail to do this, the slaves may pick up stale writes from the `Web Client` applications dating from before the point at which `Master` became unavailable.

You should be aware that there is no synchronization between slaves, even when they share the same master, and thus some slaves might be considerably ahead of others. This means that in some cases the
procedure outlined in the previous example might not work as expected. In practice, however, relay logs on all slaves should be relatively close together.

One way to keep applications informed about the location of the master is to have a dynamic DNS entry for the master. With `bind` you can use `nsupdate` to update the DNS dynamically.

### 17.3.7 Setting Up Replication Using SSL

To use SSL for encrypting the transfer of the binary log required during replication, both the master and the slave must support SSL network connections. If either host does not support SSL connections (because it has not been compiled or configured for SSL), replication through an SSL connection is not possible.

Setting up replication using an SSL connection is similar to setting up a server and client using SSL. You must obtain (or create) a suitable security certificate that you can use on the master, and a similar certificate (from the same certificate authority) on each slave.

For more information on setting up a server and client for SSL connectivity, see Section 6.3.9.2, “Configuring MySQL for SSL”.

To enable SSL on the master you must create or obtain suitable certificates, and then add the following configuration options to the master's configuration within the `[mysqld]` section of the master's `my.cnf` file:

```ini
[mysqld]
ssl-ca=cacert.pem
ssl-cert=server-cert.pem
ssl-key=server-key.pem
```

The paths to the certificates may be relative or absolute; we recommend that you always use complete paths for this purpose.

The options are as follows:

- **ssl-ca** identifies the Certificate Authority (CA) certificate.
- **ssl-cert** identifies the server public key. This can be sent to the client and authenticated against the CA certificate that it has.
- **ssl-key** identifies the server private key.

On the slave, you have two options available for setting the SSL information. You can either add the slave certificates to the `[client]` section of the slave's `my.cnf` file, or you can explicitly specify the SSL information using the `CHANGE MASTER TO` statement:

- To add the slave certificates using an option file, add the following lines to the `[client]` section of the slave's `my.cnf` file:

```ini
[client]
ssl-ca=cacert.pem
ssl-cert=client-cert.pem
ssl-key=client-key.pem
```

Restart the slave server, using the `--skip-slave-start` option to prevent the slave from connecting to the master. Use `CHANGE MASTER TO` to specify the master configuration, using the `MASTER_SSL` option to enable SSL connectivity:

```sql
mysql> CHANGE MASTER TO
    -> MASTER_HOST='master_hostname',
    -> MASTER_SSL=ON;
```
Semisynchronous Replication

- MASTER_USER='replicate',
- MASTER_PASSWORD='password',
- MASTER_SSL=1;

- To specify the SSL certificate options using the CHANGE MASTER TO statement, append the SSL options:

```sql
mysql> CHANGE MASTER TO
    -> MASTER_HOST='master_hostname',
    -> MASTER_USER='replicate',
    -> MASTER_PASSWORD='password',
    -> MASTER_SSL=1,
    -> MASTER_SSL_CA = 'ca_file_name',
    -> MASTER_SSL_CAPATH = 'ca_directory_name',
    -> MASTER_SSL_CERT = 'cert_file_name',
    -> MASTER_SSL_KEY = 'key_file_name';
```

After the master information has been updated, start the slave replication process:

```sql
mysql> START SLAVE;
```

You can use the SHOW SLAVE STATUS statement to confirm that the SSL connection was established successfully.

For more information on the CHANGE MASTER TO statement, see Section 13.4.2.1, "CHANGE MASTER TO Syntax".

If you want to enforce the use of SSL connections during replication, then create a user with the REPLICATION SLAVE privilege and use the REQUIRE SSL option for that user. For example:

```sql
mysql> CREATE USER 'repl'@'%.mydomain.com' IDENTIFIED BY 'slavepass';
mysql> GRANT REPLICATION SLAVE ON *.*
    -> TO 'repl'@'%.mydomain.com' REQUIRE SSL;
```

If the account already exists, you can add REQUIRE SSL to it with this statement:

```sql
mysql> GRANT USAGE ON *.*
    -> TO 'repl'@'%.mydomain.com' REQUIRE SSL;
```

17.3.8 Semisynchronous Replication

In addition to the built-in asynchronous replication, MySQL 5.5 supports an interface to semisynchronous replication that is implemented by plugins. This section discusses what semisynchronous replication is and how it works. The following sections cover the administrative interface to semisynchronous replication and how to install, configure, and monitor it.

MySQL replication by default is asynchronous. The master writes events to its binary log but does not know whether or when a slave has retrieved and processed them. With asynchronous replication, if the master crashes, transactions that it has committed might not have been transmitted to any slave. Consequently, failover from master to slave in this case may result in failover to a server that is missing transactions relative to the master.

Semisynchronous replication can be used as an alternative to asynchronous replication:

- A slave indicates whether it is semisynchronous-capable when it connects to the master.
- If semisynchronous replication is enabled on the master side and there is at least one semisynchronous slave, a thread that performs a transaction commit on the master blocks after the commit is done and
waits until at least one semisynchronous slave acknowledges that it has received all events for the transaction, or until a timeout occurs.

- The slave acknowledges receipt of a transaction's events only after the events have been written to its relay log and flushed to disk.

- If a timeout occurs without any slave having acknowledged the transaction, the master reverts to asynchronous replication. When at least one semisynchronous slave catches up, the master returns to semisynchronous replication.

- Semisynchronous replication must be enabled on both the master and slave sides. If semisynchronous replication is disabled on the master, or enabled on the master but on no slaves, the master uses asynchronous replication.

While the master is blocking (waiting for acknowledgment from a slave after having performed a commit), it does not return to the session that performed the transaction. When the block ends, the master returns to the session, which then can proceed to execute other statements. At this point, the transaction has committed on the master side, and receipt of its events has been acknowledged by at least one slave.

Blocking also occurs after rollbacks that are written to the binary log, which occurs when a transaction that modifies nontransactional tables is rolled back. The rolled-back transaction is logged even though it has no effect for transactional tables because the modifications to the nontransactional tables cannot be rolled back and must be sent to slaves.

For statements that do not occur in transactional context (that is, when no transaction has been started with `START TRANSACTION` or `SET autocommit = 0`), autocommit is enabled and each statement commits implicitly. With semisynchronous replication, the master blocks after committing each such statement, just as it does for explicit transaction commits.

To understand what the “semi” in “semisynchronous replication” means, compare it with asynchronous and fully synchronous replication:

- With asynchronous replication, the master writes events to its binary log and slaves request them when they are ready. There is no guarantee that any event will ever reach any slave.

- With fully synchronous replication, when a master commits a transaction, all slaves also will have committed the transaction before the master returns to the session that performed the transaction. The drawback of this is that there might be a lot of delay to complete a transaction.

- Semisynchronous replication falls between asynchronous and fully synchronous replication. The master waits after commit only until at least one slave has received and logged the events. It does not wait for all slaves to acknowledge receipt, and it requires only receipt, not that the events have been fully executed and committed on the slave side.

Compared to asynchronous replication, semisynchronous replication provides improved data integrity. When a commit returns successfully, it is known that the data exists in at least two places (on the master and at least one slave). If the master commits but a crash occurs while the master is waiting for acknowledgment from a slave, it is possible that the transaction may not have reached any slave.

Semisynchronous replication also places a rate limit on busy sessions by constraining the speed at which binary log events can be sent from master to slave. When one user is too busy, this will slow it down, which is useful in some deployment situations.

Semisynchronous replication does have some performance impact because commits are slower due to the need to wait for slaves. This is the tradeoff for increased data integrity. The amount of slowdown is at least the TCP/IP roundtrip time to send the commit to the slave and wait for the acknowledgment of receipt by the slave. This means that semisynchronous replication works best for close servers communicating over fast networks, and worst for distant servers communicating over slow networks.
17.3.8.1 Semisynchronous Replication Administrative Interface

The administrative interface to semisynchronous replication has several components:

- Two plugins implement semisynchronous capability. There is one plugin for the master side and one for the slave side.
- System variables control plugin behavior. Some examples:
  - `rpl_semi_sync_master_enabled`
    Controls whether semisynchronous replication is enabled on the master. To enable or disable the plugin, set this variable to 1 or 0, respectively. The default is 0 (off).
  - `rpl_semi_sync_master_timeout`
    A value in milliseconds that controls how long the master waits on a commit for acknowledgment from a slave before timing out and reverting to asynchronous replication. The default value is 10000 (10 seconds).
  - `rpl_semi_sync_slave_enabled`
    Similar to `rpl_semi_sync_master_enabled`, but controls the slave plugin.

All `rpl_semi_sync_` system variables are described at Section 5.1.4, “Server System Variables”.

- Status variables enable semisynchronous replication monitoring. Some examples:
  - `Rpl_semi_sync_master_clients`
    The number of semisynchronous slaves.
  - `Rpl_semi_sync_master_status`
    Whether semisynchronous replication currently is operational on the master. The value is 1 if the plugin has been enabled and a commit acknowledgment has occurred. It is 0 if the plugin is not enabled or the master has fallen back to asynchronous replication due to commit acknowledgment timeout.
  - `Rpl_semi_sync_master_no_tx`
    The number of commits that were not acknowledged successfully by a slave.
  - `Rpl_semi_sync_master_yes_tx`
    The number of commits that were acknowledged successfully by a slave.
  - `Rpl_semi_sync_slave_status`
    Whether semisynchronous replication currently is operational on the slave. This is 1 if the plugin has been enabled and the slave I/O thread is running, 0 otherwise.

All `Rpl_semi_sync_` status variables are described at Section 5.1.6, “Server Status Variables”.

The system and status variables are available only if the appropriate master or slave plugin has been installed with `INSTALL PLUGIN`.

17.3.8.2 Semisynchronous Replication Installation and Configuration
Semisynchronous replication is implemented using plugins, so the plugins must be installed into the server to make them available. After a plugin has been installed, you control it by means of the system variables associated with it. These system variables are unavailable until the associated plugin has been installed.

To use semisynchronous replication, the following requirements must be satisfied:

- MySQL 5.5 or higher must be installed.

- The capability of installing plugins requires a MySQL server that supports dynamic loading. To verify this, check that the value of the `have_dynamic_loading` system variable is `YES`. Binary distributions should support dynamic loading.

- Replication must already be working. For information on creating a master/slave relationship, see [Section 17.1.1, “How to Set Up Replication”](#).

To set up semisynchronous replication, use the following instructions. The `INSTALL PLUGIN`, `SET GLOBAL`, `STOP SLAVE`, and `START SLAVE` statements mentioned here require the `SUPER` privilege.

The semisynchronous replication plugins are included with MySQL distributions.

Unpack the component distribution, which contains files for the master side and the slave side.

Install the component files in the plugin directory of the appropriate server. Install the `semisync_master*` files in the plugin directory of the master server. Install the `semisync_slave*` files in the plugin directory of each slave server. The location of the plugin directory is available as the value of the server's `plugin_dir` system variable.

To load the plugins, use the `INSTALL PLUGIN` statement on the master and on each slave that is to be semisynchronous.

On the master:

```sql
mysql> INSTALL PLUGIN rpl_semi_sync_master SONAME 'semisync_master.so';
```

On each slave:

```sql
mysql> INSTALL PLUGIN rpl_semi_sync_slave SONAME 'semisync_slave.so';
```

The preceding commands use a plugin file name suffix of `.so`. A different suffix might apply on your system. If you are not sure about the plugin file name, look for the plugins in the server's plugin directory.

If an attempt to install a plugin results in an error on Linux similar to that shown here, you will need to install `libimf`:

```sql
mysql> INSTALL PLUGIN rpl_semi_sync_master SONAME 'semisync_master.so';
ERROR 1126 (HY000): Can't open shared library
' /usr/local/mysql/lib/plugin/semisync_master.so' (errno: 22 libimf.so: cannot open
shared object file: No such file or directory)
```

To see which plugins are installed, use the `SHOW PLUGINS` statement, or query the `INFORMATION_SCHEMA.PLUGINS` table.
After a semisynchronous replication plugin has been installed, it is disabled by default. The plugins must be enabled both on the master side and the slave side to enable semisynchronous replication. If only one side is enabled, replication will be asynchronous.

To control whether an installed plugin is enabled, set the appropriate system variables. You can set these variables at runtime using `SET GLOBAL`, or at server startup on the command line or in an option file.

At runtime, these master-side system variables are available:

```
mysql> SET GLOBAL rpl_semi_sync_master_enabled = {0|1};
mysql> SET GLOBAL rpl_semi_sync_master_timeout = N;
```

On the slave side, this system variable is available:

```
mysql> SET GLOBAL rpl_semi_sync_slave_enabled = {0|1};
```

For `rpl_semi_sync_master_enabled` or `rpl_semi_sync_slave_enabled`, the value should be 1 to enable semisynchronous replication or 0 to disable it. By default, these variables are set to 0.

For `rpl_semi_sync_master_timeout`, the value `N` is given in milliseconds. The default value is 10000 (10 seconds).

If you enable semisynchronous replication on a slave at runtime, you must also start the slave I/O thread (stopping it first if it is already running) to cause the slave to connect to the master and register as a semisynchronous slave:

```
mysql> STOP SLAVE IO_THREAD; START SLAVE IO_THREAD;
```

If the I/O thread is already running and you do not restart it, the slave continues to use asynchronous replication.

At server startup, the variables that control semisynchronous replication can be set as command-line options or in an option file. A setting listed in an option file takes effect each time the server starts. For example, you can set the variables in `my.cnf` files on the master and slave sides as follows.

On the master:

```
[mysqld]
rpl_semi_sync_master_enabled=1
rpl_semi_sync_master_timeout=1000 # 1 second
```

On each slave:

```
[mysqld]
rpl_semi_sync_slave_enabled=1
```

17.3.8.3 Semisynchronous Replication Monitoring

The plugins for the semisynchronous replication capability expose several system and status variables that you can examine to determine its configuration and operational state.

The system variable reflect how semisynchronous replication is configured. To check their values, use `SHOW VARIABLES;`
Replication Notes and Tips

SHOW VARIABLES LIKE 'rpl_semi_sync%';

The status variables enable you to monitor the operation of semisynchronous replication. To check their values, use SHOW STATUS:

SHOW STATUS LIKE 'Rpl_semi_sync%';

When the master switches between asynchronous or semisynchronous replication due to commit-blocking timeout or a slave catching up, it sets the value of the Rpl_semi_sync_master_status status variable appropriately. Automatic fallback from semisynchronous to asynchronous replication on the master means that it is possible for the rpl_semi_sync_master_enabled system variable to have a value of 1 on the master side even when semisynchronous replication is in fact not operational at the moment. You can monitor the Rpl_semi_sync_master_status status variable to determine whether the master currently is using asynchronous or semisynchronous replication.

To see how many semisynchronous slaves are connected, check Rpl_semi_sync_master_clients.

The number of commits that have been acknowledged successfully or unsuccessfully by slaves are indicated by the Rpl_semi_sync_master_yes_tx and Rpl_semi_sync_master_no_tx variables.

On the slave side, Rpl_semi_sync_slave_status indicates whether semisynchronous replication currently is operational.

17.4 Replication Notes and Tips

17.4.1 Replication Features and Issues

The following sections provide information about what is supported and what is not in MySQL replication, and about specific issues and situations that may occur when replicating certain statements.

Statement-based replication depends on compatibility at the SQL level between the master and slave. In others, successful SBR requires that any SQL features used be supported by both the master and the slave servers. For example, if you use a feature on the master server that is available only in MySQL 5.5 (or later), you cannot replicate to a slave that uses MySQL 5.1 (or earlier).

Such incompatibilities also can occur within a release series when using pre-production releases of MySQL. For example, the SLEEP() function is available beginning with MySQL 5.0.12. If you use this function on the master, you cannot replicate to a slave that uses MySQL 5.0.11 or earlier.

For this reason, use Generally Available (GA) releases of MySQL for statement-based replication in a production setting, since we do not introduce new SQL statements or change their behavior within a given release series once that series reaches GA release status.

If you are planning to use statement-based replication between MySQL 5.5 and a previous MySQL release series, it is also a good idea to consult the edition of the MySQL Reference Manual corresponding to the earlier release series for information regarding the replication characteristics of that series.

With MySQL's statement-based replication, there may be issues with replicating stored routines or triggers. You can avoid these issues by using MySQL's row-based replication instead. For a detailed list of issues, see Section 20.7, "Binary Logging of Stored Programs". For more information about row-based logging and row-based replication, see Section 5.2.4.1, "Binary Logging Formats", and Section 17.1.2, "Replication Formats".
For additional information specific to replication and InnoDB, see Section 14.20, “InnoDB and MySQL Replication”. For information relating to replication with MySQL Cluster, see Section 18.6, “MySQL Cluster Replication”.

### 17.4.1.1 Replication and `AUTO_INCREMENT`

Statement-based replication of `AUTO_INCREMENT`, `LAST_INSERT_ID()`, and `TIMESTAMP` values is done correctly, subject to the following exceptions:

- When using statement-based replication prior to MySQL 5.5.30, `AUTO_INCREMENT` columns in tables on the slave must match the same columns on the master; that is, `AUTO_INCREMENT` columns must be replicated to `AUTO_INCREMENT` columns. (Bug #12669186)

- A statement invoking a trigger or function that causes an update to an `AUTO_INCREMENT` column is not replicated correctly using statement-based replication. In MySQL 5.5, such statements are marked as unsafe. (Bug #45677)

- An `INSERT` into a table that has a composite primary key that includes an `AUTO_INCREMENT` column that is not the first column of this composite key is not safe for statement-based logging or replication. Beginning with MySQL 5.5.25, such statements are marked as unsafe. (Bug #11754117, Bug #45670)

  This issue does not affect tables using the InnoDB storage engine, since an InnoDB table with an `AUTO_INCREMENT` column requires at least one key where the auto-increment column is the only or leftmost column.

- Adding an `AUTO_INCREMENT` column to a table with `ALTER TABLE` might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to a table `t1` that has columns `col1` and `col2`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

**Important**

To guarantee the same ordering on both master and slave, the `ORDER BY` clause must name *all* columns of `t1`.

The instructions just given are subject to the limitations of `CREATE TABLE ... LIKE`: Foreign key definitions are ignored, as are the `DATA DIRECTORY` and `INDEX DIRECTORY` table options. If a table definition includes any of those characteristics, create `t2` using a `CREATE TABLE` statement that is identical to the one used to create `t1`, but with the addition of the `AUTO_INCREMENT` column.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```
DROP t1;
ALTER TABLE t2 RENAME t1;
```

See also Section B.5.7.1, “Problems with `ALTER TABLE`”.

### 17.4.1.2 Replication and `BLACKHOLE` Tables
The **BLACKHOLE** storage engine accepts data but discards it and does not store it. When performing binary logging, all inserts to such tables are always logged, regardless of the logging format in use. Updates and deletes are handled differently depending on whether statement based or row based logging is in use. With the statement based logging format, all statements affecting **BLACKHOLE** tables are logged, but their effects ignored. When using row-based logging, updates and deletes to such tables are simply skipped—they are not written to the binary log. In MySQL 5.5.32 and later, a warning is logged whenever this occurs (Bug #13004581)

For this reason we recommend when you replicate to tables using the **BLACKHOLE** storage engine that you have the `binlog_format` server variable set to `STATEMENT`, and not to either `ROW` or `MIXED`.

### 17.4.1.3 Replication and Character Sets

The following applies to replication between MySQL servers that use different character sets:

- If the master uses MySQL 4.1, you must always use the same global character set and collation on the master and the slave, regardless of the slave MySQL version. (These are controlled by the `--character-set-server` and `--collation-server` options.) Otherwise, you may get duplicate-key errors on the slave, because a key that is unique in the master character set might not be unique in the slave character set. Note that this is not a cause for concern when master and slave are both MySQL 5.0 or later.

- If the master is older than MySQL 4.1.3, the character set of any client should never be made different from its global value because this character set change is not known to the slave. In other words, clients should not use `SET NAMES`, `SET CHARACTER SET`, and so forth. If both the master and the slave are 4.1.3 or newer, clients can freely set session values for character set variables because these settings are written to the binary log and so are known to the slave. That is, clients can use `SET NAMES` or `SET CHARACTER SET` or can set variables such as `collation_client` or `collation_server`. However, clients are prevented from changing the global value of these variables; as stated previously, the master and slave must always have identical global character set values. This is true whether you are using statement-based or row-based replication.

- If the master has databases with a character set different from the global `character_set_server` value, you should design your `CREATE TABLE` statements so that they do not implicitly rely on the database default character set. A good workaround is to state the character set and collation explicitly in `CREATE TABLE` statements.

### 17.4.1.4 Replication of `CREATE ... IF NOT EXISTS` Statements

MySQL applies these rules when various `CREATE ... IF NOT EXISTS` statements are replicated:

- Every `CREATE DATABASE IF NOT EXISTS` statement is replicated, whether or not the database already exists on the master.

- Similarly, every `CREATE TABLE IF NOT EXISTS` statement without a `SELECT` is replicated, whether or not the table already exists on the master. This includes `CREATE TABLE IF NOT EXISTS ... LIKE`. Replication of `CREATE TABLE IF NOT EXISTS ... SELECT` follows somewhat different rules; see Section 17.4.1.5, “Replication of `CREATE TABLE ... SELECT` Statements”, for more information.

- `CREATE EVENT IF NOT EXISTS` is always replicated in MySQL 5.5, whether or not the event named in the statement already exists on the master.

See also Bug #45574.

### 17.4.1.5 Replication of `CREATE TABLE ... SELECT` Statements
This section discusses how MySQL replicates `CREATE TABLE ... SELECT` statements.

These behaviors are not dependent on MySQL version:

- `CREATE TABLE ... SELECT` always performs an implicit commit (Section 13.3.3, “Statements That Cause an Implicit Commit”).

- If destination table does not exist, logging occurs as follows. It does not matter whether `IF NOT EXISTS` is present.
  - `STATEMENT` or `MIXED` format: The statement is logged as written.
  - `ROW` format: The statement is logged as a `CREATE TABLE` statement followed by a series of insert-row events.

- If the statement fails, nothing is logged. This includes the case that the destination table exists and `IF NOT EXISTS` is not given.

When the destination table exists and `IF NOT EXISTS` is given, MySQL handles the statement in a version-dependent way.

In MySQL 5.1 before 5.1.51 and in MySQL 5.5 before 5.5.6 (this is the original behavior):

- `STATEMENT` or `MIXED` format: The statement is logged as written.
- `ROW` format: The statement is logged as a `CREATE TABLE` statement followed by a series of insert-row events.

In MySQL 5.1 as of 5.1.51:

- `STATEMENT` or `MIXED` format: The statement is logged as the equivalent pair of `CREATE TABLE` and `INSERT INTO ... SELECT` statements.
- `ROW` format: The statement is logged as a `CREATE TABLE` statement followed by a series of insert-row events.

In MySQL 5.5 as of 5.5.6:

- Nothing is inserted or logged.

These version dependencies arise due to a change in MySQL 5.5.6 in handling of `CREATE TABLE ... SELECT` not to insert rows if the destination table already exists, and a change made in MySQL 5.1.51 to preserve forward compatibility in replication of such statements from a 5.1 master to a 5.5 slave. For details, see Section 13.1.17.1, “CREATE TABLE ... SELECT Syntax”.

When using statement-based replication between a MySQL 5.6 or later slave and a master running a previous version of MySQL, a `CREATE TABLE ... SELECT` statement causing changes in other tables on the master fails on the slave, causing replication to stop. This is due to the fact that MySQL 5.6 does not allow a `CREATE TABLE ... SELECT` statement to make any changes in tables other than the table that is created by the statement—a change in behavior from previous versions of MySQL, which permitted these statements to do so. To keep this from happening, you should use row-based replication, rewrite the offending statement before running it on the master, or upgrade the master to MySQL 5.6 (or later). (If you choose to upgrade the master, keep in mind that such a `CREATE TABLE ... SELECT` statement will fail there as well, following the upgrade, unless the statement is rewritten to remove any side effects on other tables.) This is not an issue when using row-based replication, because the statement is logged as a `CREATE TABLE` statement with any changes to table data logged as row-insert events (or possibly row-update events), rather than as the entire `CREATE TABLE ... SELECT` statement.
17.4.1.6 Replication of **CREATE SERVER, ALTER SERVER, and DROP SERVER**

In MySQL 5.5, the statements **CREATE SERVER, ALTER SERVER,** and **DROP SERVER** are not written to the binary log, regardless of the binary logging format that is in use.

17.4.1.7 Replication of **CURRENT_USER()**

The following statements support use of the **CURRENT_USER()** function to take the place of the name of (and, possibly, the host for) an affected user or a definer; in such cases, **CURRENT_USER()** is expanded where and as needed:

- DROP USER
- RENAME USER
- GRANT
- REVOKE
- CREATE FUNCTION
- CREATE PROCEDURE
- CREATE TRIGGER
- CREATE EVENT
- CREATE VIEW
- ALTER EVENT
- ALTER VIEW
- SET PASSWORD

When **CURRENT_USER()** or **CURRENT_USER** is used as the definer in any of the statements CREATE FUNCTION, CREATE PROCEDURE, CREATE TRIGGER, CREATE EVENT, CREATE VIEW, or ALTER VIEW when binary logging is enabled, the function reference is expanded before it is written to the binary log, so that the statement refers to the same user on both the master and the slave when the statement is replicated. **CURRENT_USER()** or **CURRENT_USER** is also expanded prior to being written to the binary log when used in DROP USER, RENAME USER, GRANT, REVOKE, or ALTER EVENT.

17.4.1.8 Replication of **DROP ... IF EXISTS** Statements

The **DROP DATABASE IF EXISTS, DROP TABLE IF EXISTS,** and **DROP VIEW IF EXISTS** statements are always replicated, even if the database, table, or view to be dropped does not exist on the master. This is to ensure that the object to be dropped no longer exists on either the master or the slave, once the slave has caught up with the master.

**DROP ... IF EXISTS** statements for stored programs (stored procedures and functions, triggers, and events) are also replicated, even if the stored program to be dropped does not exist on the master.

17.4.1.9 Replication with Differing Table Definitions on Master and Slave

Source and target tables for replication do not have to be identical. A table on the master can have more or fewer columns than the slave's copy of the table. In addition, corresponding table columns on the master and the slave can use different data types, subject to certain conditions.
In all cases where the source and target tables do not have identical definitions, the database and table names must be the same on both the master and the slave. Additional conditions are discussed, with examples, in the following two sections.

**Replication with More Columns on Master or Slave**

You can replicate a table from the master to the slave such that the master and slave copies of the table have differing numbers of columns, subject to the following conditions:

- Columns common to both versions of the table must be defined in the same order on the master and the slave.
  
  (This is true even if both tables have the same number of columns.)

- Columns common to both versions of the table must be defined before any additional columns.

  This means that executing an `ALTER TABLE` statement on the slave where a new column is inserted into the table within the range of columns common to both tables causes replication to fail, as shown in the following example:

Suppose that a table `t`, existing on the master and the slave, is defined by the following `CREATE TABLE` statement:

```sql
CREATE TABLE t (  
  c1 INT,  
  c2 INT,  
  c3 INT  
);
```

Suppose that the `ALTER TABLE` statement shown here is executed on the slave:

```sql
ALTER TABLE t ADD COLUMN cnew1 INT AFTER c3;
```

The previous `ALTER TABLE` is permitted on the slave because the columns `c1`, `c2`, and `c3` that are common to both versions of table `t` remain grouped together in both versions of the table, before any columns that differ.

However, the following `ALTER TABLE` statement cannot be executed on the slave without causing replication to break:

```sql
ALTER TABLE t ADD COLUMN cnew2 INT AFTER c2;
```

Replication fails after execution on the slave of the `ALTER TABLE` statement just shown, because the new column `cnew2` comes between columns common to both versions of `t`.

- Each “extra” column in the version of the table having more columns must have a default value.

**Note**

A column’s default value is determined by a number of factors, including its type, whether it is defined with a `DEFAULT` option, whether it is declared as `NULL`, and the server SQL mode in effect at the time of its creation; for more information, see Section 11.6, “Data Type Default Values”.

In addition, when the slave’s copy of the table has more columns than the master’s copy, each column common to the tables must use the same data type in both tables.
Examples. The following examples illustrate some valid and invalid table definitions:

More columns on the master. The following table definitions are valid and replicate correctly:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT);
```

The following table definitions would raise Error 1532 (ER_BINLOG_ROW_RBR_TO_SBR) because the definitions of the columns common to both versions of the table are in a different order on the slave than they are on the master:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave> CREATE TABLE t1 (c2 INT, c1 INT);
```

The following table definitions would also raise Error 1532 because the definition of the extra column on the master appears before the definitions of the columns common to both versions of the table:

```
master> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT);
```

More columns on the slave. The following table definitions are valid and replicate correctly:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

The following definitions raise Error 1532 because the columns common to both versions of the table are not defined in the same order on both the master and the slave:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c2 INT, c1 INT, c3 INT);
```

The following table definitions also raise Error 1532 because the definition for the extra column in the slave's version of the table appears before the definitions for the columns which are common to both versions of the table:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
```

The following table definitions fail because the slave's version of the table has additional columns compared to the master's version, and the two versions of the table use different data types for the common column `c2`:

```
master> CREATE TABLE t1 (c1 INT, c2 BIGINT);
slave> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

Replication of Columns Having Different Data Types

Corresponding columns on the master’s and the slave's copies of the same table ideally should have the same data type. However, beginning with MySQL 5.1.21, this is not always strictly enforced, as long as certain conditions are met.

All other things being equal, it is always possible to replicate from a column of a given data type to another column of the same type and same size or width, where applicable, or larger. For example, you can
replicate from a `CHAR(10)` column to another `CHAR(10)`, or from a `CHAR(10)` column to a `CHAR(25)` column without any problems. In certain cases, it also possible to replicate from a column having one data type (on the master) to a column having a different data type (on the slave); when the data type of the master's version of the column is promoted to a type that is the same size or larger on the slave, this is known as **attribute promotion**.

Attribute promotion can be used with both statement-based and row-based replication, and is not dependent on the storage engine used by either the master or the slave. However, the choice of logging format does have an effect on the type conversions that are permitted; the particulars are discussed later in this section.

---

**Important**

Whether you use statement-based or row-based replication, the slave's copy of the table cannot contain more columns than the master's copy if you wish to employ attribute promotion.

**Statement-based replication.** When using statement-based replication, a simple rule of thumb to follow is, “If the statement run on the master would also execute successfully on the slave, it should also replicate successfully”. In other words, if the statement uses a value that is compatible with the type of a given column on the slave, the statement can be replicated. For example, you can insert any value that fits in a `TINYINT` column into a `BIGINT` column as well; it follows that, even if you change the type of a `TINYINT` column in the slave's copy of a table to `BIGINT`, any insert into that column on the master that succeeds should also succeed on the slave, since it is impossible to have a legal `TINYINT` value that is large enough to exceed a `BIGINT` column.

Prior to MySQL 5.5.30, when using statement-based replication, `AUTO_INCREMENT` columns were required to be the same on both the master and the slave; otherwise, updates could be applied to the wrong table on the slave. (Bug #12669186)

**Row-based replication: attribute promotion and demotion.** Formerly, due to the fact that in row-based replication changes rather than statements are replicated, and that these changes are transmitted using formats that do not always map directly to MySQL server column data types, you could not replicate between different subtypes of the same general type (for example, from `TINYINT` to `BIGINT`, both `INT` subtypes). However, beginning with MySQL 5.5.3, MySQL Replication supports attribute promotion and demotion between smaller data types and larger types. It is also possible to specify whether or not to permit lossy (truncated) or non-lossy conversions of demoted column values, as explained later in this section.

**Lossy and non-lossy conversions.** In the event that the target type cannot represent the value being inserted, a decision must be made on how to handle the conversion. If we permit the conversion but truncate (or otherwise modify) the source value to achieve a “fit” in the target column, we make what is known as a **lossy conversion**. A conversion which does not require truncation or similar modifications to fit the source column value in the target column is a **non-lossy** conversion.

**Type conversion modes (``slave_type_conversions`` variable).** The setting of the `slave_type_conversions` global server variable controls the type conversion mode used on the slave. This variable takes a set of values from the following table, which shows the effects of each mode on the slave's type-conversion behavior:

<table>
<thead>
<tr>
<th>Mode</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ALL_LOSSY</strong></td>
<td>In this mode, type conversions that would mean loss of information are permitted.</td>
</tr>
</tbody>
</table>
Replication Features and Issues

<table>
<thead>
<tr>
<th>Mode</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This does not imply that non-lossy conversions are permitted, merely that only cases requiring either lossy conversions or no conversion at all are permitted; for example, enabling only this mode permits an INT column to be converted to TINYINT (a lossy conversion), but not a TINYINT column to an INT column (non-lossy). Attempting the latter conversion in this case would cause replication to stop with an error on the slave.</td>
</tr>
<tr>
<td>ALL_NON_LOSSY</td>
<td>This mode permits conversions that do not require truncation or other special handling of the source value; that is, it permits conversions where the target type has a wider range than the source type. Setting this mode has no bearing on whether lossy conversions are permitted; this is controlled with the ALL_LOSSY mode. If only ALL_NON_LOSSY is set, but not ALL_LOSSY, then attempting a conversion that would result in the loss of data (such as INT to TINYINT, or CHAR(25) to VARCHAR(20)) causes the slave to stop with an error.</td>
</tr>
<tr>
<td>ALL_LOSSY, ALL_NON_LOSSY</td>
<td>When this mode is set, all supported type conversions are permitted, whether or not they are lossy conversions.</td>
</tr>
<tr>
<td>[empty]</td>
<td>When slave_type_conversions is not set, no attribute promotion or demotion is permitted; this means that all columns in the source and target tables must be of the same types. This mode is the default.</td>
</tr>
</tbody>
</table>

Changing the type conversion mode requires restarting the slave with the new slave_type_conversions setting.

**Supported conversions.** Supported conversions between different but similar data types are shown in the following list:

- Between any of the integer types TINYINT, SMALLINT, MEDIUMINT, INT, and BIGINT.

  This includes conversions between the signed and unsigned versions of these types.

  Lossy conversions are made by truncating the source value to the maximum (or minimum) permitted by the target column. For insuring non-lossy conversions when going from unsigned to signed types, the target column must be large enough to accommodate the range of values in the source column. For example, you can demote TINYINT UNSIGNED non-lossily to SMALLINT, but not to TINYINT.

- Between any of the decimal types DECIMAL, FLOAT, DOUBLE, and NUMERIC.

  FLOAT to DOUBLE is a non-lossy conversion; DOUBLE to FLOAT can only be handled lossily. A conversion from \( \text{DECIMAL}(M, D) \) to \( \text{DECIMAL}(M', D') \) where \( M' \geq M \) and \( D' \geq D \) is non-lossy; for any case where \( M' < M, D' < D \), or both, only a lossy conversion can be made.

  For any of the decimal types, if a value to be stored cannot be fit in the target type, the value is rounded down according to the rounding rules defined for the server elsewhere in the documentation. See Section 12.18.4, “Rounding Behavior”, for information about how this is done for decimal types.

- Between any of the string types CHAR, VARCHAR, and TEXT, including conversions between different widths.
Conversion of a `CHAR`, `VARCHAR`, or `TEXT` to a `CHAR`, `VARCHAR`, or `TEXT` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first $N$ characters of the string on the slave, where $N$ is the width of the target column.

**Important**

Replication between columns using different character sets is not supported.

- Between any of the binary data types `BINARY`, `VARBINARY`, and `BLOB`, including conversions between different widths.

Conversion of a `BINARY`, `VARBINARY`, or `BLOB` to a `BINARY`, `VARBINARY`, or `BLOB` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first $N$ bytes of the string on the slave, where $N$ is the width of the target column.

- Between any 2 `BIT` columns of any 2 sizes.

When inserting a value from a `BIT(M)` column into a `BIT(M')` column, where $M' > M$, the most significant bits of the `BIT(M')` columns are cleared (set to zero) and the $M$ bits of the `BIT(M)` value are set as the least significant bits of the `BIT(M')` column.

When inserting a value from a source `BIT(M)` column into a target `BIT(M')` column, where $M' < M$, the maximum possible value for the `BIT(M')` column is assigned; in other words, an “all-set” value is assigned to the target column.

Conversions between types not in the previous list are not permitted.

**Replication type conversions in MySQL 5.5.3 and earlier.** Prior to MySQL 5.5.3, with row-based binary logging, you could not replicate between different `INT` subtypes, such as from `TINYINT` to `BIGINT`, because changes to columns of these types were represented differently from one another in the binary log when using row-based logging. (However, you could replicate from `BLOB` to `TEXT` using row-based replication because changes to `BLOB` and `TEXT` columns were represented using the same format in the binary log.)

Supported conversions for attribute promotion when using row-based replication prior to MySQL 5.5.3 are shown in the following table:

<table>
<thead>
<tr>
<th>From (Master)</th>
<th>To (Slave)</th>
</tr>
</thead>
<tbody>
<tr>
<td>BINARY</td>
<td>CHAR</td>
</tr>
<tr>
<td>BLOB</td>
<td>TEXT</td>
</tr>
<tr>
<td>CHAR</td>
<td>BINARY</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>NUMERIC</td>
</tr>
<tr>
<td>NUMERIC</td>
<td>DECIMAL</td>
</tr>
<tr>
<td>TEXT</td>
<td>BLOB</td>
</tr>
<tr>
<td>VARBINARY</td>
<td>VARCHAR</td>
</tr>
<tr>
<td>VARCHAR</td>
<td>VARBINARY</td>
</tr>
</tbody>
</table>

**Note**

In all cases, the size or width of the column on the slave must be equal to or greater than that of the column on the master. For example, you could replicate from a `CHAR(10)` column on the master to a column that used `BINARY(10)` or
BINARY(25) on the slave, but you could not replicate from a CHAR(10) column on the master to BINARY(5) column on the slave.

Any unique index (including primary keys) having a prefix must use a prefix of the same length on both master and slave; in such cases, differing prefix lengths are disallowed. It is possible to use a nonunique index whose prefix length differs between master and slave, but this can cause serious performance issues, particularly when the prefix used on the master is longer. This is due to the fact that 2 unique prefixes of a given length may no longer be unique at a shorter length; for example, the words catalogue and catamount have the 5-character prefixes catal and catam, respectively, but share the same 4-character prefix (cata). This can lead to queries that use such indexes executing less efficiently on the slave, when a shorter prefix is employed in the slave’s definition of the same index than on the master.

For DECIMAL and NUMERIC columns, both the mantissa (M) and the number of decimals (D) must be the same size or larger on the slave as compared with the master. For example, replication from a NUMERIC(5,4) to a DECIMAL(6,4) worked, but not from a NUMERIC(5,4) to a DECIMAL(5,3).

Prior to MySQL 5.5.3, MySQL replication did not support attribute promotion of any of the following data types to or from any other data type when using row-based replication:

- INT (including TINYINT, SMALLINT, MEDIUMINT, BIGINT).
- Promotion between INT subtypes—for example, from SMALLINT to BIGINT—was also not supported prior to MySQL 5.5.3.
- SET or ENUM.
- FLOAT or DOUBLE.
- All of the data types relating to dates, times, or both: DATE, TIME, DATETIME, TIMESTAMP, and YEAR.

17.4.1.10 Replication and DIRECTORY Table Options

If a DATA DIRECTORY or INDEX DIRECTORY table option is used in a CREATE TABLE statement on the master server, the table option is also used on the slave. This can cause problems if no corresponding directory exists in the slave host file system or if it exists but is not accessible to the slave server. This can be overridden by using the NO_DIR_IN_CREATE server SQL mode on the slave, which causes the slave to ignore the DATA DIRECTORY and INDEX DIRECTORY table options when replicating CREATE TABLE statements. The result is that MyISAM data and index files are created in the table’s database directory.

For more information, see Section 5.1.7, “Server SQL Modes”.

17.4.1.11 Replication of Invoked Features

Replication of invoked features such as user-defined functions (UDFs) and stored programs (stored procedures and functions, triggers, and events) provides the following characteristics:

- The effects of the feature are always replicated.
- The following statements are replicated using statement-based replication:
  - CREATE EVENT
  - ALTER EVENT
Replication Features and Issues

- DROP EVENT
- CREATE PROCEDURE
- DROP PROCEDURE
- CREATE FUNCTION
- DROP FUNCTION
- CREATE TRIGGER
- DROP TRIGGER

However, the effects of features created, modified, or dropped using these statements are replicated using row-based replication.

**Note**

Attempting to replicate invoked features using statement-based replication produces the warning *Statement is not safe to log in statement format*. For example, trying to replicate a UDF with statement-based replication generates this warning because it currently cannot be determined by the MySQL server whether the UDF is deterministic. If you are absolutely certain that the invoked feature's effects are deterministic, you can safely disregard such warnings.

- In the case of **CREATE EVENT** and **ALTER EVENT**:
  - The status of the event is set to **SLAVESIDE_DISABLED** on the slave regardless of the state specified (this does not apply to **DROP EVENT**).
  - The master on which the event was created is identified on the slave by its server ID. The **ORIGINATOR** column in **INFORMATION_SCHEMA.EVENTS** and the **originator** column in **mysql.event** store this information. See Section 21.7, “The INFORMATION_SCHEMA EVENTS Table”, and Section 13.7.5.19, “SHOW EVENTS Syntax”, for more information.
  - The feature implementation resides on the slave in a renewable state so that if the master fails, the slave can be used as the master without loss of event processing.

To determine whether there are any scheduled events on a MySQL server that were created on a different server (that was acting as a replication master), query the **INFORMATION_SCHEMA.EVENTS** table in a manner similar to what is shown here:

```sql
SELECT EVENT_SCHEMA, EVENT_NAME
FROM INFORMATION_SCHEMA.EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED';
```

Alternatively, you can use the **SHOW EVENTS** statement, like this:

```sql
SHOW EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED';
```

When promoting a replication slave having such events to a replication master, you must enable each event using **ALTER EVENT event_name ENABLED**, where **event_name** is the name of the event.
If more than one master was involved in creating events on this slave, and you wish to identify events that were created only on a given master having the server ID `master_id`, modify the previous query on the `EVENTS` table to include the `ORIGINATOR` column, as shown here:

```sql
SELECT EVENT_SCHEMA, EVENT_NAME, ORIGINATOR
FROM INFORMATION_SCHEMA.EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED'
AND ORIGINATOR = 'master_id'
```

You can employ `ORIGINATOR` with the `SHOW EVENTS` statement in a similar fashion:

```sql
SHOW EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED'
AND ORIGINATOR = 'master_id'
```

Before enabling events that were replicated from the master, you should disable the MySQL Event Scheduler on the slave (using a statement such as `SET GLOBAL event_scheduler = OFF;`), run any necessary `ALTER EVENT` statements, restart the server, then re-enable the Event Scheduler on the slave afterward (using a statement such as `SET GLOBAL event_scheduler = ON;`).

If you later demote the new master back to being a replication slave, you must disable manually all events enabled by the `ALTER EVENT` statements. You can do this by storing in a separate table the event names from the `SELECT` statement shown previously, or using `ALTER EVENT` statements to rename the events with a common prefix such as `replicated_` to identify them.

If you rename the events, then when demoting this server back to being a replication slave, you can identify the events by querying the `EVENTS` table, as shown here:

```sql
SELECT CONCAT(EVENT_SCHEMA, '.', EVENT_NAME) AS 'Db.Event'
FROM INFORMATION_SCHEMA.EVENTS
WHERE INSTR(EVENT_NAME, 'replicated_') = 1;
```

### 17.4.1.12 Replication and Floating-Point Values

With statement-based replication, values are converted from decimal to binary. Because conversions between decimal and binary representations of them may be approximate, comparisons involving floating-point values are inexact. This is true for operations that use floating-point values explicitly, or that use values that are converted to floating-point implicitly. Comparisons of floating-point values might yield different results on master and slave servers due to differences in computer architecture, the compiler used to build MySQL, and so forth. See Section 12.2, “Type Conversion in Expression Evaluation”, and Section B.5.5.8, “Problems with Floating-Point Values”.

### 17.4.1.13 Replication and `FLUSH`

Some forms of the `FLUSH` statement are not logged because they could cause problems if replicated to a slave: `FLUSH LOGS`, `FLUSH MASTER`, `FLUSH SLAVE`, and `FLUSH TABLES WITH READ LOCK`. For a syntax example, see Section 13.7.6.3, “`FLUSH Syntax`”. The `FLUSH TABLES`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements are written to the binary log and thus replicated to slaves. This is not normally a problem because these statements do not modify table data.

However, this behavior can cause difficulties under certain circumstances. If you replicate the privilege tables in the `mysql` database and update those tables directly without using `GRANT`, you must issue a `FLUSH PRIVILEGES` on the slaves to put the new privileges into effect. In addition, if you use `FLUSH TABLES` when renaming a `MyISAM` table that is part of a `MERGE` table, you must issue `FLUSH TABLES` manually on the slaves. These statements are written to the binary log unless you specify `NO_WRITE_TO_BINLOG` or its alias `LOCAL`.
17.4.1.14 Replication and System Functions

Certain functions do not replicate well under some conditions:

- The `USER()`, `CURRENT_USER()` (or `CURRENT_USER`), `UUID()`, `VERSION()`, and `LOAD_FILE()` functions are replicated without change and thus do not work reliably on the slave unless row-based replication is enabled. (See Section 17.1.2, “Replication Formats”.)

`USER()` and `CURRENT_USER()` are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (Bug #28086) (See also Section 17.4.1.7, “Replication of `CURRENT_USER()`”.)

Beginning with MySQL 5.5.1, `VERSION()` is also automatically replicated using row-based replication when using `MIXED` mode, and generates a warning in `STATEMENT` mode. (Bug #47995) Beginning with MySQL 5.5.2, this is also true with regard to the `RAND()` function. (Bug #49222)

- For `NOW()`, the binary log includes the timestamp. This means that the value as returned by the call to this function on the master is replicated to the slave. This can lead to a possibly unexpected result when replicating between MySQL servers in different time zones. Suppose that the master is located in New York, the slave is located in Stockholm, and both servers are using local time. Suppose further that, on the master, you create a table `mytable`, perform an `INSERT` statement on this table, and then select from the table, as shown here:

```sql
mysql> CREATE TABLE mytable (mycol TEXT);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO mytable VALUES ( NOW() );
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM mytable;
+---------------------+
<table>
<thead>
<tr>
<th>mycol</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-09-01 12:00:00</td>
</tr>
</tbody>
</table>
+---------------------+
1 row in set (0.00 sec)
```

Local time in Stockholm is 6 hours later than in New York; so, if you issue `SELECT NOW()` on the slave at that exact same instant, the value `2009-09-01 18:00:00` is returned. For this reason, if you select from the slave’s copy of `mytable` after the `CREATE TABLE` and `INSERT` statements just shown have been replicated, you might expect `mycol` to contain the value `2009-09-01 18:00:00`. However, this is not the case; when you select from the slave’s copy of `mytable`, you obtain exactly the same result as on the master:

```sql
mysql> SELECT * FROM mytable;
+---------------------+
<table>
<thead>
<tr>
<th>mycol</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-09-01 12:00:00</td>
</tr>
</tbody>
</table>
+---------------------+
1 row in set (0.00 sec)
```

Unlike `NOW()`, the `SYSDATE()` function is not replication-safe because it is not affected by `SET TIMESTAMP` statements in the binary log and is nondeterministic if statement-based logging is used. This is not a problem if row-based logging is used.

An alternative is to use the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`. This must be done on the master and the slave to work correctly. In such cases, a warning is still issued.
by this function, but can safely be ignored as long as `--sysdate-is-now` is used on both the master and the slave.

Beginning with MySQL 5.5.1, `SYSDATE()` is automatically replicated using row-based replication when using `MIXED` mode, and generates a warning in `STATEMENT` mode. (Bug #47995)

See also Section 17.4.1.32, "Replication and Time Zones".

- **The following restriction applies to statement-based replication only, not to row-based replication.**
  The `GET_LOCK()`, `RELEASE_LOCK()`, `IS_FREE_LOCK()`, and `IS_USED_LOCK()` functions that handle user-level locks are replicated without the slave knowing the concurrency context on the master. Therefore, these functions should not be used to insert into a master table because the content on the slave would differ. For example, do not issue a statement such as `INSERT INTO mytable VALUES(GET_LOCK(...))`.

  Beginning with MySQL 5.5.1, these functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (Bug #47995)

  As a workaround for the preceding limitations when statement-based replication is in effect, you can use the strategy of saving the problematic function result in a user variable and referring to the variable in a later statement. For example, the following single-row `INSERT` is problematic due to the reference to the `UUID()` function:

  ```sql
  INSERT INTO t VALUES(UUID());
  ```

  To work around the problem, do this instead:

  ```sql
  SET @my_uuid = UUID();
  INSERT INTO t VALUES(@my_uuid);
  ```

  That sequence of statements replicates because the value of `@my_uuid` is stored in the binary log as a user-variable event prior to the `INSERT` statement and is available for use in the `INSERT`.

  The same idea applies to multiple-row inserts, but is more cumbersome to use. For a two-row insert, you can do this:

  ```sql
  SET @my_uuid1 = UUID(); @my_uuid2 = UUID();
  INSERT INTO t VALUES(@my_uuid1),(@my_uuid2);
  ```

  However, if the number of rows is large or unknown, the workaround is difficult or impracticable. For example, you cannot convert the following statement to one in which a given individual user variable is associated with each row:

  ```sql
  INSERT INTO t2 SELECT UUID(), * FROM t1;
  ```

  Within a stored function, `RAND()` replicates correctly as long as it is invoked only once during the execution of the function. (You can consider the function execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

  The `FOUND_ROWS()` and `ROW_COUNT()` functions are not replicated reliably using statement-based replication. A workaround is to store the result of the function call in a user variable, and then use that in the `INSERT` statement. For example, if you wish to store the result in a table named `mytable`, you might normally do so like this:

  ```sql
  SELECT SQL_CALC_FOUND_ROWS FROM mytable LIMIT 1;
  ```
INSERT INTO mytable VALUES( FOUND_ROWS() );

However, if you are replicating `mytable`, you should use `SELECT ... INTO`, and then store the variable in the table, like this:

```
SELECT SQL_CALC_FOUND_ROWS INTO @found_rows FROM mytable LIMIT 1;
INSERT INTO mytable VALUES(@found_rows);
```

In this way, the user variable is replicated as part of the context, and applied on the slave correctly.

These functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (Bug #12092, Bug #30244)

Prior to MySQL 5.5.35, the value of `LAST_INSERT_ID()` was not replicated correctly if any filtering options such as `--replicate-ignore-db` and `--replicate-do-table` were enabled on the slave. (Bug #17234370, BUG# 69861)

### 17.4.1.15 Replication and `LIMIT`

Statement-based replication of `LIMIT` clauses in `DELETE`, `UPDATE`, and `INSERT ... SELECT` statements is unsafe since the order of the rows affected is not defined. (Such statements can be replicated correctly with statement-based replication only if they also contain an `ORDER BY` clause.) When such a statement is encountered:

- When using `STATEMENT` mode, a warning that the statement is not safe for statement-based replication is now issued.

  Currently, when using `STATEMENT` mode, warnings are issued for DML statements containing `LIMIT` even when they also have an `ORDER BY` clause (and so are made deterministic). This is a known issue. (Bug #42851)

- When using `MIXED` mode, the statement is now automatically replicated using row-based mode.

### 17.4.1.16 Replication and `LOAD DATA INFILE`

The `LOAD DATA INFILE` statement was not always replicated correctly to a slave running MySQL 5.5.0 or earlier from a master running MySQL 4.0 or earlier. When using statement-based replication, the `LOAD DATA INFILE` statement `CONCURRENT` option was not replicated. This issue was fixed in MySQL 5.5.0. This issue does not have any impact on `CONCURRENT` option handling when using row-based replication in MySQL 5.1 or later. (Bug #34628)

In MySQL 5.5.6 and later, `LOAD DATA INFILE` is considered unsafe (see Section 17.1.2.3, “Determination of Safe and Unsafe Statements in Binary Logging”). It causes a warning when using statement-based logging format, and is logged using row-based format when using mixed-format logging.

### 17.4.1.17 Replication and the Slow Query Log

In older versions of MySQL, replication slaves did not write replicated queries to the slow query log, even if the same queries were written to the slow query log on the master. This is no longer an issue in MySQL 5.5. (Bug #23300)

### 17.4.1.18 Replication and `REPAIR TABLE`

When used on a corrupted or otherwise damaged table, it is possible for the `REPAIR TABLE` statement to delete rows that cannot be recovered. However, any such modifications of table data performed by this statement are not replicated, which can cause master and slave to lose synchronization. For this reason, in the event that a table on the master becomes damaged and you use `REPAIR TABLE` to repair it, you
Replication Features and Issues

should first stop replication (if it is still running) before using `REPAIR TABLE`, then afterward compare the master's and slave's copies of the table and be prepared to correct any discrepancies manually, before restarting replication.

17.4.1.19 Replication and Master or Slave Shutdowns

It is safe to shut down a master server and restart it later. When a slave loses its connection to the master, the slave tries to reconnect immediately and retries periodically if that fails. The default is to retry every 60 seconds. This may be changed with the `CHANGE MASTER TO` statement. A slave also is able to deal with network connectivity outages. However, the slave notices the network outage only after receiving no data from the master for `slave_net_timeout` seconds. If your outages are short, you may want to decrease `slave_net_timeout`. See Section 5.1.4, “Server System Variables”.

An unclean shutdown (for example, a crash) on the master side can result in the master binary log having a final position less than the most recent position read by the slave, due to the master binary log file not being flushed. This can cause the slave not to be able to replicate when the master comes back up. Setting `sync_binlog=1` in the master `my.cnf` file helps to minimize this problem because it causes the master to flush its binary log more frequently.

Shutting down a slave cleanly is safe because it keeps track of where it left off. However, be careful that the slave does not have temporary tables open; see Section 17.4.1.22, “Replication and Temporary Tables”. Unclean shutdowns might produce problems, especially if the disk cache was not flushed to disk before the problem occurred:

- For transactions, the slave commits and then updates `relay-log.info`. If a crash occurs between these two operations, relay log processing will have proceeded further than the information file indicates and the slave will re-execute the events from the last transaction in the relay log after it has been restarted.

- A similar problem can occur if the slave updates `relay-log.info` but the server host crashes before the write has been flushed to disk. To minimize the chance of this occurring, set `sync_relay_log_info=1` in the slave `my.cnf` file. The default value of `sync_relay_log_info` is 0, which does not cause writes to be forced to disk; the server relies on the operating system to flush the file from time to time.

The fault tolerance of your system for these types of problems is greatly increased if you have a good uninterruptible power supply.

17.4.1.20 Replication and `max_allowed_packet`

`max_allowed_packet` sets an upper limit on the size of any single message between the MySQL server and clients, including replication slaves. If you are replicating large column values (such as might be found in `TEXT` or `BLOB` columns) and `max_allowed_packet` is too small on the master, the master fails with an error, and the slave shuts down the I/O thread. If `max_allowed_packet` is too small on the slave, this also causes the slave to stop the I/O thread.

Row-based replication currently sends all columns and column values for updated rows from the master to the slave, including values of columns that were not actually changed by the update. This means that, when you are replicating large column values using row-based replication, you must take care to set `max_allowed_packet` large enough to accommodate the largest row in any table to be replicated, even if you are replicating updates only, or you are inserting only relatively small values.

17.4.1.21 Replication and `MEMORY` Tables

When a master server shuts down and restarts, its `MEMORY` tables become empty. To replicate this effect to slaves, the first time that the master uses a given `MEMORY` table after startup, it logs an event that notifies slaves that the table must be emptied by writing a `DELETE` statement for that table to the binary log.
When a slave server shuts down and restarts, its MEMORY tables become empty. This causes the slave to be out of synchrony with the master and may lead to other failures or cause the slave to stop:

- Row-format updates and deletes received from the master may fail with `Can't find record in 'memory_table'`.
- Statements such as `INSERT INTO ... SELECT FROM memory_table` may insert a different set of rows on the master and slave.

The safe way to restart a slave that is replicating MEMORY tables is to first drop or delete all rows from the MEMORY tables on the master and wait until those changes have replicated to the slave. Then it is safe to restart the slave.

An alternative restart method may apply in some cases. When `binlog_format=ROW`, you can prevent the slave from stopping if you set `slave_exec_mode=IDEMPOTENT` before you start the slave again. This allows the slave to continue to replicate, but its MEMORY tables will still be different from those on the master. This can be okay if the application logic is such that the contents of MEMORY tables can be safely lost (for example, if the MEMORY tables are used for caching). `slave_exec_mode=IDEMPOTENT` applies globally to all tables, so it may hide other replication errors in non-MEMORY tables.

(The method just described is not applicable in MySQL Cluster, where `slave_exec_mode` is always IDEMPOTENT, and cannot be changed.)

The size of MEMORY tables is limited by the value of the `max_heap_table_size` system variable, which is not replicated (see Section 17.4.1.36, “Replication and Variables”). A change in `max_heap_table_size` takes effect for MEMORY tables that are created or updated using `ALTER TABLE ... ENGINE = MEMORY` or `TRUNCATE TABLE` following the change, or for all MEMORY tables following a server restart. If you increase the value of this variable on the master without doing so on the slave, it becomes possible for a table on the master to grow larger than its counterpart on the slave, leading to inserts that succeed on the master but fail on the slave with `Table is full` errors. This is a known issue (Bug #48666). In such cases, you must set the global value of `max_heap_table_size` on the slave as well as on the master, then restart replication. It is also recommended that you restart both the master and slave MySQL servers, to insure that the new value takes complete (global) effect on each of them.

See Section 15.4, “The MEMORY Storage Engine”, for more information about MEMORY tables.

### 17.4.1.22 Replication and Temporary Tables

The discussion in the following paragraphs does not apply when `binlog_format=ROW` because, in that case, temporary tables are not replicated; this means that there are never any temporary tables on the slave to be lost in the event of an unplanned shutdown by the slave. The remainder of this section applies only when using statement-based or mixed-format replication. Loss of replicated temporary tables on the slave can be an issue, whenever `binlog_format` is STATEMENT or MIXED, for statements involving temporary tables that can be logged safely using statement-based format. For more information about row-based replication and temporary tables, see RBL, RBR, and temporary tables.

**Safe slave shutdown when using temporary tables.** Temporary tables are replicated except in the case where you stop the slave server (not just the slave threads) and you have replicated temporary tables that are open for use in updates that have not yet been executed on the slave. If you stop the slave server, the temporary tables needed by those updates are no longer available when the slave is restarted. To avoid this problem, do not shut down the slave while it has temporary tables open. Instead, use the following procedure:

1. Issue a `STOP SLAVE SQL_THREAD` statement.
2. Use `SHOW STATUS` to check the value of the `Slave_open_temp_tables` variable.
3. If the value is not 0, restart the slave SQL thread with `START SLAVE SQL_THREAD` and repeat the procedure later.

4. When the value is 0, issue a `mysqladmin shutdown` command to stop the slave.

**Temporary tables and replication options.** By default, all temporary tables are replicated; this happens whether or not there are any matching `--replicate-do-db`, `--replicate-do-table`, or `--replicate-wild-do-table` options in effect. However, the `--replicate-ignore-table` and `--replicate-wild-ignore-table` options are honored for temporary tables.

A recommended practice when using statement-based or mixed-format replication is to designate a prefix for exclusive use in naming temporary tables that you do not want replicated, then employ a `--replicate-wild-ignore-table` option to match that prefix. For example, you might give all such tables names beginning with `norep` (such as `norepmytable`, `norepyourtable`, and so on), then use `--replicate-wild-ignore-table=norep%` to prevent them from being replicated.

### 17.4.1.23 Replication of the `mysql` System Database

Data modification statements made to tables in the `mysql` database are replicated according to the value of `binlog_format`; if this value is `MIXED`, these statements are replicated using row-based format. However, statements that would normally update this information indirectly—such as `GRANT`, `REVOKE`, and statements manipulating triggers, stored routines, and views—are replicated to slaves using statement-based replication.

### 17.4.1.24 Replication and the Query Optimizer

It is possible for the data on the master and slave to become different if a statement is written in such a way that the data modification is nondeterministic; that is, left up the query optimizer. (In general, this is not a good practice, even outside of replication.) Examples of nondeterministic statements include `DELETE` or `UPDATE` statements that use `LIMIT` with no `ORDER BY` clause; see Section 17.4.1.15, “Replication and `LIMIT`”, for a detailed discussion of these.

### 17.4.1.25 Replication and Reserved Words

You can encounter problems when you attempt to replicate from an older master to a newer slave and you make use of identifiers on the master that are reserved words in the newer MySQL version running on the slave. An example of this is using a table column named `current_user` on a 4.0 master that is replicating to a 4.1 or higher slave because `CURRENT_USER` is a reserved word beginning in MySQL 4.1. Replication can fail in such cases with Error 1064 *You have an error in your SQL syntax.... even if a database or table named using the reserved word or a table having a column named using the reserved word is excluded from replication.* This is due to the fact that each SQL event must be parsed by the slave prior to execution, so that the slave knows which database object or objects would be affected; only after the event is parsed can the slave apply any filtering rules defined by `--replicate-do-db`, `--replicate-do-table`, `--replicate-ignore-db`, and `--replicate-ignore-table`.

To work around the problem of database, table, or column names on the master which would be regarded as reserved words by the slave, do one of the following:

- Use one or more `ALTER TABLE` statements on the master to change the names of any database objects where these names would be considered reserved words on the slave, and change any SQL statements that use the old names to use the new names instead.

- In any SQL statements using these database object names, write the names as quoted identifiers using backtick characters (``).

For listings of reserved words by MySQL version, see `Reserved Words`, in the MySQL Server Version Reference. For identifier quoting rules, see Section 9.2, “Schema Object Names”.
17.4.1.26 **SET PASSWORD** and Row-Based Replication

Row-based replication of **SET PASSWORD** statements from a MySQL 5.1 master to a MySQL 5.5 slave did not work correctly prior to MySQL 5.1.53 on the master and MySQL 5.5.7 on the slave (see Bug #57098, Bug #57357).

17.4.1.27 Slave Errors During Replication

If a statement produces the same error (identical error code) on both the master and the slave, the error is logged, but replication continues.

If a statement produces different errors on the master and the slave, the slave SQL thread terminates, and the slave writes a message to its error log and waits for the database administrator to decide what to do about the error. This includes the case that a statement produces an error on the master or the slave, but not both. To address the issue, connect to the slave manually and determine the cause of the problem. **SHOW SLAVE STATUS** is useful for this. Then fix the problem and run **START SLAVE**. For example, you might need to create a nonexistent table before you can start the slave again.

If this error code validation behavior is not desirable, some or all errors can be masked out (ignored) with the **--slave-skip-errors** option.

For nontransactional storage engines such as **MyISAM**, it is possible to have a statement that only partially updates a table and returns an error code. This can happen, for example, on a multiple-row insert that has one row violating a key constraint, or if a long update statement is killed after updating some of the rows. If that happens on the master, the slave expects execution of the statement to result in the same error code. If it does not, the slave SQL thread stops as described previously.

If you are replicating between tables that use different storage engines on the master and slave, keep in mind that the same statement might produce a different error when run against one version of the table, but not the other, or might cause an error for one version of the table, but not the other. For example, since **MyISAM** ignores foreign key constraints, an **INSERT** or **UPDATE** statement accessing an **InnoDB** table on the master might cause a foreign key violation but the same statement performed on a **MyISAM** version of the same table on the slave would produce no such error, causing replication to stop.

17.4.1.28 Replication of Server-Side Help Tables

The server maintains tables in the **mysql** database that store information for the **HELP** statement (see Section 13.8.3, “HELP Syntax”). These tables can be loaded manually as described at Section 5.1.10, “Server-Side Help”.

Help table content is derived from the MySQL Reference Manual. There are versions of the manual specific to each MySQL release series, so help content is specific to each series as well. Normally, you load a version of help content that matches the server version. This has implications for replication. For example, you would load MySQL 5.5 help content into a MySQL 5.5 master server, but not necessarily replicate that content to a MySQL 5.6 slave server for which 5.6 help content is more appropriate.

This section describes how to manage help table content upgrades when your servers participate in replication. Server versions are one factor in this task. Another is that help table structure may differ between the master and the slave.

Assume that help content is stored in a file named **fill_help_tables.sql**. In MySQL distributions, this file is located under the **share** or **share/mysql** directory, and the most recent version is always available for download from [http://dev.mysql.com/doc/index-other.html](http://dev.mysql.com/doc/index-other.html).

To upgrade help tables, using the following procedure. Connection parameters are not shown for the **mysql** commands discussed here; in all cases, connect to the server using an account such as root that has privileges for modifying tables in the **mysql** database.
1. Upgrade your servers by running `mysql_upgrade`, first on the slaves and then on the master. This is the usual principle of upgrading slaves first.

2. Decide whether you want to replicate help table content from the master to its slaves. If not, load the content on the master and each slave individually. Otherwise, check for and resolve any incompatibilities between help table structure on the master and its slaves, then load the content into the master and let it replicate to the slaves.

More detail about these two methods of loading help table content follows.

**Loading Help Table Content Without Replication to Slaves**

To load help table content without replication, run this command on the master and each slave individually, using a `fill_help_tables.sql` file containing content appropriate to the server version (enter the command on one line):

```bash
mysql --init-command="SET sql_log_bin=0"
mysql < fill_help_tables.sql
```

Use the `--init-command` option on each server, including the slaves, in case a slave also acts as a master to other slaves in your replication topology. The `SET` statement suppresses binary logging. After the command has been run on each server to be upgraded, you are done.

**Loading Help Table Content With Replication to Slaves**

If you do want to replicate help table content, check for help table incompatibilities between your master and its slaves. The `url` column in the `help_category` and `help_topic` tables was originally `CHAR(128)`, but is `TEXT` in newer MySQL versions to accommodate longer URLs. To check help table structure, use this statement:

```sql
SELECT TABLE_NAME, COLUMN_NAME, COLUMN_TYPE
FROM INFORMATION_SCHEMA.COLUMNS
WHERE TABLE_SCHEMA = 'mysql'
AND COLUMN_NAME = 'url';
```

For tables with the old structure, the statement produces this result:

```
+---------------+-------------+-------------+
<table>
<thead>
<tr>
<th>TABLE_NAME</th>
<th>COLUMN_NAME</th>
<th>COLUMN_TYPE</th>
</tr>
</thead>
<tbody>
<tr>
<td>help_category</td>
<td>url</td>
<td>char(128)</td>
</tr>
<tr>
<td>help_topic</td>
<td>url</td>
<td>char(128)</td>
</tr>
</tbody>
</table>
+---------------+-------------+-------------+
```

For tables with the new structure, the statement produces this result:

```
+---------------+-------------+-------------+
<table>
<thead>
<tr>
<th>TABLE_NAME</th>
<th>COLUMN_NAME</th>
<th>COLUMN_TYPE</th>
</tr>
</thead>
<tbody>
<tr>
<td>help_category</td>
<td>url</td>
<td>text</td>
</tr>
<tr>
<td>help_topic</td>
<td>url</td>
<td>text</td>
</tr>
</tbody>
</table>
+---------------+-------------+-------------+
```

If the master and slave both have the old structure or both have the new structure, they are compatible and you can replicate help table content by executing this command on the master:

```bash
mysql mysql < fill_help_tables.sql
```
The table content will load into the master, then replicate to the slaves.

If the master and slave have incompatible help tables (one server has the old structure and the other has the new), you have a choice between not replicating help table content after all, or making the table structures compatible so that you can replicate the content.

- If you decide not to replicate the content after all, upgrade the master and slaves individually using `mysql` with the `--init-command` option, as described previously.

- If instead you decide to make the table structures compatible, upgrade the tables on the server that has the old structure. Suppose that your master server has the old table structure. Upgrade its tables to the new structure manually by executing these statements (binary logging is disabled here to prevent replication of the changes to the slaves, which already have the new structure):

  ```
  SET sql_log_bin=0;
  ALTER TABLE mysql.help_category ALTER COLUMN url TEXT;
  ALTER TABLE mysql.help_topic ALTER COLUMN url TEXT;
  ```

  Then run this command on the master:

  ```
  mysql mysql < fill_help_tables.sql
  ```

  The table content will load into the master, then replicate to the slaves.

### 17.4.1.29 Replication and Server SQL Mode

Using different server SQL mode settings on the master and the slave may cause the same `INSERT` statements to be handled differently on the master and the slave, leading the master and slave to diverge. For best results, you should always use the same server SQL mode on the master and on the slave. This advice applies whether you are using statement-based or row-based replication.

If you are replicating partitioned tables, using different SQL modes on the master and the slave is likely to cause issues. At a minimum, this is likely to cause the distribution of data among partitions to be different in the master's and slave's copies of a given table. It may also cause inserts into partitioned tables that succeed on the master to fail on the slave.

For more information, see Section 5.1.7, “Server SQL Modes”.

### 17.4.1.30 Replication Retries and Timeouts

The global system variable `slave_transaction_retries` affects replication as follows:

If the slave SQL thread fails to execute a transaction because of an `InnoDB` deadlock or because it exceeded the `InnoDB innodb_lock_wait_timeout` value, or the `NDBCLUSTER TransactionDeadlockDetectionTimeout` or `TransactionInactiveTimeout` value, the slave automatically retries the transaction `slave_transaction_retries` times before stopping with an error. The default value is 10. The total retry count can be seen in the output of `SHOW STATUS`; see Section 5.1.6, “Server Status Variables”.

### 17.4.1.31 Replication and `TIMESTAMP`

Older versions of MySQL (prior to 4.1) differed significantly in several ways in their handling of the `TIMESTAMP` data type from what is supported in MySQL versions 5.5 and newer; these include syntax extensions which are deprecated in MySQL 5.1, and that no longer supported in MySQL 5.5. This can cause problems (including replication failures) when replicating between MySQL Server versions, if you are using columns that are defined using the old `TIMESTAMP(N)` syntax. See Section 2.11.1.1,
“Upgrading from MySQL 5.1 to 5.5”, for more information about the differences, how they can impact MySQL replication, and what you can do if you encounter such problems.

17.4.1.32 Replication and Time Zones

The same system time zone should be set for both master and slave. Otherwise, statements depending on the local time on the master are not replicated properly, such as statements that use the NOW() or FROM_UNIXTIME() functions. You can set the time zone in which MySQL server runs by using the --timezone=timezone_name option of the mysqld_safe script or by setting the TZ environment variable. See also Section 17.4.1.14, “Replication and System Functions”.

If the master is MySQL 4.1 or earlier, both master and slave should also use the same default connection time zone. That is, the --default-time-zone parameter should have the same value for both master and slave.

CONVERT_TZ(...,...,@@session.time_zone) is properly replicated only if both master and slave are running MySQL 5.0.4 or newer.

17.4.1.33 Replication and Transactions

Mixing transactional and nontransactional statements within the same transaction. In general, you should avoid transactions that update both transactional and nontransactional tables in a replication environment. You should also avoid using any statement that accesses both transactional (or temporary) and nontransactional tables and writes to any of them.

As of MySQL 5.5.2, the server uses these rules for binary logging:

- If the initial statements in a transaction are nontransactional, they are written to the binary log immediately. The remaining statements in the transaction are cached and not written to the binary log until the transaction is committed. (If the transaction is rolled back, the cached statements are written to the binary log only if they make nontransactional changes that cannot be rolled back. Otherwise, they are discarded.)

- For statement-based logging, logging of nontransactional statements is affected by the binlog_direct_non_transactional_updates system variable. When this variable is OFF (the default), logging is as just described. When this variable is ON, logging occurs immediately for nontransactional statements occurring anywhere in the transaction (not just initial nontransactional statements). Other statements are kept in the transaction cache and logged when the transaction commits. binlog_direct_non_transactional_updates has no effect for row-format or mixed-format binary logging.

Transactional, nontransactional, and mixed statements.

To apply those rules, the server considers a statement nontransactional if it changes only nontransactional tables, and transactional if it changes only transactional tables. Prior to MySQL 5.5.6, a statement that changed both nontransactional and transactional tables was considered “mixed”. Beginning with MySQL 5.5.6, a statement that references both nontransactional and transactional tables and updates any of the tables involved, is considered a mixed statement. Mixed statements, like transactional statements, are cached and logged when the transaction commits.

Beginning with MySQL 5.5.6, a mixed statement that updates a transactional table is considered unsafe if the statement also performs either of the following actions:

- Updates or reads a transactional table
- Reads a nontransactional table and the transaction isolation level is less than REPEATABLE_READ

Also beginning with MySQL 5.5.6, any mixed statement following the update of a transactional table within a transaction is considered unsafe if it performs either of the following actions:
Replication Features and Issues

- Updates any table and reads from any temporary table
- Updates a nontransactional table and binlog_direct_non_trans_update is OFF

For more information, see Section 17.1.2.3, “Determination of Safe and Unsafe Statements in Binary Logging”.

**Note**

A mixed statement is unrelated to mixed binary logging format.

Before MySQL 5.5.2, the rules for binary logging are similar to those just described, except that there is no binlog_direct_non_transactional_updates system variable to affect logging of transactional statements. Thus, the server immediately logs only the initial nontransactional statements in a transaction and caches the rest until commit time.

In situations where transactions mix updates to transactional and nontransactional tables, the order of statements in the binary log is correct, and all needed statements are written to the binary log even in case of a ROLLBACK. However, when a second connection updates the nontransactional table before the first connection transaction is complete, statements can be logged out of order because the second connection update is written immediately after it is performed, regardless of the state of the transaction being performed by the first connection.

**Using different storage engines on master and slave.** It is possible to replicate transactional tables on the master using nontransactional tables on the slave. For example, you can replicate an InnoDB master table as a MyISAM slave table. However, if you do this, there are problems if the slave is stopped in the middle of a BEGIN ... COMMIT block because the slave restarts at the beginning of the BEGIN block.

Beginning with MySQL 5.5.0, it is also safe to replicate transactions from MyISAM tables on the master to transactional tables—such as tables that use the InnoDB storage engine—on the slave. In such cases (beginning with MySQL 5.5.0), an AUTOCOMMIT=1 statement issued on the master is replicated, thus enforcing AUTOCOMMIT mode on the slave.

When the storage engine type of the slave is nontransactional, transactions on the master that mix updates of transactional and nontransactional tables should be avoided because they can cause inconsistency of the data between the master transactional table and the slave nontransactional table. That is, such transactions can lead to master storage engine-specific behavior with the possible effect of replication going out of synchrony. MySQL does not issue a warning about this currently, so extra care should be taken when replicating transactional tables from the master to nontransactional tables on the slaves.

**Changing the binary logging format within transactions.** Beginning with MySQL 5.5.3, the binlog_format system variable is read-only as long as a transaction is in progress. (Bug #47863)

Every transaction (including autocommit transactions) is recorded in the binary log as though it starts with a BEGIN statement, and ends with either a COMMIT or a ROLLBACK statement. In MySQL 5.5, this true is even for statements affecting tables that use a nontransactional storage engine (such as MyISAM).

### 17.4.1.34 Replication and Triggers

With statement-based replication, triggers executed on the master also execute on the slave. With row-based replication, triggers executed on the master do not execute on the slave. Instead, the row changes on the master resulting from trigger execution are replicated and applied on the slave.

This behavior is by design. If under row-based replication the slave applied the triggers as well as the row changes caused by them, the changes would in effect be applied twice on the slave, leading to different data on the master and the slave.
If you want triggers to execute on both the master and the slave—perhaps because you have different triggers on the master and slave—you must use statement-based replication. However, to enable slave-side triggers, it is not necessary to use statement-based replication exclusively. It is sufficient to switch to statement-based replication only for those statements where you want this effect, and to use row-based replication the rest of the time.

A statement invoking a trigger (or function) that causes an update to an AUTO_INCREMENT column is not replicated correctly using statement-based replication. MySQL 5.5 marks such statements as unsafe. (Bug #45677)

17.4.1.35 Replication and TRUNCATE TABLE

TRUNCATE TABLE is normally regarded as a DML statement, and so would be expected to be logged and replicated using row-based format when the binary logging mode is ROW or MIXED. However this caused issues when logging or replicating, in STATEMENT or MIXED mode, tables that used transactional storage engines such as InnoDB when the transaction isolation level was READ COMMITTED or READ UNCOMMITTED, which precludes statement-based logging.

TRUNCATE TABLE is treated for purposes of logging and replication as DDL rather than DML so that it can be logged and replicated as a statement. However, the effects of the statement as applicable to InnoDB and other transactional tables on replication slaves still follow the rules described in Section 13.1.33, “TRUNCATE TABLE Syntax” governing such tables. (Bug #36763)

17.4.1.36 Replication and Variables

System variables are not replicated correctly when using STATEMENT mode, except for the following variables when they are used with session scope:

- auto_increment_increment
- auto_increment_offset
- character_set_client
- character_set_connection
- character_set_database
- character_set_server
- collation_connection
- collation_database
- collation_server
- foreign_key_checks
- identity
- last_insert_id
- lc_time_names
- pseudo_thread_id
- sql_auto_is_null
- time_zone
Replication Features and Issues

- `timestamp`
- `unique_checks`

When MIXED mode is used, the variables in the preceding list, when used with session scope, cause a switch from statement-based to row-based logging. See Section 5.2.4.3, “Mixed Binary Logging Format”.

`sql_mode` is also replicated except for the `NO_DIR_IN_CREATE` mode; the slave always preserves its own value for `NO_DIR_IN_CREATE`, regardless of changes to it on the master. This is true for all replication formats.

However, when `mysqlbinlog` parses a `SET @@sql_mode = mode` statement, the full `mode` value, including `NO_DIR_IN_CREATE`, is passed to the receiving server. For this reason, replication of such a statement may not be safe when STATEMENT mode is in use.

The `default_storage_engine` and `storage_engine` system variables are not replicated, regardless of the logging mode; this is intended to facilitate replication between different storage engines.

The `read_only` system variable is not replicated. In addition, the enabling this variable has different effects with regard to temporary tables, table locking, and the `SET PASSWORD` statement in different MySQL versions.

The `max_heap_table_size` system variable is not replicated. Increasing the value of this variable on the master without doing so on the slave can lead eventually to `Table is full` errors on the slave when trying to execute `INSERT` statements on a `MEMORY` table on the master that is thus permitted to grow larger than its counterpart on the slave. For more information, see Section 17.4.1.21, “Replication and MEMORY Tables”.

In statement-based replication, session variables are not replicated properly when used in statements that update tables. For example, the following sequence of statements will not insert the same data on the master and the slave:

```sql
SET max_join_size=1000;
INSERT INTO mytable VALUES(@@max_join_size);
```

This does not apply to the common sequence:

```sql
SET time_zone=...;
INSERT INTO mytable VALUES(CONVERT_TZ(..., ..., @@time_zone));
```

Replication of session variables is not a problem when row-based replication is being used, in which case, session variables are always replicated safely. See Section 17.1.2, “Replication Formats”.

In MySQL 5.5, the following session variables are written to the binary log and honored by the replication slave when parsing the binary log, regardless of the logging format:

- `sql_mode`
- `foreign_key_checks`
- `unique_checks`
- `character_set_client`
- `collation_connection`
- `collation_database`
• collation_server
• sql_auto_is_null

Important
Even though session variables relating to character sets and collations are written to the binary log, replication between different character sets is not supported.

It is strongly recommended that you always use the same setting for the lower_case_table_names system variable on both master and slave. In particular, when a case-sensitive file system is used, setting this variable to 1 on the slave, but to a different value on the master, can cause two types of problems: Names of databases are not converted to lowercase; in addition, when using row-based replication names of tables are also not converted. Either of these problems can cause replication to fail. This is a known issue, which is fixed in MySQL 5.6.

17.4.1.37 Replication and Views

Views are always replicated to slaves. Views are filtered by their own name, not by the tables they refer to. This means that a view can be replicated to the slave even if the view contains a table that would normally be filtered out by replication-ignore-table rules. Care should therefore be taken to ensure that views do not replicate table data that would normally be filtered for security reasons.

Replication from a table to a samed-named view is supported using statement-based logging, but not when using row-based logging. In MySQL 5.5.31 and later, trying to do so when row-based logging is in effect causes an error. (Bug #11752707, Bug #43975)

17.4.2 Replication Compatibility Between MySQL Versions

MySQL supports replication from one major version to the next higher major version. For example, you can replicate from a master running MySQL 4.1 to a slave running MySQL 5.0, from a master running MySQL 5.0 to a slave running MySQL 5.1, and so on.

However, one may encounter difficulties when replicating from an older master to a newer slave if the master uses statements or relies on behavior no longer supported in the version of MySQL used on the slave. For example, in MySQL 5.5, CREATE TABLE ... SELECT statements are permitted to change tables other than the one being created, but are no longer allowed to do so in MySQL 5.6 (see Section 17.4.1.5, “Replication of CREATE TABLE ... SELECT Statements”).

The use of more than 2 MySQL Server versions is not supported in replication setups involving multiple masters, regardless of the number of master or slave MySQL servers. This restriction applies not only to major versions, but to minor versions within the same major version as well. For example, if you are using a chained or circular replication setup, you cannot use MySQL 5.5.1, MySQL 5.5.2, and MySQL 5.5.4 concurrently, although you could use any 2 of these releases together.

In some cases, it is also possible to replicate between a master and a slave that is more than one major version newer than the master. However, there are known issues with trying to replicate from a master running MySQL 4.1 or earlier to a slave running MySQL 5.1 or later. To work around such problems, you can insert a MySQL server running an intermediate version between the two; for example, rather than replicating directly from a MySQL 4.1 master to a MySQL 5.1 slave, it is possible to replicate from a MySQL 4.1 server to a MySQL 5.0 server, and then from the MySQL 5.0 server to a MySQL 5.1 server.

Important
It is strongly recommended to use the most recent release available within a given MySQL major version because replication (and other) capabilities are continually
Upgrading a Replication Setup

Replication from newer masters to older slaves may be possible, but is generally not supported. This is due to a number of factors:

- **Binary log format changes.** The binary log format can change between major releases. While we attempt to maintain backward compatibility, this is not always possible. For example, the binary log format implemented in MySQL 5.0 changed considerably from that used in previous versions, especially with regard to handling of character sets, `LOAD DATA INFILE`, and time zones. This means that replication from a MySQL 5.0 (or later) master to a MySQL 4.1 (or earlier) slave is generally not supported.

  This also has significant implications for upgrading replication servers; see Section 17.4.3, “Upgrading a Replication Setup”, for more information.

- **Use of row-based replication.** Row-based replication was implemented in MySQL 5.1.5, so you cannot replicate using row-based replication from any MySQL 5.5 or later master to a slave older than MySQL 5.1.5.

  For more information about row-based replication, see Section 17.1.2, “Replication Formats”.

- **SQL incompatibilities.** You cannot replicate from a newer master to an older slave using statement-based replication if the statements to be replicated use SQL features available on the master but not on the slave.

  However, if both the master and the slave support row-based replication, and there are no data definition statements to be replicated that depend on SQL features found on the master but not on the slave, you can use row-based replication to replicate the effects of data modification statements even if the DDL run on the master is not supported on the slave.

  For more information on potential replication issues, see Section 17.4.1, “Replication Features and Issues”.

## 17.4.3 Upgrading a Replication Setup

When you upgrade servers that participate in a replication setup, the procedure for upgrading depends on the current server versions and the version to which you are upgrading.

This section applies to upgrading replication from older versions of MySQL to MySQL 5.5. A 4.0 server should be 4.0.3 or newer.

When you upgrade a master to 5.5 from an earlier MySQL release series, you should first ensure that all the slaves of this master are using the same 5.5.x release. If this is not the case, you should first upgrade the slaves. To upgrade each slave, shut it down, upgrade it to the appropriate 5.5.x version, restart it, and restart replication. The 5.5 slave is able to read the old relay logs written prior to the upgrade and to execute the statements they contain. Relay logs created by the slave after the upgrade are in 5.5 format.

After the slaves have been upgraded, shut down the master, upgrade it to the same 5.5.x release as the slaves, and restart it. The 5.5 master is able to read the old binary logs written prior to the upgrade and to send them to the 5.5 slaves. The slaves recognize the old format and handle it properly. Binary logs created by the master subsequent to the upgrade are in 5.5 format. These too are recognized by the 5.5 slaves.

In other words, when upgrading to MySQL 5.5, the slaves must be MySQL 5.5 before you can upgrade the master to 5.5. Note that downgrading from 5.5 to older versions does not work so simply: You must ensure...
that any 5.5 binary log or relay log has been fully processed, so that you can remove it before proceeding with the downgrade.

Downgrading a replication setup to a previous version cannot be done once you have switched from statement-based to row-based replication, and after the first row-based statement has been written to the binlog. See Section 17.1.2, “Replication Formats”.

Some upgrades may require that you drop and re-create database objects when you move from one MySQL series to the next. For example, collation changes might require that table indexes be rebuilt. Such operations, if necessary, will be detailed at Section 2.11.1.1, “Upgrading from MySQL 5.1 to 5.5”. It is safest to perform these operations separately on the slaves and the master, and to disable replication of these operations from the master to the slave. To achieve this, use the following procedure:

1. Stop all the slaves and upgrade them. Restart them with the --skip-slave-start option so that they do not connect to the master. Perform any table repair or rebuilding operations needed to re-create database objects, such as use of REPAIR TABLE or ALTER TABLE, or dumping and reloading tables or triggers.

2. Disable the binary log on the master. To do this without restarting the master, execute a SET sql_log_bin = 0 statement. Alternatively, stop the master and restart it without the --log-bin option. If you restart the master, you might also want to disallow client connections. For example, if all clients connect using TCP/IP, use the --skip-networking option when you restart the master.

3. With the binary log disabled, perform any table repair or rebuilding operations needed to re-create database objects. The binary log must be disabled during this step to prevent these operations from being logged and sent to the slaves later.

4. Re-enable the binary log on the master. If you set sql_log_bin to 0 earlier, execute a SET sql_log_bin = 1 statement. If you restarted the master to disable the binary log, restart it with --log-bin, and without --skip-networking so that clients and slaves can connect.

5. Restart the slaves, this time without the --skip-slave-start option.

17.4.4 Troubleshooting Replication

If you have followed the instructions but your replication setup is not working, the first thing to do is check the error log for messages. Many users have lost time by not doing this soon enough after encountering problems.

If you cannot tell from the error log what the problem was, try the following techniques:

• Verify that the master has binary logging enabled by issuing a SHOW MASTER STATUS statement. If logging is enabled, Position is nonzero. If binary logging is not enabled, verify that you are running the master with the --log-bin option.

• Verify that the master and slave both were started with the --server-id [1974] option and that the ID value is unique on each server.

• Verify that the slave is running. Use SHOW SLAVE STATUS to check whether the Slave_IO_Running and Slave_SQL_Running values are both Yes. If not, verify the options that were used when starting the slave server. For example, --skip-slave-start prevents the slave threads from starting until you issue a START SLAVE statement.

• If the slave is running, check whether it established a connection to the master. Use SHOW PROCESSLIST, find the I/O and SQL threads and check their State column to see what they display. See Section 17.2.1, “Replication Implementation Details”. If the I/O thread state says Connecting to master, check the following:
• Verify the privileges for the user being used for replication on the master.

• Check that the host name of the master is correct and that you are using the correct port to connect to the master. The port used for replication is the same as used for client network communication (the default is 3306). For the host name, ensure that the name resolves to the correct IP address.

• Check that networking has not been disabled on the master or slave. Look for the `skip-networking` option in the configuration file. If present, comment it out or remove it.

• If the master has a firewall or IP filtering configuration, ensure that the network port being used for MySQL is not being filtered.

• Check that you can reach the master by using `ping` or `traceroute/tracert` to reach the host.

• If the slave was running previously but has stopped, the reason usually is that some statement that succeeded on the master failed on the slave. This should never happen if you have taken a proper snapshot of the master, and never modified the data on the slave outside of the slave thread. If the slave stops unexpectedly, it is a bug or you have encountered one of the known replication limitations described in Section 17.4.1, “Replication Features and Issues”. If it is a bug, see Section 17.4.5, “How to Report Replication Bugs or Problems”, for instructions on how to report it.

• If a statement that succeeded on the master refuses to run on the slave, try the following procedure if it is not feasible to do a full database resynchronization by deleting the slave’s databases and copying a new snapshot from the master:

  1. Determine whether the affected table on the slave is different from the master table. Try to understand how this happened. Then make the slave’s table identical to the master’s and run `START SLAVE`.

  2. If the preceding step does not work or does not apply, try to understand whether it would be safe to make the update manually (if needed) and then ignore the next statement from the master.

  3. If you decide that the slave can skip the next statement from the master, issue the following statements:

     ```
     mysql> SET GLOBAL sql_slave_skip_counter = N;
     mysql> START SLAVE;
     ```

     The value of `N` should be 1 if the next statement from the master does not use `AUTO_INCREMENT` or `LAST_INSERT_ID()`. Otherwise, the value should be 2. The reason for using a value of 2 for statements that use `AUTO_INCREMENT` or `LAST_INSERT_ID()` is that they take two events in the binary log of the master.

     See also Section 13.4.2.4, “SET GLOBAL sql_slave_skip_counter Syntax”.

  4. If you are sure that the slave started out perfectly synchronized with the master, and that no one has updated the tables involved outside of the slave thread, then presumably the discrepancy is the result of a bug. If you are running the most recent version of MySQL, please report the problem. If you are running an older version, try upgrading to the latest production release to determine whether the problem persists.

### 17.4.5 How to Report Replication Bugs or Problems

When you have determined that there is no user error involved, and replication still either does not work at all or is unstable, it is time to send us a bug report. We need to obtain as much information as possible
from you to be able to track down the bug. Please spend some time and effort in preparing a good bug report.

If you have a repeatable test case that demonstrates the bug, please enter it into our bugs database using the instructions given in Section 1.7, “How to Report Bugs or Problems”. If you have a “phantom” problem (one that you cannot duplicate at will), use the following procedure:

1. Verify that no user error is involved. For example, if you update the slave outside of the slave thread, the data goes out of synchrony, and you can have unique key violations on updates. In this case, the slave thread stops and waits for you to clean up the tables manually to bring them into synchrony. This is not a replication problem. It is a problem of outside interference causing replication to fail.

2. Run the slave with the \texttt{--log-slave-updates} and \texttt{--log-bin} options. These options cause the slave to log the updates that it receives from the master into its own binary logs.

3. Save all evidence before resetting the replication state. If we have no information or only sketchy information, it becomes difficult or impossible for us to track down the problem. The evidence you should collect is:
   - All binary log files from the master
   - All binary log files from the slave
   - The output of \texttt{SHOW MASTER STATUS} from the master at the time you discovered the problem
   - The output of \texttt{SHOW SLAVE STATUS} from the slave at the time you discovered the problem
   - Error logs from the master and the slave

4. Use \texttt{mysqlbinlog} to examine the binary logs. The following should be helpful to find the problem statement. \texttt{log_file} and \texttt{log_pos} are the \texttt{Master_Log_File} and \texttt{Read_Master_Log_Pos} values from \texttt{SHOW SLAVE STATUS}.

   \begin{verbatim}
   shell> mysqlbinlog --start-position=log_pos log_file | head
   \end{verbatim}

   After you have collected the evidence for the problem, try to isolate it as a separate test case first. Then enter the problem with as much information as possible into our bugs database using the instructions at Section 1.7, “How to Report Bugs or Problems”.

This chapter contains information about MySQL Cluster, which is a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. Recent releases of MySQL Cluster use version 7 of the NDBCLUSTER storage engine (also known as NDB) to enable running several computers with MySQL servers and other software in a cluster; the latest releases available for production use incorporate NDB version 7.2.

Support for the NDBCLUSTER storage engine is not included in the standard MySQL Server 5.5 binaries built by Oracle. Instead, users of MySQL Cluster binaries from Oracle should upgrade to the most recent binary release of MySQL Cluster for supported platforms—these include RPMs that should work with most Linux distributions. MySQL Cluster users who build from source should use the sources provided for MySQL Cluster. (Locations where the sources can be obtained are listed later in this section.)

This chapter contains information about MySQL Cluster NDB 7.2 releases through 5.5.38-ndb-7.2.18. Currently, the MySQL Cluster NDB 7.2 release series is Generally Available (GA), as is MySQL Cluster NDB 7.1. MySQL Cluster NDB 7.0 and MySQL Cluster NDB 6.3 are previous GA release series; although they are still supported, we recommend that new deployments use MySQL Cluster NDB 7.2. For information about MySQL Cluster NDB 7.1, MySQL Cluster NDB 7.0, and previous versions of MySQL Cluster, see MySQL Cluster NDB 6.1 - 7.1, in the MySQL 5.1 Manual.

Release notes for the changes in each release of MySQL Cluster are located at MySQL Cluster 7.2 Release Notes.
Supported Platforms. MySQL Cluster is currently available and supported on a number of platforms. For exact levels of support available for on specific combinations of operating system versions, operating system distributions, and hardware platforms, please refer to http://www.mysql.com/support/supportedplatforms/cluster.html.

Availability. MySQL Cluster binary and source packages are available for supported platforms from http://dev.mysql.com/downloads/cluster/.

MySQL Cluster release numbers. MySQL Cluster follows a somewhat different release pattern from the mainline MySQL Server 5.5 series of releases. In this Manual and other MySQL documentation, we identify these and later MySQL Cluster releases employing a version number that begins with “NDB”. This version number is that of the NDBCLUSTER storage engine used in the release, and not of the MySQL server version on which the MySQL Cluster release is based.

Version strings used in MySQL Cluster software. The version string displayed by MySQL Cluster programs uses this format:

```
mysql-mysql_server_version-ndb-ndb_engine_version
```

`mysql_server_version` represents the version of the MySQL Server on which the MySQL Cluster release is based. For all MySQL Cluster NDB 6.x and 7.x releases, this is “5.1”. `ndb_engine_version` is the version of the NDB storage engine used by this release of the MySQL Cluster software. You can see this format used in the mysql client, as shown here:

```
shell> mysql
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 2
Server version: 5.5.38-ndb-7.2.18 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql> SELECT VERSION()\G
*************************** 1. row ***************************
VERSION(): 5.5.38-ndb-7.2.18
1 row in set (0.00 sec)
```

This version string is also displayed in the output of the SHOW command in the ndb_mgm client:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)] 2 node(s)
id=1  @10.0.10.6 (5.5.38-ndb-7.2.18, Nodegroup: 0, *)
id=2  @10.0.10.8 (5.5.38-ndb-7.2.18, Nodegroup: 0)

[ndb_mgmd(MGM)] 1 node(s)
id=3  @10.0.10.2 (5.5.38-ndb-7.2.18)

[mysqld(API)] 2 node(s)
id=4  @10.0.10.10 (5.5.38-ndb-7.2.18)
id=5 (not connected, accepting connect from any host)
```

The version string identifies the mainline MySQL version from which the MySQL Cluster release was branched and the version of the NDBCLUSTER storage engine used. For example, the full version string for MySQL Cluster NDB 7.2.4 (the first MySQL Cluster production release based on MySQL Server 5.5) is mysql-5.5.19-ndb-7.2.4. From this we can determine the following:
Since the portion of the version string preceding “-ndb-” is the base MySQL Server version, this means that MySQL Cluster NDB 7.2.4 derives from the MySQL 5.5.19, and contains all feature enhancements and bugfixes from MySQL 5.5 up to and including MySQL 5.5.19.

Since the portion of the version string following “-ndb-” represents the version number of the NDB (or NDBCLUSTER) storage engine, MySQL Cluster NDB 7.2.4 uses version 7.2.4 of the NDBCLUSTER storage engine.

New MySQL Cluster releases are numbered according to updates in the NDB storage engine, and do not necessarily correspond in a one-to-one fashion with mainline MySQL Server releases. For example, MySQL Cluster NDB 7.2.4 (as previously noted) is based on MySQL 5.5.19, while MySQL Cluster NDB 7.2.0 was based on MySQL 5.1.51 (version string: mysql-5.1.51-ndb-7.2.0).

Compatibility with standard MySQL 5.5 releases. While many standard MySQL schemas and applications can work using MySQL Cluster, it is also true that unmodified applications and database schemas may be slightly incompatible or have suboptimal performance when run using MySQL Cluster (see Section 18.1.6, “Known Limitations of MySQL Cluster”). Most of these issues can be overcome, but this also means that you are very unlikely to be able to switch an existing application datastore—that currently uses, for example, MyISAM or InnoDB—to use the NDB storage engine without allowing for the possibility of changes in schemas, queries, and applications. In addition, the MySQL Server and MySQL Cluster codebases diverge considerably, so that the standard mysqld cannot function as a drop-in replacement for the version of mysqld supplied with MySQL Cluster.

MySQL Cluster development source trees. MySQL Cluster development trees can also be accessed from https://code.launchpad.net/~mysql/:

The MySQL Cluster development sources maintained at https://code.launchpad.net/~mysql/ are licensed under the GPL. For information about obtaining MySQL sources using Bazaar and building them yourself, see Section 2.9.3, “Installing MySQL Using a Development Source Tree”.

Note

As with MySQL Server 5.5, MySQL Cluster NDB 7.2 is built using CMake.

Currently, MySQL Cluster NDB 7.0, MySQL Cluster NDB 7.1, and MySQL Cluster NDB 7.2 releases are all Generally Available (GA), although we recommend that new deployments use MySQL Cluster NDB 7.2. MySQL Cluster NDB 6.1, MySQL Cluster NDB 6.2, and MySQL Cluster NDB 6.3, are no longer in active development. For an overview of major features added in MySQL Cluster NDB 7.2, see Section 18.1.4, “MySQL Cluster Development History”. For an overview of major features added in past MySQL Cluster releases through MySQL Cluster NDB 7.1, see MySQL Cluster Development History.

This chapter represents a work in progress, and its contents are subject to revision as MySQL Cluster continues to evolve. Additional information regarding MySQL Cluster can be found on the MySQL Web site at http://www.mysql.com/products/cluster/.

Additional Resources. More information about MySQL Cluster can be found in the following places:

- For answers to some commonly asked questions about MySQL Cluster, see Section A.10, “MySQL FAQ: MySQL 5.5 and MySQL Cluster”.
- Many MySQL Cluster users and developers blog about their experiences with MySQL Cluster, and make feeds of these available through PlanetMySQL.
MySQL Cluster Overview

18.1 MySQL Cluster Overview

MySQL Cluster is a technology that enables clustering of in-memory databases in a shared-nothing system. The shared-nothing architecture enables the system to work with very inexpensive hardware, and with a minimum of specific requirements for hardware or software.

MySQL Cluster is designed not to have any single point of failure. In a shared-nothing system, each component is expected to have its own memory and disk, and the use of shared storage mechanisms such as network shares, network file systems, and SANs is not recommended or supported.

MySQL Cluster integrates the standard MySQL server with an in-memory clustered storage engine called NDB (which stands for “Network DataBase”). In our documentation, the term NDB refers to the part of the setup that is specific to the storage engine, whereas “MySQL Cluster” refers to the combination of one or more MySQL servers with the NDB storage engine.

A MySQL Cluster consists of a set of computers, known as hosts, each running one or more processes. These processes, known as nodes, may include MySQL servers (for access to NDB data), data nodes (for storage of the data), one or more management servers, and possibly other specialized data access programs. The relationship of these components in a MySQL Cluster is shown here:

All these programs work together to form a MySQL Cluster (see Section 18.4, “MySQL Cluster Programs”. When data is stored by the NDB storage engine, the tables (and table data) are stored in the data nodes. Such tables are directly accessible from all other MySQL servers (SQL nodes) in the cluster. Thus, in a payroll application storing data in a cluster, if one application updates the salary of an employee, all other MySQL servers that query this data can see this change immediately.

Although a MySQL Cluster SQL node uses the mysql server daemon, it differs in a number of critical respects from the mysql binary supplied with the MySQL 5.5 distributions, and the two versions of mysql are not interchangeable.

In addition, a MySQL server that is not connected to a MySQL Cluster cannot use the NDB storage engine and cannot access any MySQL Cluster data.

The data stored in the data nodes for MySQL Cluster can be mirrored; the cluster can handle failures of individual data nodes with no other impact than that a small number of transactions are aborted due to
losing the transaction state. Because transactional applications are expected to handle transaction failure, this should not be a source of problems.

Individual nodes can be stopped and restarted, and can then rejoin the system (cluster). Rolling restarts (in which all nodes are restarted in turn) are used in making configuration changes and software upgrades (see Section 18.5.5, “Performing a Rolling Restart of a MySQL Cluster”). Rolling restarts are also used as part of the process of adding new data nodes online (see Section 18.5.13, “Adding MySQL Cluster Data Nodes Online”). For more information about data nodes, how they are organized in a MySQL Cluster, and how they handle and store MySQL Cluster data, see Section 18.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”.

Backing up and restoring MySQL Cluster databases can be done using the NDB-native functionality found in the MySQL Cluster management client and the ndb_restore program included in the MySQL Cluster distribution. For more information, see Section 18.5.3, “Online Backup of MySQL Cluster”, and Section 18.4.19, “ndb_restore — Restore a MySQL Cluster Backup”. You can also use the standard MySQL functionality provided for this purpose in mysqldump and the MySQL server. See Section 4.5.4, “mysqldump — A Database Backup Program”, for more information.

MySQL Cluster nodes can use a number of different transport mechanisms for inter-node communications, including TCP/IP using standard 100 Mbps or faster Ethernet hardware. It is also possible to use the high-speed Scalable Coherent Interface (SCI) protocol with MySQL Cluster, although this is not required to use MySQL Cluster. SCI requires special hardware and software; see Section 18.3.5, “Using High-Speed Interconnects with MySQL Cluster”, for more about SCI and using it with MySQL Cluster.

**18.1.1 MySQL Cluster Core Concepts**

NDBCLUSTER (also known as NDB) is an in-memory storage engine offering high-availability and data-persistence features.

The NDBCLUSTER storage engine can be configured with a range of failover and load-balancing options, but it is easiest to start with the storage engine at the cluster level. MySQL Cluster's NDB storage engine contains a complete set of data, dependent only on other data within the cluster itself.

The “Cluster” portion of MySQL Cluster is configured independently of the MySQL servers. In a MySQL Cluster, each part of the cluster is considered to be a node.

---

Note

In many contexts, the term “node” is used to indicate a computer, but when discussing MySQL Cluster it means a process. It is possible to run multiple nodes on a single computer; for a computer on which one or more cluster nodes are being run we use the term cluster host.

There are three types of cluster nodes, and in a minimal MySQL Cluster configuration, there will be at least three nodes, one of each of these types:

- **Management node**: The role of this type of node is to manage the other nodes within the MySQL Cluster, performing such functions as providing configuration data, starting and stopping nodes, running backup, and so forth. Because this node type manages the configuration of the other nodes, a node of this type should be started first, before any other node. An MGM node is started with the command ndb_mgmd.

- **Data node**: This type of node stores cluster data. There are as many data nodes as there are replicas, times the number of fragments (see Section 18.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”). For example, with two replicas, each having two fragments, you need four data nodes. One replica is sufficient for data storage, but provides no redundancy; therefore, it is recommended to have 2 (or more) replicas to provide redundancy, and thus high availability. A data node is started with
MySQL Cluster tables are normally stored completely in memory rather than on disk (this is why we refer to MySQL Cluster as an *in-memory* database). However, some MySQL Cluster data can be stored on disk; see Section 18.5.12, "MySQL Cluster Disk Data Tables", for more information.

- **SQL node**: This is a node that accesses the cluster data. In the case of MySQL Cluster, an SQL node is a traditional MySQL server that uses the NDBCLUSTER storage engine. An SQL node is a mysqld process started with the --ndbcluster and --ndb-connectstring options, which are explained elsewhere in this chapter, possibly with additional MySQL server options as well.

An SQL node is actually just a specialized type of *API node*, which designates any application which accesses MySQL Cluster data. Another example of an API node is the ndb_restore utility that is used to restore a cluster backup. It is possible to write such applications using the NDB API. For basic information about the NDB API, see Getting Started with the NDB API.

---

It is not realistic to expect to employ a three-node setup in a production environment. Such a configuration provides no redundancy; to benefit from MySQL Cluster’s high-availability features, you must use multiple data and SQL nodes. The use of multiple management nodes is also highly recommended.

For a brief introduction to the relationships between nodes, node groups, replicas, and partitions in MySQL Cluster, see Section 18.1.2, "MySQL Cluster Nodes, Node Groups, Replicas, and Partitions".

Configuration of a cluster involves configuring each individual node in the cluster and setting up individual communication links between nodes. MySQL Cluster is currently designed with the intention that data nodes are homogeneous in terms of processor power, memory space, and bandwidth. In addition, to provide a single point of configuration, all configuration data for the cluster as a whole is located in one configuration file.

The management server manages the cluster configuration file and the cluster log. Each node in the cluster retrieves the configuration data from the management server, and so requires a way to determine where the management server resides. When interesting events occur in the data nodes, the nodes transfer information about these events to the management server, which then writes the information to the cluster log.

In addition, there can be any number of cluster client processes or applications. These include standard MySQL clients, NDB-specific API programs, and management clients. These are described in the next few paragraphs.

**Standard MySQL clients.** MySQL Cluster can be used with existing MySQL applications written in PHP, Perl, C, C++, Java, Python, Ruby, and so on. Such client applications send SQL statements to and receive responses from MySQL servers acting as MySQL Cluster SQL nodes in much the same way that they interact with standalone MySQL servers.

MySQL clients using a MySQL Cluster as a data source can be modified to take advantage of the ability to connect with multiple MySQL servers to achieve load balancing and failover. For example, Java clients using Connector/J 5.0.6 and later can use `jdbc:mysql:loadbalance://` URLs (improved in Connector/J 5.1.7) to achieve load balancing transparently; for more information about using Connector/J with MySQL Cluster, see Using Connector/J with MySQL Cluster.

**NDB client programs.** Client programs can be written that access MySQL Cluster data directly from the NDBCLUSTER storage engine, bypassing any MySQL Servers that may connected to the cluster, using the
**NDB API**, a high-level C++ API. Such applications may be useful for specialized purposes where an SQL interface to the data is not needed. For more information, see The NDB API.

NDB-specific Java applications can also be written for MySQL Cluster using the MySQL Cluster Connector for Java. This MySQL Cluster Connector includes ClusterJ, a high-level database API similar to object-relational mapping persistence frameworks such as Hibernate and JPA that connect directly to NDBCLUSTER, and so does not require access to a MySQL Server. Support is also provided in MySQL Cluster NDB 7.1 and later for ClusterJPA, an OpenJPA implementation for MySQL Cluster that leverages the strengths of ClusterJ and JDBC; ID lookups and other fast operations are performed using ClusterJ (bypassing the MySQL Server), while more complex queries that can benefit from MySQL's query optimizer are sent through the MySQL Server, using JDBC. See Java and MySQL Cluster, and The ClusterJ API and Data Object Model, for more information.

The Memcache API for MySQL Cluster, implemented as the loadable ndbmemcache storage engine for memcached version 1.6 and later, is available beginning with MySQL Cluster NDB 7.2.2. This API can be used to provide a persistent MySQL Cluster data store, accessed using the memcache protocol.

The standard memcached caching engine is included in the MySQL Cluster NDB 7.2 distribution (7.2.2 and later). Each memcached server has direct access to data stored in MySQL Cluster, but is also able to cache data locally and to serve (some) requests from this local cache.

For more information, see ndbmemcache—Memcache API for MySQL Cluster.

**Management clients.** These clients connect to the management server and provide commands for starting and stopping nodes gracefully, starting and stopping message tracing (debug versions only), showing node versions and status, starting and stopping backups, and so on. An example of this type of program is the ndb_mgm management client supplied with MySQL Cluster (see Section 18.4.5, “ndb_mgm — The MySQL Cluster Management Client”). Such applications can be written using the MGM API, a C-language API that communicates directly with one or more MySQL Cluster management servers. For more information, see The MGM API.

Oracle also makes available MySQL Cluster Manager, which provides an advanced command-line interface simplifying many complex MySQL Cluster management tasks, such as restarting a MySQL Cluster with a large number of nodes. The MySQL Cluster Manager client also supports commands for getting and setting the values of most node configuration parameters as well as mysqld server options and variables relating to MySQL Cluster. See MySQL™ Cluster Manager 1.3.0 User Manual, for more information.

**Event logs.** MySQL Cluster logs events by category (startup, shutdown, errors, checkpoints, and so on), priority, and severity. A complete listing of all reportable events may be found in Section 18.5.6, “Event Reports Generated in MySQL Cluster”. Event logs are of the two types listed here:

- **Cluster log**: Keeps a record of all desired reportable events for the cluster as a whole.
- **Node log**: A separate log which is also kept for each individual node.

**Note**

Under normal circumstances, it is necessary and sufficient to keep and examine only the cluster log. The node logs need be consulted only for application development and debugging purposes.

**Checkpoint.** Generally speaking, when data is saved to disk, it is said that a checkpoint has been reached. More specific to MySQL Cluster, a checkpoint is a point in time where all committed transactions are stored on disk. With regard to the NDB storage engine, there are two types of checkpoints which work together to ensure that a consistent view of the cluster's data is maintained. These are shown in the following list:
Local Checkpoint (LCP): This is a checkpoint that is specific to a single node; however, LCPs take place for all nodes in the cluster more or less concurrently. An LCP involves saving all of a node's data to disk, and so usually occurs every few minutes. The precise interval varies, and depends upon the amount of data stored by the node, the level of cluster activity, and other factors.

Global Checkpoint (GCP): A GCP occurs every few seconds, when transactions for all nodes are synchronized and the redo-log is flushed to disk.

For more information about the files and directories created by local checkpoints and global checkpoints, see MySQL Cluster Data Node FileSystemDir Files.

### 18.1.2 MySQL Cluster Nodes, Node Groups, Replicas, and Partitions

This section discusses the manner in which MySQL Cluster divides and duplicates data for storage.

A number of concepts central to an understanding of this topic are discussed in the next few paragraphs.

(Data) Node. An ndbd process, which stores a replica—that is, a copy of the partition (see below) assigned to the node group of which the node is a member.

Each data node should be located on a separate computer. While it is also possible to host multiple ndbd processes on a single computer, such a configuration is not supported.

It is common for the terms "node" and "data node" to be used interchangeably when referring to an ndbd process; where mentioned, management nodes (ndb_mgmd processes) and SQL nodes (mysqld processes) are specified as such in this discussion.

Node Group. A node group consists of one or more nodes, and stores partitions, or sets of replicas (see next item).

The number of node groups in a MySQL Cluster is not directly configurable; it is a function of the number of data nodes and of the number of replicas (NoOfReplicas configuration parameter), as shown here:

\[
\text{number of node groups} = \frac{\text{number of data nodes}}{\text{NoOfReplicas}}
\]

Thus, a MySQL Cluster with 4 data nodes has 4 node groups if NoOfReplicas is set to 1 in the config.ini file, 2 node groups if NoOfReplicas is set to 2, and 1 node group if NoOfReplicas is set to 4. Replicas are discussed later in this section; for more information about NoOfReplicas, see Section 18.3.2.6, “Defining MySQL Cluster Data Nodes”.

Note

All node groups in a MySQL Cluster must have the same number of data nodes.

You can add new node groups (and thus new data nodes) online, to a running MySQL Cluster; see Section 18.5.13, “Adding MySQL Cluster Data Nodes Online”, for more information.

Partition. This is a portion of the data stored by the cluster. There are as many cluster partitions as nodes participating in the cluster. Each node is responsible for keeping at least one copy of any partitions assigned to it (that is, at least one replica) available to the cluster.

A replica belongs entirely to a single node; a node can (and usually does) store several replicas.

**NDB and user-defined partitioning.** MySQL Cluster normally partitions NDBCLUSTER tables automatically. However, it is also possible to employ user-defined partitioning with NDBCLUSTER tables. This is subject to the following limitations:
1. Only **KEY** and **LINEAR KEY** partitioning schemes can be used with **NDB** tables.

2. When using **ndbd**, the maximum number of partitions that may be defined explicitly for any **NDB** table is $8 \times [\text{number of node groups}]$. (The number of node groups in a MySQL Cluster is determined as discussed previously in this section.)

   When using **ndbmtd**, this maximum is also affected by the number of local query handler threads, which is determined by the value of the **MaxNoOfExecutionThreads** configuration parameter. In such cases, the maximum number of partitions that may be defined explicitly for an **NDB** table is equal to $4 \times \text{MaxNoOfExecutionThreads} \times [\text{number of node groups}]$.

   See Section 18.4.3, "**ndbmtd** — The MySQL Cluster Data Node Daemon (Multi-Threaded)", for more information.

For more information relating to MySQL Cluster and user-defined partitioning, see Section 18.1.6, "Known Limitations of MySQL Cluster", and Section 19.5.2, "Partitioning Limitations Relating to Storage Engines".

**Replica.** This is a copy of a cluster partition. Each node in a node group stores a replica. Also sometimes known as a **partition replica**. The number of replicas is equal to the number of nodes per node group.

The following diagram illustrates a MySQL Cluster with four data nodes, arranged in two node groups of two nodes each; nodes 1 and 2 belong to node group 0, and nodes 3 and 4 belong to node group 1. Note that only data (**ndbd**) nodes are shown here; although a working cluster requires an **ndb_mgm** process for cluster management and at least one SQL node to access the data stored by the cluster, these have been omitted in the figure for clarity.
The data stored by the cluster is divided into four partitions, numbered 0, 1, 2, and 3. Each partition is stored—in multiple copies—on the same node group. Partitions are stored on alternate node groups as follows:

- Partition 0 is stored on node group 0; a primary replica (primary copy) is stored on node 1, and a backup replica (backup copy of the partition) is stored on node 2.

- Partition 1 is stored on the other node group (node group 1); this partition's primary replica is on node 3, and its backup replica is on node 4.

- Partition 2 is stored on node group 0. However, the placing of its two replicas is reversed from that of Partition 0; for Partition 2, the primary replica is stored on node 2, and the backup on node 1.

- Partition 3 is stored on node group 1, and the placement of its two replicas are reversed from those of partition 1. That is, its primary replica is located on node 4, with the backup on node 3.

What this means regarding the continued operation of a MySQL Cluster is this: so long as each node group participating in the cluster has at least one node operating, the cluster has a complete copy of all data and remains viable. This is illustrated in the next diagram.
In this example, where the cluster consists of two node groups of two nodes each, any combination of at least one node in node group 0 and at least one node in node group 1 is sufficient to keep the cluster “alive” (indicated by arrows in the diagram). However, if both nodes from either node group fail, the remaining two nodes are not sufficient (shown by the arrows marked out with an X); in either case, the cluster has lost an entire partition and so can no longer provide access to a complete set of all cluster data.

### 18.1.3 MySQL Cluster Hardware, Software, and Networking Requirements

One of the strengths of MySQL Cluster is that it can be run on commodity hardware and has no unusual requirements in this regard, other than for large amounts of RAM, due to the fact that all live data storage is done in memory. (It is possible to reduce this requirement using Disk Data tables—see Section 18.5.12, “MySQL Cluster Disk Data Tables”, for more information about these.) Naturally, multiple and faster CPUs can enhance performance. Memory requirements for other MySQL Cluster processes are relatively small.

The software requirements for MySQL Cluster are also modest. Host operating systems do not require any unusual modules, services, applications, or configuration to support MySQL Cluster. For supported operating systems, a standard installation should be sufficient. The MySQL software requirements are simple: all that is needed is a production release of MySQL Cluster. It is not strictly necessary to compile MySQL yourself merely to be able to use MySQL Cluster. We assume that you are using the binaries appropriate to your platform, available from the MySQL Cluster software downloads page at http://dev.mysql.com/downloads/cluster/.

For communication between nodes, MySQL Cluster supports TCP/IP networking in any standard topology, and the minimum expected for each host is a standard 100 Mbps Ethernet card, plus a switch, hub, or router to provide network connectivity for the cluster as a whole. We strongly recommend that a MySQL Cluster be run on its own subnet which is not shared with machines not forming part of the cluster for the following reasons:
• **Security.** Communications between MySQL Cluster nodes are not encrypted or shielded in any way. The only means of protecting transmissions within a MySQL Cluster is to run your MySQL Cluster on a protected network. If you intend to use MySQL Cluster for Web applications, the cluster should definitely reside behind your firewall and not in your network's De-Militarized Zone (DMZ) or elsewhere.

See Section 18.5.11.1, “MySQL Cluster Security and Networking Issues”, for more information.

• **Efficiency.** Setting up a MySQL Cluster on a private or protected network enables the cluster to make exclusive use of bandwidth between cluster hosts. Using a separate switch for your MySQL Cluster not only helps protect against unauthorized access to MySQL Cluster data, it also ensures that MySQL Cluster nodes are shielded from interference caused by transmissions between other computers on the network. For enhanced reliability, you can use dual switches and dual cards to remove the network as a single point of failure; many device drivers support failover for such communication links.

**Network communication and latency.** MySQL Cluster requires communication between data nodes and API nodes (including SQL nodes), as well as between data nodes and other data nodes, to execute queries and updates. Communication latency between these processes can directly affect the observed performance and latency of user queries. In addition, to maintain consistency and service despite the silent failure of nodes, MySQL Cluster uses heartbeating and timeout mechanisms which treat an extended loss of communication from a node as node failure. This can lead to reduced redundancy. Recall that, to maintain data consistency, a MySQL Cluster shuts down when the last node in a node group fails. Thus, to avoid increasing the risk of a forced shutdown, breaks in communication between nodes should be avoided wherever possible.

The failure of a data or API node results in the abort of all uncommitted transactions involving the failed node. Data node recovery requires synchronization of the failed node's data from a surviving data node, and re-establishment of disk-based redo and checkpoint logs, before the data node returns to service. This recovery can take some time, during which the Cluster operates with reduced redundancy.

Heartbeating relies on timely generation of heartbeat signals by all nodes. This may not be possible if the node is overloaded, has insufficient machine CPU due to sharing with other programs, or is experiencing delays due to swapping. If heartbeat generation is sufficiently delayed, other nodes treat the node that is slow to respond as failed.

This treatment of a slow node as a failed one may or may not be desirable in some circumstances, depending on the impact of the node's slowed operation on the rest of the cluster. When setting timeout values such as `HeartbeatIntervalDbDb` and `HeartbeatIntervalDbApi` for MySQL Cluster, care must be taken care to achieve quick detection, failover, and return to service, while avoiding potentially expensive false positives.

Where communication latencies between data nodes are expected to be higher than would be expected in a LAN environment (on the order of 100 µs), timeout parameters must be increased to ensure that any allowed periods of latency periods are well within configured timeouts. Increasing timeouts in this way has a corresponding effect on the worst-case time to detect failure and therefore time to service recovery.

LAN environments can typically be configured with stable low latency, and such that they can provide redundancy with fast failover. Individual link failures can be recovered from with minimal and controlled latency visible at the TCP level (where MySQL Cluster normally operates). WAN environments may offer a range of latencies, as well as redundancy with slower failover times. Individual link failures may require route changes to propagate before end-to-end connectivity is restored. At the TCP level this can appear as large latencies on individual channels. The worst-case observed TCP latency in these scenarios is related to the worst-case time for the IP layer to reroute around the failures.

**SCI support.** It is also possible to use the high-speed Scalable Coherent Interface (SCI) with MySQL Cluster, but this is not a requirement. See Section 18.3.5, “Using High-Speed Interconnects with MySQL Cluster”, for more about this protocol and its use with MySQL Cluster.
18.1.4 MySQL Cluster Development History

In this section, we discuss changes in the implementation of MySQL Cluster in MySQL MySQL Cluster NDB 7.2, as compared to MySQL Cluster NDB 7.1 and earlier releases. Changes and features most likely to be of interest are shown in the following table:

<table>
<thead>
<tr>
<th>MySQL Cluster NDB 7.2</th>
<th>MySQL Cluster NDB 7.2.1 and later MySQL Cluster NDB 7.2 releases are based on MySQL 5.5. For more information about new features in MySQL Server 5.5, see Section 1.4, “What Is New in MySQL 5.5”.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version 2 binary log row events, to provide support for improvements in MySQL Cluster Replication conflict detection (see next item). A given mysqld can be made to use Version 1 or Version 2 binary logging row events with the --log-bin-use-v1-row-events option.</td>
<td></td>
</tr>
<tr>
<td>Two new “primary wins” conflict detection and resolution functions NDB$EPOCH() and NDB$EPOCH_TRANS() for use in replication setups with 2 MySQL Clusters. For more information, see Section 18.6, “MySQL Cluster Replication”.</td>
<td></td>
</tr>
<tr>
<td>Distribution of MySQL users and privileges across MySQL Cluster SQL nodes is now supported—see Section 18.5.14, “Distributed MySQL Privileges for MySQL Cluster”.</td>
<td></td>
</tr>
<tr>
<td>Improved support for distributed pushed-down joins, which greatly improve performance for many joins that can be executed in parallel on the data nodes.</td>
<td></td>
</tr>
<tr>
<td>Default values for a number of data node configuration parameters such as HeartbeatIntervalDbDb and ArbitrationTimeout have been improved.</td>
<td></td>
</tr>
<tr>
<td>Support for the Memcache API using the loadable ndbmemcache storage engine. See ndbmemcache—Memcache API for MySQL Cluster</td>
<td></td>
</tr>
</tbody>
</table>

This section contains information about MySQL Cluster NDB 7.2 releases through 5.5.38-ndb-7.2.18, which is currently available for use in production beginning with MySQL Cluster NDB 7.2.4. MySQL Cluster NDB 7.1, MySQL Cluster NDB 7.0, and MySQL Cluster NDB 6.3 are previous GA release series; although these are still supported, we recommend that new deployments use MySQL Cluster NDB 7.2. For information about MySQL Cluster NDB 7.1 and previous releases, see MySQL Cluster NDB 6.1 - 7.1, in the MySQL 5.1 Manual.

18.1.4.1 MySQL Cluster Development in MySQL Cluster NDB 7.2

The following improvements to MySQL Cluster have been made in MySQL Cluster NDB 7.2:

- **Based on MySQL Server 5.5.** Previous MySQL Cluster release series, including MySQL Cluster NDB 7.1, used MySQL 5.1 as a base. Beginning with MySQL Cluster NDB 7.2.1, MySQL Cluster NDB 7.2 is based on MySQL Server 5.5, so that MySQL Cluster users can benefit from MySQL 5.5's improvements in scalability and performance monitoring. As with MySQL 5.5, MySQL Cluster NDB 7.2.1 and later use CMake for configuring and building from source in place of GNU Autotools (used in MySQL 5.1 and MySQL Cluster releases based on MySQL 5.1). For more information about changes and improvements in MySQL 5.5, see Section 1.4, “What Is New in MySQL 5.5”.

- **Conflict detection using GCI Reflection.** MySQL Cluster Replication implements a new “primary wins” conflict detection and resolution mechanism. GCI Reflection applies in two-cluster circulation “active-active” replication setups, tracking the order in which changes are applied on the MySQL Cluster designated as primary relative to changes originating on the other MySQL Cluster (referred to as the secondary). This relative ordering is used to determine whether changes originating on the slave are concurrent with any changes that originate locally, and are therefore potentially in conflict. Two new conflict detection functions are added: When using NDB$EPOCH(), rows that are out of sync on the secondary are realigned with those on the primary; with NDB$EPOCH_TRANS(), this realignment is
applied to transactions. For more information, see Section 18.6.11, “MySQL Cluster Replication Conflict Resolution”.

- **Version 2 binary log row events.** A new format for binary log row events, known as Version 2 binary log row events, provides support for improvements in MySQL Cluster Replication conflict detection (see previous item) and is intended to facilitate further improvements in MySQL Replication. You can cause a given mysqld use Version 1 or Version 2 binary logging row events with the `--log-bin-use-v1-row-events` option. For backwards compatibility, Version 2 binary log row events are also available in MySQL Cluster NDB 7.0 (7.0.27 and later) and MySQL Cluster NDB 7.1 (7.1.16 and later). However, MySQL Cluster NDB 7.0 and MySQL Cluster NDB 7.1 continue to use Version 1 binary log row events as the default, whereas the default in MySQL Cluster NDB 7.2.1 and later is use Version 2 row events for binary logging.

- **Distribution of MySQL users and privileges.** Automatic distribution of MySQL users and privileges across all SQL nodes in a given MySQL Cluster is now supported. To enable this support, you must first import an SQL script `share/mysql/ndb_dist_priv.sql` that is included with the MySQL Cluster NDB 7.2 distribution. This script creates several stored procedures which you can use to enable privilege distribution and perform related tasks.

  When a new MySQL Server joins a MySQL Cluster where privilege distribution is in effect, it also participates in the privilege distribution automatically.

  Once privilege distribution is enabled, all changes to the grant tables made on any mysqld attached to the cluster are immediately available on any other attached MySQL Servers. This is true whether the changes are made using `CREATE USER`, `GRANT`, or any of the other statements described elsewhere in this Manual (see Section 13.7.1, “Account Management Statements”). This includes privileges relating to stored routines and views; however, automatic distribution of the views or stored routines themselves is not currently supported.

  For more information, see Section 18.5.14, “Distributed MySQL Privileges for MySQL Cluster”.

- **Distributed pushed-down joins.** Many joins can now be pushed down to the NDB kernel for processing on MySQL Cluster data nodes. Previously, a join was handled in MySQL Cluster by means of repeated accesses of NDB by the SQL node; however, when pushed-down joins are enabled, a pushable join is sent in its entirety to the data nodes, where it can be distributed among the data nodes and executed in parallel on multiple copies of the data, with a single, merged result being returned to mysqld. This can reduce greatly the number of round trips between an SQL node and the data nodes required to handle such a join, leading to greatly improved performance of join processing.

  It is possible to determine when joins can be pushed down to the data nodes by examining the join with `EXPLAIN`. A number of new system status variables (`Ndb_pushed_queries_defined`, `Ndb_pushed_queries_dropped`, `Ndb_pushed_queries_executed`, and `Ndb_pushed_reads`) and additions to the `counters` table (in the `ndbinfo` information database) can also be helpful in determining when and how well joins are being pushed down.

  More information and examples are available in the description of the `ndb_join_pushdown` server system variable. See also the description of the status variables referenced in the previous paragraph, as well as Section 18.5.10.7, “The `ndbinfo` counters Table”.

- **Improved default values for data node configuration parameters.** In order to provide more resiliency to environmental issues and better handling of some potential failure scenarios, and to perform more reliably with increases in memory and other resource requirements brought about by recent improvements in join handling by NDB, the default values for a number of MySQL Cluster data node configuration parameters have been changed. The parameters and changes are described in the following list:
MySQL Server Using InnoDB Compared with MySQL Cluster

- **HeartbeatIntervalDbDb**: Default increased from 1500 ms to 5000 ms.
- **ArbitrationTimeout**: Default increased from 3000 ms to 7500 ms.
- **TimeBetweenEpochsTimeout**: Now effectively disabled by default (default changed from 4000 ms to 0).
- **SharedGlobalMemory**: Default increased from 20 MB to 128 MB.
- **MaxParallelScansPerFragment**: Default increased from 32 to 256.
- **CrashOnCorruptedTuple** changed from FALSE to TRUE.

Beginning with MySQL Cluster NDB 7.2.10, **DefaultOperationRedoProblemAction** changed from **ABORT** to **QUEUE**.

In addition, the value computed for **MaxNoOfLocalScans** when this parameter is not set in **config.ini** has been increased by a factor of 4.

- **Fail-fast data nodes.** Beginning with MySQL Cluster NDB 7.2.1, data nodes handle corrupted tuples in a fail-fast manner by default. This is a change from previous versions of MySQL Cluster where this behavior had to be enabled explicitly by enabling the **CrashOnCorruptedTuple** configuration parameter. In MySQL Cluster NDB 7.2.1 and later, this parameter is enabled by default and must be explicitly disabled, in which case data nodes merely log a warning whenever they detect a corrupted tuple.

- **Memcache API support (ndbmemcache).** The Memcached server is a distributed in-memory caching server that uses a simple text-based protocol. It is often employed with key-value stores. The Memcache API for MySQL Cluster, available beginning with MySQL Cluster NDB 7.2.2, is implemented as a loadable storage engine for memcached version 1.6 and later. This API can be used to access a persistent MySQL Cluster data store employing the memcache protocol. It is also possible for the **memcached** server to provide a strictly defined interface to existing MySQL Cluster tables.

  Each memcache server can both cache data locally and access data stored in MySQL Cluster directly. Caching policies are configurable. For more information, see **ndbmemcache—Memcache API for MySQL Cluster**, in the *MySQL Cluster API Developers Guide*.

- **Rows per partition limit removed.** Previously it was possible to store a maximum of 46137488 rows in a single MySQL Cluster partition—that is, per data node. Beginning with MySQL Cluster NDB 7.2.9, this limitation has been lifted, and there is no longer any practical upper limit to this number. (Bug #13844405, Bug #14000373)

MySQL Cluster NDB 7.2 is also supported by MySQL Cluster Manager, which provides an advanced command-line interface that can simplify many complex MySQL Cluster management tasks. See **MySQL™ Cluster Manager 1.3.0 User Manual**, for more information.

### 18.1.5 MySQL Server Using InnoDB Compared with MySQL Cluster

MySQL Server offers a number of choices in storage engines. Since both **NDBCLUSTER** and **InnoDB** can serve as transactional MySQL storage engines, users of MySQL Server sometimes become interested in MySQL Cluster. They see **NDB** as a possible alternative or upgrade to the default **InnoDB** storage engine in MySQL 5.5. While **NDB** and **InnoDB** share common characteristics, there are differences in architecture and implementation, so that some existing MySQL Server applications and usage scenarios can be a good fit for MySQL Cluster, but not all of them.
In this section, we discuss and compare some characteristics of the NDB storage engine used by MySQL Cluster NDB 7.2 with InnoDB used in MySQL 5.5. The next few sections provide a technical comparison. In many instances, decisions about when and where to use MySQL Cluster must be made on a case-by-case basis, taking all factors into consideration. While it is beyond the scope of this documentation to provide specifics for every conceivable usage scenario, we also attempt to offer some very general guidance on the relative suitability of some common types of applications for NDB as opposed to InnoDB backends.

Recent MySQL Cluster NDB 7.2 releases use a mysqld based on MySQL 5.5, including support for InnoDB 1.1. While it is possible to use InnoDB tables with MySQL Cluster, such tables are not clustered. It is also not possible to use programs or libraries from a MySQL Cluster NDB 7.2 distribution with MySQL Server 5.5, or the reverse.

While it is also true that some types of common business applications can be run either on MySQL Cluster or on MySQL Server (most likely using the InnoDB storage engine), there are some important architectural and implementation differences. Section 18.1.5.1, “Differences Between the NDB and InnoDB Storage Engines”, provides a summary of the these differences. Due to the differences, some usage scenarios are clearly more suitable for one engine or the other; see Section 18.1.5.2, “NDB and InnoDB Workloads”. This in turn has an impact on the types of applications that better suited for use with NDB or InnoDB. See Section 18.1.5.3, “NDB and InnoDB Feature Usage Summary”, for a comparison of the relative suitability of each for use in common types of database applications.

For information about the relative characteristics of the NDB and MEMORY storage engines, see When to Use MEMORY or MySQL Cluster.

See Chapter 15, Alternative Storage Engines, for additional information about MySQL storage engines.

### 18.1.5.1 Differences Between the NDB and InnoDB Storage Engines

The MySQL Cluster NDB storage engine is implemented using a distributed, shared-nothing architecture, which causes it to behave differently from InnoDB in a number of ways. For those unaccustomed to working with NDB, unexpected behaviors can arise due to its distributed nature with regard to transactions, foreign keys, table limits, and other characteristics. These are shown in the following table:

<table>
<thead>
<tr>
<th>Feature</th>
<th>InnoDB 1.1</th>
<th>MySQL Cluster NDB 7.2</th>

18.1.5.2 **NDB and InnoDB Workloads**

MySQL Cluster has a range of unique attributes that make it ideal to serve applications requiring high availability, fast failover, high throughput, and low latency. Due to its distributed architecture and multi-node implementation, MySQL Cluster also has specific constraints that may keep some workloads from performing well. A number of major differences in behavior between the NDB and InnoDB storage engines with regard to some common types of database-driven application workloads are shown in the following table:

<table>
<thead>
<tr>
<th>Workload</th>
<th>InnoDB</th>
<th>MySQL Cluster (NDB)</th>
</tr>
</thead>
<tbody>
<tr>
<td>High-Volume OLTP Applications</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>DSS Applications (data marts, analytics)</td>
<td>Yes</td>
<td>Limited (Join operations across OLTP datasets not exceeding 3TB in size)</td>
</tr>
<tr>
<td>Custom Applications</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>

Known Limitations of MySQL Cluster

18.1.6 Known Limitations of MySQL Cluster

In the sections that follow, we discuss known limitations in current releases of MySQL Cluster as compared with the features available when using the MyISAM and InnoDB storage engines. If you check the “Cluster” category in the MySQL bugs database at http://bugs.mysql.com, you can find known bugs in the following categories under “MySQL Server:” in the MySQL bugs database at http://bugs.mysql.com, which we intend to correct in upcoming releases of MySQL Cluster:

- MySQL Cluster
- Cluster Direct API (NDBAPI)
- Cluster Disk Data
- Cluster Replication
- ClusterJ

This information is intended to be complete with respect to the conditions just set forth. You can report any discrepancies that you encounter to the MySQL bugs database using the instructions given in Section 1.7, “How to Report Bugs or Problems”. If we do not plan to fix the problem in MySQL Cluster NDB 7.2, we will add it to the list.

See Section 18.1.6.11, “Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x” for a list of issues in MySQL Cluster in MySQL 5.1 that have been resolved in the current version.

18.1.6.1 Noncompliance with SQL Syntax in MySQL Cluster

Some SQL statements relating to certain MySQL features produce errors when used with NDB tables, as described in the following list:

- **Temporary tables.** Temporary tables are not supported. Trying either to create a temporary table that uses the NDB storage engine or to alter an existing temporary table to use NDB fails with the error Table storage engine 'ndbcluster' does not support the create option 'TEMPORARY'.

- **Indexes and keys in NDB tables.** Keys and indexes on MySQL Cluster tables are subject to the following limitations:
Known Limitations of MySQL Cluster

- **Column width.** Attempting to create an index on an NDB table column whose width is greater than 3072 bytes succeeds, but only the first 3072 bytes are actually used for the index. In such cases, a warning `Specified key was too long; max key length is 3072 bytes` is issued, and a `SHOW CREATE TABLE` statement shows the length of the index as 3072.

- **TEXT and BLOB columns.** You cannot create indexes on NDB table columns that use any of the TEXT or BLOB data types.

- **FULLTEXT indexes.** The NDB storage engine does not support FULLTEXT indexes, which are possible for MyISAM tables only.

  However, you can create indexes on VARCHAR columns of NDB tables.

- **USING HASH keys and NULL.** Using nullable columns in unique keys and primary keys means that queries using these columns are handled as full table scans. To work around this issue, make the column `NOT NULL`, or re-create the index without the USING HASH option.

- **Prefixes.** There are no prefix indexes; only entire columns can be indexed. (The size of an NDB column index is always the same as the width of the column in bytes, up to and including 3072 bytes, as described earlier in this section. Also see Section 18.1.6.6, "Unsupported or Missing Features in MySQL Cluster", for additional information.)

- **BIT columns.** A BIT column cannot be a primary key, unique key, or index, nor can it be part of a composite primary key, unique key, or index.

- **AUTO_INCREMENT columns.** Like other MySQL storage engines, the NDB storage engine can handle a maximum of one AUTO_INCREMENT column per table. However, in the case of a Cluster table with no explicit primary key, an AUTO_INCREMENT column is automatically defined and used as a “hidden” primary key. For this reason, you cannot define a table that has an explicit AUTO_INCREMENT column unless that column is also declared using the PRIMARY KEY option. Attempting to create a table with an AUTO_INCREMENT column that is not the table’s primary key, and using the NDB storage engine, fails with an error.

- **MySQL Cluster and geometry data types.** Geometry data types (WKT and WKB) are supported for NDB tables. However, spatial indexes are not supported.

- **Character sets and binary log files.** Currently, the ndb_apply_status and ndb_binlog_index tables are created using the latin1 (ASCII) character set. Because names of binary logs are recorded in this table, binary log files named using non-Latin characters are not referenced correctly in these tables. This is a known issue, which we are working to fix. (Bug #50226)

  To work around this problem, use only Latin-1 characters when naming binary log files or setting any the `--basedir`, `--log-bin`, or `--log-bin-index` options.

- **Creating NDBCLUSTER tables with user-defined partitioning.** Support for user-defined partitioning in MySQL Cluster is restricted to [LINEAR] KEY partitioning. Using any other partitioning type with ENGINE=NDB or ENGINE=NDBCLUSTER in a CREATE TABLE statement results in an error.

  **Default partitioning scheme.** All MySQL Cluster tables are by default partitioned by KEY using the table’s primary key as the partitioning key. If no primary key is explicitly set for the table, the “hidden” primary key automatically created by the NDB storage engine is used instead. For additional discussion of these and related issues, see Section 19.2.5, "KEY Partitioning".
**CREATE TABLE** and **ALTER TABLE** statements that would cause a user-partitioned **NDBCLUSTER** table not to meet either or both of the following two requirements are not permitted, and fail with an error:

1. The table must have an explicit primary key.

2. All columns listed in the table’s partitioning expression must be part of the primary key.

**Exception.** If a user-partitioned **NDBCLUSTER** table is created using an empty column-list (that is, using **PARTITION BY [LINEAR] KEY()**), then no explicit primary key is required.

**Maximum number of partitions for **NDBCLUSTER** tables.** The maximum number of partitions that can defined for a **NDBCLUSTER** table when employing user-defined partitioning is 8 per node group. (See Section 18.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”, for more information about MySQL Cluster node groups.

**DROP PARTITION not supported.** It is not possible to drop partitions from **NDB** tables using **ALTER TABLE ... DROP PARTITION**. The other partitioning extensions to **ALTER TABLE**—**ADD PARTITION**, **REORGANIZE PARTITION**, and **COALESCE PARTITION**—are supported for Cluster tables, but use copying and so are not optimized. See Section 19.3.1, “Management of **RANGE** and **LIST** Partitions” and Section 13.1.7, “**ALTER TABLE** Syntax”.

**• Row-based replication.**
When using row-based replication with MySQL Cluster, binary logging cannot be disabled. That is, the **NDB** storage engine ignores the value of **sql_log_bin**. (Bug #16680)

### 18.1.6.2 Limits and Differences of MySQL Cluster from Standard MySQL Limits

In this section, we list limits found in MySQL Cluster that either differ from limits found in, or that are not found in, standard MySQL.

**Memory usage and recovery.** Memory consumed when data is inserted into an **NDB** table is not automatically recovered when deleted, as it is with other storage engines. Instead, the following rules hold true:

- A **DELETE** statement on an **NDB** table makes the memory formerly used by the deleted rows available for re-use by inserts on the same table only. However, this memory can be made available for general re-use by performing **OPTIMIZE TABLE**.

  A rolling restart of the cluster also frees any memory used by deleted rows. See Section 18.5.5, “Performing a Rolling Restart of a MySQL Cluster”.

- A **DROP TABLE** or **TRUNCATE TABLE** operation on an **NDB** table frees the memory that was used by this table for re-use by any **NDB** table, either by the same table or by another **NDB** table.

  **Note**
  Recall that **TRUNCATE TABLE** drops and re-creates the table. See Section 13.1.33, “**TRUNCATE TABLE Syntax**”.

- **Limits imposed by the cluster’s configuration.**
A number of hard limits exist which are configurable, but available main memory in the cluster sets limits. See the complete list of configuration parameters in Section 18.3.2, “MySQL Cluster Configuration Files”. Most configuration parameters can be upgraded online. These hard limits include:

- Database memory size and index memory size (**DataMemory** and **IndexMemory**, respectively).
Known Limitations of MySQL Cluster

**DataMemory** is allocated as 32KB pages. As each **DataMemory** page is used, it is assigned to a specific table; once allocated, this memory cannot be freed except by dropping the table.

See **Section 18.3.2.6, “Defining MySQL Cluster Data Nodes”**, for more information.

- The maximum number of operations that can be performed per transaction is set using the configuration parameters **MaxNoOfConcurrentOperations** and **MaxNoOfLocalOperations**.

**Note**

Bulk loading, **TRUNCATE TABLE**, and **ALTER TABLE** are handled as special cases by running multiple transactions, and so are not subject to this limitation.

- Different limits related to tables and indexes. For example, the maximum number of ordered indexes in the cluster is determined by **MaxNoOfOrderedIndexes**, and the maximum number of ordered indexes per table is 16.

**Node and data object maximums.** The following limits apply to numbers of cluster nodes and metadata objects:

- The maximum number of data nodes is 48.

  A data node must have a node ID in the range of 1 to 48, inclusive. (Management and API nodes may use node IDs in the range 1 to 255, inclusive.)

- The total maximum number of nodes in a MySQL Cluster is 255. This number includes all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers.

- The maximum number of metadata objects in current versions of MySQL Cluster is 20320. This limit is hard-coded.

See **Section 18.1.6.11, “Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x”**, for more information.

**18.1.6.3 Limits Relating to Transaction Handling in MySQL Cluster**

A number of limitations exist in MySQL Cluster with regard to the handling of transactions. These include the following:

- **Transaction isolation level.** The **NDBCLUSTER** storage engine supports only the **READ COMMITTED** transaction isolation level. (**InnoDB**, for example, supports **READ COMMITTED**, **READ UNCOMMITTED**, **REPEATABLE READ**, and **SERIALIZABLE**.) See **Section 18.5.3.4, “MySQL Cluster Backup Troubleshooting”**, for information on how this can affect backing up and restoring Cluster databases.)

- **Transactions and **BLOB** or **TEXT** columns.** **NDBCLUSTER** stores only part of a column value that uses any of MySQL’s **BLOB** or **TEXT** data types in the table visible to MySQL; the remainder of the **BLOB** or **TEXT** is stored in a separate internal table that is not accessible to MySQL. This gives rise to two related issues of which you should be aware whenever executing **SELECT** statements on tables that contain columns of these types:

  1. For any **SELECT** from a MySQL Cluster table: If the **SELECT** includes a **BLOB** or **TEXT** column, the **READ COMMITTED** transaction isolation level is converted to a read with read lock. This is done to guarantee consistency.
2. For any `SELECT` which uses a unique key lookup to retrieve any columns that use any of the `BLOB` or `TEXT` data types and that is executed within a transaction, a shared read lock is held on the table for the duration of the transaction—that is, until the transaction is either committed or aborted.

This issue does not occur for queries that use index or table scans, even against `NDB` tables having `BLOB` or `TEXT` columns.

For example, consider the table `t` defined by the following `CREATE TABLE` statement:

```
CREATE TABLE t (  
    a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
    b INT NOT NULL,  
    c INT NOT NULL,  
    d TEXT,  
    INDEX i(b),  
    UNIQUE KEY u(c)  
) ENGINE = NDB,
```

Either of the following queries on `t` causes a shared read lock, because the first query uses a primary key lookup and the second uses a unique key lookup:

```
SELECT * FROM t WHERE a = 1;
SELECT * FROM t WHERE c = 1;
```

However, none of the four queries shown here causes a shared read lock:

```
SELECT * FROM t WHERE b = 1;
SELECT * FROM t WHERE d = '1';
SELECT * FROM t;
SELECT b,c WHERE a = 1;
```

This is because, of these four queries, the first uses an index scan, the second and third use table scans, and the fourth, while using a primary key lookup, does not retrieve the value of any `BLOB` or `TEXT` columns.

You can help minimize issues with shared read locks by avoiding queries that use unique key lookups that retrieve `BLOB` or `TEXT` columns, or, in cases where such queries are not avoidable, by committing transactions as soon as possible afterward.

- **Rollbacks.** There are no partial transactions, and no partial rollbacks of transactions. A duplicate key or similar error causes the entire transaction to be rolled back.

  This behavior differs from that of other transactional storage engines such as `InnoDB` that may roll back individual statements.

- **Transactions and memory usage.**
  As noted elsewhere in this chapter, MySQL Cluster does not handle large transactions well; it is better to perform a number of small transactions with a few operations each than to attempt a single large transaction containing a great many operations. Among other considerations, large transactions require very large amounts of memory. Because of this, the transactional behavior of a number of MySQL statements is effected as described in the following list:
Known Limitations of MySQL Cluster

• TRUNCATE TABLE is not transactional when used on NDB tables. If a TRUNCATE TABLE fails to empty the table, then it must be re-run until it is successful.

• DELETE FROM (even with no WHERE clause) is transactional. For tables containing a great many rows, you may find that performance is improved by using several DELETE FROM ... LIMIT ... statements to “chunk” the delete operation. If your objective is to empty the table, then you may wish to use TRUNCATE TABLE instead.

• LOAD DATA statements. LOAD DATA INFILE is not transactional when used on NDB tables.

Important
When executing a LOAD DATA INFILE statement, the NDB engine performs commits at irregular intervals that enable better utilization of the communication network. It is not possible to know ahead of time when such commits take place.

LOAD DATA FROM MASTER is not supported in MySQL Cluster.

• ALTER TABLE and transactions. When copying an NDB table as part of an ALTER TABLE, the creation of the copy is nontransactional. (In any case, this operation is rolled back when the copy is deleted.)

• Transactions and the COUNT() function. When using MySQL Cluster Replication, it is not possible to guarantee the transactional consistency of the COUNT() function on the slave. In other words, when performing on the master a series of statements (INSERT, DELETE, or both) that changes the number of rows in a table within a single transaction, executing SELECT COUNT(*) FROM table queries on the slave may yield intermediate results. This is due to the fact that SELECT COUNT(...) may perform dirty reads, and is not a bug in the NDB storage engine. (See Bug #31321 for more information.)

18.1.6.4 MySQL Cluster Error Handling

Starting, stopping, or restarting a node may give rise to temporary errors causing some transactions to fail. These include the following cases:

• Temporary errors. When first starting a node, it is possible that you may see Error 1204 Temporary failure, distribution changed and similar temporary errors.

• Errors due to node failure. The stopping or failure of any data node can result in a number of different node failure errors. (However, there should be no aborted transactions when performing a planned shutdown of the cluster.)

In either of these cases, any errors that are generated must be handled within the application. This should be done by retrying the transaction.

See also Section 18.1.6.2, “Limits and Differences of MySQL Cluster from Standard MySQL Limits”.

18.1.6.5 Limits Associated with Database Objects in MySQL Cluster

Some database objects such as tables and indexes have different limitations when using the NDBCLUSTER storage engine:

• Number of database objects. The maximum number of all NDB database objects in a single MySQL Cluster—including databases, tables, and indexes—is limited to 20320.

• Attributes per table. The maximum number of attributes (that is, columns and indexes) that can belong to a given table is 512.
Known Limitations of MySQL Cluster

- **Attributes per key.** The maximum number of attributes per key is 32.

- **Row size.** The maximum permitted size of any one row is 14000 bytes (as of MySQL Cluster NDB 7.0). Each `BLOB` or `TEXT` column contributes 256 + 8 = 264 bytes to this total.

### 18.1.6.6 Unsupported or Missing Features in MySQL Cluster

A number of features supported by other storage engines are not supported for NDB tables. Trying to use any of these features in MySQL Cluster does not cause errors in or of itself; however, errors may occur in applications that expects the features to be supported or enforced:

- **Foreign key constraints.** Prior to MySQL Cluster NDB 7.3, the foreign key construct is ignored, just as it is by MyISAM tables. Foreign keys are supported in MySQL Cluster NDB 7.3 and later.

- **Index prefixes.** Prefixes on indexes are not supported for NDBCLUSTER tables. If a prefix is used as part of an index specification in a statement such as `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX`, the prefix is ignored.

- **Savepoints and rollbacks.** Savepoints and rollbacks to savepoints are ignored as in MyISAM.

- **Durability of commits.** There are no durable commits on disk. Commits are replicated, but there is no guarantee that logs are flushed to disk on commit.

- **Replication.** Statement-based replication is not supported. Use `--binlog-format=ROW` (or `--binlog-format=MIXED`) when setting up cluster replication. See Section 18.6, "MySQL Cluster Replication", for more information.

#### Note

See Section 18.1.6.3, “Limits Relating to Transaction Handling in MySQL Cluster”, for more information relating to limitations on transaction handling in NDB.

### 18.1.6.7 Limitations Relating to Performance in MySQL Cluster

The following performance issues are specific to or especially pronounced in MySQL Cluster:

- **Range scans.** There are query performance issues due to sequential access to the NDB storage engine; it is also relatively more expensive to do many range scans than it is with either MyISAM or InnoDB.

- **Reliability of Records in range.** The Records in range statistic is available but is not completely tested or officially supported. This may result in nonoptimal query plans in some cases. If necessary, you can employ `USE INDEX` or `FORCE INDEX` to alter the execution plan. See Section 13.2.9.3, “Index Hint Syntax”, for more information on how to do this.

- **Unique hash indexes.** Unique hash indexes created with `USING HASH` cannot be used for accessing a table if NULL is given as part of the key.

### 18.1.6.8 Issues Exclusive to MySQL Cluster

The following are limitations specific to the NDBCLUSTER storage engine:

- **Machine architecture.** All machines used in the cluster must have the same architecture. That is, all machines hosting nodes must be either big-endian or little-endian, and you cannot use a mixture of both. For example, you cannot have a management node running on a PowerPC which directs a data node that is running on an x86 machine. This restriction does not apply to machines simply running `mysql` or other clients that may be accessing the cluster's SQL nodes.
Known Limitations of MySQL Cluster

- **Binary logging.**
  MySQL Cluster has the following limitations or restrictions with regard to binary logging:
  
  - `sql_log_bin` has no effect on data operations; however, it is supported for schema operations.
  
  - MySQL Cluster cannot produce a binary log for tables having `BLOB` columns but no primary key.
  
  - Only the following schema operations are logged in a cluster binary log which is *not* on the `mysqld` executing the statement:
    
    - `CREATE TABLE`
    - `ALTER TABLE`
    - `DROP TABLE`
    - `CREATE DATABASE / CREATE SCHEMA`
    - `DROP DATABASE / DROP SCHEMA`
    - `CREATE TABLESPACE`
    - `ALTER TABLESPACE`
    - `DROP TABLESPACE`
    - `CREATE LOGFILE GROUP`
    - `ALTER LOGFILE GROUP`
    - `DROP LOGFILE GROUP`

  See also Section 18.1.6.10, "Limitations Relating to Multiple MySQL Cluster Nodes".

### 18.1.6.9 Limitations Relating to MySQL Cluster Disk Data Storage

**Disk Data object maximums and minimums.** Disk data objects are subject to the following maximums and minimums:

- Maximum number of tablespaces: $2^{32}$ (4294967296)
- Maximum number of data files per tablespace: $2^{16}$ (65536)
- Maximum data file size: The theoretical limit is 64G; however, the practical upper limit is 32G. This is equivalent to 32768 extents of 1M each.

  Since a MySQL Cluster Disk Data table can use at most 1 tablespace, this means that the theoretical upper limit to the amount of data (in bytes) that can be stored on disk by a single NDB table is $32G * 65536 = 2251799813685248$, or approximately 2 petabytes.

- The theoretical maximum number of extents per tablespace data file is $2^{16}$ (65536); however, for practical purposes, the recommended maximum number of extents per data file is $2^{15}$ (32768).

  The minimum and maximum possible sizes of extents for tablespace data files are 32K and 2G, respectively. See Section 13.1.18, "CREATE TABLESPACE Syntax", for more information.

**Disk Data tables and diskless mode.** Use of Disk Data tables is not supported when running the cluster in diskless mode. Beginning with MySQL 5.1.12, it is prohibited altogether. (Bug #20008)
18.1.6.10 Limitations Relating to Multiple MySQL Cluster Nodes

Multiple SQL nodes.  
The following are issues relating to the use of multiple MySQL servers as MySQL Cluster SQL nodes, and are specific to the NDBCLUSTER storage engine:

- **No distributed table locks.**  
  A `LOCK TABLES` works only for the SQL node on which the lock is issued; no other SQL node in the cluster "sees" this lock. This is also true for a lock issued by any statement that locks tables as part of its operations. (See next item for an example.)

- **ALTER TABLE operations.**  
  `ALTER TABLE` is not fully locking when running multiple MySQL servers (SQL nodes). (As discussed in the previous item, MySQL Cluster does not support distributed table locks.)

Multiple management nodes.  
When using multiple management servers:

- You must give nodes explicit IDs in connect strings because automatic allocation of node IDs does not work across multiple management servers.

- When a management server starts, it first checks for any other management server in the same MySQL Cluster, and upon successful connection to the other management server uses its configuration data. This means that the management server `--reload` and `--initial` startup options are ignored unless the management server is the only one running. It also means that, when performing a rolling restart of a MySQL Cluster with multiple management nodes, the management server reads its own configuration file if (and only if) it is the only management server running in this MySQL Cluster. See Section 18.5.5, "Performing a Rolling Restart of a MySQL Cluster", for more information.

Multiple network addresses.  
Multiple network addresses per data node are not supported. Use of these is liable to cause problems: In the event of a data node failure, an SQL node waits for confirmation that the data node went down but never receives it because another route to that data node remains open. This can effectively make the cluster inoperable.

Note

It is possible to use multiple network hardware *interfaces* (such as Ethernet cards) for a single data node, but these must be bound to the same address. This also means that it not possible to use more than one [tcp] section per connection in the config.ini file. See Section 18.3.2.8, "MySQL Cluster TCP/IP Connections", for more information.

18.1.6.11 Previous MySQL Cluster Issues Resolved in MySQL 5.1, MySQL Cluster NDB 6.x, and MySQL Cluster NDB 7.x

A number of limitations and related issues existing in earlier versions of MySQL Cluster have been resolved:

- **Variable-length column support.**  
  The NDBCLUSTER storage engine now supports variable-length column types for in-memory tables.

  Previously, for example, any Cluster table having one or more VARCHAR fields which contained only relatively small values, much more memory and disk space were required when using the NDBCLUSTER storage engine than would have been the case for the same table and data using the MyISAM engine. In other words, in the case of a VARCHAR column, such a column required the same amount of storage as a CHAR column of the same size. In MySQL 5.1, this is no longer the case for in-memory tables, where
storage requirements for variable-length column types such as VARCHAR and BINARY are comparable to those for these column types when used in MyISAM tables (see Section 11.7, “Data Type Storage Requirements”).

Important
For MySQL Cluster Disk Data tables, the fixed-width limitation continues to apply. See Section 18.5.12, “MySQL Cluster Disk Data Tables”.

• Replication with MySQL Cluster. It is now possible to use MySQL replication with Cluster databases. For details, see Section 18.6, “MySQL Cluster Replication”.

  Circular Replication. Circular replication is also supported with MySQL Cluster, beginning with MySQL 5.1.18. See Section 18.6.10, “MySQL Cluster Replication: Multi-Master and Circular Replication”.

  auto_increment_increment and auto_increment_offset. The auto_increment_increment and auto_increment_offset server system variables are supported for MySQL Cluster Replication.

• Backup and restore between architectures. It is possible to perform a Cluster backup and restore between different architectures. Previously—for example—you could not back up a cluster running on a big-endian platform and then restore from that backup to a cluster running on a little-endian system. (Bug #19255)

• Multiple data nodes, multi-threaded data nodes. MySQL Cluster NDB 7.2 supports multiple data node processes on a single host as well as multi-threaded data node processes. See Section 18.4.3, “ndbmt.d — The MySQL Cluster Data Node Daemon (Multi-Threaded)”, for more information.

• Identifiers. Formerly (in MySQL 5.0 and earlier), database names, table names and attribute names could not be as long for NDB tables as tables using other storage engines, because attribute names were truncated internally. In MySQL 5.1 and later, names of MySQL Cluster databases, tables, and table columns follow the same rules regarding length as they do for any other storage engine.

• Length of CREATE TABLE statements. CREATE TABLE statements may be no more than 4096 characters in length. This limitation affects MySQL 5.1.6, 5.1.7, and 5.1.8 only. (See Bug #17813)

• IGNORE and REPLACE functionality. In MySQL 5.1.7 and earlier, INSERT IGNORE, UPDATE IGNORE, and REPLACE were supported only for primary keys, but not for unique keys. It was possible to work around this issue by removing the constraint, then dropping the unique index, performing any inserts, and then adding the unique index again.

  This limitation was removed for INSERT IGNORE and REPLACE in MySQL 5.1.8. (See Bug #17431.)

• AUTO_INCREMENT columns. In MySQL 5.1.10 and earlier versions, the maximum number of tables having AUTO_INCREMENT columns—including those belonging to hidden primary keys—was 2048.

  This limitation was lifted in MySQL 5.1.11.

• Maximum number of cluster nodes. The total maximum number of nodes in a MySQL Cluster is 255, including all SQL nodes (MySQL Servers), API nodes (applications accessing the cluster other than MySQL servers), data nodes, and management servers. The total number of data nodes and management nodes is 63, of which up to 48 can be data nodes.

Note
A data node cannot have a node ID greater than 49.
• **Recovery of memory from deleted rows.** Memory can be reclaimed from an NDB table for reuse with any NDB table by employing `OPTIMIZE TABLE`, subject to the following limitations:

  - Only in-memory tables are supported; the `OPTIMIZE TABLE` statement has no effect on MySQL Cluster Disk Data tables.
  - Only variable-length columns (such as those declared as VARCHAR, TEXT, or BLOB) are supported.

    However, you can force columns defined using fixed-length data types (such as CHAR) to be dynamic using the `ROW_FORMAT` or `COLUMN_FORMAT` option with a `CREATE TABLE` or `ALTER TABLE` statement.

    See Section 13.1.17, “CREATE TABLE Syntax”, and Section 13.1.7, “ALTER TABLE Syntax”, for information on these options.

You can regulate the effects of `OPTIMIZE` on performance by adjusting the value of the global system variable `ndb_optimization_delay`, which sets the number of milliseconds to wait between batches of rows being processed by `OPTIMIZE`. The default value is 10 milliseconds. It is possible to set a lower value (to a minimum of 0), but not recommended. The maximum is 100000 milliseconds (that is, 100 seconds).

• **Number of tables.** The maximum number of NDBCLUSTER tables in a single MySQL Cluster is included in the total maximum number of NDBCLUSTER database objects (20320). (See Section 18.1.6.5, “Limits Associated with Database Objects in MySQL Cluster”.)

• **Adding and dropping of data nodes.** In MySQL Cluster NDB 7.2 (MySQL Cluster NDB 7.0 and later), it is possible to add new data nodes to a running MySQL Cluster by performing a rolling restart, so that the cluster and the data stored in it remain available to applications.

When planning to increase the number of data nodes in the cluster online, you should be aware of and take into account the following issues:

  - New data nodes can be added online to a MySQL Cluster only as part of a new node group.
  - New data nodes can be added online, but cannot be dropped online. Reducing the number of data nodes requires a system restart of the cluster.
  - As in previous MySQL Cluster releases, it is not possible to change online either the number of replicas (`NoOfReplicas` configuration parameter) or the number of data nodes per node group. These changes require a system restart.
  - Redistribution of existing cluster data using the new data nodes is not automatic; however, this can be accomplished using simple SQL statements in the `mysql` client or other MySQL client application once the nodes have been added. During this procedure, it is not possible to perform DDL operations, although DML operations can continue as normal.

    The distribution of new cluster data (that is, data stored in the cluster after the new nodes have been added) uses the new nodes without manual intervention.

    For more information, see Section 18.5.13, “Adding MySQL Cluster Data Nodes Online”.

• **Distribution of MySQL users and privileges.** Previously, MySQL users and privileges created on one SQL node were unique to that SQL node, due to the fact that the MySQL grant tables were restricted to using the MyISAM storage engine. Beginning with MySQL Cluster NDB 7.2.0, it is possible, following installation of the MySQL Cluster software and setup of the desired users and privileges on one SQL node, to convert the grant tables to use NDB and thus to distribute the users and privileges across all SQL nodes connected to the cluster. You can do this by loading and making use of a set of stored
procedures defined in an SQL script supplied with the MySQL Cluster distribution. For more information, see Section 18.5.14, “Distributed MySQL Privileges for MySQL Cluster”.

- **Number of rows per partition.** Previously, a single MySQL Cluster partition could hold a maximum of 46137488 rows. This limitation was removed in MySQL Cluster NDB 7.2.9. (Bug #13844405, Bug #14000373)

If you are still using a previous MySQL Cluster release, you can work around this limitation by taking advantage of the fact that the number of partitions is the same as the number of data nodes in the cluster (see Section 18.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”). This means that, by increasing the number of data nodes, you can increase the available space for storing data.

MySQL Cluster NDB 7.2 also supports increasing the number of data nodes in the cluster while the cluster remains in operation. See Section 18.5.13, “Adding MySQL Cluster Data Nodes Online”, for more information.

It is also possible to increase the number of partitions for NDB tables by using explicit KEY or LINEAR KEY partitioning (see Section 19.2.5, “KEY Partitioning”).

## 18.2 MySQL Cluster Installation and Upgrades

This section describes the basics for planning, installing, configuring, and running a MySQL Cluster. Whereas the examples in Section 18.3, “Configuration of MySQL Cluster NDB 7.2” provide more in-depth information on a variety of clustering options and configuration, the result of following the guidelines and procedures outlined here should be a usable MySQL Cluster which meets the minimum requirements for availability and safeguarding of data.

For information about upgrading or downgrading a MySQL Cluster between release versions, see Section 18.2.7, “Upgrading and Downgrading MySQL Cluster NDB 7.2”.

This section covers hardware and software requirements; networking issues; installation of MySQL Cluster; configuration issues; starting, stopping, and restarting the cluster; loading of a sample database; and performing queries.

**Assumptions.** The following sections make a number of assumptions regarding the cluster's physical and network configuration. These assumptions are discussed in the next few paragraphs.

**Cluster nodes and host computers.** The cluster consists of four nodes, each on a separate host computer, and each with a fixed network address on a typical Ethernet network as shown here:

<table>
<thead>
<tr>
<th>Node</th>
<th>IP Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Management node (mgmd)</td>
<td>192.168.0.10</td>
</tr>
<tr>
<td>SQL node (mysqld)</td>
<td>192.168.0.20</td>
</tr>
<tr>
<td>Data node &quot;A&quot; (ndbd)</td>
<td>192.168.0.30</td>
</tr>
<tr>
<td>Data node &quot;B&quot; (ndbd)</td>
<td>192.168.0.40</td>
</tr>
</tbody>
</table>

This may be made clearer by the following diagram:
Network addressing. In the interest of simplicity (and reliability), this How-To uses only numeric IP addresses. However, if DNS resolution is available on your network, it is possible to use host names in lieu of IP addresses in configuring Cluster. Alternatively, you can use the hosts file (typically /etc/hosts for Linux and other Unix-like operating systems, C:\WINDOWS\system32\drivers\etc\hosts on Windows, or your operating system's equivalent) for providing a means to do host lookup if such is available.

Potential hosts file issues. A common problem when trying to use host names for Cluster nodes arises because of the way in which some operating systems (including some Linux distributions) set up the system's own host name in the /etc/hosts during installation. Consider two machines with the host names ndb1 and ndb2, both in the cluster network domain. Red Hat Linux (including some derivatives such as CentOS and Fedora) places the following entries in these machines' /etc/hosts files:

```
# ndb1 /etc/hosts:
127.0.0.1   ndb1.cluster ndb1 localhost.localdomain localhost
```

```
# ndb2 /etc/hosts:
127.0.0.1   ndb2.cluster ndb2 localhost.localdomain localhost
```

SUSE Linux (including OpenSUSE) places these entries in the machines' /etc/hosts files:

```
# ndb1 /etc/hosts:
127.0.0.1   localhost
127.0.0.2   ndb1.cluster ndb1
```

```
# ndb2 /etc/hosts:
127.0.0.1   localhost
127.0.0.2   ndb2.cluster ndb2
```
In both instances, ndb1 routes ndb1.cluster to a loopback IP address, but gets a public IP address from DNS for ndb2.cluster, while ndb2 routes ndb2.cluster to a loopback address and obtains a public address for ndb1.cluster. The result is that each data node connects to the management server, but cannot tell when any other data nodes have connected, and so the data nodes appear to hang while starting.

**Caution**

You cannot mix localhost and other host names or IP addresses in config.ini. For these reasons, the solution in such cases (other than to use IP addresses for all config.ini HostName entries) is to remove the fully qualified host names from /etc/hosts and use these in config.ini for all cluster hosts.

**Host computer type.** Each host computer in our installation scenario is an Intel-based desktop PC running a supported operating system installed to disk in a standard configuration, and running no unnecessary services. The core operating system with standard TCP/IP networking capabilities should be sufficient. Also for the sake of simplicity, we also assume that the file systems on all hosts are set up identically. In the event that they are not, you should adapt these instructions accordingly.

**Network hardware.** Standard 100 Mbps or 1 gigabit Ethernet cards are installed on each machine, along with the proper drivers for the cards, and that all four hosts are connected through a standard-issue Ethernet networking appliance such as a switch. (All machines should use network cards with the same throughout. That is, all four machines in the cluster should have 100 Mbps cards or all four machines should have 1 Gbps cards.) MySQL Cluster works in a 100 Mbps network; however, gigabit Ethernet provides better performance.

**Important**

MySQL Cluster is not intended for use in a network for which throughput is less than 100 Mbps or which experiences a high degree of latency. For this reason (among others), attempting to run a MySQL Cluster over a wide area network such as the Internet is not likely to be successful, and is not supported in production.

**Sample data.** We use the world database which is available for download from the MySQL Web site (see http://dev.mysql.com/doc/index-other.html). We assume that each machine has sufficient memory for running the operating system, required MySQL Cluster processes, and (on the data nodes) storing the database.

For general information about installing MySQL, see Chapter 2, *Installing and Upgrading MySQL*. For information about installation of MySQL Cluster on Linux and other Unix-like operating systems, see Section 18.2.1, “Installing MySQL Cluster on Linux”. For information about installation of MySQL Cluster on Windows operating systems, see Section 18.2.2, “Installing MySQL Cluster on Windows”.

For general information about MySQL Cluster hardware, software, and networking requirements, see Section 18.1.3, “MySQL Cluster Hardware, Software, and Networking Requirements”.

### 18.2.1 Installing MySQL Cluster on Linux

This section covers installation of MySQL Cluster on Linux and other Unix-like operating systems. While the next few sections refer to a Linux operating system, the instructions and procedures given there should be easily adaptable to other supported Unix-like platforms.

MySQL Cluster NDB 7.2 is also available for Windows operating systems; for installation and setup instructions specific to Windows, see Section 18.2.2, “Installing MySQL Cluster on Windows”.

Each MySQL Cluster host computer must have the correct executable programs installed. A host running an SQL node must have installed on it a MySQL Server binary (mysqld). Management nodes require the
management server daemon (ndb_mgmd); data nodes require the data node daemon (ndbd or ndbmt.d). It is not necessary to install the MySQL Server binary on management node hosts and data node hosts. It is recommended that you also install the management client (ndb_mgm) on the management server host.

Installation of MySQL Cluster on Linux can be done using precompiled binaries from Oracle (downloaded as a .tar.gz archive), with RPM packages (also available from Oracle), or from source code. All three of these installation methods are described in the section that follow.

Regardless of the method used, it is still necessary following installation of the MySQL Cluster binaries to create configuration files for all cluster nodes, before you can start the cluster. See Section 18.2.3, “Initial Configuration of MySQL Cluster”.

### 18.2.1.1 Installing a MySQL Cluster Binary Release on Linux

This section covers the steps necessary to install the correct executables for each type of Cluster node from precompiled binaries supplied by Oracle.

For setting up a cluster using precompiled binaries, the first step in the installation process for each cluster host is to download the latest MySQL Cluster NDB 7.2 binary archive (mysql-cluster-gpl-7.2.18-linux-i686-glibc23.tar.gz) from the MySQL Cluster downloads area. We assume that you have placed this file in each machine’s /var/tmp directory. (If you do require a custom binary, see Section 2.9.3, “Installing MySQL Using a Development Source Tree”.)

**Note**

After completing the installation, do not yet start any of the binaries. We show you how to do so following the configuration of the nodes (see Section 18.2.3, “Initial Configuration of MySQL Cluster”).

**SQL nodes.** On each of the machines designated to host SQL nodes, perform the following steps as the system root user:

1. Check your /etc/passwd and /etc/group files (or use whatever tools are provided by your operating system for managing users and groups) to see whether there is already a mysql group and mysql user on the system. Some OS distributions create these as part of the operating system installation process. If they are not already present, create a new mysql user group, and then add a mysql user to this group:

   ```
   shell> groupadd mysql
   shell> useradd -g mysql mysql
   ```

   The syntax for useradd and groupadd may differ slightly on different versions of Unix, or they may have different names such as adduser and addgroup.

2. Change location to the directory containing the downloaded file, unpack the archive, and create a symbolic link named mysql to the mysql directory. Note that the actual file and directory names vary according to the MySQL Cluster version number.

   ```
   shell> cd /var/tmp
   shell> tar -C /usr/local -xzvf mysql-cluster-gpl-7.2.18-linux2.6.tar.gz
   shell> ln -s /usr/local/mysql-cluster-gpl-7.2.18-linux2.6-i686 /usr/local/mysql
   ```

3. Change location to the mysql directory and run the supplied script for creating the system databases:

   ```
   shell> cd mysql
   ```
4. Set the necessary permissions for the MySQL server and data directories:

```
shell> chown -R root .
shell> chown -R mysql data
shell> chgrp -R mysql .
```

5. Copy the MySQL startup script to the appropriate directory, make it executable, and set it to start when the operating system is booted up:

```
shell> cp support-files/mysql.server /etc/rc.d/init.d/
shell> chmod +x /etc/rc.d/init.d/mysql.server
shell> chkconfig --add mysql.server
```

(The startup scripts directory may vary depending on your operating system and version—for example, in some Linux distributions, it is /etc/init.d.)

Here we use Red Hat's `chkconfig` for creating links to the startup scripts; use whatever means is appropriate for this purpose on your platform, such as `update-rc.d` on Debian.

Remember that the preceding steps must be repeated on each machine where an SQL node is to reside.

**Data nodes.** Installation of the data nodes does not require the `mysql` binary. Only the MySQL Cluster data node executable `ndbd` (single-threaded) or `ndbmd` (multi-threaded) is required. These binaries can also be found in the `.tar.gz` archive. Again, we assume that you have placed this archive in `/var/tmp`.

As system `root` (that is, after using `sudo`, `su root`, or your system's equivalent for temporarily assuming the system administrator account's privileges), perform the following steps to install the data node binaries on the data node hosts:

1. Change location to the `/var/tmp` directory, and extract the `ndbd` and `ndbmd` binaries from the archive into a suitable directory such as `/usr/local/bin`:

```
shell> cd /var/tmp
shell> tar -zxvf mysql-5.5.38-ndb-7.2.18-linux-i686-glibc23.tar.gz
shell> cd mysql-5.5.38-ndb-7.2.18-linux-i686-glibc23
shell> cp bin/ndbd /usr/local/bin/ndbd
shell> cp bin/ndbmd /usr/local/bin/ndbmd
```

(You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from `/var/tmp` once `ndb_mgm` and `ndb_mgmd` have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

```
shell> cd /usr/local/bin
shell> chmod +x ndb*
```

The preceding steps should be repeated on each data node host.

Although only one of the data node executables is required to run a MySQL Cluster data node, we have shown you how to install both `ndbd` and `ndbmd` in the preceding instructions. We recommend that you do this when installing or upgrading MySQL Cluster, even if you plan to use only one of them, since this will save time and trouble in the event that you later decide to change from one to the other.
Note

The data directory on each machine hosting a data node is /usr/local/mysql/data. This piece of information is essential when configuring the management node. (See Section 18.2.3, “Initial Configuration of MySQL Cluster”.)

Management nodes. Installation of the management node does not require the mysqld binary. Only the MySQL Cluster management server (ndb_mgm) is required; you most likely want to install the management client (ndb_mgm) as well. Both of these binaries also be found in the .tar.gz archive. Again, we assume that you have placed this archive in /var/tmp.

As system root, perform the following steps to install ndb_mgm and ndb_mgd on the management node host:

1. Change location to the /var/tmp directory, and extract the ndb_mgm and ndb_mgm from the archive into a suitable directory such as /usr/local/bin:

   ```bash
   shell> cd /var/tmp
   shell> tar -zxvf mysql-5.5.38-ndb-7.2.18-linux2.6-i686.tar.gz
   shell> cd mysql-5.5.38-ndb-7.2.18-linux2.6-i686
   shell> cp bin/ndb_mgm* /usr/local/bin
   ```
   (You can safely delete the directory created by unpacking the downloaded archive, and the files it contains, from /var/tmp once ndb_mgm and ndb_mgm have been copied to the executables directory.)

2. Change location to the directory into which you copied the files, and then make both of them executable:

   ```bash
   shell> cd /usr/local/bin
   shell> chmod +x ndb_mgm*
   ```

In Section 18.2.3, “Initial Configuration of MySQL Cluster”, we create configuration files for all of the nodes in our example MySQL Cluster.

18.2.1.2 Installing MySQL Cluster from RPM

This section covers the steps necessary to install the correct executables for each type of MySQL Cluster node using RPM packages supplied by Oracle.

RPMs are available for both 32-bit and 64-bit Linux platforms. The filenames for these RPMs use the following pattern:

```
MySQL-Cluster-component-producttype-ndbversion.distribution.architecture.rpm
```

- **component**: {server | client [ | other]}
- **producttype**: {gpl | advanced}
- **ndbversion**: major.minor.release
- **distribution**: {sles10 | rhel5 | el6}
- **architecture**: {i386 | x86_64}

The **component** can be server or client. (Other values are possible, but since only the server and client components are required for a working MySQL Cluster installation, we do not discuss them here.) The **producttype** for Community RPMs downloaded from [http://dev.mysql.com/downloads/cluster/](http://dev.mysql.com/downloads/cluster/) is
always gpl; advanced is used to indicate commercial releases. ndbversion represents the three-part NDB storage engine version number in 7.2.x format. The distribution can be one of sles11 (SUSE Enterprise Linux 11), rhel5 (Oracle Linux 5, Red Hat Enterprise Linux 4 and 5), or el6 (Oracle Linux 6, Red Hat Enterprise Linux 6). The architecture is i386 for 32-bit RPMs and x86_64 for 64-bit versions.

For a MySQL Cluster, one and possibly two RPMs are required:

- The server RPM (for example, MySQL-Cluster-server-gpl-7.2.18-1.sles11.i386.rpm), which supplies the core files needed to run a MySQL Server with NDBCLUSTER storage engine support (that is, as a MySQL Cluster SQL node) as well as all MySQL Cluster executables, including the management node, data node, and ndb_mgm client binaries. This RPM is always required for installing MySQL Cluster NDB 7.2.

- If you do not have your own client application capable of administering a MySQL server, you should also obtain and install the client RPM (for example, MySQL-Cluster-client-gpl-7.2.18-1.sles11.i386.rpm), which supplies the mysql client.

The MySQL Cluster version number in the RPM file names (shown here as 7.2.18) can vary according to the version which you are actually using. It is very important that all of the Cluster RPMs to be installed have the same version number. The architecture designation should be appropriate to the machine on which the RPM is to be installed; in particular, you should keep in mind that 64-bit RPMs cannot be used with 32-bit operating system.

**Data nodes.** On a computer that is to host a cluster data node it is necessary to install only the server RPM. To do so, copy this RPM to the data node host, and run the following command as the system root user, replacing the name shown for the RPM as necessary to match that of the RPM downloaded from the MySQL web site:

```
shell> rpm -Uhv MySQL-Cluster-server-gpl-7.2.18-1.sles11.i386.rpm
```

Although this installs all MySQL Cluster binaries, only the program ndbd or ndbmtd (both in /usr/sbin) is actually needed to run a MySQL Cluster data node.

**SQL nodes.** On each machine to be used for hosting a cluster SQL node, install the server RPM by executing the following command as the system root user, replacing the name shown for the RPM as necessary to match the name of the RPM downloaded from the MySQL web site:

```
shell> rpm -Uhv MySQL-Cluster-server-gpl-7.2.18-1.sles11.i386.rpm
```

This installs the MySQL server binary (mysqld) with NDB storage engine support in the /usr/sbin directory, as well as all needed MySQL Server support files. It also installs the mysql.server and mysql_safe startup scripts (in /usr/share/mysql and /usr/bin, respectively). The RPM installer should take care of general configuration issues (such as creating the mysql user and group, if needed) automatically.

To administer the SQL node (MySQL server), you should also install the client RPM, as shown here:

```
shell> rpm -Uhv MySQL-Cluster-client-gpl-7.2.18-1.sles11.i386.rpm
```

This installs the mysql client program.

**Management nodes.** To install the MySQL Cluster management server, it is necessary only to use the server RPM. Copy this RPM to the computer intended to host the management node, and then install it by running the following command as the system root user (replace the name shown for the RPM as necessary to match that of the server RPM downloaded from the MySQL web site):
Installing MySQL Cluster on Linux

```
shell> rpm -Uhv MySQL-Cluster-server-gpl-7.2.18-1.sles11.i386.rpm
```

Although this RPM installs many other files, only the management server binary `ndb_mgmd` (in the `/usr/sbin` directory) is actually required for running a management node. The `server` RPM also installs `ndb_mgm`, the NDB management client.

See Section 2.5.1, “Installing MySQL on Linux Using RPM Packages”, for general information about installing MySQL using RPMs supplied by Oracle.

After installing from RPM, you still need to configure the cluster as discussed in Section 18.2.3, “Initial Configuration of MySQL Cluster”.

**Note**

A number of RPMs used by MySQL Cluster NDB 7.1 were made obsolete and discontinued in MySQL Cluster NDB 7.2. These include the former `MySQL-Cluster-clusterj`, `MySQL-Cluster-extra`, `MySQL-Cluster-management`, `MySQL-Cluster-storage`, and `MySQL Cluster-tools` RPMs; all of these have been merged into the `MySQL-Cluster-server` RPM. When upgrading from a MySQL Cluster NDB 7.1 RPM installation to MySQL Cluster NDB 7.2.3 or an earlier MySQL Cluster NDB 7.2 release, it was necessary to remove these packages manually before installing the MySQL Cluster NDB 7.2 `MySQL-Cluster-server` RPM. This issue is fixed in MySQL Cluster NDB 7.2.4 and later, where the `MySQL-Cluster-server` package specifically obsoletes the discontinued packages (BUG #13545589).

### 18.2.1.3 Building MySQL Cluster from Source on Linux

This section provides information about compiling MySQL Cluster on Linux and other Unix-like platforms. Building MySQL Cluster from source is similar to building the standard MySQL Server, although it differs in a few key respects discussed here. For general information about building MySQL from source, see Section 2.9, “Installing MySQL from Source”. For information about compiling MySQL Cluster on Windows platforms, see Section 18.2.2.2, “Compiling and Installing MySQL Cluster from Source on Windows”.

Building MySQL Cluster requires using the MySQL Cluster sources. These are available from the MySQL Cluster downloads page at [http://dev.mysql.com/downloads/cluster/](http://dev.mysql.com/downloads/cluster/). The archived source file should have a name similar to `mysql-cluster-gpl-7.2.18.tar.gz`. You can also obtain MySQL development sources from [launchpad.net](http://launchpad.net). Attempting to build MySQL Cluster from standard MySQL Server 5.5 sources is not supported.

The `WITH_NDBCLUSTER_STORAGE_ENGINE` option for CMake causes the binaries for the management nodes, data nodes, and other MySQL Cluster programs to be built; it also causes `mysqld` to be compiled with NDB storage engine support. This option is enabled by default in the MySQL Cluster NDB 7.2 sources.

**Important**

Beginning with MySQL Cluster NDB 7.2.9, the `WITH_NDB_JAVA` option is enabled by default. This means that, by default, if CMake cannot find the location of Java on your system, the configuration process fails; if you do not wish to enable Java and ClusterJ support, you must indicate this explicitly by configuring the build using `-DWITH_NDB_JAVA=OFF` (Bug #12379735) Use `WITH_CLASSPATH` to provide the Java classpath if needed.

For more information about CMake options specific to building MySQL Cluster, see Options for Compiling MySQL Cluster.
After you have run `make && make install` (or your system’s equivalent), the result is similar to what is obtained by unpacking a precompiled binary to the same location.

**Management nodes.** When building from source and running the default `make install`, the management server and management client binaries (`ndb_mgmd` and `ndb_mgm`) can be found in `/usr/local/mysql/bin`. Only `ndb_mgmd` is required to be present on a management node host; however, it is also a good idea to have `ndb_mgm` present on the same host machine. Neither of these executables requires a specific location on the host machine’s file system.

**Data nodes.** The only executable required on a data node host is the data node binary `ndbd` or `ndbmtd`. (`mysqld`, for example, does not have to be present on the host machine.) By default, when building from source, this file is placed in the directory `/usr/local/mysql/bin`. For installing on multiple data node hosts, only `ndbd` or `ndbmtd` need be copied to the other host machine or machines. (This assumes that all data node hosts use the same architecture and operating system; otherwise you may need to compile separately for each different platform.) The data node binary need not be in any particular location on the host's file system, as long as the location is known.

When compiling MySQL Cluster from source, no special options are required for building multi-threaded data node binaries. Configuring the build with NDB storage engine support causes `ndbmtd` to be built automatically; `make install` places the `ndbmtd` binary in the installation `bin` directory along with `mysqld`, `ndbd`, and `ndb_mgm`.

**SQL nodes.** If you compile MySQL with clustering support, and perform the default installation (using `make install` as the system root user), `mysqld` is placed in `/usr/local/mysql/bin`. Follow the steps given in Section 2.9, “Installing MySQL from Source” to make `mysqld` ready for use. If you want to run multiple SQL nodes, you can use a copy of the same `mysqld` executable and its associated support files on several machines. The easiest way to do this is to copy the entire `/usr/local/mysql` directory and all directories and files contained within it to the other SQL node host or hosts, then repeat the steps from Section 2.9, “Installing MySQL from Source” on each machine. If you configure the build with a nondefault `PREFIX` option, you must adjust the directory accordingly.

In Section 18.2.3, “Initial Configuration of MySQL Cluster”, we create configuration files for all of the nodes in our example MySQL Cluster.

### 18.2.2 Installing MySQL Cluster on Windows

MySQL Cluster NDB 7.2 binaries for Windows can be obtained from [http://dev.mysql.com/downloads/cluster/](http://dev.mysql.com/downloads/cluster/). For information about installing MySQL Cluster on Windows from a binary release provided by Oracle, see Section 18.2.2.1, “Installing MySQL Cluster on Windows from a Binary Release”.

It is also possible to compile and install MySQL Cluster from source on Windows using Microsoft Visual Studio. For more information, see Section 18.2.2.2, “Compiling and Installing MySQL Cluster from Source on Windows”.

#### 18.2.2.1 Installing MySQL Cluster on Windows from a Binary Release

This section describes a basic installation of MySQL Cluster on Windows using a binary `no-install` MySQL Cluster release provided by Oracle, using the same 4-node setup outlined in the beginning of this section (see Section 18.2, “MySQL Cluster Installation and Upgrades”), as shown in the following table:

<table>
<thead>
<tr>
<th>Node</th>
<th>IP Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Management (MGMD) node</td>
<td>192.168.0.10</td>
</tr>
<tr>
<td>MySQL server (SQL) node</td>
<td>192.168.0.20</td>
</tr>
<tr>
<td>Data (NDBD) node &quot;A&quot;</td>
<td>192.168.0.30</td>
</tr>
</tbody>
</table>
As on other platforms, the MySQL Cluster host computer running an SQL node must have installed on it a MySQL Server binary (\texttt{mysqld.exe}). You should also have the MySQL client (\texttt{mysql.exe}) on this host. For management nodes and data nodes, it is not necessary to install the MySQL Server binary; however, each management node requires the management server daemon (\texttt{ndb_mgmd.exe}); each data node requires the data node daemon (\texttt{ndbd.exe} or \texttt{ndbmtd.exe}). For this example, we refer to \texttt{ndbd.exe} as the data node executable, but you can install \texttt{ndbmtd.exe}, the multi-threaded version of this program, instead, in exactly the same way. You should also install the management client (\texttt{ndb_mgm.exe}) on the management server host. This section covers the steps necessary to install the correct Windows binaries for each type of MySQL Cluster node.

\begin{table}[h]
\centering
\begin{tabular}{|l|l|}
\hline
\textbf{Node} & \textbf{IP Address} \\
\hline
Data (NDBD) node “B” & 192.168.0.40 \\
\hline
\end{tabular}
\end{table}

For setting up a MySQL Cluster using Oracles's \texttt{no-install} binaries, the first step in the installation process is to download the latest MySQL Cluster Windows binary archive from \url{http://dev.mysql.com/downloads/cluster/}. This archive has a filename of the form \texttt{mysql-cluster-gpl-noinstall-ver-winarch.zip}, where \texttt{ver} is the NDB storage engine version (such as 7.2.1), and \texttt{arch} is the architecture (32 for 32-bit binaries, and 64 for 64-bit binaries). For example, the MySQL Cluster NDB 7.2.1 \texttt{no-install} archive for 32-bit Windows systems is named \texttt{mysql-cluster-gpl-noinstall-7.2.1-win32.zip}.

You can run 32-bit MySQL Cluster binaries on both 32-bit and 64-bit versions of Windows; however, 64-bit MySQL Cluster binaries can be used only on 64-bit versions of Windows. If you are using a 32-bit version of Windows on a computer that has a 64-bit CPU, then you must use the 32-bit MySQL Cluster binaries.

To minimize the number of files that need to be downloaded from the Internet or copied between machines, we start with the computer where you intend to run the SQL node.

\textbf{SQL node.} We assume that you have placed a copy of the \texttt{no-install} archive in the directory \texttt{C:\Documents and Settings\username\My Documents\Downloads} on the computer having the IP address 192.168.0.20, where \texttt{username} is the name of the current user. (You can obtain this name using \texttt{ECHO %USERNAME%} on the command line.) To install and run MySQL Cluster executables as Windows services, this user should be a member of the \texttt{Administrators} group.

Extract all the files from the archive. The Extraction Wizard integrated with Windows Explorer is adequate for this task. (If you use a different archive program, be sure that it extracts all files and directories from the archive, and that it preserves the archive's directory structure.) When you are asked for a destination directory, enter \texttt{C:\}, which causes the Extraction Wizard to extract the archive to the directory \texttt{C:\mysql-cluster-gpl-noinstall-ver-winarch}. Rename this directory to \texttt{C:\mysql}.

Extract all the files from the archive. The Extraction Wizard integrated with Windows Explorer is adequate for this task. (If you use a different archive program, be sure that it extracts all files and directories from the archive, and that it preserves the archive's directory structure.) When you are asked for a destination directory, enter \texttt{C:\}, which causes the Extraction Wizard to extract the archive to the directory \texttt{C:\mysql-cluster-gpl-noinstall-ver-winarch}. Rename this directory to \texttt{C:\mysql}.

It is possible to install the MySQL Cluster binaries to directories other than \texttt{C:\mysql\bin}; however, if you do so, you must modify the paths shown in this procedure accordingly. In particular, if the MySQL Server (SQL node) binary is installed to a location other than \texttt{C:\mysql} or \texttt{C:\Program Files\MySQL\MySQL Server 5.5}, or if the SQL node's data directory is in a location other than \texttt{C:\mysql\data} or \texttt{C:\Program Files\MySQL\MySQL Server 5.5\data}, extra configuration options must be used on the command line or added to the \texttt{my.ini} or \texttt{my.cnf} file when starting the SQL node. For
Installing MySQL Cluster on Windows

more information about configuring a MySQL Server to run in a nonstandard location, see Section 2.3.7, “Installing MySQL on Microsoft Windows Using a noinstall Zip Archive”.

For a MySQL Server with MySQL Cluster support to run as part of a MySQL Cluster, it must be started with the options --ndbcluster and --ndb-connectstring. While you can specify these options on the command line, it is usually more convenient to place them in an option file. To do this, create a new text file in Notepad or another text editor. Enter the following configuration information into this file:

```
[mysqld]
# Options for mysqld process:
ndbcluster                      # run NDB storage engine
ndb-connectstring=192.168.0.10  # location of management server
```

You can add other options used by this MySQL Server if desired (see Section 2.3.7.2, “Creating an Option File”), but the file must contain the options shown, at a minimum. Save this file as C:\mysql\my.ini. This completes the installation and setup for the SQL node.

Data nodes. A MySQL Cluster data node on a Windows host requires only a single executable, one of either ndbd.exe or ndbmtd.exe. For this example, we assume that you are using ndbd.exe, but the same instructions apply when using ndbmtd.exe. On each computer where you wish to run a data node (the computers having the IP addresses 192.168.0.30 and 192.168.0.40), create the directories C:\mysql, C:\mysql\bin, and C:\mysql\cluster-data; then, on the computer where you downloaded and extracted the no-install archive, locate ndbd.exe in the C:\mysql\bin directory. Copy this file to the C:\mysql\bin directory on each of the two data node hosts.

To function as part of a MySQL Cluster, each data node must be given the address or hostname of the management server. You can supply this information on the command line using the --ndb-connectstring or -c option when starting each data node process. However, it is usually preferable to put this information in an option file. To do this, create a new text file in Notepad or another text editor and enter the following text:

```
[mysql_cluster]
# Options for data node process:
ndb-connectstring=192.168.0.10  # location of management server
```

Save this file as C:\mysql\my.ini on the data node host. Create another text file containing the same information and save it on as C:\mysql\my.ini on the other data node host, or copy the my.ini file from the first data node host to the second one, making sure to place the copy in the second data node’s C:\mysql directory. Both data node hosts are now ready to be used in the MySQL Cluster, which leaves only the management node to be installed and configured.

Management node. The only executable program required on a computer used for hosting a MySQL Cluster management node is the management server program ndb_mgmd.exe. However, in order to administer the MySQL Cluster once it has been started, you should also install the MySQL Cluster management client program ndb_mgm.exe on the same machine as the management server. Locate these two programs on the machine where you downloaded and extracted the no-install archive; this should be the directory C:\mysql\bin on the SQL node host. Create the directory C:\mysql\bin on the computer having the IP address 192.168.0.10, then copy both programs to this directory.

You should now create two configuration files for use by ndb_mgmd.exe:

1. A local configuration file to supply configuration data specific to the management node itself. Typically, this file needs only to supply the location of the MySQL Cluster global configuration file (see item 2).

To create this file, start a new text file in Notepad or another text editor, and enter the following information:
[mysql_cluster]
# Options for management node process
cfg-file=C:/mysql/bin/config.ini

Save this file as the plaintext file C:\mysql\bin\my.ini.

2. A global configuration file from which the management node can obtain configuration information governing the MySQL Cluster as a whole. At a minimum, this file must contain a section for each node in the MySQL Cluster, and the IP addresses or hostnames for the management node and all data nodes (HostName configuration parameter). It is also advisable to include the following additional information:

- The IP address or hostname of any SQL nodes
- The data memory and index memory allocated to each data node (DataMemory and IndexMemory configuration parameters)
- The number of replicas, using the NoOfReplicas configuration parameter (see Section 18.1.2, “MySQL Cluster Nodes, Node Groups, Replicas, and Partitions”)
- The directory where each data node stores its data and log file, and the directory where the management node keeps its log files (in both cases, the DataDir configuration parameter)

Create a new text file using a text editor such as Notepad, and input the following information:

[nbddefault]
# Options affecting ndbd processes on all data nodes:
NoOfReplicas=2                      # Number of replicas
DataDir=C:/mysql/bin/cluster-data   # Directory for each data node's data files
# Forward slashes used in directory path, rather than backslashes. This is correct; # see Important note in text
DataMemory=80M    # Memory allocated to data storage
IndexMemory=18M   # Memory allocated to index storage
# For DataMemory and IndexMemory, we have used the default values. Since the "world" database takes up only about 500KB, this should be more than enough for this example Cluster setup.

[ndb_mgmd]
# Management process options:
HostName=192.168.0.10               # Hostname or IP address of management node
DataDir=C:/mysql/bin/cluster-logs   # Directory for management node log files

[nbd]
# Options for data node "A":
HostName=192.168.0.30           # Hostname or IP address

[nbd]
# Options for data node "B":
HostName=192.168.0.40           # Hostname or IP address

[mysqld]
# SQL node options:
HostName=192.168.0.20           # Hostname or IP address

Save this file as the plaintext file C:\mysql\bin\config.ini.
Important

A single backslash character (\) cannot be used when specifying directory paths in program options or configuration files used by MySQL Cluster on Windows. Instead, you must either escape each backslash character with a second backslash (\\), or replace the backslash with a forward slash character (/). For example, the following line from the [ndb_mgmd] section of a MySQL Cluster config.ini file does not work:

```
DataDir=C:\mysql\bin\cluster-logs
```

Instead, you may use either of the following:

```
DataDir=C:\mysql\bin\cluster-logs  # Escaped backslashes
```
```
DataDir=C:/mysql/bin/cluster-logs     # Forward slashes
```

For reasons of brevity and legibility, we recommend that you use forward slashes in directory paths used in MySQL Cluster program options and configuration files on Windows.

18.2.2.2 Compiling and Installing MySQL Cluster from Source on Windows

Oracle provides precompiled MySQL Cluster binaries for Windows which should be adequate for most users. However, if you wish, it is also possible to compile MySQL Cluster for Windows from source code. The procedure for doing this is almost identical to the procedure used to compile the standard MySQL Server binaries for Windows, and uses the same tools. However, there are two major differences:

- To build MySQL Cluster, you must use the MySQL Cluster sources, which you can obtain from http://dev.mysql.com/downloads/cluster/.

  Attempting to build MySQL Cluster from the source code for the standard MySQL Server is likely not to be successful, and is not supported by Oracle.

- You must configure the build using the WITH_NDBCLUSTER_STORAGE_ENGINE or WITH_NDBCLUSTER option in addition to any other build options you wish to use with CMake. (WITH_NDBCLUSTER is supported as an alias for WITH_NDBCLUSTER_STORAGE_ENGINE, and works in exactly the same way.)

Important

Beginning with MySQL Cluster NDB 7.2.9, the WITH_NDB_JAVA option is enabled by default. This means that, by default, if CMake cannot find the location of Java on your system, the configuration process fails; if you do not wish to enable Java and ClusterJ support, you must indicate this explicitly by configuring the build using -DWITH_NDB_JAVA=OFF. (Bug #12379735) Use WITH_CLASSPATH to provide the Java classpath if needed.

For more information about CMake options specific to building MySQL Cluster, see Options for Compiling MySQL Cluster.

Once the build process is complete, you can create a Zip archive containing the compiled binaries; Section 2.9.2, “Installing MySQL Using a Standard Source Distribution” provides the commands needed to perform this task on Windows systems. The MySQL Cluster binaries can be found in the bin directory of the resulting archive, which is equivalent to the no-install archive, and which can be installed and
configured in the same manner. For more information, see Section 18.2.2.1, “Installing MySQL Cluster on Windows from a Binary Release”.

18.2.2.3 Initial Startup of MySQL Cluster on Windows

Once the MySQL Cluster executables and needed configuration files are in place, performing an initial start of the cluster is simply a matter of starting the MySQL Cluster executables for all nodes in the cluster. Each cluster node process must be started separately, and on the host computer where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes.

1. On the management node host, issue the following command from the command line to start the management node process:

```
C:\mysql\bin> ndb_mgmd
2010-06-23 07:53:34 [MgmtSrvr] INFO -- NDB Cluster Management Server. mysql-5.5.38-ndb-7.2.18
2010-06-23 07:53:34 [MgmtSrvr] INFO -- Reading cluster configuration from 'config.ini'
```

The management node process continues to print logging output to the console. This is normal, because the management node is not running as a Windows service. (If you have used MySQL Cluster on a Unix-like platform such as Linux, you may notice that the management node's default behavior in this regard on Windows is effectively the opposite of its behavior on Unix systems, where it runs by default as a Unix daemon process. This behavior is also true of MySQL Cluster data node processes running on Windows.) For this reason, do not close the window in which ndb_mgmd.exe is running; doing so kills the management node process. (See Section 18.2.2.4, “Installing MySQL Cluster Processes as Windows Services”, where we show how to install and run MySQL Cluster processes as Windows services.)

The required -f option tells the management node where to find the global configuration file (config.ini). The long form of this option is --config-file.

**Important**

A MySQL Cluster management node caches the configuration data that it reads from config.ini; once it has created a configuration cache, it ignores the config.ini file on subsequent starts unless forced to do otherwise. This means that, if the management node fails to start due to an error in this file, you must make the management node re-read config.ini after you have corrected any errors in it. You can do this by starting ndb_mgmd.exe with the --reload or --initial option on the command line. Either of these options works to refresh the configuration cache.

It is not necessary or advisable to use either of these options in the management node's my.ini file.

For additional information about options which can be used with ndb_mgmd, see Section 18.4.4, "ndb_mgmd — The MySQL Cluster Management Server Daemon", as well as Section 18.4.25, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

2. On each of the data node hosts, run the command shown here to start the data node processes:

```
C:\mysql\bin> ndbd
```

In each case, the first line of output from the data node process should resemble what is shown in the preceding example, and is followed by additional lines of logging output. As with the management node process, this is normal, because the data node is not running as a Windows service. For this reason, do
not close the console window in which the data node process is running; doing so kills ndbd.exe. (For more information, see Section 18.2.2.4, “Installing MySQL Cluster Processes as Windows Services”.)

3. Do not start the SQL node yet; it cannot connect to the cluster until the data nodes have finished starting, which may take some time. Instead, in a new console window on the management node host, start the MySQL Cluster management client ndb_mgm.exe, which should be in C:\mysql\bin on the management node host. (Do not try to re-use the console window where ndb_mgmd.exe is running by typing CTRL+C, as this kills the management node.) The resulting output should look like this:

C:\mysql\bin> ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm>

When the prompt ndb_mgm> appears, this indicates that the management client is ready to receive MySQL Cluster management commands. You can observe the status of the data nodes as they start by entering ALL STATUS at the management client prompt. This command causes a running report of the data nodes’s startup sequence, which should look something like this:

ndb_mgm> ALL STATUS
Connected to Management Server at: localhost:1186
Node 2: starting (Last completed phase 3) (mysql-5.5.38-ndb-7.2.18)
Node 3: starting (Last completed phase 3) (mysql-5.5.38-ndb-7.2.18)

Node 2: starting (Last completed phase 4) (mysql-5.5.38-ndb-7.2.18)
Node 3: starting (Last completed phase 4) (mysql-5.5.38-ndb-7.2.18)

Node 2: Started (version 7.2.18)
Node 3: Started (version 7.2.18)

ndb_mgm>

Note

Commands issued in the management client are not case-sensitive; we use uppercase as the canonical form of these commands, but you are not required to observe this convention when inputting them into the ndb_mgm client. For more information, see Section 18.5.2, “Commands in the MySQL Cluster Management Client”.

The output produced by ALL STATUS is likely to vary from what is shown here, according to the speed at which the data nodes are able to start, the release version number of the MySQL Cluster software you are using, and other factors. What is significant is that, when you see that both data nodes have started, you are ready to start the SQL node.

You can leave ndb_mgm.exe running; it has no negative impact on the performance of the MySQL Cluster, and we use it in the next step to verify that the SQL node is connected to the cluster after you have started it.

4. On the computer designated as the SQL node host, open a console window and navigate to the directory where you unpacked the MySQL Cluster binaries (if you are following our example, this is C: \mysql\bin).

Start the SQL node by invoking mysqld.exe from the command line, as shown here:

C:\mysql\bin> mysqld --console
Installing MySQL Cluster on Windows

The `--console` option causes logging information to be written to the console, which can be helpful in the event of problems. (Once you are satisfied that the SQL node is running in a satisfactory manner, you can stop it and restart it without the `--console` option, so that logging is performed normally.)

In the console window where the management client (`ndb_mgm.exe`) is running on the management node host, enter the `SHOW` command, which should produce output similar to what is shown here:

```
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[ndbd(NDB)] 2 node(s)  
id=2 192.168.0.30 (Version: 5.5.38-ndb-7.2.18, Nodegroup: 0, *)
id=3 192.168.0.40 (Version: 5.5.38-ndb-7.2.18, Nodegroup: 0)
[ndb_mgmd(MGM)] 1 node(s)  
id=1 192.168.0.10 (Version: 5.5.38-ndb-7.2.18)
[mysqld(API)] 1 node(s)  
id=4 192.168.0.20 (Version: 5.5.38-ndb-7.2.18)
```

You can also verify that the SQL node is connected to the MySQL Cluster in the `mysql` client (`mysql.exe`) using the `SHOW ENGINE NDB STATUS` statement.

You should now be ready to work with database objects and data using MySQL Cluster's NDBCLUSTER storage engine. See Section 18.2.5, “MySQL Cluster Example with Tables and Data”, for more information and examples.

You can also install `ndb_mgmd.exe`, `ndbd.exe`, and `ndbmtd.exe` as Windows services. For information on how to do this, see Section 18.2.2.4, “Installing MySQL Cluster Processes as Windows Services”).

### 18.2.2.4 Installing MySQL Cluster Processes as Windows Services

Once you are satisfied that MySQL Cluster is running as desired, you can install the management nodes and data nodes as Windows services, so that these processes are started and stopped automatically whenever Windows is started or stopped. This also makes it possible to control these processes from the command line with the appropriate `NET START` or `NET STOP` command, or using the Windows graphical Services utility.

Installing programs as Windows services usually must be done using an account that has Administrator rights on the system.

To install the management node as a service on Windows, invoke `ndb_mgmd.exe` from the command line on the machine hosting the management node, using the `--install` option, as shown here:

```
C:\> C:\mysql\bin\ndb_mgmd.exe --install
Installing service 'MySQL Cluster Management Server'  
as "C:\mysql\bin\ndb_mgmd.exe" "--service=ndb_mgmd"
Service successfully installed.
```

---

**Important**

When installing a MySQL Cluster program as a Windows service, you should always specify the complete path; otherwise the service installation may fail with the error **The system cannot find the file specified.**

The `--install` option must be used first, ahead of any other options that might be specified for `ndb_mgmd.exe`. However, it is preferable to specify such options in an options file instead. If your options
file is not in one of the default locations as shown in the output of `ndb_mgmd.exe --help`, you can specify the location using the `--config-file` option.

Now you should be able to start and stop the management server like this:

```cmd
C:\> NET START ndb_mgmd
The MySQL Cluster Management Server service is starting.
The MySQL Cluster Management Server service was started successfully.
C:\> NET STOP ndb_mgmd
The MySQL Cluster Management Server service is stopping..
The MySQL Cluster Management Server service was stopped successfully.
```

You can also start or stop the management server as a Windows service using the descriptive name, as shown here:

```cmd
C:\> NET START 'MySQL Cluster Management Server'
The MySQL Cluster Management Server service is starting.
The MySQL Cluster Management Server service was started successfully.
C:\> NET STOP 'MySQL Cluster Management Server'
The MySQL Cluster Management Server service is stopping..
The MySQL Cluster Management Server service was stopped successfully.
```

However, it is usually simpler to specify a short service name or to permit the default service name to be used when installing the service, and then reference that name when starting or stopping the service. To specify a service name other than `ndb_mgmd`, append it to the `--install` option, as shown in this example:

```cmd
C:\> C:\mysql\bin\ndb_mgmd.exe --install=mgmd1
Installing service 'MySQL Cluster Management Server' as '"C:\mysql\bin\ndb_mgmd.exe" "--service=mgmd1"'
Service successfully installed.
```

Now you should be able to start or stop the service using the name you have specified, like this:

```cmd
C:\> NET START mgmd1
The MySQL Cluster Management Server service is starting.
The MySQL Cluster Management Server service was started successfully.
C:\> NET STOP mgmd1
The MySQL Cluster Management Server service is stopping..
The MySQL Cluster Management Server service was stopped successfully.
```

To remove the management node service, invoke `ndb_mgmd.exe` with the `--remove` option, as shown here:

```cmd
C:\> C:\mysql\bin\ndb_mgmd.exe --remove
Removing service 'MySQL Cluster Management Server'
Service successfully removed.
```

If you installed the service using a service name other than the default, you can remove the service by passing this name as the value of the `--remove` option, like this:

```cmd
C:\> C:\mysql\bin\ndb_mgmd.exe --remove=mgmd1
Removing service 'mgmd1'
Service successfully removed.
```
Installation of a MySQL Cluster data node process as a Windows service can be done in a similar fashion, using the `--install` option for `ndbd.exe` (or `ndbmtd.exe`), as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --install
Installing service 'MySQL Cluster Data Node Daemon' as "C:\mysql\bin\ndbd.exe" "--service=ndbd"
Service successfully installed.
```

Now you can start or stop the data node using either the default service name or the descriptive name with `net start` or `net stop`, as shown in the following example:

```
C:\> NET START ndbd
The MySQL Cluster Data Node Daemon service is starting.
The MySQL Cluster Data Node Daemon service was started successfully.
C:\> NET STOP ndbd
The MySQL Cluster Data Node Daemon service is stopping..
The MySQL Cluster Data Node Daemon service was stopped successfully.
C:\> NET START 'MySQL Cluster Data Node Daemon'
The MySQL Cluster Data Node Daemon service is starting.
The MySQL Cluster Data Node Daemon service was started successfully.
C:\> NET STOP 'MySQL Cluster Data Node Daemon'
The MySQL Cluster Data Node Daemon service is stopping..
The MySQL Cluster Data Node Daemon service was stopped successfully.
```

To remove the data node service, invoke `ndbd.exe` with the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --remove
Removing service 'MySQL Cluster Data Node Daemon'
Service successfully removed.
```

As with `ndb_mgmd.exe` (and `mysqld.exe`), when installing `ndbd.exe` as a Windows service, you can also specify a name for the service as the value of `--install`, and then use it when starting or stopping the service, like this:

```
C:\> C:\mysql\bin\ndbd.exe --install=dnode1
Installing service 'dnode1' as "C:\mysql\bin\ndbd.exe" "--service=dnode1"
Service successfully installed.
C:\> NET START dnode1
The MySQL Cluster Data Node Daemon service is starting.
The MySQL Cluster Data Node Daemon service was started successfully.
C:\> NET STOP dnode1
The MySQL Cluster Data Node Daemon service is stopping..
The MySQL Cluster Data Node Daemon service was stopped successfully.
```

If you specified a service name when installing the data node service, you can use this name when removing it as well, by passing it as the value of the `--remove` option, as shown here:

```
C:\> C:\mysql\bin\ndbd.exe --remove=dnode1
Removing service 'dnode1'
Service successfully removed.
```

Installation of the SQL node as a Windows service, starting the service, stopping the service, and removing the service are done in a similar fashion, using `mysqld --install`, `NET START`, `NET STOP`, and `mysqld --remove`. For additional information, see Section 2.3.7.7, “Starting MySQL as a Windows Service”. 
18.2.3 Initial Configuration of MySQL Cluster

For our four-node, four-host MySQL Cluster, it is necessary to write four configuration files, one per node host.

- Each data node or SQL node requires a `my.cnf` file that provides two pieces of information: a **connection string** that tells the node where to find the management node, and a line telling the MySQL server on this host (the machine hosting the data node) to enable the **ndbcluster** storage engine.

  For more information on connection strings, see Section 18.3.2.3, “MySQL Cluster Connection Strings”.

- The management node needs a `config.ini` file telling it how many replicas to maintain, how much memory to allocate for data and indexes on each data node, where to find the data nodes, where to save data to disk on each data node, and where to find any SQL nodes.

**Configuring the data nodes and SQL nodes.** The `my.cnf` file needed for the data nodes is fairly simple. The configuration file should be located in the `/etc` directory and can be edited using any text editor. (Create the file if it does not exist.) For example:

```shell
vi /etc/my.cnf
```

*Note*

We show `vi` being used here to create the file, but any text editor should work just as well.

For each data node and SQL node in our example setup, `my.cnf` should look like this:

```ini
[mysqld]
# Options for mysqld process:
ndbcluster # run NDB storage engine

[mysql_cluster]
# Options for MySQL Cluster processes:
ndb-connectstring=192.168.0.10 # location of management server
```

After entering the preceding information, save this file and exit the text editor. Do this for the machines hosting data node “A”, data node “B”, and the SQL node.

*Important*

Once you have started a `mysqld` process with the `ndbcluster` and `ndb-connectstring` parameters in the `[mysqld]` and `[mysql_cluster]` sections of the `my.cnf` file as shown previously, you cannot execute any `CREATE TABLE` or `ALTER TABLE` statements without having actually started the cluster. Otherwise, these statements will fail with an error. This is by design.

**Configuring the management node.** The first step in configuring the management node is to create the directory in which the configuration file can be found and then to create the file itself. For example (running as `root`):

```shell
mkdir /var/lib/mysql-cluster
cd /var/lib/mysql-cluster
vi config.ini
```

For our representative setup, the `config.ini` file should read as follows:
Initial Startup of MySQL Cluster

---

```
[ndbd default]
# Options affecting ndbd processes on all data nodes:
NoOfReplicas=2    # Number of replicas
DataMemory=80M    # How much memory to allocate for data storage
IndexMemory=18M   # How much memory to allocate for index storage
# For DataMemory and IndexMemory, we have used the
# default values. Since the "world" database takes up
# only about 500KB, this should be more than enough for
# this example Cluster setup.

[tcp default]
# TCP/IP options:
portnumber=2202   # This the default; however, you can use any
# port that is free for all the hosts in the cluster
# Note: It is recommended that you do not specify the port
# number at all and simply allow the default value to be used
# instead

[ndb_mgmd]
# Management process options:
hostname=192.168.0.10           # Hostname or IP address of MGM node
datadir=/var/lib/mysql-cluster  # Directory for MGM node log files

[ndbd]
# Options for data node "A":
hostname=192.168.0.30           # Hostname or IP address
datadir=/usr/local/mysql/data   # Directory for this data node's data files

[ndbd]
# Options for data node "B":
hostname=192.168.0.40           # Hostname or IP address
datadir=/usr/local/mysql/data   # Directory for this data node's data files

[mysqld]
# SQL node options:
hostname=192.168.0.20           # Hostname or IP address
# (additional mysqld connections can be
# specified for this node for various
# purposes such as running ndb_restore)
```

---

**Note**

The `world` database can be downloaded from [http://dev.mysql.com/doc/](http://dev.mysql.com/doc/), where it can be found listed under "Examples".

After all the configuration files have been created and these minimal options have been specified, you are ready to proceed with starting the cluster and verifying that all processes are running. We discuss how this is done in Section 18.2.4, “Initial Startup of MySQL Cluster”.

For more detailed information about the available MySQL Cluster configuration parameters and their uses, see Section 18.3.2, “MySQL Cluster Configuration Files”, and Section 18.3, “Configuration of MySQL Cluster NDB 7.2”. For configuration of MySQL Cluster as relates to making backups, see Section 18.5.3.3, “Configuration for MySQL Cluster Backups”.

---

**Note**

The default port for Cluster management nodes is 1186; the default port for data nodes is 2202. However, the cluster can automatically allocate ports for data nodes from those that are already free.

---

18.2.4 Initial Startup of MySQL Cluster
Starting the cluster is not very difficult after it has been configured. Each cluster node process must be started separately, and on the host where it resides. The management node should be started first, followed by the data nodes, and then finally by any SQL nodes:

1. On the management host, issue the following command from the system shell to start the management node process:
   
   ```shell
   ndb_mgmd -f /var/lib/mysql-cluster/config.ini
   ```
   
   The first time that it is started, `ndb_mgmd` must be told where to find its configuration file, using the `-f` or `--config-file` option. (See Section 18.4.4, “`ndb_mgmd` — The MySQL Cluster Management Server Daemon”, for details.)

   For additional options which can be used with `ndb_mgmd`, see Section 18.4.25, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

2. On each of the data node hosts, run this command to start the `ndbd` process:
   
   ```shell
   ndbd
   ```

3. If you used RPM files to install MySQL on the cluster host where the SQL node is to reside, you can (and should) use the supplied startup script to start the MySQL server process on the SQL node.

If all has gone well, and the cluster has been set up correctly, the cluster should now be operational. You can test this by invoking the `ndb_mgm` management node client. The output should look like that shown here, although you might see some slight differences in the output depending upon the exact version of MySQL that you are using:

```shell
ndb_mgm
-- NDB Cluster -- Management Client --
ndb_mgm> SHOW
Connected to Management Server at: localhost:1186
Cluster Configuration
---------------------
[nbd(NDB)] 2 node(s)
id=2 @192.168.0.30 (Version: 5.5.38-ndb-7.2.18, Nodegroup: 0, *)
id=3 @192.168.0.40 (Version: 5.5.38-ndb-7.2.18, Nodegroup: 0)

[nbd_mgmd(MGM)] 1 node(s)
id=1 @192.168.0.10 (Version: 5.5.38-ndb-7.2.18)

[mysqld(API)] 1 node(s)
id=4 @192.168.0.20 (Version: 5.5.38-ndb-7.2.18)
```

The SQL node is referenced here as `[mysqld(API)]`, which reflects the fact that the `mysqld` process is acting as a MySQL Cluster API node.

**Note**

The IP address shown for a given MySQL Cluster SQL or other API node in the output of `SHOW` is the address used by the SQL or API node to connect to the cluster data nodes, and not to any management node.

You should now be ready to work with databases, tables, and data in MySQL Cluster. See Section 18.2.5, “MySQL Cluster Example with Tables and Data”, for a brief discussion.
MySQL Cluster Example with Tables and Data

Note
The information in this section applies to MySQL Cluster running on both Unix and Windows platforms.

Working with database tables and data in MySQL Cluster is not much different from doing so in standard MySQL. There are two key points to keep in mind:

- For a table to be replicated in the cluster, it must use the NDBCLUSTER storage engine. To specify this, use the ENGINE=NDBCLUSTER or ENGINE=NDB option when creating the table:

  ```sql
  CREATE TABLE tbl_name (col_name column_definitions) ENGINE=NDBCLUSTER;
  ```

  Alternatively, for an existing table that uses a different storage engine, use ALTER TABLE to change the table to use NDBCLUSTER:

  ```sql
  ALTER TABLE tbl_name ENGINE=NDBCLUSTER;
  ```

- Every NDBCLUSTER table has a primary key. If no primary key is defined by the user when a table is created, the NDBCLUSTER storage engine automatically generates a hidden one. Such a key takes up space just as does any other table index. (It is not uncommon to encounter problems due to insufficient memory for accommodating these automatically created indexes.)

If you are importing tables from an existing database using the output of mysqldump, you can open the SQL script in a text editor and add the ENGINE option to any table creation statements, or replace any existing ENGINE options. Suppose that you have the world sample database on another MySQL server that does not support MySQL Cluster, and you want to export the City table:

```shell
shell> mysqldump --add-drop-table world City > city_table.sql
```

The resulting city_table.sql file will contain this table creation statement (and the INSERT statements necessary to import the table data):

```sql
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
  `CountryCode` char(3) NOT NULL default '',
  `District` char(20) NOT NULL default '',
  `Population` int(11) NOT NULL default '0',
  PRIMARY KEY (`ID`)
) ENGINE=MyISAM DEFAULT CHARSET=latin1;
```

You need to make sure that MySQL uses the NDBCLUSTER storage engine for this table. There are two ways that this can be accomplished. One of these is to modify the table definition before importing it into the Cluster database. Using the City table as an example, modify the ENGINE option of the definition as follows:

```sql
DROP TABLE IF EXISTS `City`;
CREATE TABLE `City` (
  `ID` int(11) NOT NULL auto_increment,
  `Name` char(35) NOT NULL default '',
```
This must be done for the definition of each table that is to be part of the clustered database. The easiest way to accomplish this is to do a search-and-replace on the file that contains the definitions and replace all instances of `TYPE=engine_name` or `ENGINE=engine_name` with `ENGINE=NDBCLUSTER`. If you do not want to modify the file, you can use the unmodified file to create the tables, and then use `ALTER TABLE` to change their storage engine. The particulars are given later in this section.

Assuming that you have already created a database named `world` on the SQL node of the cluster, you can then use the `mysql` command-line client to read `city_table.sql`, and create and populate the corresponding table in the usual manner:

```
shell> mysql world < city_table.sql
```

It is very important to keep in mind that the preceding command must be executed on the host where the SQL node is running (in this case, on the machine with the IP address `192.168.0.20`).

To create a copy of the entire `world` database on the SQL node, use `mysqldump` on the noncluster server to export the database to a file named `world.sql`; for example, in the `/tmp` directory. Then modify the table definitions as just described and import the file into the SQL node of the cluster like this:

```
shell> mysql world < /tmp/world.sql
```

If you save the file to a different location, adjust the preceding instructions accordingly.

Running `SELECT` queries on the SQL node is no different from running them on any other instance of a MySQL server. To run queries from the command line, you first need to log in to the MySQL Monitor in the usual way (specify the `root` password at the `Enter password:` prompt):

```
shell> mysql -u root -p
Enter password:
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 1 to server version: 5.5.38-ndb-7.2.18
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
mysql>
```

We simply use the MySQL server's `root` account and assume that you have followed the standard security precautions for installing a MySQL server, including setting a strong `root` password. For more information, see Section 2.10.2, “Securing the Initial MySQL Accounts”.

It is worth taking into account that Cluster nodes do not make use of the MySQL privilege system when accessing one another. Setting or changing MySQL user accounts (including the `root` account) effects only applications that access the SQL node, not interaction between nodes. See Section 18.5.11.2, “MySQL Cluster and MySQL Privileges”, for more information.

If you did not modify the `ENGINE` clauses in the table definitions prior to importing the SQL script, you should run the following statements at this point:
Selecting a database and running a `SELECT` query against a table in that database is also accomplished in the usual manner, as is exiting the MySQL Monitor:

```
mysql> USE world;
mysql> SELECT Name, Population FROM City ORDER BY Population DESC LIMIT 5;
+-----------+------------+
<table>
<thead>
<tr>
<th>Name</th>
<th>Population</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bombay</td>
<td>10500000</td>
</tr>
<tr>
<td>Seoul</td>
<td>9981619</td>
</tr>
<tr>
<td>São Paulo</td>
<td>9968485</td>
</tr>
<tr>
<td>Shanghai</td>
<td>9696300</td>
</tr>
<tr>
<td>Jakarta</td>
<td>9604900</td>
</tr>
</tbody>
</table>
+-----------+------------+
5 rows in set (0.34 sec)
```

Applications that use MySQL can employ standard APIs to access NDB tables. It is important to remember that your application must access the SQL node, and not the management or data nodes. This brief example shows how we might execute the `SELECT` statement just shown by using the PHP 5.X `mysqli` extension running on a Web server elsewhere on the network:

```php
<?php
    # connect to SQL node:
    $link = new mysqli('192.168.0.20', 'root', 'root_password', 'world');
    # parameters for mysqli constructor are:
    # host, user, password, database
    if( mysqli_connect_errno() )
        die("Connect failed: ". mysqli_connect_error());
    $query = "SELECT Name, Population
                FROM City
                ORDER BY Population DESC
                LIMIT 5";
    # if no errors...
    if( $result = $link->query($query) )
    {
        ?>
        <table border="1" width="40%" cellpadding="4" cellspacing ="1">
        <tbody>
            <tr>
                <th width="10%">City</th>
                <th>Population</th>
```
Safe Shutdown and Restart of MySQL Cluster

18.2.6 Safe Shutdown and Restart of MySQL Cluster

To shut down the cluster, enter the following command in a shell on the machine hosting the management node:

```
shell> ndb_mgm -e shutdown
```

The `-e` option here is used to pass a command to the `ndb_mgm` client from the shell. (See Section 18.4.25, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”, for more information about this option.) The command causes the `ndb_mgm`, `ndb_mgmd`, and any `ndbd` or `ndbmtd` processes to terminate gracefully. Any SQL nodes can be terminated using `mysqladmin shutdown` and other means. On Windows platforms, assuming that you have installed the SQL node as a Windows service, you can use `NET STOP MYSQL`.

To restart the cluster on Unix platforms, run these commands:

- On the management host (**192.168.0.10** in our example setup):

  ```
  shell> ndb_mgmd -f /var/lib/mysql-cluster/config.ini
  ```

- On each of the data node hosts (**192.168.0.30** and **192.168.0.40**):

  ```
  shell> ndbd
  ```

- Use the `ndb_mgm` client to verify that both data nodes have started successfully.

- On the SQL host (**192.168.0.20**):

  ```
  shell> mysqld_safe &
  ```

We assume that the process running on the Web server can reach the IP address of the SQL node.

In a similar fashion, you can use the MySQL C API, Perl-DBI, Python-mysql, or MySQL Connectors to perform the tasks of data definition and manipulation just as you would normally with MySQL.
On Windows platforms, assuming that you have installed all MySQL Cluster processes as Windows services using the default service names (see Section 18.2.2.4, “Installing MySQL Cluster Processes as Windows Services”), you can restart the cluster as follows:

- On the management host (192.168.0.10 in our example setup), execute the following command:

  C:\> NET START ndb_mgmd

- On each of the data node hosts (192.168.0.30 and 192.168.0.40), execute the following command:

  C:\> NET START ndbd

- On the management node host, use the ndb_mgm client to verify that the management node and both data nodes have started successfully (see Section 18.2.2.3, “Initial Startup of MySQL Cluster on Windows”).

- On the SQL node host (192.168.0.20), execute the following command:

  C:\> NET START mysql

In a production setting, it is usually not desirable to shut down the cluster completely. In many cases, even when making configuration changes, or performing upgrades to the cluster hardware or software (or both), which require shutting down individual host machines, it is possible to do so without shutting down the cluster as a whole by performing a rolling restart of the cluster. For more information about doing this, see Section 18.5.5, “Performing a Rolling Restart of a MySQL Cluster”.

### 18.2.7 Upgrading and Downgrading MySQL Cluster NDB 7.2

This section provides information about MySQL Cluster software and table file compatibility between different MySQL Cluster NDB 7.2 releases with regard to performing upgrades and downgrades as well as compatibility matrices and notes. You are expected already to be familiar with installing and configuring a MySQL Cluster prior to attempting an upgrade or downgrade. See Section 18.3, “Configuration of MySQL Cluster NDB 7.2”.

For information regarding the rolling restart procedure used to perform an online upgrade, see Section 18.5.5, “Performing a Rolling Restart of a MySQL Cluster”.

**Important**

Only compatibility between MySQL versions with regard to NDBCLUSTER is taken into account in this section, and there are likely other issues to be considered. As with any other MySQL software upgrade or downgrade, you are strongly encouraged to review the relevant portions of the MySQL Manual for the MySQL versions from which and to which you intend to migrate, before attempting an upgrade or downgrade of the MySQL Cluster software. This is especially true when planning a migration from MySQL Cluster NDB 7.1 (or earlier) to MySQL Cluster NDB 7.2, since the version of the underlying MySQL Server also changes from MySQL 5.1 to MySQL 5.5. See Section 2.11.1, “Upgrading MySQL”.

The table shown here provides information on MySQL Cluster upgrade and downgrade compatibility among different releases of MySQL Cluster NDB 7.2. Additional notes about upgrades and downgrades to, from, or within the MySQL Cluster NDB 7.2 release series can be found immediately following the table.

</tr>
</tbody>
</table>

* Not released, or withdrawn following release.
Notes: MySQL Cluster NDB 7.2

**Versions supported.** The following versions of MySQL Cluster are supported for upgrades to MySQL Cluster NDB 7.2 (7.2.4 and later):

- MySQL Cluster NDB 7.1 GA releases (7.1.3 and later)
- MySQL Cluster NDB 7.0 GA releases (7.0.5 and later)
- MySQL Cluster NDB 6.3 GA releases (6.3.8 and later) that can be upgraded to MySQL Cluster NDB 7.1

For information about upgrades and downgrades in previous MySQL Cluster release series, see Upgrade and Downgrade Compatibility: MySQL Cluster NDB 6.x, and Upgrade and downgrade compatibility: MySQL Cluster NDB 7.x.

NDB API, ClusterJ, and other applications used with recent releases of MySQL Cluster NDB 6.3 and later should continue to work with MySQL Cluster NDB 7.2.4 and later without rewriting or recompiling.

In MySQL Cluster NDB 7.2, the default values for a number of node configuration parameters have changed. See Improved default values for data node configuration parameters, for a listing of these.

Other known issues include the following:

- In MySQL Cluster NDB 7.2.7 and later, the size of the hash map is 3840 LDM threads, an increase from 240 in previous versions. When upgrading a MySQL Cluster from MySQL Cluster NDB 7.2.6 and earlier to MySQL Cluster NDB 7.2.9 or later, you can modify existing tables online to take advantage of the new size: following the upgrade, increase the number of fragments by (for example) adding new data nodes to the cluster, and then execute `ALTER ONLINE TABLE ... REORGANIZE PARTITION` on any tables that were created in the older version. Following this, these tables can use the larger hash map size. (Bug #14645319)

  Due to this change, it was not possible to downgrade online to MySQL Cluster NDB 7.2.6 or earlier. This issue was resolved in MySQL Cluster NDB 7.2.11, where the size is made configurable using the `DefaultHashMapSize` parameter. (Bug #14800539) See the description of this parameter for more information.

- It is not possible to downgrade online to MySQL Cluster NDB 7.2.13 or earlier from MySQL Cluster NDB 7.2.14 or later. Online upgrades from MySQL Cluster NDB 7.2.13 to later MySQL Cluster NDB 7.2 releases are supported.

### 18.3 Configuration of MySQL Cluster NDB 7.2

A MySQL server that is part of a MySQL Cluster differs in one chief respect from a normal (nonclustered) MySQL server, in that it employs the **NDB** storage engine. This engine is also referred to sometimes as **NDBCLUSTER**, although **NDB** is preferred.

To avoid unnecessary allocation of resources, the server is configured by default with the **NDB** storage engine disabled. To enable **NDB**, you must modify the server’s `my.cnf` configuration file, or start the server with the **--ndbcluster** option.

This MySQL server is a part of the cluster, so it also must know how to access an management node to obtain the cluster configuration data. The default behavior is to look for the management node on **localhost**. However, should you need to specify that its location is elsewhere, this can be done in `my.cnf`, or with the `mysql` client. Before the **NDB** storage engine can be used, at least one management node must be operational, as well as any desired data nodes.
Quick Test Setup of MySQL Cluster

For more information about `--ndbcluster` and other `mysqld` options specific to MySQL Cluster, see Section 18.3.4.2, “MySQL Server Options for MySQL Cluster”.

For information about installing MySQL Cluster, see Section 18.2, “MySQL Cluster Installation and Upgrades”.

18.3.1 Quick Test Setup of MySQL Cluster

To familiarize you with the basics, we will describe the simplest possible configuration for a functional MySQL Cluster. After this, you should be able to design your desired setup from the information provided in the other relevant sections of this chapter.

First, you need to create a configuration directory such as `/var/lib/mysql-cluster`, by executing the following command as the system root user:

```
shell> mkdir /var/lib/mysql-cluster
```

In this directory, create a file named `config.ini` that contains the following information. Substitute appropriate values for `HostName` and `DataDir` as necessary for your system.

```ini
# file "config.ini" - showing minimal setup consisting of 1 data node,
# 1 management server, and 3 MySQL servers.
# The empty default sections are not required, and are shown only for
# the sake of completeness.
# Data nodes must provide a hostname but MySQL Servers are not required
# to do so.
# If you don't know the hostname for your machine, use localhost.
# The DataDir parameter also has a default value, but it is recommended to
# set it explicitly.
# Note: [db], [api], and [mgm] are aliases for [ndbd], [mysqld], and [ndb_mgmd],
# respectively. [db] is deprecated and should not be used in new installations.

[ndbd default]
NoOfReplicas= 1

[mysqld default]
[ndb_mgmd default]
[tcp default]

[ndb_mgmd]
HostName= myhost.example.com

[ndbd]
HostName= myhost.example.com
DataDir= /var/lib/mysql-cluster

[mysqld]
[mysqld]
[mysqld]
```

You can now start the `ndb_mgmd` management server. By default, it attempts to read the `config.ini` file in its current working directory, so change location into the directory where the file is located and then invoke `ndb_mgmd`:

```
shell> cd /var/lib/mysql-cluster
shell> ndb_mgmd
```

Then start a single data node by running `ndbd`:

```
shell> ndbd
```
Quick Test Setup of MySQL Cluster

For command-line options which can be used when starting `ndbd`, see Section 18.4.25, “Options Common to MySQL Cluster Programs — Options Common to MySQL Cluster Programs”.

By default, `ndbd` looks for the management server at `localhost` on port 1186.

**Note**

If you have installed MySQL from a binary tarball, you will need to specify the path of the `ndb_mgmd` and `ndbd` servers explicitly. (Normally, these will be found in `/usr/local/mysql/bin`.)

Finally, change location to the MySQL data directory (usually `/var/lib/mysql` or `/usr/local/mysql/data`), and make sure that the `my.cnf` file contains the option necessary to enable the NDB storage engine:

    [mysqld]
    ndbcluster

You can now start the MySQL server as usual:

    shell> mysqld_safe --user=mysql &

Wait a moment to make sure the MySQL server is running properly. If you see the notice `mysql ended`, check the server's `.err` file to find out what went wrong.

If all has gone well so far, you now can start using the cluster. Connect to the server and verify that the `NDBCLUSTER` storage engine is enabled:

    shell> mysql
    Welcome to the MySQL monitor.  Commands end with ; or \g.
    Your MySQL connection id is 1 to server version: 5.5.40
    Type 'help;' or '\h' for help. Type '\c' to clear the buffer.
    mysql> SHOW ENGINES\G
    ...  
    ********************** 12. row **********************
    Engine: NDBCLUSTER
    Support: YES
    Comment: Clustered, fault-tolerant, memory-based tables
    ********************** 13. row **********************
    Engine: NDB
    Support: YES
    Comment: Alias for NDBCLUSTER
    ...

The row numbers shown in the preceding example output may be different from those shown on your system, depending upon how your server is configured.

Try to create an `NDBCLUSTER` table:

    shell> mysql
    mysql> USE test;
    Database changed
    mysql> CREATE TABLE ctest (i INT) ENGINE=NDBCLUSTER;
    Query OK, 0 rows affected (0.09 sec)
    mysql> SHOW CREATE TABLE ctest \G
To check that your nodes were set up properly, start the management client:

```
shell> ndb_mgm
```

Use the `SHOW` command from within the management client to obtain a report on the cluster's status:

```
nldb_mgm> SHOW
Cluster Configuration
----------------------
[nbdb(NDB)] 1 node(s)
id=2 @127.0.0.1 (Version: 5.5.38-ndb-7.2.18, Nodegroup: 0, *)

[nbdb_mgmd(MGM)] 1 node(s)
id=1 @127.0.0.1 (Version: 5.5.38-ndb-7.2.18)

[mysqld(API)] 3 node(s)
id=3 @127.0.0.1 (Version: 5.5.38-ndb-7.2.18)
id=4 (not connected, accepting connect from any host)
id=5 (not connected, accepting connect from any host)
```

At this point, you have successfully set up a working MySQL Cluster. You can now store data in the cluster by using any table created with `ENGINE=NDBCLUSTER` or its alias `ENGINE=NDB`.

### 18.3.2 MySQL Cluster Configuration Files

Configuring MySQL Cluster requires working with two files:

- **my.cnf**: Specifies options for all MySQL Cluster executables. This file, with which you should be familiar with from previous work with MySQL, must be accessible by each executable running in the cluster.

- **config.ini**: This file, sometimes known as the **global configuration file**, is read only by the MySQL Cluster management server, which then distributes the information contained therein to all processes participating in the cluster. `config.ini` contains a description of each node involved in the cluster. This includes configuration parameters for data nodes and configuration parameters for connections between all nodes in the cluster. For a quick reference to the sections that can appear in this file, and what sorts of configuration parameters may be placed in each section, see [Sections of the config.ini File](#). 

**Caching of configuration data.** In MySQL Cluster NDB 7.2, MySQL Cluster uses **stateful configuration**. Rather than reading the global configuration file every time the management server is restarted, the management server caches the configuration the first time it is started, and thereafter, the global configuration file is read only when one of the following conditions is true:

- **The management server is started using the **--initial option**.** In this case, the global configuration file is re-read, any existing cache files are deleted, and the management server creates a new configuration cache.

- **The management server is started using the **--reload option**.** In this case, the management server compares its cache with the global configuration file. If they differ, the management server creates a new configuration cache; any existing configuration cache is preserved, but not used. If the management server's cache and the global configuration file contain the same configuration data, then the existing cache is used, and no new cache is created.
• **The management server is started using a **--config-cache** **option.** This option can be used to force the management server to bypass configuration caching altogether. In this case, the management server ignores any configuration files that may be present, always reading its configuration data from the config.ini file instead.

• **No configuration cache is found.** In this case, the management server reads the global configuration file and creates a cache containing the same configuration data as found in the file.

**Configuration cache files.** The management server by default creates configuration cache files in a directory named mysql-cluster in the MySQL installation directory. (If you build MySQL Cluster from source on a Unix system, the default location is /usr/local/mysql-cluster.) This can be overridden at runtime by starting the management server with the **--configdir** option. Configuration cache files are binary files named according to the pattern ndb_node_id_config.bin.seq_id, where node_id is the management server's node ID in the cluster, and seq_id is a cache identifier. Cache files are numbered sequentially using seq_id, in the order in which they are created. The management server uses the latest cache file as determined by the seq_id.

**Note**  
It is possible to roll back to a previous configuration by deleting later configuration cache files, or by renaming an earlier cache file so that it has a higher seq_id. However, since configuration cache files are written in a binary format, you should not attempt to edit their contents by hand.

For more information about the **--configdir, --config-cache, --initial,** and **--reload** options for the MySQL Cluster management server, see Section 18.4.4, "ndb_mgmd — The MySQL Cluster Management Server Daemon".

We are continuously making improvements in Cluster configuration and attempting to simplify this process. Although we strive to maintain backward compatibility, there may be times when introduce an incompatible change. In such cases we will try to let Cluster users know in advance if a change is not backward compatible. If you find such a change and we have not documented it, please report it in the MySQL bugs database using the instructions given in Section 1.7, "How to Report Bugs or Problems".

**18.3.2.1 MySQL Cluster Configuration: Basic Example**

To support MySQL Cluster, you will need to update my.cnf as shown in the following example. You may also specify these parameters on the command line when invoking the executables.

**Note**  
The options shown here should not be confused with those that are used in config.ini global configuration files. Global configuration options are discussed later in this section.

```bash
# my.cnf  
# example additions to my.cnf for MySQL Cluster  
# (valid in MySQL 5.5)

# enable ndbcluster storage engine, and provide connection string for  
# management server host (default port is 1186)
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com

# provide connection string for management server host (default port: 1186)
```
MySQL Cluster Configuration Files

```
[ndbd]
connect-string=ndb_mgmd.mysql.com

# provide connection string for management server host (default port: 1186)
[ndb_mgm]
connect-string=ndb_mgmd.mysql.com

# provide location of cluster configuration file
[ndb_mgmd]
config-file=/etc/config.ini
```

(For more information on connection strings, see Section 18.3.2.3, “MySQL Cluster Connection Strings”.)

```
# my.cnf
# example additions to my.cnf for MySQL Cluster
# (will work on all versions)
# enable ndbcluster storage engine, and provide connection string for management
# server host to the default port 1186
[mysqld]
ndbcluster
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

**Important**

Once you have started a mysqld process with the NDBCLUSTER and ndb-connectstring parameters in the [mysqld] in the my.cnf file as shown previously, you cannot execute any CREATE TABLE or ALTER TABLE statements without having actually started the cluster. Otherwise, these statements will fail with an error. **This is by design.**

You may also use a separate [mysql_cluster] section in the cluster my.cnf file for settings to be read and used by all executables:

```
# cluster-specific settings
[mysql_cluster]
ndb-connectstring=ndb_mgmd.mysql.com:1186
```

For additional NDB variables that can be set in the my.cnf file, see Section 18.3.4.3, “MySQL Cluster System Variables”.

The MySQL Cluster global configuration file is by convention named config.ini (but this is not required). If needed, it is read by ndb_mgmd at startup and can be placed in any location that can be read by it. The location and name of the configuration are specified using --config-file=path_name with ndb_mgmd on the command line. This option has no default value, and is ignored if ndb_mgmd uses the configuration cache.

The global configuration file for MySQL Cluster uses INI format, which consists of sections preceded by section headings (surrounded by square brackets), followed by the appropriate parameter names and values. One deviation from the standard INI format is that the parameter name and value can be separated by a colon ("=") as well as the equal sign ("="); however, the equal sign is preferred. Another deviation is that sections are not uniquely identified by section name. Instead, unique sections (such as two different nodes of the same type) are identified by a unique ID specified as a parameter within the section.

Default values are defined for most parameters, and can also be specified in config.ini. To create a default value section, simply add the word default to the section name. For example, an [ndbd] section contains parameters that apply to a particular data node, whereas an [ndbd default] section contains parameters that apply to all data nodes. Suppose that all data nodes should use the same data memory
size. To configure them all, create an `ndbd default` section that contains a `DataMemory` line to specify the data memory size.

**Note**

In some older releases of MySQL Cluster, there was no default value for `NoOfReplicas`, which always had to be specified explicitly in the `ndbd default` section. Although this parameter now has a default value of 2, which is the recommended setting in most common usage scenarios, it is still recommended practice to set this parameter explicitly.

The global configuration file must define the computers and nodes involved in the cluster and on which computers these nodes are located. An example of a simple configuration file for a cluster consisting of one management server, two data nodes and two MySQL servers is shown here:

```ini
# file "config.ini" - 2 data nodes and 2 SQL nodes
# This file is placed in the startup directory of ndb_mgmd (the
# management server)
# The first MySQL Server can be started from any host. The second
# can be started only on the host mysqld_5.mysql.com

[ndbd default]
NoOfReplicas= 2
DataDir= /var/lib/mysql-cluster

[ndb_mgmd]
Hostname= ndb_mgmd.mysql.com
DataDir= /var/lib/mysql-cluster

[ndbd]
HostName= ndbd_2.mysql.com

[ndbd]
HostName= ndbd_3.mysql.com

[mysqld]
[mysqld]
HostName= mysqld_5.mysql.com

```

**Note**

The preceding example is intended as a minimal starting configuration for purposes of familiarization with MySQL Cluster, and is almost certain not to be sufficient for production settings. See Section 18.3.2.2, “Recommended Starting Configuration for MySQL Cluster”, which provides a more complete example starting configuration.

Each node has its own section in the `config.ini` file. For example, this cluster has two data nodes, so the preceding configuration file contains two `ndbd` sections defining these nodes.

**Note**

Do not place comments on the same line as a section heading in the `config.ini` file; this causes the management server not to start because it cannot parse the configuration file in such cases.

**Sections of the `config.ini` File**

There are six different sections that you can use in the `config.ini` configuration file, as described in the following list:
MySQL Cluster Configuration Files

- **[computer]**: Defines cluster hosts. This is not required to configure a viable MySQL Cluster, but may be used as a convenience when setting up a large cluster. See Section 18.3.2.4, “Defining Computers in a MySQL Cluster”, for more information.

- **[ndbd]**: Defines a cluster data node (ndbd process). See Section 18.3.2.6, “Defining MySQL Cluster Data Nodes”, for details.

- **[mysqld]**: Defines the cluster’s MySQL server nodes (also called SQL or API nodes). For a discussion of SQL node configuration, see Section 18.3.2.7, “Defining SQL and Other API Nodes in a MySQL Cluster”.

- **[mgm]** or **[ndb_mgmd]**: Defines a cluster management server (MGM) node. For information concerning the configuration of management nodes, see Section 18.3.2.5, “Defining a MySQL Cluster Management Server”.

- **[tcp]**: Defines a TCP/IP connection between cluster nodes, with TCP/IP being the default connection protocol. Normally, [tcp] or [tcp default] sections are not required to set up a MySQL Cluster, as the cluster handles this automatically; however, it may be necessary in some situations to override the defaults provided by the cluster. See Section 18.3.2.8, “MySQL Cluster TCP/IP Connections”, for information about available TCP/IP configuration parameters and how to use them. (You may also find Section 18.3.2.9, “MySQL Cluster TCP/IP Connections Using Direct Connections” to be of interest in some cases.)

- **[shm]**: Defines shared-memory connections between nodes. In MySQL 5.5, it is enabled by default, but should still be considered experimental. For a discussion of SHM interconnects, see Section 18.3.2.10, “MySQL Cluster Shared-Memory Connections”.

- **[sci]**: Defines Scalable Coherent Interface connections between cluster data nodes. Such connections require software which, while freely available, is not part of the MySQL Cluster distribution, as well as specialized hardware. See Section 18.3.2.11, “SCI Transport Connections in MySQL Cluster” for detailed information about SCI interconnects.

You can define default values for each section. All Cluster parameter names are case-insensitive, which differs from parameters specified in my.cnf or my.ini files.

### 18.3.2.2 Recommended Starting Configuration for MySQL Cluster

Achieving the best performance from a MySQL Cluster depends on a number of factors including the following:

- MySQL Cluster software version
- Numbers of data nodes and SQL nodes
- Hardware
- Operating system
- Amount of data to be stored
- Size and type of load under which the cluster is to operate

Therefore, obtaining an optimum configuration is likely to be an iterative process, the outcome of which can vary widely with the specifics of each MySQL Cluster deployment. Changes in configuration are also likely to be indicated when changes are made in the platform on which the cluster is run, or in applications that use the MySQL Cluster's data. For these reasons, it is not possible to offer a single configuration that is ideal for all usage scenarios. However, in this section, we provide a recommended base configuration.
Starting `config.ini` file. The following `config.ini` file is a recommended starting point for configuring a cluster running MySQL Cluster NDB 7.2:

```ini
# TCP PARAMETERS
[tcp default]
SendBufferMemory=2M
ReceiveBufferMemory=2M

# Increasing the sizes of these 2 buffers beyond the default values
# helps prevent bottlenecks due to slow disk I/O.

# MANAGEMENT NODE PARAMETERS
[ndb_mgmd default]
DataDir=path/to/management/server/data/directory

# It is possible to use a different data directory for each management
# server, but for ease of administration it is preferable to be
# consistent.
[ndb_mgmd]
HostName=management-server-A-hostname
  # NodeId=management-server-A-nodeid
[ndb_mgmd]
HostName=management-server-B-hostname
  # NodeId=management-server-B-nodeid

# Using 2 management servers helps guarantee that there is always an
# arbitrator in the event of network partitioning, and so is
# recommended for high availability. Each management server must be
# identified by a HostName. You may for the sake of convenience specify
# a NodeId for any management server, although one will be allocated
# for it automatically; if you do so, it must be in the range 1-255
# inclusive and must be unique among all IDs specified for cluster
# nodes.

# DATA NODE PARAMETERS
[ndbd default]
NoOfReplicas=2

# Using 2 replicas is recommended to guarantee availability of data;
# using only 1 replica does not provide any redundancy, which means
# that the failure of a single data node causes the entire cluster to
# shut down. We do not recommend using more than 2 replicas, since 2 is
# sufficient to provide high availability, and we do not currently test
# with greater values for this parameter.
LockPagesInMainMemory=1

# On Linux and Solaris systems, setting this parameter locks data node
# processes into memory. Doing so prevents them from swapping to disk,
# which can severely degrade cluster performance.
DataMemory=3072M
IndexMemory=384M

# The values provided for DataMemory and IndexMemory assume 4 GB RAM
# per data node. However, for best results, you should first calculate
# the memory that would be used based on the data you actually plan to
# store (you may find the ndb_size.pl utility helpful in estimating
# this), then allow an extra 20% over the calculated values. Naturally,
# you should ensure that each data node host has at least as much
# physical memory as the sum of these two values.
```
MySQL Cluster Configuration Files

# ODirect=1
# Enabling this parameter causes NDBCLUSTER to try using O_DIRECT
# writes for local checkpoints and redo logs; this can reduce load on
# CPUs. We recommend doing so when using MySQL Cluster on systems running
# Linux kernel 2.6 or later.

NoOfFragmentLogFiles=300
DataDir=path/to/data/node/data/directory
MaxNoOfConcurrentOperations=100000

SchedulerSpinTimer=400
SchedulerExecutionTimer=100
RealTimeScheduler=1
# Setting these parameters allows you to take advantage of real-time scheduling
# of NDB threads to achieve increased throughput when using ndbd. They
# are not needed when using ndbmd; in particular, you should not set
# RealTimeScheduler for ndbmd data nodes.

TimeBetweenGlobalCheckpoints=1000
TimeBetweenEpochs=200
DiskCheckpointSpeed=10M
DiskCheckpointSpeedInRestart=100M
RedoBuffer=32M

# CompressedLCP=1
# CompressedBackup=1
# Enabling CompressedLCP and CompressedBackup causes, respectively, local
# checkpoint files and backup files to be compressed, which can result in a space
# savings of up to 50% over uncompressed LCPs and backups.

# MaxNoOfLocalScans=64
MaxNoOfTables=1024
MaxNoOfOrderedIndexes=256

[ndbd]
HostName=data-node-A-hostname
# NodeId=data-node-A-nodeid

LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0
# On systems with multiple CPUs, these parameters can be used to lock NDBCLUSTER
# threads to specific CPUs

[ndbd]
HostName=data-node-B-hostname
# NodeId=data-node-B-nodeid

LockExecuteThreadToCPU=1
LockMaintThreadsToCPU=0
# You must have an [ndbd] section for every data node in the cluster;
# each of these sections must include a HostName. Each section may
# optionally include a NodeId for convenience, but in most cases, it is
# sufficient to allow the cluster to allocate node IDs dynamically. If
# you do specify the node ID for a data node, it must be in the range 1
# to 48 inclusive and must be unique among all IDs specified for
# cluster nodes.

# SQL NODE / API NODE PARAMETERS

[mysqld]
HostName=sql-node-A-hostname
# NodeId=sql-node-A-nodeid

[mysqld]
MySQL Cluster Configuration Files

[mysqld]
# Each API or SQL node that connects to the cluster requires a [mysqld]
# or [api] section of its own. Each such section defines a connection
# "slot"; you should have at least as many of these sections in the
# config.ini file as the total number of API nodes and SQL nodes that
# you wish to have connected to the cluster at any given time. There is
# no performance or other penalty for having extra slots available in
# case you find later that you want or need more API or SQL nodes to
# connect to the cluster at the same time.
# If no HostName is specified for a given [mysqld] or [api] section,
# then any API or SQL node may use that slot to connect to the
# cluster. You may wish to use an explicit HostName for one connection slot
# to guarantee that an API or SQL node from that host can always
# connect to the cluster. If you wish to prevent API or SQL nodes from
# connecting from other than a desired host or hosts, then use a
# HostName for every [mysqld] or [api] section in the config.ini file.
# You can if you wish define a node ID (NodeId parameter) for any API or
# SQL node, but this is not necessary; if you do so, it must be in the
# range 1 to 255 inclusive and must be unique among all IDs specified
# for cluster nodes.

Recommended my.cnf options for SQL nodes. MySQL Servers acting as MySQL Cluster SQL
nodes must always be started with the --ndbcluster and --ndb-connectstring options, either
on the command line or in my.cnf. In addition, set the following options for all mysqld processes in the
cluster, unless your setup requires otherwise:

- --ndb-use-exact-count=0
- --ndb-index-stat-enable=0
- --ndb-force-send=1
- --engine-condition-pushdown=1

18.3.2.3 MySQL Cluster Connection Strings

With the exception of the MySQL Cluster management server (ndb_mgmd), each node that is part of
a MySQL Cluster requires a connection string that points to the management server's location. This
connection string is used in establishing a connection to the management server as well as in performing
other tasks depending on the node's role in the cluster. The syntax for a connection string is as follows:

[nodeid=node_id, ]host-definition[, host-definition[, ...]]

host-definition:
    host_name[:port_number]

node_id is an integer greater than or equal to 1 which identifies a node in config.ini.host_name is
a string representing a valid Internet host name or IP address. port_number is an integer referring to a
TCP/IP port number.

example 1 (long):  "nodeid=2,myhost1:1100,myhost2:1100,192.168.0.3:1200"
example 2 (short):  "myhost1"

localhost:1186 is used as the default connection string value if none is provided. If port_num is
omitted from the connection string, the default port is 1186. This port should always be available on the
network because it has been assigned by IANA for this purpose (see http://www.iana.org/assignments/
port-numbers for details).
By listing multiple host definitions, it is possible to designate several redundant management servers. A MySQL Cluster data or API node attempts to contact successive management servers on each host in the order specified, until a successful connection has been established.

It is also possible to specify in a connection string one or more bind addresses to be used by nodes having multiple network interfaces for connecting to management servers. A bind address consists of a hostname or network address and an optional port number. This enhanced syntax for connection strings is shown here:

```
[nodeid=node_id, ]
  [bind-address=host-definition, ]
  host-definition[; bind-address=host-definition]
  host-definition[; bind-address=host-definition]
  [, ...]
  host-definition:
    host_name[:port_number]
```

If a single bind address is used in the connection string prior to specifying any management hosts, then this address is used as the default for connecting to any of them (unless overridden for a given management server; see later in this section for an example). For example, the following connection string causes the node to use `192.168.178.242` regardless of the management server to which it connects:

```
bind-address=192.168.178.242, poseidon:1186, perch:1186
```

If a bind address is specified following a management host definition, then it is used only for connecting to that management node. Consider the following connection string:

```
poseidon:1186;bind-address=localhost, perch:1186;bind-address=192.168.178.242
```

In this case, the node uses `localhost` to connect to the management server running on the host named `poseidon` and `192.168.178.242` to connect to the management server running on the host named `perch`.

You can specify a default bind address and then override this default for one or more specific management hosts. In the following example, `localhost` is used for connecting to the management server running on host `poseidon`; since `192.168.178.242` is specified first (before any management server definitions), it is the default bind address and so is used for connecting to the management servers on hosts `perch` and `orca`:

```
bind-address=192.168.178.242,poseidon:1186;bind-address=localhost,perch:1186,orca:2200
```

There are a number of different ways to specify the connection string:

- Each executable has its own command-line option which enables specifying the management server at startup. (See the documentation for the respective executable.)

- It is also possible to set the connection string for all nodes in the cluster at once by placing it in a [mysql_cluster] section in the management server's my.cnf file.

- For backward compatibility, two other options are available, using the same syntax:
  1. Set the NDB_CONNECTSTRING environment variable to contain the connection string.
  2. Write the connection string for each executable into a text file named Ndb.cfg and place this file in the executable's startup directory.
However, these are now deprecated and should not be used for new installations.

The recommended method for specifying the connection string is to set it on the command line or in the `my.cnf` file for each executable.

### 18.3.2.4 Defining Computers in a MySQL Cluster

The `[computer]` section has no real significance other than serving as a way to avoid the need of defining host names for each node in the system. All parameters mentioned here are required.

- **Id**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>string</td>
<td>[none]</td>
<td>...</td>
</tr>
</tbody>
</table>

**Restart Type:** IS

(See Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”, for information about restart types.)

This is a unique identifier, used to refer to the host computer elsewhere in the configuration file.

**Important**

The computer ID is *not* the same as the node ID used for a management, API, or data node. Unlike the case with node IDs, you cannot use `NodeId` in place of `Id` in the `[computer]` section of the `config.ini` file.

- **HostName**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>name or IP address</td>
<td>[none]</td>
<td>...</td>
</tr>
</tbody>
</table>

**Restart Type:** S

(See Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”, for information about restart types.)

This is the computer's hostname or IP address.

### 18.3.2.5 Defining a MySQL Cluster Management Server

The `[ndb_mgmd]` section is used to configure the behavior of the management server. If multiple management servers are employed, you can specify parameters common to all of them in an `[ndb_mgmd default]` section. `[mgm]` and `[mgm default]` are older aliases for these, supported for backward compatibility.

All parameters in the following list are optional and assume their default values if omitted.

**Note**

If neither the `ExecuteOnComputer` nor the `HostName` parameter is present, the default value `localhost` will be assumed for both.

- **Id**
MySQL Cluster Configuration Files

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>1 - 255</td>
</tr>
</tbody>
</table>

**Restart Type**: IS

(See Section 18.3.3.2, “MySQL Cluster Management Node Configuration Parameters”, for information about restart types.)

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 255, inclusive. This ID is used by all internal cluster messages for addressing the node, and so must be unique for each MySQL Cluster node, regardless of the type of node.

**Note**

Data node IDs must be less than 49. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 48.

The use of the `Id` parameter for identifying management nodes is deprecated in favor of `NodeId`. Although `Id` continues to be supported for backward compatibility, it now generates a warning and is subject to removal in a future version of MySQL Cluster.

- **NodeId**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>1 - 255</td>
</tr>
</tbody>
</table>

**Restart Type**: IS

(See Section 18.3.3.2, “MySQL Cluster Management Node Configuration Parameters”, for information about restart types.)

Each node in the cluster has a unique identity. For a management node, this is represented by an integer value in the range 1 to 255 inclusive. This ID is used by all internal cluster messages for addressing the node, and so must be unique for each MySQL Cluster node, regardless of the type of node.

**Note**

Data node IDs must be less than 49. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for management nodes (and API nodes) to values greater than 48.

`NodeId` is the preferred parameter name to use when identifying management nodes. Although the older `Id` continues to be supported for backward compatibility, it is now deprecated and generates a warning when used; it is also subject to removal in a future MySQL Cluster release.

- **ExecuteOnComputer**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>name</td>
<td>[none]</td>
<td>...</td>
</tr>
</tbody>
</table>

**Restart Type**: S
MySQL Cluster Configuration Files

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

(See Section 18.3.3.2, “MySQL Cluster Management Node Configuration Parameters”, for information about restart types.)

This refers to the \textit{Id} set for one of the computers defined in a [computer] section of the \texttt{config.ini} file.

- \textit{PortNumber}

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>unsigned</td>
<td>1186</td>
<td>0 - 64K</td>
</tr>
</tbody>
</table>

\textbf{Restart Type: N}

(See Section 18.3.3.2, “MySQL Cluster Management Node Configuration Parameters”, for information about restart types.)

This is the port number on which the management server listens for configuration requests and management commands.

- \textit{HostName}

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>name or IP address</td>
<td>[none]</td>
<td>...</td>
</tr>
</tbody>
</table>

\textbf{Restart Type: S}

(See Section 18.3.3.2, “MySQL Cluster Management Node Configuration Parameters”, for information about restart types.)

Specifying this parameter defines the hostname of the computer on which the management node is to reside. To specify a hostname other than \texttt{localhost}, either this parameter or \texttt{ExecuteOnComputer} is required.

- \textit{LogDestination}

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>{CONSOLE</td>
<td>SYSLOG</td>
<td>FILE}</td>
</tr>
</tbody>
</table>

\textbf{Restart Type: N}

(See Section 18.3.3.2, “MySQL Cluster Management Node Configuration Parameters”, for information about restart types.)

This parameter specifies where to send cluster logging information. There are three options in this regard—\texttt{CONSOLE}, \texttt{SYSLOG}, and \texttt{FILE}—with \texttt{FILE} being the default:

- \texttt{CONSOLE} outputs the log to \texttt{stdout}:

  \begin{verbatim}
  CONSOLE
  \end{verbatim}
MySQL Cluster Configuration Files

• **SYSLOG** sends the log to a **syslog** facility, possible values being one of **auth, authpriv, cron, daemon, ftp, kern, lpr, mail, news, syslog, user, uucp, local0, local1, local2, local3, local4, local5, local6**, or **local7**.

  **Note**

  Not every facility is necessarily supported by every operating system.

**SYSLOG:facility=syslog**

• **FILE** pipes the cluster log output to a regular file on the same machine. The following values can be specified:

  • **filename**: The name of the log file.

     In MySQL Cluster NDB 7.2.6 and earlier, the log file's default name, used if **FILE** was specified without also setting **filename**, was **logger.log**. Beginning with MySQL Cluster NDB 7.2.7, the default log file name used in such cases is **ndb_nodeid_cluster.log**.

  • **maxsize**: The maximum size (in bytes) to which the file can grow before logging rolls over to a new file. When this occurs, the old log file is renamed by appending **.N** to the file name, where **N** is the next number not yet used with this name.

  • **maxfiles**: The maximum number of log files.

**FILE:filename=cluster.log,maxsize=1000000,maxfiles=6**

The default value for the **FILE** parameter is

**FILE:filename=ndb_nodeid_cluster.log,maxsize=1000000,maxfiles=6**, where **node_id** is the ID of the node.

It is possible to specify multiple log destinations separated by semicolons as shown here:

**CONSOLE;SYSLOG:facility=local0;FILE:filename=/var/log/mgmd**

• **ArbitrationRank**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>0-2</td>
<td>1</td>
<td>0 - 2</td>
</tr>
</tbody>
</table>

**Restart Type**: N

(See Section 18.3.3.2, "MySQL Cluster Management Node Configuration Parameters", for information about restart types.)

This parameter is used to define which nodes can act as arbitrators. Only management nodes and SQL nodes can be arbitrators. **ArbitrationRank** can take one of the following values:

• **0**: The node will never be used as an arbitrator.

• **1**: The node has high priority; that is, it will be preferred as an arbitrator over low-priority nodes.
MySQL Cluster Configuration Files

- **2**: Indicates a low-priority node which can be used as an arbitrator only if a node with a higher priority is not available for that purpose.

Normally, the management server should be configured as an arbitrator by setting its `ArbitrationRank` to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).

You can disable arbitration completely either by setting `ArbitrationRank` to 0 on all management and SQL nodes, or by setting the `Arbitration` parameter in the `[ndbd default]` section of the `config.ini` global configuration file. Setting `Arbitration` causes any settings for `ArbitrationRank` to be disregarded.

- **ArbitrationDelay**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>milliseconds</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type: N**

(See Section 18.3.3.2, “MySQL Cluster Management Node Configuration Parameters”, for information about restart types.)

An integer value which causes the management server’s responses to arbitration requests to be delayed by that number of milliseconds. By default, this value is 0; it is normally not necessary to change it.

- **DataDir**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>path</td>
<td>.</td>
<td>...</td>
</tr>
</tbody>
</table>

**Restart Type: N**

(See Section 18.3.3.2, “MySQL Cluster Management Node Configuration Parameters”, for information about restart types.)

This specifies the directory where output files from the management server will be placed. These files include cluster log files, process output files, and the daemon’s process ID (PID) file. (For log files, this location can be overridden by setting the `FILE` parameter for `LogDestination` as discussed previously in this section.)

The default value for this parameter is the directory in which `ndb_mgmd` is located.

- **PortNumberStats**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>0 - 64K</td>
</tr>
</tbody>
</table>

**Restart Type: N**

(See Section 18.3.3.2, “MySQL Cluster Management Node Configuration Parameters”, for information about restart types.)

This parameter specifies the port number used to obtain statistical information from a MySQL Cluster management server. It has no default value.
MySQL Cluster Configuration Files

- **Wan**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>boolean</td>
<td>false</td>
<td>true, false</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.2, “MySQL Cluster Management Node Configuration Parameters”, for information about restart types.)

Use WAN TCP setting as default.

- **HeartbeatThreadPriority**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>string</td>
<td>[none]</td>
<td>...</td>
</tr>
</tbody>
</table>

**Restart Type:** S

(See Section 18.3.3.2, “MySQL Cluster Management Node Configuration Parameters”, for information about restart types.)

Set the scheduling policy and priority of heartbeat threads for management and API nodes.

The syntax for setting this parameter is shown here:

```sql
HeartbeatThreadPriority = policy[, priority]
```

**policy:**

```sql
{FIFO | RR}
```

When setting this parameter, you must specify a policy. This is one of **FIFO** (first in, first out) or **RR** (round robin). The policy value is followed optionally by the priority (an integer).

- **ExtraSendBufferMemory**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>bytes</td>
<td>0</td>
<td>0 - 32G</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.2, “MySQL Cluster Management Node Configuration Parameters”, for information about restart types.)

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any that has been set using **TotalSendBufferMemory**, **SendBufferMemory**, or both.

This parameter was added in MySQL Cluster NDB 7.2.14. (Bug #14555359)

- **TotalSendBufferMemory**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>bytes</td>
<td>2161</td>
<td>0 - 4294967039</td>
</tr>
</tbody>
</table>

**Restart Type:** N
MySQL Cluster Configuration Files

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>milliseconds</td>
<td>1500</td>
<td>100 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>NDB 7.2.12</td>
<td>milliseconds</td>
<td>1500</td>
<td>100 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Note**

After making changes in a management node's configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect.

To add new management servers to a running MySQL Cluster, it is also necessary to perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see Section 18.1.6.10, “Limitations Relating to Multiple MySQL Cluster Nodes”.

### 18.3.2.6 Defining MySQL Cluster Data Nodes

The `[ndbd]` and `[ndbd default]` sections are used to configure the behavior of the cluster's data nodes.

`[ndbd]` and `[ndbd default]` are always used as the section names whether you are using `ndbd` or `ndbmt` binaries for the data node processes.

There are many parameters which control buffer sizes, pool sizes, timeouts, and so forth. The only mandatory parameter is either one of `ExecuteOnComputer` or `HostName`; this must be defined in the local `[ndbd]` section.
The parameter `NoOfReplicas` should be defined in the `[ndbd default]` section, as it is common to all Cluster data nodes. It is not strictly necessary to set `NoOfReplicas`, but it is good practice to set it explicitly.

Most data node parameters are set in the `[ndbd default]` section. Only those parameters explicitly stated as being able to set local values are permitted to be changed in the `[ndbd]` section. Where present, `HostName`, `NodeId` and `ExecuteOnComputer` must be defined in the local `[ndbd]` section, and not in any other section of `config.ini`. In other words, settings for these parameters are specific to one data node.

For those parameters affecting memory usage or buffer sizes, it is possible to use K, M, or G as a suffix to indicate units of 1024, 1024×1024, or 1024×1024×1024. (For example, `100K` means `100 × 1024 = 102400`.) Parameter names and values are currently case-sensitive.

Information about configuration parameters specific to MySQL Cluster Disk Data tables can be found later in this section (see Disk Data Configuration Parameters).

All of these parameters also apply to `ndbmtd` (the multi-threaded version of `ndbd`). Three additional data node configuration parameters—`MaxNoOfExecutionThreads`, `ThreadConfig`, and `NoOfFragmentLogParts`—apply to `ndbmtd` only; these have no effect when used with `ndbd`. For more information, see Multi-Threading Configuration Parameters (`ndbmtd`). See also Section 18.4.3, "`ndbmtd` — The MySQL Cluster Data Node Daemon (Multi-Threaded)".

**Identifying data nodes.** The `NodeId` or `Id` value (that is, the data node identifier) can be allocated on the command line when the node is started or in the configuration file.

- `Id`

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>1 - 48</td>
</tr>
</tbody>
</table>

**Restart Type:** IS

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

A unique node ID is used as the node’s address for all cluster internal messages. For data nodes, this is an integer in the range 1 to 48 inclusive. Each node in the cluster must have a unique identifier.

`NodeId` is the preferred parameter name to use when identifying data nodes. Although the older `Id` is still supported for backward compatibility, it is now deprecated, and generates a warning when used. `Id` is also subject to removal in a future MySQL Cluster release.

- `NodeId`

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>1 - 48</td>
</tr>
</tbody>
</table>

**Restart Type:** IS

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

A unique node ID is used as the node’s address for all cluster internal messages. For data nodes, this is an integer in the range 1 to 48 inclusive. Each node in the cluster must have a unique identifier.
**NodeId** is the preferred parameter name to use when identifying data nodes. Although **Id** continues to be supported for backward compatibility, it is now deprecated, generates a warning when used, and is subject to removal in a future version of MySQL Cluster.

- **ExecuteOnComputer**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>name</td>
<td>[none]</td>
<td>...</td>
</tr>
</tbody>
</table>

**Restart Type:** S

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

This refers to the **Id** set for one of the computers defined in a `[computer]` section.

- **HostName**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>name or IP address</td>
<td>localhost</td>
<td>...</td>
</tr>
</tbody>
</table>

**Restart Type:** S

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

Specifying this parameter defines the hostname of the computer on which the data node is to reside. To specify a hostname other than `localhost`, either this parameter or `ExecuteOnComputer` is required.

- **ServerPort**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>1 - 64K</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

Each node in the cluster uses a port to connect to other nodes. By default, this port is allocated dynamically in such a way as to ensure that no two nodes on the same host computer receive the same port number, so it should normally not be necessary to specify a value for this parameter.

However, if you need to be able to open specific ports in a firewall to permit communication between data nodes and API nodes (including SQL nodes), you can set this parameter to the number of the desired port in an `[ndbd]` section or (if you need to do this for multiple data nodes) the `[ndbd default]` section of the `config.ini` file, and then open the port having that number for incoming connections from SQL nodes, API nodes, or both.

**Note**

Connections from data nodes to management nodes is done using the `ndb_mgmd` management port (the management server's **PortNumber**; see Section 18.3.2.5, “Defining a MySQL Cluster Management Server”) so outgoing connections to that port from any data nodes should always be permitted.
MySQL Cluster Configuration Files

- **TcpBind_INADDR_ANY**
  Setting this parameter to `TRUE` or `1` binds `IP_ADDR_ANY` so that connections can be made from anywhere (for autogenerated connections). The default is `FALSE (0)`.

- **NodeGroup**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>[none]</td>
<td>0 - 65536</td>
<td></td>
</tr>
</tbody>
</table>

  **Restart Type**: IS
  (See [Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”](#), for information about restart types.)

  This parameter can be used to assign a data node to a specific node group. It is read only when the cluster is started for the first time, and cannot be used to reassign a data node to a different node group online. It is generally not desirable to use this parameter in the `[ndbd default]` section of the `config.ini` file, and care must be taken not to assign nodes to node groups in such a way that an invalid numbers of nodes are assigned to any node groups.

  The **NodeGroup** parameter is chiefly intended for use in adding a new node group to a running MySQL Cluster without having to perform a rolling restart. For this purpose, you should set it to 65536 (the maximum value). You are not required to set a **NodeGroup** value for all cluster data nodes, only for those nodes which are to be started and added to the cluster as a new node group at a later time.

  For more information, see [Section 18.5.13.3, “Adding MySQL Cluster Data Nodes Online: Detailed Example”](#).

- **NoOfReplicas**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>integer</td>
<td>2</td>
<td>1 - 4</td>
</tr>
</tbody>
</table>

  **Restart Type**: IS
  (See [Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”](#), for information about restart types.)

  This global parameter can be set only in the `[ndbd default]` section, and defines the number of replicas for each table stored in the cluster. This parameter also specifies the size of node groups. A node group is a set of nodes all storing the same information.

  Node groups are formed implicitly. The first node group is formed by the set of data nodes with the lowest node IDs, the next node group by the set of the next lowest node identities, and so on. By way of example, assume that we have 4 data nodes and that **NoOfReplicas** is set to 2. The four data nodes have node IDs 2, 3, 4 and 5. Then the first node group is formed from nodes 2 and 3, and the second node group by nodes 4 and 5. It is important to configure the cluster in such a manner that nodes in the same node groups are not placed on the same computer because a single hardware failure would cause the entire cluster to fail.

  If no node IDs are provided, the order of the data nodes will be the determining factor for the node group. Whether or not explicit assignments are made, they can be viewed in the output of the management client’s `SHOW` command.

  The default value for **NoOfReplicas** is 2, which is the recommended setting in most common usage scenarios.
The maximum possible value is 4; currently, only the values 1 and 2 are actually supported.

Important

Setting `NoOfReplicas` to 1 means that there is only a single copy of all Cluster data; in this case, the loss of a single data node causes the cluster to fail because there are no additional copies of the data stored by that node.

The value for this parameter must divide evenly into the number of data nodes in the cluster. For example, if there are two data nodes, then `NoOfReplicas` must be equal to either 1 or 2, since 2/3 and 2/4 both yield fractional values; if there are four data nodes, then `NoOfReplicas` must be equal to 1, 2, or 4.

• **DataDir**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>path</td>
<td>.</td>
<td>...</td>
</tr>
</tbody>
</table>

**Restart Type:** IN

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

This parameter specifies the directory where trace files, log files, pid files and error logs are placed.

The default is the data node process working directory.

• **FileSystemPath**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>path</td>
<td>DataDir</td>
<td>...</td>
</tr>
</tbody>
</table>

**Restart Type:** IN

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

This parameter specifies the directory where all files created for metadata, REDO logs, UNDO logs (for Disk Data tables), and data files are placed. The default is the directory specified by `DataDir`.

Note

This directory must exist before the `ndbd` process is initiated.

The recommended directory hierarchy for MySQL Cluster includes `/var/lib/mysql-cluster`, under which a directory for the node's file system is created. The name of this subdirectory contains the node ID. For example, if the node ID is 2, this subdirectory is named `ndb_2_fs`.

• **BackupDataDir**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>path</td>
<td>[see text]</td>
<td>...</td>
</tr>
</tbody>
</table>

**Restart Type:** IN
MySQL Cluster Configuration Files

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

This parameter specifies the directory in which backups are placed.

⚠️ Important

The string '/BACKUP' is always appended to this value. For example, if you set the value of `BackupDataDir` to `/var/lib/cluster-data`, then all backups are stored under `/var/lib/cluster-data/BACKUP`. This also means that the effective default backup location is the directory named `BACKUP` under the location specified by the `FileSystemPath` parameter.

### Data Memory, Index Memory, and String Memory

`DataMemory` and `IndexMemory` are [ndbd] parameters specifying the size of memory segments used to store the actual records and their indexes. In setting values for these, it is important to understand how `DataMemory` and `IndexMemory` are used, as they usually need to be updated to reflect actual usage by the cluster:

- **DataMemory**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>bytes</td>
<td>80M</td>
<td>1M - 1024G</td>
</tr>
</tbody>
</table>

Restart Type: N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

This parameter defines the amount of space (in bytes) available for storing database records. The entire amount specified by this value is allocated in memory, so it is extremely important that the machine has sufficient physical memory to accommodate it.

The memory allocated by `DataMemory` is used to store both the actual records and indexes. There is a 16-byte overhead on each record; an additional amount for each record is incurred because it is stored in a 32KB page with 128 byte page overhead (see below). There is also a small amount wasted per page due to the fact that each record is stored in only one page.

For variable-size table attributes, the data is stored on separate data pages, allocated from `DataMemory`. Variable-length records use a fixed-size part with an extra overhead of 4 bytes to reference the variable-size part. The variable-size part has 2 bytes overhead plus 2 bytes per attribute.

The maximum record size is 14000 bytes.

The memory space defined by `DataMemory` is also used to store ordered indexes, which use about 10 bytes per record. Each table row is represented in the ordered index. A common error among users is to assume that all indexes are stored in the memory allocated by `IndexMemory`, but this is not the case: Only primary key and unique hash indexes use this memory; ordered indexes use the memory allocated by `DataMemory`. However, creating a primary key or unique hash index also creates an ordered index on the same keys, unless you specify `USING HASH` in the index creation statement. This can be verified by running `ndb_desc -d db_name table_name` in the management client.
Currently, MySQL Cluster can use a maximum of 512 MB for hash indexes per partition, which means in some cases it is possible to get Table is full errors in MySQL client applications even when `ndb_mgm -e "ALL REPORT MEMORYUSAGE"` shows significant free DataMemory. This can also pose a problem with data node restarts on nodes that are heavily loaded with data. You can force NDB to create extra partitions for MySQL Cluster tables and thus have more memory available for hash indexes by using the `MAX_ROWS` option for `CREATE TABLE`. In general, setting `MAX_ROWS` to twice the number of rows that you expect to store in the table should be sufficient. In MySQL Cluster 7.2.3 and later, you can also use the `MinFreePct` configuration parameter to help avoid problems with node restarts. (Bug #13436216)

The memory space allocated by DataMemory consists of 32KB pages, which are allocated to table fragments. Each table is normally partitioned into the same number of fragments as there are data nodes in the cluster. Thus, for each node, there are the same number of fragments as are set in NoOfReplicas.

Once a page has been allocated, it is currently not possible to return it to the pool of free pages, except by deleting the table. (This also means that DataMemory pages, once allocated to a given table, cannot be used by other tables.) Performing a data node recovery also compresses the partition because all records are inserted into empty partitions from other live nodes.

The DataMemory memory space also contains UNDO information: For each update, a copy of the unaltered record is allocated in the DataMemory. There is also a reference to each copy in the ordered table indexes. Unique hash indexes are updated only when the unique index columns are updated, in which case a new entry in the index table is inserted and the old entry is deleted upon commit. For this reason, it is also necessary to allocate enough memory to handle the largest transactions performed by applications using the cluster. In any case, performing a few large transactions holds no advantage over using many smaller ones, for the following reasons:

- Large transactions are not any faster than smaller ones
- Large transactions increase the number of operations that are lost and must be repeated in event of transaction failure
- Large transactions use more memory

The default value for DataMemory is 80MB; the minimum is 1MB. There is no maximum size, but in reality the maximum size has to be adapted so that the process does not start swapping when the limit is reached. This limit is determined by the amount of physical RAM available on the machine and by the amount of memory that the operating system may commit to any one process. 32-bit operating systems are generally limited to 2–4GB per process; 64-bit operating systems can use more. For large databases, it may be preferable to use a 64-bit operating system for this reason.

- **IndexMemory**

<table>
<thead>
<tr>
<th>Effective Version</th>

<td>bytes</td>
<td>18M</td>
<td>1M - 1T</td>
</tr>
</tbody>
</table>

**Restart Type: N**

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

This parameter controls the amount of storage used for hash indexes in MySQL Cluster. Hash indexes are always used for primary key indexes, unique indexes, and unique constraints. When defining a
primary key or a unique index, two indexes are created, one of which is a hash index used for all tuple accesses as well as lock handling. This index is also used to enforce unique constraints.

You can estimate the size of a hash index using this formula:

\[
\text{size} = ( (\text{fragments} \times 32K) + (\text{rows} \times 18) ) \times \text{replicas}
\]

*fragments* is the number of fragments, *replicas* is the number of replicas (normally 2), and *rows* is the number of rows. If a table has one million rows, 8 fragments, and 2 replicas, the expected index memory usage is calculated as shown here:

\[
((8 \times 32K) + (1000000 \times 18)) \times 2 = ((8 \times 32768) + (1000000 \times 18)) \times 2
\]
\[
= (262144 + 18000000) \times 2
\]
\[
= 18262144 \times 2 = 36524288 \text{ bytes} = \sim 35 \text{MB}
\]

In MySQL Cluster NDB 7.2 and later, index statistics (when enabled) for ordered indexes are stored in the `mysql.ndb_index_stat_sample` table. Since this table has a hash index, this adds to index memory usage. An upper bound to the number of rows for a given ordered index can be calculated as follows:

\[
\text{sample_size} = \text{key_size} + ((\text{key_attributes} + 1) \times 4)
\]
\[
\text{sample_rows} = \frac{\text{IndexStatSaveSize} \times (0.01 \times \text{IndexStatSaveScale} \times \log_2(\text{rows} \times \text{sample_size}) + 1)}{\text{sample_size}}
\]

In the preceding formula, *key_size* is the size of the ordered index key in bytes, *key_attributes* is the number of attributes in the ordered index key, and *rows* is the number of rows in the base table.

Assume that table *t1* has 1 million rows and an ordered index named *ix1* on two four-byte integers. Assume in addition that *IndexStatSaveSize* and *IndexStatSaveScale* are set to their default values (32K and 100, respectively). Using the previous 2 formulas, we can calculate as follows:

\[
\text{sample_size} = 8 + ((1 + 2) \times 4) = 20 \text{ bytes}
\]
\[
\text{sample_rows} = \frac{32K \times (0.01 \times 100 \times \log_2(1000000 \times 20) + 1)}{20}
\]
\[
= 32768 \times (1 \times 16.811 + 1) / 20
\]
\[
= 32768 \times 17.811 / 20
\]
\[
= \sim 29182 \text{ rows}
\]

The expected index memory usage is thus \(2 \times 18 \times 29182 = \sim 1050550 \text{ bytes}\).

The default value for *IndexMemory* is 18MB. The minimum is 1MB.

• **StringMemory**

<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Restart Type: S</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

This parameter determines how much memory is allocated for strings such as table names, and is specified in an [ndbd] or [ndbd default] section of the config.ini file. A value between 0 and 100 inclusive is interpreted as a percent of the maximum default value, which is calculated based on a number of factors including the number of tables, maximum table name size, maximum size of .FRM files, MaxNoOfTriggers, maximum column name size, and maximum default column value.

A value greater than 100 is interpreted as a number of bytes.

The default value is 25—that is, 25 percent of the default maximum.

Under most circumstances, the default value should be sufficient, but when you have a great many Cluster tables (1000 or more), it is possible to get Error 773 Out of string memory, please modify StringMemory config parameter: Permanent error: Schema error, in which case you should increase this value. 25 (25 percent) is not excessive, and should prevent this error from recurring in all but the most extreme conditions.

The following example illustrates how memory is used for a table. Consider this table definition:

```
CREATE TABLE example (  
  a INT NOT NULL,  
  b INT NOT NULL,  
  c INT NOT NULL,  
  PRIMARY KEY(a),  
  UNIQUE(b)  
) ENGINE=NDBCLUSTER;
```

For each record, there are 12 bytes of data plus 12 bytes overhead. Having no nullable columns saves 4 bytes of overhead. In addition, we have two ordered indexes on columns a and b consuming roughly 10 bytes each per record. There is a primary key hash index on the base table using roughly 29 bytes per record. The unique constraint is implemented by a separate table with b as primary key and a as a column. This other table consumes an additional 29 bytes of index memory per record in the example table as well 8 bytes of record data plus 12 bytes of overhead.

Thus, for one million records, we need 58MB for index memory to handle the hash indexes for the primary key and the unique constraint. We also need 64MB for the records of the base table and the unique index table, plus the two ordered index tables.

You can see that hash indexes takes up a fair amount of memory space; however, they provide very fast access to the data in return. They are also used in MySQL Cluster to handle uniqueness constraints.

Currently, the only partitioning algorithm is hashing and ordered indexes are local to each node. Thus, ordered indexes cannot be used to handle uniqueness constraints in the general case.

An important point for both IndexMemory and DataMemory is that the total database size is the sum of all data memory and all index memory for each node group. Each node group is used to store replicated information, so if there are four nodes with two replicas, there will be two node groups. Thus, the total data memory available is 2 × DataMemory for each data node.

It is highly recommended that DataMemory and IndexMemory be set to the same values for all nodes. Data distribution is even over all nodes in the cluster, so the maximum amount of space available for any node can be no greater than that of the smallest node in the cluster.
MySQL Cluster Configuration Files

DataMemory and IndexMemory can be changed, but decreasing either of these can be risky; doing so can easily lead to a node or even an entire MySQL Cluster that is unable to restart due to there being insufficient memory space. Increasing these values should be acceptable, but it is recommended that such upgrades are performed in the same manner as a software upgrade, beginning with an update of the configuration file, and then restarting the management server followed by restarting each data node in turn.

Beginning with MySQL Cluster NDB 7.2.3, a proportion (5% by default) of data node resources including DataMemory and IndexMemory is kept in reserve to insure that the data node does not exhaust its memory when performing a restart. This can be adjusted using the MinFreePct [2171] data node configuration parameter (default 5) introduced in the same version of MySQL Cluster.

<table>

</tbody>
</table>

Restart Type: N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

Updates do not increase the amount of index memory used. Inserts take effect immediately; however, rows are not actually deleted until the transaction is committed.

Transaction parameters. The next few [ndbd] parameters that we discuss are important because they affect the number of parallel transactions and the sizes of transactions that can be handled by the system. MaxNoOfConcurrentTransactions sets the number of parallel transactions possible in a node. MaxNoOfConcurrentOperations sets the number of records that can be in update phase or locked simultaneously.

Both of these parameters (especially MaxNoOfConcurrentOperations) are likely targets for users setting specific values and not using the default value. The default value is set for systems using small transactions, to ensure that these do not use excessive memory.

MaxDMLOperationsPerTransaction sets the maximum number of DML operations that can be performed in a given transaction.

- MaxNoOfConcurrentTransactions

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>integer</td>
<td>4096</td>
<td>32 - 4294967039 (0xFFFFFFFF)</td>
</tr>
</tbody>
</table>

Restart Type: N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

Each cluster data node requires a transaction record for each active transaction in the cluster. The task of coordinating transactions is distributed among all of the data nodes. The total number of transaction records in the cluster is the number of transactions in any given node times the number of nodes in the cluster.

Transaction records are allocated to individual MySQL servers. Each connection to a MySQL server requires at least one transaction record, plus an additional transaction object per table accessed by that connection. This means that a reasonable minimum for the total number of transactions in the cluster can be expressed as
MySQL Cluster Configuration Files

TotalNoOfConcurrentTransactions =
    (maximum number of tables accessed in any single transaction + 1) * number of cluster SQL nodes

Suppose that there are 10 SQL nodes using the cluster. A single join involving 10 tables requires 11 transaction records; if there are 10 such joins in a transaction, then 10 * 11 = 110 transaction records are required for this transaction, per MySQL server, or 110 * 10 = 1100 transaction records total. Each data node can be expected to handle TotalNoOfConcurrentTransactions / number of data nodes. For a MySQL Cluster having 4 data nodes, this would mean setting MaxNoOfConcurrentTransactions on each data node to 1100 / 4 = 275. In addition, you should provide for failure recovery by ensuring that a single node group can accommodate all concurrent transactions; in other words, that each data node's MaxNoOfConcurrentTransactions is sufficient to cover a number of transaction equal to TotalNoOfConcurrentTransactions / number of node groups. If this cluster has a single node group, then MaxNoOfConcurrentTransactions should be set to 1100 (the same as the total number of concurrent transactions for the entire cluster).

In addition, each transaction involves at least one operation; for this reason, the value set for MaxNoOfConcurrentTransactions should always be no more than the value of MaxNoOfConcurrentOperations.

This parameter must be set to the same value for all cluster data nodes. This is due to the fact that, when a data node fails, the oldest surviving node re-creates the transaction state of all transactions that were ongoing in the failed node.

It is possible to change this value using a rolling restart, but the amount of traffic on the cluster must be such that no more transactions occur than the lower of the old and new levels while this is taking place.

The default value is 4096.

- MaxNoOfConcurrentOperations

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>integer</td>
<td>32K</td>
<td>32 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

Restart Type: N
(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

It is a good idea to adjust the value of this parameter according to the size and number of transactions. When performing transactions which involve only a few operations and records, the default value for this parameter is usually sufficient. Performing large transactions involving many records usually requires that you increase its value.

Records are kept for each transaction updating cluster data, both in the transaction coordinator and in the nodes where the actual updates are performed. These records contain state information needed to find UNDO records for rollback, lock queues, and other purposes.

This parameter should be set at a minimum to the number of records to be updated simultaneously in transactions, divided by the number of cluster data nodes. For example, in a cluster which has four data nodes and which is expected to handle one million concurrent updates using transactions, you should set this value to 1000000 / 4 = 250000. To help provide resiliency against failures, it is suggested that you set this parameter to a value that is high enough to permit an individual data node to handle the load...
for its node group. In other words, you should set the value equal to total number of concurrent operations / number of node groups. (In the case where there is a single node group, this is the same as the total number of concurrent operations for the entire cluster.)

Because each transaction always involves at least one operation, the value of MaxNoOfConcurrentOperations should always be greater than or equal to the value of MaxNoOfConcurrentTransactions.

Read queries which set locks also cause operation records to be created. Some extra space is allocated within individual nodes to accommodate cases where the distribution is not perfect over the nodes.

When queries make use of the unique hash index, there are actually two operation records used per record in the transaction. The first record represents the read in the index table and the second handles the operation on the base table.

The default value is 32768.

This parameter actually handles two values that can be configured separately. The first of these specifies how many operation records are to be placed with the transaction coordinator. The second part specifies how many operation records are to be local to the database.

A very large transaction performed on an eight-node cluster requires as many operation records in the transaction coordinator as there are reads, updates, and deletes involved in the transaction. However, the operation records of the are spread over all eight nodes. Thus, if it is necessary to configure the system for one very large transaction, it is a good idea to configure the two parts separately. MaxNoOfConcurrentOperations will always be used to calculate the number of operation records in the transaction coordinator portion of the node.

It is also important to have an idea of the memory requirements for operation records. These consume about 1KB per record.

• MaxNoOfLocalOperations

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>integer</td>
<td>UNDEFINED</td>
<td>32 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

Restart Type: N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

By default, this parameter is calculated as 1.1 × MaxNoOfConcurrentOperations. This fits systems with many simultaneous transactions, none of them being very large. If there is a need to handle one very large transaction at a time and there are many nodes, it is a good idea to override the default value by explicitly specifying this parameter.

• MaxDMLOperationsPerTransaction

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>operations (DML)</td>
<td>4294967295</td>
<td>32 - 4294967295</td>
</tr>
</tbody>
</table>

Restart Type: N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)
This parameter limits the size of a transaction. The transaction is aborted if it requires more than this many DML operations. The minimum number of operations per transaction is 32; however, you can set MaxDMLOperationsPerTransaction to 0 to disable any limitation on the number of DML operations per transaction. The maximum (and default) is 4294967295.

**Transaction temporary storage.** The next set of [ndbd] parameters is used to determine temporary storage when executing a statement that is part of a Cluster transaction. All records are released when the statement is completed and the cluster is waiting for the commit or rollback.

The default values for these parameters are adequate for most situations. However, users with a need to support transactions involving large numbers of rows or operations may need to increase these values to enable better parallelism in the system, whereas users whose applications require relatively small transactions can decrease the values to save memory.

- MaxNoOfConcurrentIndexOperations

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>integer</td>
<td>8K</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

For queries using a unique hash index, another temporary set of operation records is used during a query's execution phase. This parameter sets the size of that pool of records. Thus, this record is allocated only while executing a part of a query. As soon as this part has been executed, the record is released. The state needed to handle aborts and commits is handled by the normal operation records, where the pool size is set by the parameter MaxNoOfConcurrentOperations.

The default value of this parameter is 8192. Only in rare cases of extremely high parallelism using unique hash indexes should it be necessary to increase this value. Using a smaller value is possible and can save memory if the DBA is certain that a high degree of parallelism is not required for the cluster.

- MaxNoOfFiredTriggers

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>integer</td>
<td>4000</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

The default value of MaxNoOfFiredTriggers is 4000, which is sufficient for most situations. In some cases it can even be decreased if the DBA feels certain the need for parallelism in the cluster is not high.

A record is created when an operation is performed that affects a unique hash index. Inserting or deleting a record in a table with unique hash indexes or updating a column that is part of a unique hash index fires an insert or a delete in the index table. The resulting record is used to represent this index table operation while waiting for the original operation that fired it to complete. This operation is short-lived but can still require a large number of records in its pool for situations with many parallel write operations on a base table containing a set of unique hash indexes.
• **TransactionBufferMemory**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>bytes</td>
<td>1M</td>
<td>1K - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

The memory affected by this parameter is used for tracking operations fired when updating index tables and reading unique indexes. This memory is used to store the key and column information for these operations. It is only very rarely that the value for this parameter needs to be altered from the default.

The default value for **TransactionBufferMemory** is 1MB.

Normal read and write operations use a similar buffer, whose usage is even more short-lived. The compile-time parameter `ZATTRBUF_FILESIZE` (found in `ndb/src/kernel/blocks/Dbtc/Dbtc.hpp`) set to `4000 × 128` bytes (500KB). A similar buffer for key information, `ZDATABUF_FILESIZE` (also in `Dbtc.hpp`) contains `4000 × 16 = 62.5KB` of buffer space. `Dbtc` is the module that handles transaction coordination.

**Scans and buffering.** There are additional [ndbd] parameters in the `Dblqh` module (in `ndb/src/kernel/blocks/Dblqh/Dblqh.hpp`) that affect reads and updates. These include `ZATTRINBUF_FILESIZE`, set by default to `10000 × 128` bytes (1250KB) and `ZDATABUF_FILE_SIZE`, set by default to `10000*16` bytes (roughly 156KB) of buffer space. To date, there have been neither any reports from users nor any results from our own extensive tests suggesting that either of these compile-time limits should be increased.

• **MaxNoOfConcurrentScans**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>integer</td>
<td>256</td>
<td>2 - 500</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

This parameter is used to control the number of parallel scans that can be performed in the cluster. Each transaction coordinator can handle the number of parallel scans defined for this parameter. Each scan query is performed by scanning all partitions in parallel. Each partition scan uses a scan record in the node where the partition is located, the number of records being the value of this parameter times the number of nodes. The cluster should be able to sustain **MaxNoOfConcurrentScans** scans concurrently from all nodes in the cluster.

Scans are actually performed in two cases. The first of these cases occurs when no hash or ordered indexes exists to handle the query, in which case the query is executed by performing a full table scan. The second case is encountered when there is no hash index to support the query but there is an ordered index. Using the ordered index means executing a parallel range scan. The order is kept on the local partitions only, so it is necessary to perform the index scan on all partitions.

The default value of **MaxNoOfConcurrentScans** is 256. The maximum value is 500.

• **MaxNoOfLocalScans**
### MySQL Cluster Configuration Files

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>integer</td>
<td>[see text]</td>
<td>32 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type: N**

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

Specifies the number of local scan records if many scans are not fully parallelized. In MySQL Cluster NDB 7.2.0 and later, when the number of local scan records is not provided, it is calculated as shown here:

\[
4 \times \text{MaxNoOfConcurrentScans} \times \text{[# data nodes]} + 2
\]

The minimum value is 32.

- **BatchSizePerLocalScan**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>integer</td>
<td>64</td>
<td>1 - 992</td>
</tr>
<tr>
<td>NDB 7.2.1</td>
<td>integer</td>
<td>256</td>
<td>1 - 992</td>
</tr>
</tbody>
</table>

**Restart Type: N**

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

This parameter is used to calculate the number of lock records used to handle concurrent scan operations.

**BatchSizePerLocalScan** has a strong connection to the **BatchSize** defined in the SQL nodes.

- **LongMessageBuffer**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>bytes</td>
<td>4M</td>
<td>512K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>NDB 7.2.16</td>
<td>bytes</td>
<td>64M</td>
<td>512K - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type: N**

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

This is an internal buffer used for passing messages within individual nodes and between nodes. The default is 64MB. (Prior to MySQL Cluster NDB 7.2.16, this was 4MB.)

This parameter seldom needs to be changed from the default.

- **MaxParallelScansPerFragment**
MySQL Cluster Configuration Files

<table>

<td>1 - 4294967039</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>(0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

It is possible to configure the maximum number of parallel scans (TUP scans and TUX scans) allowed before they begin queuing for serial handling. You can increase this to take advantage of any unused CPU when performing large number of scans in parallel and improve their performance.

Beginning with MySQL Cluster NDB 7.2.0, the default value for this parameter was increased from 32 to 256.

**Memory Allocation**

**MaxAllocate** [2177]

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>unsigned</td>
<td>32M</td>
<td>1M - 1G</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

This is the maximum size of the memory unit to use when allocating memory for tables. In cases where NDB gives Out of memory errors, but it is evident by examining the cluster logs or the output of DUMP 1000 (see DUMP 1000) that all available memory has not yet been used, you can increase the value of this parameter (or MaxNoOfTables, or both) to cause NDB to make sufficient memory available.

**Hash Map Size**

**DefaultHashMapSize** [2177]

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>LDM threads</td>
<td>240</td>
<td>0 - 3840</td>
</tr>
<tr>
<td>NDB 7.2.11</td>
<td>LDM threads</td>
<td>3840</td>
<td>0 - 3840</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

MySQL Cluster NDB 7.2.7 and later use a larger default table hash map size (3840) than in previous releases (240). Beginning with MySQL Cluster NDB 7.2.11, the size of the table hash maps used by NDB is configurable using this parameter; previously this value was hard-coded. DefaultHashMapSize can take any of three possible values (0, 240, 3840). These values and their effects are described in the following table:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description / Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Use the lowest value set, if any, for this parameter among all data nodes and API nodes in the cluster; if it is not set on any data or API node, use the default value.</td>
</tr>
</tbody>
</table>
MySQL Cluster Configuration Files

<table>
<thead>
<tr>
<th>Value</th>
<th>Description / Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>240</td>
<td>Original hash map size, used by default in all MySQL Cluster releases prior to MySQL Cluster NDB 7.2.7.</td>
</tr>
<tr>
<td>3840</td>
<td>Larger hash map size as used by default in MySQL Cluster NDB 7.2.7 and later</td>
</tr>
</tbody>
</table>

The primary intended use for this parameter is to facilitate upgrades and especially downgrades between MySQL Cluster NDB 7.2.7 and later MySQL Cluster versions, in which the larger hash map size (3840) is the default, and earlier releases (in which the default was 240), due to the fact that this change is not otherwise backward compatible (Bug #14800539). By setting this parameter to 240 prior to performing an upgrade from an older version where this value is in use, you can cause the cluster to continue using the smaller size for table hash maps, in which case the tables remain compatible with earlier versions following the upgrade. DefaultHashMapSize can be set for individual data nodes, API nodes, or both, but setting it once only, in the [ndbd default] section of the config.ini file, is the recommended practice.

After increasing this parameter, to have existing tables to take advantage of the new size, you can run ALTER TABLE ... REORGANIZE PARTITION on them, after which they can use the larger hash map size. This is in addition to performing a rolling restart, which makes the larger hash maps available to new tables, but does not enable existing tables to use them.

Decreasing this parameter online after any tables have been created or modified with DefaultHashMapSize equal to 3840 is not currently supported.

Logging and checkpointing. The following [ndbd] parameters control log and checkpoint behavior.

- **NoOfFragmentLogFiles**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>integer</td>
<td>16</td>
<td>3 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

This parameter sets the number of REDO log files for the node, and thus the amount of space allocated to REDO logging. Because the REDO log files are organized in a ring, it is extremely important that the first and last log files in the set (sometimes referred to as the “head” and “tail” log files, respectively) do not meet. When these approach one another too closely, the node begins aborting all transactions encompassing updates due to a lack of room for new log records.

A REDO log record is not removed until the required number of local checkpoints has been completed since that log record was inserted. (In MySQL Cluster NDB 7.2, only 2 local checkpoints are necessary). Checkpointing frequency is determined by its own set of configuration parameters discussed elsewhere in this chapter.

The default parameter value is 16, which by default means 16 sets of 4 16MB files for a total of 1024MB. The size of the individual log files is configurable using the FragmentLogFileSize parameter. In scenarios requiring a great many updates, the value for NoOfFragmentLogFiles may need to be set as high as 300 or even higher to provide sufficient space for REDO logs.

If the checkpointing is slow and there are so many writes to the database that the log files are full and the log tail cannot be cut without jeopardizing recovery, all updating transactions are aborted with internal error code 410 (Out of log file space temporarily). This condition prevails until a checkpoint has completed and the log tail can be moved forward.
Important

This parameter cannot be changed “on the fly”; you must restart the node using `--initial`. If you wish to change this value for all data nodes in a running cluster, you can do so using a rolling node restart (using `--initial` when starting each data node).

- **FragmentLogFileSize**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>bytes</td>
<td>16M</td>
<td>4M - 1G</td>
</tr>
</tbody>
</table>

**Restart Type:** IN

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

Setting this parameter enables you to control directly the size of redo log files. This can be useful in situations when MySQL Cluster is operating under a high load and it is unable to close fragment log files quickly enough before attempting to open new ones (only 2 fragment log files can be open at one time); increasing the size of the fragment log files gives the cluster more time before having to open each new fragment log file. The default value for this parameter is 16M.

For more information about fragment log files, see the description for `NoOfFragmentLogFiles`.

- **InitFragmentLogFiles**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>[see values]</td>
<td>SPARSE</td>
<td>SPARSE, FULL</td>
</tr>
</tbody>
</table>

**Restart Type:** IN

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

By default, fragment log files are created sparsely when performing an initial start of a data node—that is, depending on the operating system and file system in use, not all bytes are necessarily written to disk. However, it is possible to override this behavior and force all bytes to be written, regardless of the platform and file system type being used, by means of this parameter. `InitFragmentLogFiles` takes either of two values:

- **SPARSE.** Fragment log files are created sparsely. This is the default value.
- **FULL.** Force all bytes of the fragment log file to be written to disk.

Depending on your operating system and file system, setting `InitFragmentLogFiles=FULL` may help eliminate I/O errors on writes to the REDO log.

- **MaxNoOfOpenFiles**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>unsigned</td>
<td>0</td>
<td>20 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type:** N
This parameter sets a ceiling on how many internal threads to allocate for open files. *Any situation requiring a change in this parameter should be reported as a bug.*

The default value is 0. However, the minimum value to which this parameter can be set is 20.

- **InitialNoOfOpenFiles**

This parameter sets the initial number of internal threads to allocate for open files.

The default value is 27.

- **MaxNoOfSavedMessages**

This parameter sets the maximum number of trace files that are kept before overwriting old ones. Trace files are generated when, for whatever reason, the node crashes.

The default is 25 trace files.

- **MaxLCPStartDelay**

In parallel data node recovery, only table data is actually copied and synchronized in parallel; synchronization of metadata such as dictionary and checkpoint information is done in a serial fashion. In addition, recovery of dictionary and checkpoint information cannot be executed in parallel with performing of local checkpoints. This means that, when starting or restarting many data nodes...
concurrently, data nodes may be forced to wait while a local checkpoint is performed, which can result in longer node recovery times.

It is possible to force a delay in the local checkpoint to permit more (and possibly all) data nodes to complete metadata synchronization; once each data node’s metadata synchronization is complete, all of the data nodes can recover table data in parallel, even while the local checkpoint is being executed. To force such a delay, set `MaxLCPStartDelay`, which determines the number of seconds the cluster can wait to begin a local checkpoint while data nodes continue to synchronize metadata. This parameter should be set in the `[ndbd default]` section of the `config.ini` file, so that it is the same for all data nodes. The maximum value is 600; the default is 0.

- **LcpScanProgressTimeout**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>second</td>
<td>60</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>NDB 7.2.14</td>
<td>second</td>
<td>60</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

A local checkpoint fragment scan watchdog checks periodically for no progress in each fragment scan performed as part of a local checkpoint, and shuts down the node if there is no progress after a given amount of time has elapsed. Prior to MySQL Cluster NDB 7.2.14, this interval is always 60 seconds (Bug #16630410). In MySQL Cluster NDB 7.2.14 and later, this interval can be set using the `LcpScanProgressTimeout` data node configuration parameter, which sets the maximum time for which the local checkpoint can be stalled before the LCP fragment scan watchdog shuts down the node. The default value is 60 seconds (providing compatibility with previous releases). Setting this parameter to 0 disables the LCP fragment scan watchdog altogether.

**Metadata objects.** The next set of `[ndbd]` parameters defines pool sizes for metadata objects, used to define the maximum number of attributes, tables, indexes, and trigger objects used by indexes, events, and replication between clusters. Note that these act merely as “suggestions” to the cluster, and any that are not specified revert to the default values shown.

- **MaxNoOfAttributes**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>integer</td>
<td>1000</td>
<td>32 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

This parameter sets a suggested maximum number of attributes that can be defined in the cluster; like `MaxNoOfTables`, it is not intended to function as a hard upper limit.

(In older MySQL Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with MySQL Cluster Replication, when it was possible to create more
MySQL Cluster Configuration Files

tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than MaxNoOfAttributes attributes.)

The default value is 1000, with the minimum possible value being 32. The maximum is 4294967039. Each attribute consumes around 200 bytes of storage per node due to the fact that all metadata is fully replicated on the servers.

When setting MaxNoOfAttributes, it is important to prepare in advance for any ALTER TABLE statements that you might want to perform in the future. This is due to the fact, during the execution of ALTER TABLE on a Cluster table, 3 times the number of attributes as in the original table are used, and a good practice is to permit double this amount. For example, if the MySQL Cluster table having the greatest number of attributes (greatest_number_of_attributes) has 100 attributes, a good starting point for the value of MaxNoOfAttributes would be $6 \times \text{greatest_number_of_attributes} = 600$.

You should also estimate the average number of attributes per table and multiply this by MaxNoOfTables. If this value is larger than the value obtained in the previous paragraph, you should use the larger value instead.

Assuming that you can create all desired tables without any problems, you should also verify that this number is sufficient by trying an actual ALTER TABLE after configuring the parameter. If this is not successful, increase MaxNoOfAttributes by another multiple of MaxNoOfTables and test it again.

- **MaxNoOfTables**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>integer</td>
<td>128</td>
<td>8 - 20320</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

A table object is allocated for each table and for each unique hash index in the cluster. This parameter sets a suggested maximum number of table objects for the cluster as a whole; like MaxNoOfAttributes, it is not intended to function as a hard upper limit.

(In older MySQL Cluster releases, this parameter was sometimes treated as a hard limit for certain operations. This caused problems with MySQL Cluster Replication, when it was possible to create more tables than could be replicated, and sometimes led to confusion when it was possible [or not possible, depending on the circumstances] to create more than MaxNoOfTables tables.)

For each attribute that has a BLOB data type an extra table is used to store most of the BLOB data. These tables also must be taken into account when defining the total number of tables.

The default value of this parameter is 128. The minimum is 8 and the maximum is 20320. Each table object consumes approximately 20KB per node.

**Note**

The sum of MaxNoOfTables, MaxNoOfOrderedIndexes, and MaxNoOfUniqueHashIndexes must not exceed $2^{32} - 2$ (4294967294).

- **MaxNoOfOrderedIndexes**
For each ordered index in the cluster, an object is allocated describing what is being indexed and its storage segments. By default, each index so defined also defines an ordered index. Each unique index and primary key has both an ordered index and a hash index. `MaxNoOfOrderedIndexes` sets the total number of ordered indexes that can be in use in the system at any one time.

The default value of this parameter is 128. Each index object consumes approximately 10KB of data per node.

```
Note

The sum of `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes` must not exceed $2^{32} - 2$ (4294967294).
```

- **MaxNoOfUniqueHashIndexes**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>integer</td>
<td>64</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

For each unique index that is not a primary key, a special table is allocated that maps the unique key to the primary key of the indexed table. By default, an ordered index is also defined for each unique index. To prevent this, you must specify the `USING HASH` option when defining the unique index.

The default value is 64. Each index consumes approximately 15KB per node.

```
Note

The sum of `MaxNoOfTables`, `MaxNoOfOrderedIndexes`, and `MaxNoOfUniqueHashIndexes` must not exceed $2^{32} - 2$ (4294967294).
```

- **MaxNoOfTriggers**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>integer</td>
<td>768</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>
Internal update, insert, and delete triggers are allocated for each unique hash index. (This means that three triggers are created for each unique hash index.) However, an ordered index requires only a single trigger object. Backups also use three trigger objects for each normal table in the cluster.

Replication between clusters also makes use of internal triggers.

This parameter sets the maximum number of trigger objects in the cluster.

The default value is 768.

- **MaxNoOfIndexes**

This parameter is deprecated and subject to removal in a future version of MySQL Cluster. You should use `MaxNoOfOrderedIndexes` and `MaxNoOfUniqueHashIndexes` instead.

This parameter is used only by unique hash indexes. There needs to be one record in this pool for each unique hash index defined in the cluster.

The default value of this parameter is 128.

- **MaxNoOfSubscriptions**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>unsigned</td>
<td>0</td>
<td>0 - 4294967039</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>(0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

*Restart Type: N*

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

Each NDB table in a MySQL Cluster requires a subscription in the NDB kernel. For some NDB API applications, it may be necessary or desirable to change this parameter. However, for normal usage with MySQL servers acting as SQL nodes, there is not any need to do so.

The default value for `MaxNoOfSubscriptions` is 0, which is treated as equal to `MaxNoOfTables`. Each subscription consumes 108 bytes.

- **MaxNoOfSubscribers**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>unsigned</td>
<td>0</td>
<td>0 - 4294967039</td>
<td>(0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

*Restart Type: N*

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

This parameter is of interest only when using MySQL Cluster Replication. The default value is 0, which is treated as \(2 \times \text{MaxNoOfTables}\); that is, there is one subscription per NDB table for each of two MySQL servers (one acting as the replication master and the other as the slave). Each subscriber uses 16 bytes of memory.

When using circular replication, multi-master replication, and other replication setups involving more than 2 MySQL servers, you should increase this parameter to the number of `mysqld` processes.
MySQL Cluster Configuration Files

included in replication (this is often, but not always, the same as the number of clusters). For example, if you have a circular replication setup using three MySQL Clusters, with one `mysqld` attached to each cluster, and each of these `mysqld` processes acts as a master and as a slave, you should set `MaxNoOfSubscribers` equal to `3 * MaxNoOfTables`.

For more information, see Section 18.6, "MySQL Cluster Replication".

• `MaxNoOfConcurrentSubOperations`

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>unsigned</td>
<td>256</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

Restart Type: N
(See Section 18.3.3.1, "MySQL Cluster Data Node Configuration Parameters", for information about restart types.)

This parameter sets a ceiling on the number of operations that can be performed by all API nodes in the cluster at one time. The default value (256) is sufficient for normal operations, and might need to be adjusted only in scenarios where there are a great many API nodes each performing a high volume of operations concurrently.

Boolean parameters. The behavior of data nodes is also affected by a set of `[ndbd]` parameters taking on boolean values. These parameters can each be specified as `TRUE` by setting them equal to `1` or `Y`, and as `FALSE` by setting them equal to `0` or `N`.

• `LateAlloc`

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>numeric</td>
<td>1</td>
<td>0 - 1</td>
</tr>
</tbody>
</table>

Restart Type: N
(See Section 18.3.3.1, "MySQL Cluster Data Node Configuration Parameters", for information about restart types.)

Allocate memory for this data node after a connection to the management server has been established. Enabled by default.

• `LockPagesInMainMemory`

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>numeric</td>
<td>0</td>
<td>0 - 2</td>
</tr>
</tbody>
</table>

Restart Type: N
(See Section 18.3.3.1, "MySQL Cluster Data Node Configuration Parameters", for information about restart types.)

For a number of operating systems, including Solaris and Linux, it is possible to lock a process into memory and so avoid any swapping to disk. This can be used to help guarantee the cluster's real-time characteristics.

This parameter takes one of the integer values `0`, `1`, or `2`, which act as shown in the following list:
• 0: Disables locking. This is the default value.
• 1: Performs the lock after allocating memory for the process.
• 2: Performs the lock before memory for the process is allocated.

If the operating system is not configured to permit unprivileged users to lock pages, then the data node process making use of this parameter may have to be run as system root. (LockPagesInMainMemory uses the mlockall function. From Linux kernel 2.6.9, unprivileged users can lock memory as limited by max locked memory. For more information, see ulimit -l and http://linux.die.net/man/2/mlock).

Note

In older MySQL Cluster releases, this parameter was a Boolean. 0 or false was the default setting, and disabled locking. 1 or true enabled locking of the process after its memory was allocated. In MySQL Cluster NDB 7.2, using true or false as the value of this parameter causes an error.

Important

Beginning with glibc 2.10, glibc uses per-thread arenas to reduce lock contention on a shared pool, which consumes real memory. In general, a data node process does not need per-thread arenas, since it does not perform any memory allocation after startup. (This difference in allocators does not appear to affect performance significantly.)

The glibc behavior is intended to be configurable via the MALLOC_ARENA_MAX environment variable, but a bug in this mechanism prior to glibc 2.16 meant that this variable could not be set to less than 8, so that the wasted memory could not be reclaimed. (Bug #15907219; see also http://sourceware.org/bugzilla/show_bug.cgi?id=13137 for more information concerning this issue.)

One possible workaround for this problem is to use the LD_PRELOAD environment variable to preload a jemalloc memory allocation library to take the place of that supplied with glibc.

• StopOnError

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>boolean</td>
<td>true</td>
<td>true, false</td>
</tr>
</tbody>
</table>

Restart Type: N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

This parameter specifies whether a data node process should exit or perform an automatic restart when an error condition is encountered.

This parameter's default value is true; this means that, by default, an error causes the data node process to halt.

• CrashOnCorruptedTuple
### MySQL Cluster Configuration Files

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>boolean</td>
<td>false</td>
<td>true, false</td>
</tr>
<tr>
<td>NDB 7.2.1</td>
<td>boolean</td>
<td>true</td>
<td>true, false</td>
</tr>
</tbody>
</table>

**Restart Type: S**

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

When this parameter is enabled, it forces a data node to shut down whenever it encounters a corrupted tuple. In MySQL Cluster NDB 7.2.1 and later, it is enabled by default. This is a change from MySQL Cluster NDB 7.0 and MySQL Cluster NDB 7.1, where it was disabled by default.

- **Diskless**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>true</td>
<td>false (1</td>
<td>0)</td>
</tr>
</tbody>
</table>

**Restart Type: IS**

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

It is possible to specify MySQL Cluster tables as diskless, meaning that tables are not checkpointed to disk and that no logging occurs. Such tables exist only in main memory. A consequence of using diskless tables is that neither the tables nor the records in those tables survive a crash. However, when operating in diskless mode, it is possible to run ndbd on a diskless computer.

⚠️ **Important**

This feature causes the entire cluster to operate in diskless mode.

When this feature is enabled, Cluster online backup is disabled. In addition, a partial start of the cluster is not possible.

**Diskless** is disabled by default.

- **ODirect**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>boolean</td>
<td>false</td>
<td>true, false</td>
</tr>
</tbody>
</table>

**Restart Type: N**

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

Enabling this parameter causes NDB to attempt using O_DIRECT writes for LCP, backups, and redo logs, often lowering kswapd and CPU usage. When using MySQL Cluster on Linux, enable ODirect if you are using a 2.6 or later kernel.

**ODirect** is disabled by default.

- **RestartOnErrorInsert**
### MySQL Cluster Configuration Files

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>error code</td>
<td>2</td>
<td>0 - 4</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

This feature is accessible only when building the debug version where it is possible to insert errors in the execution of individual blocks of code as part of testing.

This feature is disabled by default.

- **CompressedBackup**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>boolean</td>
<td>false</td>
<td>true, false</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

Setting this parameter to 1 causes backup files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed backup files. Compressed backups can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

**Important**

You cannot restore a compressed backup to a cluster running a MySQL version that does not support this feature.

The default value is 0 (disabled).

- **CompressedLCP**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>boolean</td>
<td>false</td>
<td>true, false</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

Setting this parameter to 1 causes local checkpoint files to be compressed. The compression used is equivalent to `gzip --fast`, and can save 50% or more of the space required on the data node to store uncompressed checkpoint files. Compressed LCPs can be enabled for individual data nodes, or for all data nodes (by setting this parameter in the `[ndbd default]` section of the `config.ini` file).

**Important**

You cannot restore a compressed local checkpoint to a cluster running a MySQL version that does not support this feature.
The default value is 0 (disabled).

**Controlling Timeouts, Intervals, and Disk Paging**

There are a number of [ndbd] parameters specifying timeouts and intervals between various actions in Cluster data nodes. Most of the timeout values are specified in milliseconds. Any exceptions to this are mentioned where applicable.

- **TimeBetweenWatchDogCheck**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>milliseconds</td>
<td>6000</td>
<td>70 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

  **Restart Type:** N

  (See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

  To prevent the main thread from getting stuck in an endless loop at some point, a “watchdog” thread checks the main thread. This parameter specifies the number of milliseconds between checks. If the process remains in the same state after three checks, the watchdog thread terminates it.

  This parameter can easily be changed for purposes of experimentation or to adapt to local conditions. It can be specified on a per-node basis although there seems to be little reason for doing so.

  The default timeout is 6000 milliseconds (6 seconds).

- **TimeBetweenWatchDogCheckInitial**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>milliseconds</td>
<td>6000</td>
<td>70 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

  **Restart Type:** N

  (See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

  This is similar to the **TimeBetweenWatchDogCheck** parameter, except that **TimeBetweenWatchDogCheckInitial** controls the amount of time that passes between execution checks inside a database node in the early start phases during which memory is allocated.

  The default timeout is 6000 milliseconds (6 seconds).

- **StartPartialTimeout**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>milliseconds</td>
<td>30000</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

  **Restart Type:** N

  (See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)
This parameter specifies how long the Cluster waits for all data nodes to come up before the cluster initialization routine is invoked. This timeout is used to avoid a partial Cluster startup whenever possible.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default value is 30000 milliseconds (30 seconds). 0 disables the timeout, in which case the cluster may start only if all nodes are available.

- **StartPartitionedTimeout**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>milliseconds</td>
<td>60000</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type: N**

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

If the cluster is ready to start after waiting for **StartPartialTimeout** milliseconds but is still possibly in a partitioned state, the cluster waits until this timeout has also passed. If **StartPartitionedTimeout** is set to 0, the cluster waits indefinitely.

This parameter is overridden when performing an initial start or initial restart of the cluster.

The default timeout is 60000 milliseconds (60 seconds).

- **StartFailureTimeout**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>milliseconds</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type: N**

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

If a data node has not completed its startup sequence within the time specified by this parameter, the node startup fails. Setting this parameter to 0 (the default value) means that no data node timeout is applied.

For nonzero values, this parameter is measured in milliseconds. For data nodes containing extremely large amounts of data, this parameter should be increased. For example, in the case of a data node containing several gigabytes of data, a period as long as 10–15 minutes (that is, 600000 to 1000000 milliseconds) might be required to perform a node restart.

- **StartNoNodeGroupTimeout**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>milliseconds</td>
<td>15000</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type: N**
When a data node is configured with `Nodegroup = 65536`, it is regarded as not being assigned to any node group. When that is done, the cluster waits `StartNoNodegroupTimeout` milliseconds, then treats such nodes as though they had been added to the list passed to the `--nowait-nodes` option, and starts. The default value is 15000 (that is, the management server waits 15 seconds). Setting this parameter equal to 0 means that the cluster waits indefinitely.

`StartNoNodegroupTimeout` must be the same for all data nodes in the cluster; for this reason, you should always set it in the `[ndbd default]` section of the `config.ini` file, rather than for individual data nodes.

See Section 18.5.13, “Adding MySQL Cluster Data Nodes Online”, for more information.

### HeartbeatIntervalDbDb

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>milliseconds</td>
<td>5000</td>
<td>10 - 4294967039</td>
</tr>
</tbody>
</table>

Restart Type: N

One of the primary methods of discovering failed nodes is by the use of heartbeats. This parameter states how often heartbeat signals are sent and how often to expect to receive them. After missing three heartbeat intervals in a row, the node is declared dead. Thus, the maximum time for discovering a failure through the heartbeat mechanism is four times the heartbeat interval.

In MySQL Cluster NDB 7.2.0 and later, the default heartbeat interval is 5000 milliseconds (5 seconds). (Previously, the default was 1500 milliseconds [1.5 seconds]). This parameter must not be changed drastically and should not vary widely between nodes. If one node uses 5000 milliseconds and the node watching it uses 1000 milliseconds, obviously the node will be declared dead very quickly. This parameter can be changed during an online software upgrade, but only in small increments.

See also Network communication and latency.

### HeartbeatIntervalDbApi

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>milliseconds</td>
<td>1500</td>
<td>100 - 4294967039</td>
</tr>
</tbody>
</table>

Restart Type: N

Each data node sends heartbeat signals to each MySQL server (SQL node) to ensure that it remains in contact. If a MySQL server fails to send a heartbeat in time it is declared “dead,” in which case all ongoing transactions are completed and all resources released. The SQL node cannot reconnect until all
activities initiated by the previous MySQL instance have been completed. The three-heartbeat criteria for this determination are the same as described for `HeartbeatIntervalDbDb`.

The default interval is 1500 milliseconds (1.5 seconds). This interval can vary between individual data nodes because each data node watches the MySQL servers connected to it, independently of all other data nodes.

For more information, see Network communication and latency.

- `HeartbeatOrder`

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>numeric</td>
<td>0</td>
<td>0 - 65535</td>
</tr>
</tbody>
</table>

**Restart Type:** S

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

Data nodes send heartbeats to one another in a circular fashion whereby each data node monitors the previous one. If a heartbeat is not detected by a given data node, this node declares the previous data node in the circle “dead” (that is, no longer accessible by the cluster). The determination that a data node is dead is done globally; in other words; once a data node is declared dead, it is regarded as such by all nodes in the cluster.

It is possible for heartbeats between data nodes residing on different hosts to be too slow compared to heartbeats between other pairs of nodes (for example, due to a very low heartbeat interval or temporary connection problem), such that a data node is declared dead, even though the node can still function as part of the cluster.

In this type of situation, it may be that the order in which heartbeats are transmitted between data nodes makes a difference as to whether or not a particular data node is declared dead. If this declaration occurs unnecessarily, this can in turn lead to the unnecessary loss of a node group and as thus to a failure of the cluster.

Consider a setup where there are 4 data nodes A, B, C, and D running on 2 host computers `host1` and `host2`, and that these data nodes make up 2 node groups, as shown in the following table:

<table>
<thead>
<tr>
<th>Node Group</th>
<th>Nodes Running on <code>host1</code></th>
<th>Nodes Running on <code>host2</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Node Group 0:</td>
<td>Node A</td>
<td>Node B</td>
</tr>
<tr>
<td>Node Group 1:</td>
<td>Node C</td>
<td>Node D</td>
</tr>
</tbody>
</table>

Suppose the heartbeats are transmitted in the order A->B->C->D->A. In this case, the loss of the heartbeat between the hosts causes node B to declare node A dead and node C to declare node B dead. This results in loss of Node Group 0, and so the cluster fails. On the other hand, if the order of transmission is A->B->D->C->A (and all other conditions remain as previously stated), the loss of the heartbeat causes nodes A and D to be declared dead; in this case, each node group has one surviving node, and the cluster survives.

The `HeartbeatOrder` configuration parameter makes the order of heartbeat transmission user-configurable. The default value for `HeartbeatOrder` is zero; allowing the default value to be used on all data nodes causes the order of heartbeat transmission to be determined by `NDB`. If this parameter is used, it must be set to a nonzero value (maximum 65535) for every data node in the cluster, and this value must be unique for each data node; this causes the heartbeat transmission to proceed from
data node to data node in the order of their `HeartbeatOrder` values from lowest to highest (and then directly from the data node having the highest `HeartbeatOrder` to the data node having the lowest value, to complete the circle). The values need not be consecutive; for example, to force the heartbeat transmission order A->B->D->C->A in the scenario outlined previously, you could set the `HeartbeatOrder` values as shown here:

<table>
<thead>
<tr>
<th>Node</th>
<th>HeartbeatOrder</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>10</td>
</tr>
<tr>
<td>B</td>
<td>20</td>
</tr>
<tr>
<td>C</td>
<td>30</td>
</tr>
<tr>
<td>D</td>
<td>25</td>
</tr>
</tbody>
</table>

To use this parameter to change the heartbeat transmission order in a running MySQL Cluster, you must first set `HeartbeatOrder` for each data node in the cluster in the global configuration (config.ini) file (or files). To cause the change to take effect, you must perform either of the following:

- A complete shutdown and restart of the entire cluster.
- 2 rolling restarts of the cluster in succession. *All nodes must be restarted in the same order in both rolling restarts.*

You can use `DUMP` to observe the effect of this parameter in the data node logs.

- `ConnectCheckIntervalDelay`

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>string</td>
<td>1500</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>NDB 7.2.1</td>
<td>string</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

This parameter enables connection checking between data nodes. A data node that fails to respond within an interval of `ConnectCheckIntervalDelay` seconds is considered suspect, and is considered dead after two such intervals.

The default value for this parameter is 0; this is a change from MySQL Cluster NDB 7.1.

- `TimeBetweenLocalCheckpoints`

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>number of 4-byte words, as a base-2 logarithm</td>
<td>20</td>
<td>0 - 31</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)
This parameter is an exception in that it does not specify a time to wait before starting a new local checkpoint; rather, it is used to ensure that local checkpoints are not performed in a cluster where relatively few updates are taking place. In most clusters with high update rates, it is likely that a new local checkpoint is started immediately after the previous one has been completed.

The size of all write operations executed since the start of the previous local checkpoints is added. This parameter is also exceptional in that it is specified as the base-2 logarithm of the number of 4-byte words, so that the default value 20 means $4\times 2^{20}$ of write operations, 21 would mean 8MB, and so on up to a maximum value of 31, which equates to 8GB of write operations.

All the write operations in the cluster are added together. Setting `TimeBetweenLocalCheckpoints` to 6 or less means that local checkpoints will be executed continuously without pause, independent of the cluster's workload.

- `TimeBetweenGlobalCheckpoints`

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>milliseconds</td>
<td>2000</td>
<td>20 - 32000</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

When a transaction is committed, it is committed in main memory in all nodes on which the data is mirrored. However, transaction log records are not flushed to disk as part of the commit. The reasoning behind this behavior is that having the transaction safely committed on at least two autonomous host machines should meet reasonable standards for durability.

It is also important to ensure that even the worst of cases—a complete crash of the cluster—is handled properly. To guarantee that this happens, all transactions taking place within a given interval are put into a global checkpoint, which can be thought of as a set of committed transactions that has been flushed to disk. In other words, as part of the commit process, a transaction is placed in a global checkpoint group. Later, this group's log records are flushed to disk, and then the entire group of transactions is safely committed to disk on all computers in the cluster.

This parameter defines the interval between global checkpoints. The default is 2000 milliseconds.

- `TimeBetweenEpochs`

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>milliseconds</td>
<td>100</td>
<td>0 - 32000</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

This parameter defines the interval between synchronization epochs for MySQL Cluster Replication. The default value is 100 milliseconds.

`TimeBetweenEpochs` is part of the implementation of “micro-GCPs”, which can be used to improve the performance of MySQL Cluster Replication.

- `TimeBetweenEpochsTimeout`
This parameter defines a timeout for synchronization epochs for MySQL Cluster Replication. If a node fails to participate in a global checkpoint within the time determined by this parameter, the node is shut down. In MySQL Cluster NDB 7.2.0 and later, the default value is 0; in other words, the timeout is disabled. This represents a change from previous versions of MySQL Cluster, in which the default value was 4000 milliseconds (4 seconds).

TimeBetweenEpochsTimeout is part of the implementation of “micro-GCPs”, which can be used to improve the performance of MySQL Cluster Replication.

The current value of this parameter and a warning are written to the cluster log whenever a GCP save takes longer than 1 minute or a GCP save takes longer than 10 seconds.

Setting this parameter to zero has the effect of disabling GCP stops caused by save timeouts, commit timeouts, or both. The maximum possible value for this parameter is 256000 milliseconds.

**MaxBufferedEpochs**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>epochs</td>
<td>100</td>
<td>0 - 100000</td>
</tr>
</tbody>
</table>

The number of unprocessed epochs by which a subscribing node can lag behind. Exceeding this number causes a lagging subscriber to be disconnected.

The default value of 100 is sufficient for most normal operations. If a subscribing node does lag enough to cause disconnections, it is usually due to network or scheduling issues with regard to processes or threads. (In rare circumstances, the problem may be due to a bug in the NDB client.) It may be desirable to set the value lower than the default when epochs are longer.

Disconnection prevents client issues from affecting the data node service, running out of memory to buffer data, and eventually shutting down. Instead, only the client is affected as a result of the disconnect (by, for example gap events in the binary log), forcing the client to reconnect or restart the process.

**MaxBufferedEpochBytes**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>bytes</td>
<td>26214400</td>
<td>26214400 (0x01900000) - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>NDB 7.2.13</td>
<td>bytes</td>
<td>26214400</td>
<td>26214400 (0x01900000) - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>
### MySQL Cluster Configuration Files

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Restart Type:</strong> N</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The total number of bytes allocated for buffering epochs by this node.

This parameter was introduced in MySQL Cluster NDB 7.2.13. (Bug #16203623)

- **TimeBetweenInactiveTransactionAbortCheck**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>milliseconds</td>
<td>1000</td>
<td>1000 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type:</strong> N</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Timeout handling is performed by checking a timer on each transaction once for every interval specified by this parameter. Thus, if this parameter is set to 1000 milliseconds, every transaction will be checked for timing out once per second.

The default value is 1000 milliseconds (1 second).

- **TransactionInactiveTimeout**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>milliseconds</td>
<td>[see text]</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type:</strong> N</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

This parameter states the maximum time that is permitted to lapse between operations in the same transaction before the transaction is aborted.

The default for this parameter is \(4G\) (also the maximum). For a real-time database that needs to ensure that no transaction keeps locks for too long, this parameter should be set to a relatively small value. The unit is milliseconds.

- **TransactionDeadlockDetectionTimeout**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>milliseconds</td>
<td>1200</td>
<td>50 - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td><strong>Restart Type:</strong> N</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
When a node executes a query involving a transaction, the node waits for the other nodes in the cluster to respond before continuing. A failure to respond can occur for any of the following reasons:

- The node is “dead”
- The operation has entered a lock queue
- The node requested to perform the action could be heavily overloaded.

This timeout parameter states how long the transaction coordinator waits for query execution by another node before aborting the transaction, and is important for both node failure handling and deadlock detection.

The default timeout value is 1200 milliseconds (1.2 seconds).

The minimum for this parameter is 50 milliseconds.

- **DiskSyncSize**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>bytes</td>
<td>4M</td>
<td>32K - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

  **Restart Type:** N

  (See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

  This is the maximum number of bytes to store before flushing data to a local checkpoint file. This is done to prevent write buffering, which can impede performance significantly. This parameter is not intended to take the place of TimeBetweenLocalCheckpoints.

  ![Note]

  **Note**

  When ODirect is enabled, it is not necessary to set DiskSyncSize; in fact, in such cases its value is simply ignored.

  The default value is 4M (4 megabytes).

- **DiskCheckpointSpeed**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>bytes</td>
<td>10M</td>
<td>1M - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

  **Restart Type:** N

  (See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

  The amount of data, in bytes per second, that is sent to disk during a local checkpoint. This allocation is shared by DML operations and backups (but not backup logging), which means that backups started during times of intensive DML may be impaired by flooding of the redo log buffer and may fail altogether if the contention is sufficiently severe.

  The default value is 10M (10 megabytes per second).
MySQL Cluster Configuration Files

- **DiskCheckpointSpeedInRestart**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>bytes</td>
<td>100M</td>
<td>1M - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type: N**

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

The amount of data, in bytes per second, that is sent to disk during a local checkpoint as part of a restart operation.

The default value is 100M (100 megabytes per second).

- **NoOfDiskPagesToDiskAfterRestartTUP**

  This parameter is deprecated and subject to removal in a future version of MySQL Cluster. Use DiskCheckpointSpeedInRestart and DiskSyncSize instead.

- **NoOfDiskPagesToDiskAfterRestartACC**

  This parameter is deprecated and subject to removal in a future version of MySQL Cluster. Use DiskCheckpointSpeedInRestart and DiskSyncSize instead.

- **NoOfDiskPagesToDiskDuringRestartTUP** (DEPRECATED)

  This parameter is deprecated and subject to removal in a future version of MySQL Cluster. Use DiskCheckpointSpeedInRestart and DiskSyncSize instead.

- **NoOfDiskPagesToDiskDuringRestartACC** (DEPRECATED)

  This parameter is deprecated and subject to removal in a future version of MySQL Cluster. Use DiskCheckpointSpeedInRestart and DiskSyncSize instead.

- **ArbitrationTimeout**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>milliseconds</td>
<td>7500</td>
<td>10 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type: N**

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

This parameter specifies how long data nodes wait for a response from the arbitrator to an arbitration message. If this is exceeded, the network is assumed to have split.

In MySQL Cluster NDB 7.2.0 and later, the default value is 7500 milliseconds (7.5 seconds). Previously, this was 3000 milliseconds (3 seconds).
MySQL Cluster Configuration Files

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>enumeration</td>
<td>Default</td>
<td>Default, Disabled, WaitExternal</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

The Arbitration parameter enables a choice of arbitration schemes, corresponding to one of 3 possible values for this parameter:

- **Default.** This enables arbitration to proceed normally, as determined by the ArbitrationRank settings for the management and API nodes. This is the default value.

- **Disabled.** Setting Arbitration = Disabled in the [ndbd default] section of the config.ini file to accomplishes the same task as setting ArbitrationRank to 0 on all management and API nodes. When Arbitration is set in this way, any ArbitrationRank settings are ignored.

- **WaitExternal.** The Arbitration parameter also makes it possible to configure arbitration in such a way that the cluster waits until after the time determined by ArbitrationTimeout has passed for an external cluster manager application to perform arbitration instead of handling arbitration internally. This can be done by setting Arbitration = WaitExternal in the [ndbd default] section of the config.ini file. For best results with the WaitExternal setting, it is recommended that ArbitrationTimeout be 2 times as long as the interval required by the external cluster manager to perform arbitration.

**Important**

This parameter should be used only in the [ndbd default] section of the cluster configuration file. The behavior of the cluster is unspecified when Arbitration is set to different values for individual data nodes.

**Buffering and logging.** Several [ndbd] configuration parameters enable the advanced user to have more control over the resources used by node processes and to adjust various buffer sizes at need.

These buffers are used as front ends to the file system when writing log records to disk. If the node is running in diskless mode, these parameters can be set to their minimum values without penalty due to the fact that disk writes are “faked” by the NDB storage engine’s file system abstraction layer.

- **UndoIndexBuffer**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>unsigned</td>
<td>2M</td>
<td>1M - 4294967039</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

The UNDO index buffer, whose size is set by this parameter, is used during local checkpoints. The NDB storage engine uses a recovery scheme based on checkpoint consistency in conjunction with an operational REDO log. To produce a consistent checkpoint without blocking the entire system for
writes, UNDO logging is done while performing the local checkpoint. UNDO logging is activated on a single table fragment at a time. This optimization is possible because tables are stored entirely in main memory.

The UNDO index buffer is used for the updates on the primary key hash index. Inserts and deletes rearrange the hash index; the NDB storage engine writes UNDO log records that map all physical changes to an index page so that they can be undone at system restart. It also logs all active insert operations for each fragment at the start of a local checkpoint.

Reads and updates set lock bits and update a header in the hash index entry. These changes are handled by the page-writing algorithm to ensure that these operations need no UNDO logging.

This buffer is 2MB by default. The minimum value is 1MB, which is sufficient for most applications. For applications doing extremely large or numerous inserts and deletes together with large transactions and large primary keys, it may be necessary to increase the size of this buffer. If this buffer is too small, the NDB storage engine issues internal error code 677 (`Index UNDO buffers overloaded`).

⚠️ Important
It is not safe to decrease the value of this parameter during a rolling restart.

• **UndoDataBuffer**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>unsigned</td>
<td>16M</td>
<td>1M - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

Restart Type: N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

This parameter sets the size of the UNDO data buffer, which performs a function similar to that of the UNDO index buffer, except the UNDO data buffer is used with regard to data memory rather than index memory. This buffer is used during the local checkpoint phase of a fragment for inserts, deletes, and updates.

Because UNDO log entries tend to grow larger as more operations are logged, this buffer is also larger than its index memory counterpart, with a default value of 16MB.

This amount of memory may be unnecessarily large for some applications. In such cases, it is possible to decrease this size to a minimum of 1MB.

It is rarely necessary to increase the size of this buffer. If there is such a need, it is a good idea to check whether the disks can actually handle the load caused by database update activity. A lack of sufficient disk space cannot be overcome by increasing the size of this buffer.

If this buffer is too small and gets congested, the NDB storage engine issues internal error code 891 (`Data UNDO buffers overloaded`).

⚠️ Important
It is not safe to decrease the value of this parameter during a rolling restart.

• **RedoBuffer**
### MySQL Cluster Configuration Files

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>bytes</td>
<td>32M</td>
<td>1M - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type: N**

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

All update activities also need to be logged. The REDO log makes it possible to replay these updates whenever the system is restarted. The NDB recovery algorithm uses a “fuzzy” checkpoint of the data together with the UNDO log, and then applies the REDO log to play back all changes up to the restoration point.

**RedoBuffer** sets the size of the buffer in which the REDO log is written. The default value is 32MB; the minimum value is 1MB.

If this buffer is too small, the **NDB** storage engine issues error code 1221 (**REDO log buffers overloaded**). For this reason, you should exercise care if you attempt to decrease the value of **RedoBuffer** as part of an online change in the cluster's configuration.

- **EventLogBufferSize**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>bytes</td>
<td>8192</td>
<td>0 - 64K</td>
</tr>
</tbody>
</table>

**Restart Type: S**

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

Controls the size of the circular buffer used for NDB log events within data nodes.

**Controlling log messages.** In managing the cluster, it is very important to be able to control the number of log messages sent for various event types to **stdout**. For each event category, there are 16 possible event levels (numbered 0 through 15). Setting event reporting for a given event category to level 15 means all event reports in that category are sent to **stdout**; setting it to 0 means that there will be no event reports made in that category.

By default, only the startup message is sent to **stdout**, with the remaining event reporting level defaults being set to 0. The reason for this is that these messages are also sent to the management server’s cluster log.

An analogous set of levels can be set for the management client to determine which event levels to record in the cluster log.

- **LogLevelStartup**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>

<td>0 - 15</td>
</tr>
</tbody>
</table>

**Restart Type: N**
The reporting level for events generated for information about the general state of the cluster.

The default level is 0.

- **MemReportFrequency**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>unsigned</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

This parameter controls how often data node memory usage reports are recorded in the cluster log; it is an integer value representing the number of seconds between reports.

Each data node’s data memory and index memory usage is logged as both a percentage and a number of 32 KB pages of the `DataMemory` and `IndexMemory`, respectively, set in the `config.ini` file. For example, if `DataMemory` is equal to 100 MB, and a given data node is using 50 MB for data memory storage, the corresponding line in the cluster log might look like this:

```
2006-12-24 01:18:16 [MgmSrvr] INFO -- Node 2: Data usage is 50%(1280 32K pages of total 2560)
```

**MemReportFrequency** is not a required parameter. If used, it can be set for all cluster data nodes in the `[ndbd default]` section of `config.ini`, and can also be set or overridden for individual data nodes in the corresponding `[ndbd]` sections of the configuration file. The minimum value—which is also the default value—is 0, in which case memory reports are logged only when memory usage reaches certain percentages (80%, 90%, and 100%), as mentioned in the discussion of statistics events in Section 18.5.6.2, “MySQL Cluster Log Events”.

- **StartupStatusReportFrequency**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>seconds</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

When a data node is started with the `--initial` option, it initializes the redo log file during Start Phase 4 (see Section 18.5.1, “Summary of MySQL Cluster Start Phases”). When very large values are set for `NoOfFragmentLogFiles`, `FragmentLogFileSize`, or both, this initialization can take a long time. You can force reports on the progress of this process to be logged periodically, by means of the `StartupStatusReportFrequency` configuration parameter. In this case, progress is reported in the cluster log, in terms of both the number of files and the amount of space that have been initialized, as shown here:
MySQL Cluster Configuration Files

These reports are logged each StartupStatusReportFrequency seconds during Start Phase 4. If StartupStatusReportFrequency is 0 (the default), then reports are written to the cluster log only when at the beginning and at the completion of the redo log file initialization process.

Debugging Parameters. In MySQL Cluster NDB 7.2, it is possible to cause logging of traces for events generated by creating and dropping tables using DictTrace. This parameter is useful only in debugging NDB kernel code. DictTrace takes an integer value; currently, 0 (default - no logging) and 1 (logging enabled) are the only supported values.

Backup parameters. The [ndbd] parameters discussed in this section define memory buffers set aside for execution of online backups.

- BackupDataBufferSize

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>bytes</td>
<td>16M</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

Restart Type: N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

In creating a backup, there are two buffers used for sending data to the disk. The backup data buffer is used to fill in data recorded by scanning a node's tables. Once this buffer has been filled to the level specified as BackupWriteSize, the pages are sent to disk. While flushing data to disk, the backup process can continue filling this buffer until it runs out of space. When this happens, the backup process pauses the scan and waits until some disk writes have completed freeing up memory so that scanning may continue.

The default value for this parameter is 16MB.

- BackupLogBufferSize

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>bytes</td>
<td>16M</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

Restart Type: N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

The backup log buffer fulfills a role similar to that played by the backup data buffer, except that it is used for generating a log of all table writes made during execution of the backup. The same principles apply for writing these pages as with the backup data buffer, except that when there is no more space in the backup log buffer, the backup fails. For that reason, the size of the backup log buffer must
be large enough to handle the load caused by write activities while the backup is being made. See Section 18.5.3.3, “Configuration for MySQL Cluster Backups”.

The default value for this parameter should be sufficient for most applications. In fact, it is more likely for a backup failure to be caused by insufficient disk write speed than it is for the backup log buffer to become full. If the disk subsystem is not configured for the write load caused by applications, the cluster is unlikely to be able to perform the desired operations.

It is preferable to configure cluster nodes in such a manner that the processor becomes the bottleneck rather than the disks or the network connections.

The default value for this parameter is 16MB.

- **BackupMemory**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>bytes</td>
<td>32M</td>
<td>0 - 4294967039</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>(0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

This parameter is simply the sum of `BackupDataBufferSize` and `BackupLogBufferSize`.

The default value of this parameter in MySQL Cluster NDB 7.2 is 16MB + 16MB = 32MB.

---

**Important**

If `BackupDataBufferSize` and `BackupLogBufferSize` taken together exceed the default value for `BackupMemory`, then this parameter must be set explicitly in the `config.ini` file to their sum.

- **BackupReportFrequency**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>seconds</td>
<td>0</td>
<td>0 - 4294967039</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>(0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

This parameter controls how often backup status reports are issued in the management client during a backup, as well as how often such reports are written to the cluster log (provided cluster event logging is configured to permit it—see Logging and checkpointing). `BackupReportFrequency` represents the time in seconds between backup status reports.

The default value is 0.

- **BackupWriteSize**
MySQL Cluster Configuration Files

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>bytes</td>
<td>256K</td>
<td>2K - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type: N**

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

This parameter specifies the default size of messages written to disk by the backup log and backup data buffers.

The default value for this parameter is 256KB.

- **BackupMaxWriteSize**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>bytes</td>
<td>1M</td>
<td>2K - 4294967039 (0xFFFFFEFF)</td>
</tr>
<tr>
<td>NDB 7.2.1</td>
<td>bytes</td>
<td>1M</td>
<td>2K - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type: N**

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

This parameter specifies the maximum size of messages written to disk by the backup log and backup data buffers.

The default value for this parameter is 1MB.

---

### Important

When specifying these parameters, the following relationships must hold true. Otherwise, the data node will be unable to start.

- **BackupDataBufferSize >= BackupWriteSize + 188KB**
- **BackupLogBufferSize >= BackupWriteSize + 16KB**
- **BackupMaxWriteSize >= BackupWriteSize**

---

### MySQL Cluster Realtime Performance Parameters

The `[ndbd]` parameters discussed in this section are used in scheduling and locking of threads to specific CPUs on multiprocessor data node hosts.

---

### Note

To make use of these parameters, the data node process must be run as system root.

- **LockExecuteThreadToCPU**
MySQL Cluster Configuration Files

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>CPU ID</td>
<td>64K</td>
<td>0 - 64K</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

When used with `ndbd`, this parameter (now a string) specifies the ID of the CPU assigned to handle the `NDBCLUSTER` execution thread. When used with `ndbmtd`, the value of this parameter is a comma-separated list of CPU IDs assigned to handle execution threads. Each CPU ID in the list should be an integer in the range 0 to 65535 (inclusive).

The number of IDs specified should match the number of execution threads determined by `MaxNoOfExecutionThreads`. However, there is no guarantee that threads are assigned to CPUs in any given order when using this parameter; beginning with in MySQL Cluster NDB 7.2.5, you can obtain more finely-grained control of this type using `ThreadConfig`.

`LockExecuteThreadToCPU` has no default value.

- `LockMaintThreadsToCPU`  

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>CPU ID</td>
<td>[none]</td>
<td>0 - 64K</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

This parameter specifies the ID of the CPU assigned to handle `NDBCLUSTER` maintenance threads.

The value of this parameter is an integer in the range 0 to 65535 (inclusive). In MySQL Cluster NDB 7.2, there is no default value.

- `RealtimeScheduler`  

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>boolean</td>
<td>false</td>
<td>true, false</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

Setting this parameter to 1 enables real-time scheduling of data node threads.

Prior to MySQL Cluster NDB 7.2.14, this parameter did not work correctly with data nodes running `ndbmtd`. (Bug #16961971)

The default is 0 (scheduling disabled).

- `SchedulerExecutionTimer`
### MySQL Cluster Configuration Files

#### SchedulerSpinTimer

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>µsec</td>
<td>50</td>
<td>0 - 11000</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.1, "MySQL Cluster Data Node Configuration Parameters", for information about restart types.)

This parameter specifies the time in microseconds for threads to be executed in the scheduler before being sent. Setting it to 0 minimizes the response time; to achieve higher throughput, you can increase the value at the expense of longer response times.

The default is 50 µsec, which our testing shows to increase throughput slightly in high-load cases without materially delaying requests.

- **SchedulerSpinTimer**

#### BuildIndexThreads

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>numeric</td>
<td>0</td>
<td>0 - 128</td>
</tr>
</tbody>
</table>

**Restart Type:** S

(See Section 18.3.3.1, "MySQL Cluster Data Node Configuration Parameters", for information about restart types.)

This parameter determines the number of threads to create when rebuilding ordered indexes during a system or node start, as well as when running `ndb_restore --rebuild-indexes`. It is supported only when there is more than one fragment for the table per data node (for example, when the `MAX_ROWS` option has been used with `CREATE TABLE`).

Setting this parameter to 0 (the default) disables multi-threaded building of ordered indexes.

This parameter is supported when using `ndbd` or `ndbmtd`.

You can enable multi-threaded builds during data node initial restarts by setting the `TwoPassInitialNodeRestartCopy` data node configuration parameter to TRUE.

- **TwoPassInitialNodeRestartCopy**
Multi-threaded building of ordered indexes can be enabled for initial restarts of data nodes by setting this configuration parameter to `TRUE`, which enables two-pass copying of data during initial node restarts.

You must also set `BuildIndexThreads` to a nonzero value.

- **Numa**

  - **MaxNoOfExecutionThreads**

    | Effective Version | Type/Units | Default | Range/Values |
    |-------------------|------------|---------|--------------|
    | NDB 7.2.0         | integer    | 2       | 2 - 8        |
    | NDB 7.2.5         | integer    | 2       | 2 - 36       |

    (See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

MySQL Cluster NDB 7.2.5 and later, a second method is also supported, whereby it is possible to set up more complex rules for `ndbmtd` multi-threading using `ThreadConfig`. The next few paragraphs provide information about these parameters and their use with multi-threaded data nodes.

- **MaxNoOfExecutionThreads**

  Starting with MySQL Cluster NDB 7.2.5, this parameter directly controls the number of execution threads used by `ndbmtd`, up to a maximum of 36. Although this parameter is set in `[ndbd]` or `[ndbd default]` sections of the `config.ini` file, it is exclusive to `ndbmtd` and does not apply to `ndbd`. 

  **Numa**

  NDB is extremely sensitive to Non-Uniform Memory Access settings and multi-CPU systems due to timeouts that it can cause. Due to this fact, and because most MySQL Cluster users do not employ `numactl`, support for NUMA is ignored by default by `ndbd` when running on a Linux system. If your Linux system provides NUMA support and you wish for data node memory to be subject to NUMA control, you can set this parameter equal to 0.

  The `Numa` configuration parameter is supported only on Linux systems where `libnuma.so` is installed.
Setting `MaxNoOfExecutionThreads` sets the number of threads by type as determined in the following table:

<table>
<thead>
<tr>
<th>MaxNoOfExecutionThreads Value</th>
<th>LDM Threads</th>
<th>TC Threads</th>
<th>Send Threads</th>
<th>Receive Threads</th>
</tr>

</table>

Note that the number of LDM threads must not exceed `NoOfFragmentLogParts`. If this parameter's value is the default (4), this means that you must increase it as well, when setting `MaxNoOfExecutionThreads` to 16 or greater; that is, you should set `NoOfFragmentLogParts` to the
corresponding number of LDM threads value shown for that value of MaxNoOfExecutionThreads in the preceding table.

There is always one SUMA (replication) thread. There was no separate send thread in MySQL Cluster NDB 7.2.4 and earlier, as well as no means of changing the number of TC threads.

The thread types are described later in this section (see ThreadConfig).

Setting this parameter outside the permitted range of values causes the management server to abort on startup with the error Error line number: Illegal value value for parameter MaxNoOfExecutionThreads.

For MaxNoOfExecutionThreads, a value of 0 or 1 is rounded up internally by NDB to 2, so that 2 is considered this parameter's default and minimum value.

MaxNoOfExecutionThreads is generally intended to be set equal to the number of CPU threads available, and to allocate a number of threads of each type suitable to typical workloads. It does not assign particular threads to specified CPUs. For cases where it is desirable to vary from the settings provided, or to bind threads to CPUs, you should use ThreadConfig instead, which allows you to allocate each thread directly to a desired type, CPU, or both.

In MySQL Cluster NDB 7.2.5 and later, the multi-threaded data node process always spawns at least 5 threads, listed here:

- 1 local query handler (LDM) thread
- 1 transaction coordinator (TC) thread
- 1 send thread
  (It is possible to keep any separate send threads from being employed, as explained elsewhere in this section.)
- 1 receive thread
- 1 subscription manager (SUMA or replication) thread

In MySQL Cluster NDB 7.2.4 and earlier, there were only 4 thread types, with LDM threads being responsible for their own sends. In addition, it was not possible to cause ndbmtd to use more than 1 TC thread.

- NoOfFragmentLogParts

<table>

</tbody>
</table>

Restart Type: IN

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

Set the number of log file groups for redo logs belonging to this ndbmtd. The value must be an even multiple of 4 between 4 and 16, inclusive.

Note that the number of LQH threads used by ndbmtd must not exceed NoOfFragmentLogParts, and that this number may increase when increasing MaxNoOfExecutionThreads; see the description of this parameter for more information.

</tr>
</tbody>
</table>

Restart Type: N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

This parameter is used with ndbmt to assign threads of different types to different CPUs. Its value is a string whose format has the following syntax:

```
ThreadConfig := entry[entry[,...]]
entry := type={param[,...]}
type := ldm | main | recv | send | rep | io
param := count=number | cpubind=cpu_list
```

The curly braces ( {...} ) surrounding the list of parameters is required, even if there is only one parameter in the list.

A parameter specifies the number of threads of the given type ( `count` ), the CPUs to which the threads of the given type are to be bound ( `cpubind` ), or both.

The `type` attribute represents an NDB thread type. The thread types supported in MySQL Cluster NDB 7.2 and the range of permitted `count` values for each are provided in the following list:

- **ldm**: Local query handler (DBLQH kernel block) that handles data. The more LDM threads that are used, the more highly partitioned the data becomes. Each LDM thread maintains its own sets of data and index partitions, as well as its own redo log. In MySQL Cluster NDB 7.2, the maximum is 16 such threads (in MySQL Cluster NDB 7.1, the maximum was 4).
  
  Range: 1 - 16.

- **tc**: Transaction coordinator thread (DBTC kernel block) containing the state of an ongoing transaction. In MySQL Cluster NDB 7.2.5 and later, the number of TC threads is configurable, with a total of 16 possible.

  Optimaly, every new transaction can be assigned to a new TC thread. In most cases 1 TC thread per 2 LDM threads is sufficient to guarantee that this can happen. In cases where the number of writes is relatively small when compared to the number of reads, it is possible that only 1 TC thread per 4 LQH threads is required to maintain transaction states. Conversely, in applications that perform a great many updates, it may be necessary for the ratio of TC threads to LDM threads to approach 1 (for example, 3 TC threads to 4 LDM threads).

  Range: 1 - 16 (always 1 prior to MySQL Cluster 7.2.5).

- **main**: Data dictionary and transaction coordinator (DBDIH and DBTC kernel blocks), providing schema management. This is always handled by a single dedicated thread.

  Range: 1 only.
• **recv**: Receive thread (**CMVMI** kernel block). Each receive thread handles one or more sockets for communicating with other nodes in a MySQL Cluster, with one socket per node. Previously, this was limited to a single thread, but MySQL Cluster 7.2 implements multiple receive threads (up to 8).

• **send**: Send thread (**CMVMI** kernel block). Added in MySQL Cluster NDB 7.2.5. To increase throughput, it is possible in MySQL Cluster NDB 7.2.5 and later to perform sends from one or more separate, dedicated threads (maximum 8).

  Previously, all threads handled their own sending directly; this can still be made to happen by setting the number of send threads to 0 (this also happens when **MaxNoOfExecutionThreads** is set equal to 9). While doing so can have an adverse impact on throughput, it can also in some cases provide decreased latency.

  Range: 0 - 8.

• **rep**: Replication thread (**SUMA** kernel block). Asynchronous replication operations are always handled by a single dedicated thread.

  Range: 1 only.

• **io**: File system and other miscellaneous operations. These are not demanding tasks, and are always handled as a group by a single, dedicated I/O thread.

  Range: 1 only.

Simple examples:

```bash
# Example 1.
ThreadConfig=ldm={count=2,cpubind=1,2},main={cpubind=12},rep={cpubind=11}  
# Example 2.
Threadconfig=main={cpubind=0},ldm={count=4,cpubind=1,2,5,6},io={cpubind=3}
```

It is usually desirable when configuring thread usage for a data node host to reserve one or more number of CPUs for operating system and other tasks. Thus, for a host machine with 24 CPUs, you might want to use 20 CPU threads (leaving 4 for other uses), with 8 LDM threads, 4 TC threads (half the number of LDM threads), 3 send threads, 3 receive threads, and 1 thread each for schema management, asynchronous replication, and I/O operations. (This is almost the same distribution of threads used when **MaxNoOfExecutionThreads** is set equal to 20.) The following **ThreadConfig** setting performs these assignments, additionally binding all of these threads to specific CPUs:

```bash
ThreadConfig=ldm{count=8,cpubind=1,2,3,4,5,6,7,8},main{cpubind=9},io{cpubind=9}, \  
rep{cpubind=10},tc{count=4,cpubind=11,12,13,14},recv{count=3,cpubind=15,16,17}, \  
send{count=3,cpubind=18,19,20}
```

It should be possible in most cases to bind the main (schema management) thread and the I/O thread to the same CPU, as we have done in the example just shown.

In order to take advantage of the enhanced stability that the use of **ThreadConfig** offers, it is necessary to insure that CPUs are isolated, and that they not subject to interrupts, or to being scheduled for other tasks by the operating system. On many Linux systems, you can do this by setting
**MySQL Cluster Configuration Files**

**IRQBALANCE_BANNED_CPUS** in `/etc/sysconfig/irqbalance` to 0xFFFF0, and by using the `isolcpus` boot option in `grub.conf`. For specific information, see your operating system or platform documentation.

**Disk Data Configuration Parameters.** Configuration parameters affecting Disk Data behavior include the following:

- **DiskPageBufferMemory**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>bytes</td>
<td>64M</td>
<td>4M - 1T</td>
</tr>
</tbody>
</table>

  **Restart Type:** N

  (See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

  This determines the amount of space used for caching pages on disk, and is set in the `[ndbd]` or `[ndbd default]` section of the `config.ini` file. It is measured in bytes. Each page takes up 32 KB. This means that Cluster Disk Data storage always uses $N \times 32$ KB memory where $N$ is some nonnegative integer.

  The default value for this parameter is **64M** (2000 pages of 32 KB each).

  You can query the `ndbinfo.diskpagebuffer` table to help determine whether the value for this parameter should be increased to minimize unnecessary disk seeks. See Section 18.5.10.8, “The `ndbinfo diskpagebuffer` Table”, for more information.

- **SharedGlobalMemory**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>bytes</td>
<td>128M</td>
<td>0 - 64T</td>
</tr>
</tbody>
</table>

  **Restart Type:** N

  (See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

  This parameter determines the amount of memory that is used for log buffers, disk operations (such as page requests and wait queues), and metadata for tablespaces, log file groups, UNDO files, and data files. The shared global memory pool also provides memory used for satisfying the memory requirements of the `INITIAL_SIZE` and `UNDO_BUFFER_SIZE` options used with `CREATE LOGFILE GROUP` and `ALTER LOGFILE GROUP` statements, including any default value implied for these options by the setting of the `InitialLogFileGroup` data node configuration parameter. `SharedGlobalMemory` can be set in the `[ndbd]` or `[ndbd default]` section of the `config.ini` configuration file, and is measured in bytes.

  As of MySQL Cluster NDB 7.2.0, the default value is **128M**. (Previously, this was **20M**.)

- **DiskIOThreadPool**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>threads</td>
<td>2</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

  **Restart Type:** N
MySQL Cluster Configuration Files

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>filename</td>
<td>[see text]</td>
<td>...</td>
</tr>
</tbody>
</table>

Restart Type: IN

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

This parameter determines the number of unbound threads used for Disk Data file access. Before DiskIOThreadPool was introduced, exactly one thread was spawned for each Disk Data file, which could lead to performance issues, particularly when using very large data files. With DiskIOThreadPool, you can—for example—access a single large data file using several threads working in parallel.

This parameter applies to Disk Data I/O threads only.

The optimum value for this parameter depends on your hardware and configuration, and includes these factors:

- **Physical distribution of Disk Data files.** You can obtain better performance by placing data files, undo log files, and the data node file system on separate physical disks. If you do this with some or all of these sets of files, then you can set DiskIOThreadPool higher to enable separate threads to handle the files on each disk.

- **Disk performance and types.** The number of threads that can be accommodated for Disk Data file handling is also dependent on the speed and throughput of the disks. Faster disks and higher throughput allow for more disk I/O threads. Our test results indicate that solid-state disk drives can handle many more disk I/O threads than conventional disks, and thus higher values for DiskIOThreadPool.

In MySQL Cluster NDB 7.2, the default value for this parameter is 2.

- **Disk Data file system parameters.** The parameters in the following list make it possible to place MySQL Cluster Disk Data files in specific directories without the need for using symbolic links.

  - FileSystemPathDD

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>filename</td>
<td>[see text]</td>
<td>...</td>
</tr>
</tbody>
</table>

If this parameter is specified, then MySQL Cluster Disk Data files and undo log files are placed in the indicated directory. This can be overridden for data files, undo log files, or both, by specifying values for FileSystemPathDataFiles, FileSystemPathUndoFiles, or both, as explained for these parameters. It can also be overridden for data files by specifying a path in the ADD DATAFILE clause of a CREATE TABLESPACE or ALTER TABLESPACE statement, and for undo log files by specifying a path in the ADD UNDOFILE clause of a CREATE LOGFILE GROUP or ALTER LOGFILE GROUP statement. If FileSystemPathDD is not specified, then FileSystemPath is used.

If a FileSystemPathDD directory is specified for a given data node (including the case where the parameter is specified in the [ndbd default] section of the config.ini file), then starting that data node with --initial causes all files in the directory to be deleted.

- FileSystemPathDataFiles
MySQL Cluster Configuration Files

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>filename</td>
<td>[see text]</td>
<td>...</td>
</tr>
</tbody>
</table>

**Restart Type: IN**

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

If this parameter is specified, then MySQL Cluster Disk Data data files are placed in the indicated directory. This overrides any value set for `FileSystemPathDD`. This parameter can be overridden for a given data file by specifying a path in the `ADD DATAFILE` clause of a `CREATE TABLESPACE` or `ALTER TABLESPACE` statement used to create that data file. If `FileSystemPathDataFiles` is not specified, then `FileSystemPathDD` is used (or `FileSystemPath`, if `FileSystemPathDD` has also not been set).

If a `FileSystemPathDataFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

**• FileSystemPathUndoFiles**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>filename</td>
<td>[see text]</td>
<td>...</td>
</tr>
</tbody>
</table>

**Restart Type: IN**

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

If this parameter is specified, then MySQL Cluster Disk Data undo log files are placed in the indicated directory. This overrides any value set for `FileSystemPathDD`. This parameter can be overridden for a given data file by specifying a path in the `ADD UNDO` clause of a `CREATE LOGFILE GROUP` or `CREATE LOGFILE GROUP` statement used to create that data file. If `FileSystemPathUndoFiles` is not specified, then `FileSystemPathDD` is used (or `FileSystemPath`, if `FileSystemPathDD` has also not been set).

If a `FileSystemPathUndoFiles` directory is specified for a given data node (including the case where the parameter is specified in the `[ndbd default]` section of the `config.ini` file), then starting that data node with `--initial` causes all files in the directory to be deleted.

For more information, see Section 18.5.12.1, “MySQL Cluster Disk Data Objects”.

**• Disk Data object creation parameters.** The next two parameters enable you—when starting the cluster for the first time—to cause a Disk Data log file group, tablespace, or both, to be created without the use of SQL statements.

**• InitialLogFileGroup**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>string</td>
<td>[see text]</td>
<td>...</td>
</tr>
</tbody>
</table>

**Restart Type: S**

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)
This parameter can be used to specify a log file group that is created when performing an initial start of
the cluster. `InitialLogFileGroup` is specified as shown here:

```
InitialLogFileGroup = [name=name;] [undo_buffer_size=size;] file-specification-list
```

```
file-specification-list:
  file-specification[; file-specification[; ...]]
```

```
file-specification:
  filename:size
```

The `name` of the log file group is optional and defaults to `DEFAULT-LG`. The `undo_buffer_size`
is also optional; if omitted, it defaults to `64M`. Each `file-specification` corresponds to an undo
log file, and at least one must be specified in the `file-specification-list`. Undo log files are
placed according to any values that have been set for `FileSystemPath`, `FileSystemPathDD`, and
`FileSystemPathUndoFiles`, just as if they had been created as the result of a `CREATE LOGFILE
GROUP` or `ALTER LOGFILE GROUP` statement.

Consider the following:

```
InitialLogFileGroup = name=LG1; undo_buffer_size=128M; undo1.log:250M; undo2.log:150M
```

This is equivalent to the following SQL statements:

```
CREATE LOGFILE GROUP LG1
  ADD UNDOFILE 'undo1.log'
  INITIAL_SIZE 250M
  UNDO_BUFFER_SIZE 128M
  ENGINE NDBCLUSTER;

ALTER LOGFILE GROUP LG1
  ADD UNDOFILE 'undo2.log'
  INITIAL_SIZE 150M
  ENGINE NDBCLUSTER;
```

This logfile group is created when the data nodes are started with `--initial`.

Resources for the initial log file group are taken from the global memory pool whose size is determined
by the value of the `SharedGlobalMemory` data node configuration parameter; if this parameter is set
too low and the values set in `InitialLogFileGroup` for the logfile group's initial size or undo buffer
size are too high, the cluster may fail to create the default log file group when starting, or fail to start
altogether.

This parameter, if used, should always be set in the `[ndbd default]` section of the `config.ini`
file. The behavior of a MySQL Cluster when different values are set on different data nodes is not
defined.

• `InitialTablespace`

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>string</td>
<td>[see text]</td>
<td>...</td>
</tr>
<tr>
<td>Restart Type: S</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about
restart types.)
This parameter can be used to specify a MySQL Cluster Disk Data tablespace that is created when performing an initial start of the cluster. **InitialTablespace** is specified as shown here:

```
InitialTablespace = [name= name]; [extent_size= size]; file-specification-list
```

The name of the tablespace is optional and defaults to DEFAULT-TS. The extent_size is also optional; it defaults to 1M. The file-specification-list uses the same syntax as shown with the InitialLogfileGroup parameter, the only difference being that each file-specification used with InitialTablespace corresponds to a data file. At least one must be specified in the file-specification-list. Data files are placed according to any values that have been set for FileSystemPath, FileSystemPathDD, and FileSystemPathDataFiles, just as if they had been created as the result of a CREATE TABLESPACE or ALTER TABLESPACE statement.

For example, consider the following line specifying InitialTablespace in the [ndbd default] section of the config.ini file (as with InitialLogfileGroup, this parameter should always be set in the [ndbd default] section, as the behavior of a MySQL Cluster when different values are set on different data nodes is not defined):

```
InitialTablespace = name=TS1; extent_size=8M; data1.dat:2G; data2.dat:4G
```

This is equivalent to the following SQL statements:

```
CREATE TABLESPACE TS1
  ADD DATFILE 'data1.dat'
  EXTENT_SIZE 8M
  INITIAL_SIZE 2G
  ENGINE NDBCLUSTER;

ALTER TABLESPACE TS1
  ADD UNDOFILE 'data2.dat'
  INITIAL_SIZE 4G
  ENGINE NDBCLUSTER;
```

This tablespace is created when the data nodes are started with **--initial**, and can be used whenever creating MySQL Cluster Disk Data tables thereafter.

**Disk Data and GCP Stop errors.** Errors encountered when using Disk Data tables such as Node nodeid killed this node because GCP stop was detected (error 2303) are often referred to as “GCP stop errors”. Such errors occur when the redo log is not flushed to disk quickly enough; this is usually due to slow disks and insufficient disk throughput.

You can help prevent these errors from occurring by using faster disks, and by placing Disk Data files on a separate disk from the data node file system. Reducing the value of TimeBetweenGlobalCheckpoints tends to decrease the amount of data to be written for each global checkpoint, and so may provide some protection against redo log buffer overflows when trying to write a global checkpoint; however, reducing this value also permits less time in which to write the GCP, so this must be done with caution.

In addition to the considerations given for DiskPageBufferMemory as explained previously, it is also very important that the DiskIOThreadPool configuration parameter be set correctly; having DiskIOThreadPool set too high is very likely to cause GCP stop errors (Bug #37227).

GCP stops can be caused by save or commit timeouts; the TimeBetweenEpochsTimeout data node configuration parameter determines the timeout for commits. However, it is possible to disable both types of timeouts by setting this parameter to 0.
Parameters for configuring send buffer memory allocation. Send buffer memory is allocated dynamically from a memory pool shared between all transporters, which means that the size of the send buffer can be adjusted as necessary. (Previously, the NDB kernel used a fixed-size send buffer for every node in the cluster, which was allocated when the node started and could not be changed while the node was running.) The TotalSendBufferMemory and OverLoadLimit data node configuration parameters permit the setting of limits on this memory allocation. For more information about the use of these parameters (as well as SendBufferMemory), see Section 18.3.2.12, “Configuring MySQL Cluster Send Buffer Parameters”.

- ExtraSendBufferMemory

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any set using TotalSendBufferMemory, SendBufferMemory, or both.

This parameter was added in MySQL Cluster NDB 7.2.5. (Bug #11760629, Bug #53053)

- TotalSendBufferMemory

This parameter is available beginning with MySQL Cluster NDB 6.4.0. It is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

Prior to MySQL Cluster NDB 7.2.5, this parameter did not work correctly with ndbmtd. (Bug #13633845)

If this parameter is set, its minimum permitted value is 256KB; the maximum is 4294967039.

- ReservedSendBufferMemory

This parameter is present in NDBCLUSTER source code beginning with MySQL Cluster NDB 6.4.0. However, it is not currently enabled.

As of MySQL Cluster NDB 7.2.5, this parameter is deprecated, and is subject to removal in a future release of MySQL Cluster (Bug #11760629, Bug #53053).

For more detailed information about the behavior and use of TotalSendBufferMemory and about configuring send buffer memory parameters in MySQL Cluster, see Section 18.3.2.12, “Configuring MySQL Cluster Send Buffer Parameters”.

See also Section 18.5.13, “Adding MySQL Cluster Data Nodes Online”.

Redo log over-commit handling. It is possible to control a data node’s handling of operations when too much time is taken flushing redo logs to disk. This occurs when a given redo log flush takes longer than RedoOverCommitLimit seconds, more than RedoOverCommitCounter times, causing any pending transactions to be aborted. When this happens, the API node that sent the transaction can handle the operations that should have been committed either by queuing the operations and re-trying them, or by aborting them, as determined by DefaultOperationRedoProblemAction. The data node configuration parameters for setting the timeout and number of times it may be exceeded before the API node takes this action are described in the following list:

- RedoOverCommitCounter

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>numeric</td>
<td>3</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

Restart Type: N
### RedoOverCommitCounter

When `RedoOverCommitLimit` is exceeded when trying to write a given redo log to disk this many times or more, any transactions that were not committed as a result are aborted, and an API node where any of these transactions originated handles the operations making up those transactions according to its value for `DefaultOperationRedoProblemAction` (by either queuing the operations to be re-tried, or aborting them).

- `RedoOverCommitCounter` defaults to 3. Set it to 0 to disable the limit.

### RedoOverCommitLimit

This parameter sets an upper limit in seconds for trying to write a given redo log to disk before timing out. The number of times the data node tries to flush this redo log, but takes longer than `RedoOverCommitLimit`, is kept and compared with `RedoOverCommitCounter`, and when flushing takes too long more times than the value of that parameter, any transactions that were not committed as a result of the flush timeout are aborted. When this occurs, the API node where any of these transactions originated handles the operations making up those transactions according to its `DefaultOperationRedoProblemAction` setting (it either queues the operations to be re-tried, or aborts them).

By default, `RedoOverCommitLimit` is 20 seconds. Set to 0 to disable checking for redo log flush timeouts. This parameter was added in MySQL Cluster NDB 7.1.10.

### MaxStartFailRetries

It is possible to exercise finely-grained control over restart attempts by data nodes when they fail to start using the `MaxStartFailRetries` and `StartFailRetryDelay` data node configuration parameters.

- `MaxStartFailRetries` limits the total number of retries made before giving up on starting the data node, `StartFailRetryDelay` sets the number of seconds between retry attempts. These parameters are described in more detail in the next few paragraphs.

### StartFailRetryDelay

This parameter sets a delay in seconds between retry attempts. It is used in conjunction with `MaxStartFailRetries` to control the rate at which the data node attempts to start again.

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>unsigned</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

Restart Type: N

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)
MySQL Cluster Configuration Files

Use this parameter to set the number of seconds between restart attempts by the data node in the event on failure on startup. The default is 0 (no delay).

Note
This parameter is ignored unless StopOnError is equal to 0.

MaxStartFailRetries [2222]

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>unsigned</td>
<td>3</td>

</tr>
</tbody>
</table>

Restart Type: N
(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

Use this parameter to limit the number restart attempts made by the data node in the event that it fails on startup. The default is 3 attempts.

Note
This parameter is ignored unless StopOnError is equal to 0.

NDB index statistics parameters. The parameters in the following list relate to NDB index statistics generation, which was introduced in MySQL Cluster NDB 7.2.1.

• IndexStatAutoCreate

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.1</td>
<td>boolean</td>
<td>false</td>
<td>false, true</td>
</tr>
</tbody>
</table>

Restart Type: S
(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

Enable or disable automatic statistics collection when indexes are created. Disabled by default.

This parameter was added in MySQL Cluster NDB 7.2.1.

• IndexStatAutoUpdate

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.1</td>
<td>boolean</td>
<td>false</td>
<td>false, true</td>
</tr>
</tbody>
</table>

Restart Type: S
(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

Enable or disable monitoring of indexes for changes and trigger automatic statistics updates these are detected. The amount and degree of change needed to trigger the updates are determined by the settings for the IndexStatTriggerPct and IndexStatTriggerScale options.

This parameter was added in MySQL Cluster NDB 7.2.1.
MySQL Cluster Configuration Files

- **IndexStatSaveSize**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.1</td>
<td>bytes</td>
<td>32768</td>
<td>0 - 4294967039</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>(0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

Restart Type: IN

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

Maximum space in bytes allowed for the saved statistics of any given index in the NDB system tables and in the mysqld memory cache. This consumes IndexMemory.

At least one sample is always produced, regardless of any size limit. Note that this size is scaled by IndexStatSaveScale.

This parameter was added in MySQL Cluster NDB 7.2.1.

The size specified by IndexStatSaveSize is scaled by the value of IndexStatTriggerPct for a large index, times 0.01. Note that this is further multiplied by the logarithm to the base 2 of the index size. Setting IndexStatTriggerPct equal to 0 disables the scaling effect.

- **IndexStatSaveScale**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.1</td>
<td>percentage</td>
<td>100</td>
<td>0 - 4294967039</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>(0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

Restart Type: IN

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

The size specified by IndexStatSaveSize is scaled by the value of IndexStatTriggerPct for a large index, times 0.01. Note that this is further multiplied by the logarithm to the base 2 of the index size. Setting IndexStatTriggerPct equal to 0 disables the scaling effect.

This parameter was added in MySQL Cluster NDB 7.2.1.

- **IndexStatTriggerPct**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.1</td>
<td>percentage</td>
<td>100</td>
<td>0 - 4294967039</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>(0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

Restart Type: IN

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

Percentage change in updates that triggers an index statistics update. The value is scaled by IndexStatTriggerScale. You can disable this trigger altogether by setting IndexStatTriggerPct to 0.
This parameter was added in MySQL Cluster NDB 7.2.1.

- **IndexStatTriggerScale**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.1</td>
<td>percentage</td>
<td>100</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type:** IN

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

Scale `IndexStatTriggerPct` by this amount times 0.01 for a large index. A value of 0 disables scaling.

This parameter was added in MySQL Cluster NDB 7.2.1.

- **IndexStatUpdateDelay**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.1</td>
<td>seconds</td>
<td>60</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type:** IN

(See Section 18.3.3.1, “MySQL Cluster Data Node Configuration Parameters”, for information about restart types.)

Minimum delay in seconds between automatic index statistics updates for a given index. Setting this variable to 0 disables any delay. The default is 60 seconds.

This parameter was added in MySQL Cluster NDB 7.2.1.

### 18.3.2.7 Defining SQL and Other API Nodes in a MySQL Cluster

The `[mysqld]` and `[api]` sections in the `config.ini` file define the behavior of the MySQL servers (SQL nodes) and other applications (API nodes) used to access cluster data. None of the parameters shown is required. If no computer or host name is provided, any host can use this SQL or API node.

Generally speaking, a `[mysqld]` section is used to indicate a MySQL server providing an SQL interface to the cluster, and an `[api]` section is used for applications other than `mysqld` processes accessing cluster data, but the two designations are actually synonymous; you can, for instance, list parameters for a MySQL server acting as an SQL node in an `[api]` section.

#### Note

For a discussion of MySQL server options for MySQL Cluster, see Section 18.3.4.2, “MySQL Server Options for MySQL Cluster”; for information about MySQL server system variables relating to MySQL Cluster, see Section 18.3.4.3, “MySQL Cluster System Variables”.

- **Id**
MySQL Cluster Configuration Files

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>1 - 255</td>
</tr>
</tbody>
</table>

**Restart Type:** IS

(See Section 18.3.3.3, “MySQL Cluster SQL Node and API Node Configuration Parameters”, for information about restart types.)

The **Id** is an integer value used to identify the node in all cluster internal messages. The permitted range of values is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

**Note**

Data node IDs must be less than 49, regardless of the MySQL Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 48.

**NodeId** is the preferred parameter name to use when identifying API nodes. (**Id** continues to be supported for backward compatibility, but is now deprecated and generates a warning when used. It is also subject to future removal.)

• **ConnectionMap**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>string</td>
<td>[none]</td>
<td>...</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.3, “MySQL Cluster SQL Node and API Node Configuration Parameters”, for information about restart types.)

Specifies which data nodes to connect.

• **NodeId**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>1 - 255</td>
</tr>
</tbody>
</table>

**Restart Type:** IS

(See Section 18.3.3.3, “MySQL Cluster SQL Node and API Node Configuration Parameters”, for information about restart types.)

The **NodeId** is an integer value used to identify the node in all cluster internal messages. The permitted range of values is 1 to 255 inclusive. This value must be unique for each node in the cluster, regardless of the type of node.

**Note**

Data node IDs must be less than 49, regardless of the MySQL Cluster version used. If you plan to deploy a large number of data nodes, it is a good idea to limit the node IDs for API nodes (and management nodes) to values greater than 48.
NodeID is the preferred parameter name to use when identifying management nodes in MySQL Cluster NDB 7.2 and later. Previously, Id was used for this purpose and this continues to be supported for backward compatibility. Id is now deprecated and generates a warning when used; it is subject to removal in a future release of MySQL Cluster.

- **ExecuteOnComputer**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>name</td>
<td>[none]</td>
<td>...</td>
</tr>
</tbody>
</table>

Restart Type: S

(See Section 18.3.3.3, “MySQL Cluster SQL Node and API Node Configuration Parameters”, for information about restart types.)

This refers to the Id set for one of the computers (hosts) defined in a [computer] section of the configuration file.

- **HostName**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>name or IP address</td>
<td>[none]</td>
<td>...</td>
</tr>
</tbody>
</table>

Restart Type: S

(See Section 18.3.3.3, “MySQL Cluster SQL Node and API Node Configuration Parameters”, for information about restart types.)

Specifying this parameter defines the hostname of the computer on which the SQL node (API node) is to reside. To specify a hostname, either this parameter or ExecuteOnComputer is required.

If no HostName or ExecuteOnComputer is specified in a given [mysql] or [api] section of the config.ini file, then an SQL or API node may connect using the corresponding "slot" from any host which can establish a network connection to the management server host machine. This differs from the default behavior for data nodes, where localhost is assumed for HostName unless otherwise specified.

- **ArbitrationRank**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>0-2</td>
<td>0</td>
<td>0 - 2</td>
</tr>
</tbody>
</table>

Restart Type: N

(See Section 18.3.3.3, “MySQL Cluster SQL Node and API Node Configuration Parameters”, for information about restart types.)

This parameter defines which nodes can act as arbitrators. Both management nodes and SQL nodes can be arbitrators. A value of 0 means that the given node is never used as an arbitrator, a value of 1 gives the node high priority as an arbitrator, and a value of 2 gives it low priority. A normal configuration uses the management server as arbitrator, setting its ArbitrationRank to 1 (the default for management nodes) and those for all SQL nodes to 0 (the default for SQL nodes).
By setting `ArbitrationRank` to 0 on all management and SQL nodes, you can disable arbitration completely. You can also control arbitration by overriding this parameter; to do so, set the `Arbitration` parameter in the `[ndbd default]` section of the `config.ini` global configuration file.

- **ArbitrationDelay**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>milliseconds</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

  **Restart Type:** N

  (See Section 18.3.3.3, “MySQL Cluster SQL Node and API Node Configuration Parameters”, for information about restart types.)

  Setting this parameter to any other value than 0 (the default) means that responses by the arbitrator to arbitration requests will be delayed by the stated number of milliseconds. It is usually not necessary to change this value.

- **BatchByteSize**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>bytes</td>
<td>32K</td>
<td>1024 - 1M</td>
</tr>
<tr>
<td>NDB 7.2.1</td>
<td>bytes</td>
<td>16K</td>
<td>1024 - 1M</td>
</tr>
</tbody>
</table>

  **Restart Type:** N

  (See Section 18.3.3.3, “MySQL Cluster SQL Node and API Node Configuration Parameters”, for information about restart types.)

  For queries that are translated into full table scans or range scans on indexes, it is important for best performance to fetch records in properly sized batches. It is possible to set the proper size both in terms of number of records (`BatchSize`) and in terms of bytes (`BatchByteSize`). The actual batch size is limited by both parameters.

  The speed at which queries are performed can vary by more than 40% depending upon how this parameter is set.

  This parameter is measured in bytes. The default value prior to MySQL Cluster NDB 7.2.1 was 32K; in MySQL Cluster NDB 7.2.1 and later, the default is 16K.

- **BatchSize**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>records</td>
<td>64</td>
<td>1 - 992</td>
</tr>
<tr>
<td>NDB 7.2.1</td>
<td>records</td>
<td>256</td>
<td>1 - 992</td>
</tr>
</tbody>
</table>

  **Restart Type:** N

  (See Section 18.3.3.3, “MySQL Cluster SQL Node and API Node Configuration Parameters”, for information about restart types.)

  This parameter is measured in number of records and is by default set to 256 (MySQL Cluster NDB 7.2.1 and later; previously, the default was 64). The maximum size is 992.
• **ExtraSendBufferMemory**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>bytes</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.3, “MySQL Cluster SQL Node and API Node Configuration Parameters”, for information about restart types.)

This parameter specifies the amount of transporter send buffer memory to allocate in addition to any that has been set using `TotalSendBufferMemory`, `SendBufferMemory`, or both.

This parameter was added in MySQL Cluster NDB 7.2.14. (Bug #14555359)

• **HeartbeatThreadPriority**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>string</td>
<td>[none]</td>
<td>...</td>
</tr>
</tbody>
</table>

**Restart Type:** S

(See Section 18.3.3.3, “MySQL Cluster SQL Node and API Node Configuration Parameters”, for information about restart types.)

Use this parameter to set the scheduling policy and priority of heartbeat threads for management and API nodes. The syntax for setting this parameter is shown here:

```plaintext
HeartbeatThreadPriority = policy[, priority]
```

**policy:**

<table>
<thead>
<tr>
<th>FIFO</th>
<th>RR</th>
</tr>
</thead>
</table>

When setting this parameter, you must specify a policy. This is one of **FIFO** (first in, first in) or **RR** (round robin). This followed optionally by the priority (an integer).

• **MaxScanBatchSize**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>bytes</td>
<td>256K</td>
<td>32K - 16M</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.3, “MySQL Cluster SQL Node and API Node Configuration Parameters”, for information about restart types.)

The batch size is the size of each batch sent from each data node. Most scans are performed in parallel to protect the MySQL Server from receiving too much data from many nodes in parallel; this parameter sets a limit to the total batch size over all nodes.

The default value of this parameter is set to 256KB. Its maximum size is 16MB.

• **TotalSendBufferMemory**
### MySQL Cluster Configuration Files

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>bytes</td>
<td>256K</td>
<td>0 - 4294967039</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.3, “MySQL Cluster SQL Node and API Node Configuration Parameters”, for information about restart types.)

This parameter is available beginning with MySQL Cluster NDB 6.4.0. It is used to determine the total amount of memory to allocate on this node for shared send buffer memory among all configured transporters.

If this parameter is set, its minimum permitted value is 256KB; the maximum is 4294967039. For more detailed information about the behavior and use of `TotalSendBufferMemory` and configuring send buffer memory parameters in MySQL Cluster, see Section 18.3.2.12, “Configuring MySQL Cluster Send Buffer Parameters”.

- **AutoReconnect**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>boolean</td>
<td>false</td>
<td>true, false</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.3, “MySQL Cluster SQL Node and API Node Configuration Parameters”, for information about restart types.)

This parameter is false by default. This forces disconnected API nodes (including MySQL Servers acting as SQL nodes) to use a new connection to the cluster rather than attempting to re-use an existing one, as re-use of connections can cause problems when using dynamically-allocated node IDs. (Bug #45921)

**Note**

This parameter can be overridden using the NDB API. For more information, see `Ndb_cluster_connection::set_auto_reconnect()` and `Ndb_cluster_connection::get_auto_reconnect()`.

- **DefaultOperationRedoProblemAction**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>enumeration</td>
<td>ABORT</td>
<td>ABORT, QUEUE</td>
</tr>
<tr>
<td>NDB 7.2.1</td>
<td>enumeration</td>
<td>ABORT</td>
<td>ABORT, QUEUE</td>
</tr>
<tr>
<td>NDB 7.2.10</td>
<td>enumeration</td>
<td>QUEUE</td>
<td>ABORT, QUEUE</td>
</tr>
</tbody>
</table>

**Restart Type:** S

(See Section 18.3.3.3, “MySQL Cluster SQL Node and API Node Configuration Parameters”, for information about restart types.)

This parameter (along with `RedoOverCommitLimit` and `RedoOverCommitCounter`) controls the data node’s handling of operations when too much time is taken flushing redo logs to disk. This
occurs when a given redo log flush takes longer than `RedoOverCommitLimit` seconds, more than `RedoOverCommitCounter` times, causing any pending transactions to be aborted.

When this happens, the node can respond in either of two ways, according to the value of `DefaultOperationRedoProblemAction`, listed here:

- **ABORT**: Any pending operations from aborted transactions are also aborted.
- **QUEUE**: Pending operations from transactions that were aborted are queued up to be re-tried.

Prior to MySQL Cluster NDB 7.2.10, setting this parameter did not have any effect. (Bug #15855588)

- **DefaultHashMapSize**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>LDM threads</td>
<td>240</td>
<td>0 - 3840</td>
</tr>
<tr>
<td>NDB 7.2.11</td>
<td>LDM threads</td>
<td>3840</td>
<td>0 - 3840</td>
</tr>
</tbody>
</table>

**Restart Type**: N

(See Section 18.3.3.3, “MySQL Cluster SQL Node and API Node Configuration Parameters”, for information about restart types.)

MySQL Cluster NDB 7.2.7 and later use a larger default table hash map size (3840) than in previous releases (240). Beginning with MySQL Cluster NDB 7.2.11, the size of the table hash maps used by NDB is configurable using this parameter; previously this value was hard-coded. `DefaultHashMapSize` can take any of three possible values (0, 240, 3840). These values and their effects are described in the following table.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description / Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Use the lowest value set, if any, for this parameter among all data nodes and API nodes in the cluster; if it is not set on any data or API node, use the default value.</td>
</tr>
<tr>
<td>240</td>
<td>Original hash map size, used by default in all MySQL Cluster releases prior to MySQL Cluster NDB 7.2.7.</td>
</tr>
<tr>
<td>3840</td>
<td>Larger hash map size as used by default in MySQL Cluster NDB 7.2.7 and later</td>
</tr>
</tbody>
</table>

The primary intended use for this parameter is to facilitate upgrades and especially downgrades between MySQL Cluster NDB 7.2.7 and later MySQL Cluster versions, in which the larger hash map size (3840) is the default, and earlier releases (in which the default was 240), due to the fact that this change is not otherwise backward compatible (Bug #14800539). By setting this parameter to 240 prior to performing an upgrade from an older version where this value is in use, you can cause the cluster to continue using the smaller size for table hash maps, in which case the tables remain compatible with earlier versions following the upgrade. `DefaultHashMapSize` can be set for individual data nodes, API nodes, or both, but setting it once only, in the `[ndbd default]` section of the `config.ini` file, is the recommended practice.

After increasing this parameter, to have existing tables to take advantage of the new size, you can run `ALTER TABLE ... REORGANIZE PARTITION` on them, after which they can use the larger hash map size. This is in addition to performing a rolling restart, which makes the larger hash maps available to new tables, but does not enable existing tables to use them.

Decreasing this parameter online after any tables have been created or modified with `DefaultHashMapSize` equal to 3840 is not currently supported.
MySQL Cluster Configuration Files

- Wan

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>boolean</td>
<td>false</td>
<td>true, false</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.3, "MySQL Cluster SQL Node and API Node Configuration Parameters", for information about restart types.)

Use WAN TCP setting as default.

You can obtain some information from a MySQL server running as a Cluster SQL node using **SHOW STATUS** in the **mysql** client, as shown here:

```sql
mysql> SHOW STATUS LIKE 'ndb%';
+-----------------------------+---------------+
| Variable_name               | Value         |
|-----------------------------+---------------+
| Ndb_cluster_node_id         | 5             |
| Ndb_config_from_host        | 192.168.0.112 |
| Ndb_config_from_port        | 1186          |
| Ndb_number_of_storage_nodes | 4             |
+-----------------------------+---------------+
4 rows in set (0.02 sec)
```

For information about these Cluster system status variables, see Section 5.1.6, “Server Status Variables”.

### Note

To add new SQL or API nodes to the configuration of a running MySQL Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new [mysqld] or [api] sections to the **config.ini** file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is not necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

#### 18.3.2.8 MySQL Cluster TCP/IP Connections

TCP/IP is the default transport mechanism for all connections between nodes in a MySQL Cluster. Normally it is not necessary to define TCP/IP connections; MySQL Cluster automatically sets up such connections for all data nodes, management nodes, and SQL or API nodes.

### Note

For an exception to this rule, see Section 18.3.2.9, “MySQL Cluster TCP/IP Connections Using Direct Connections”.

To override the default connection parameters, it is necessary to define a connection using one or more [tcp] sections in the **config.ini** file. Each [tcp] section explicitly defines a TCP/IP connection between two MySQL Cluster nodes, and must contain at a minimum the parameters **NodeId1** and **NodeId2** [2232], as well as any connection parameters to override.

It is also possible to change the default values for these parameters by setting them in the [tcp default] section.
Important

Any [tcp] sections in the config.ini file should be listed last, following all other sections in the file. However, this is not required for a [tcp default] section. This requirement is a known issue with the way in which the config.ini file is read by the MySQL Cluster management server.

Connection parameters which can be set in [tcp] and [tcp default] sections of the config.ini file are listed here:

- **NodeId1**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>numeric</td>
<td>[none]</td>
<td></td>
</tr>
</tbody>
</table>

Restart Type: N

(See Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”, for information about restart types.)

- **NodeId2**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>numeric</td>
<td>[none]</td>
<td></td>
</tr>
</tbody>
</table>

Restart Type: N

(See Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”, for information about restart types.)

To identify a connection between two nodes it is necessary to provide their node IDs in the [tcp] section of the configuration file. These are the same unique NodeId (or id) values for each of these nodes as described in Section 18.3.2.7, “Defining SQL and Other API Nodes in a MySQL Cluster”.

- **HostName1**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>name or IP address</td>
<td>[none]</td>
<td></td>
</tr>
</tbody>
</table>

Restart Type: N

(See Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”, for information about restart types.)

- **HostName2**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>name or IP address</td>
<td>[none]</td>
<td></td>
</tr>
</tbody>
</table>

Restart Type: N

(See Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”, for information about restart types.)
The `HostName1` and `HostName2` parameters can be used to specify specific network interfaces to be used for a given TCP connection between two nodes. The values used for these parameters can be hostnames or IP addresses.

- **OverloadLimit**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>bytes</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”, for information about restart types.)

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded.

This parameter can be used to determine the amount of unsent data that must be present in the send buffer before the connection is considered overloaded. See Section 18.3.2.12, “Configuring MySQL Cluster Send Buffer Parameters”, for more information.

In some older releases, the effective value of this parameter was limited by the size of `SendBufferMemory`; in MySQL Cluster NDB 7.2, the actual value for `OverloadLimit` (up to the stated maximum of 4G) is used instead.

- **SendBufferMemory**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>unsigned</td>
<td>2M</td>
<td>256K - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”, for information about restart types.)

TCP transporters use a buffer to store all messages before performing the send call to the operating system. When this buffer reaches 64KB its contents are sent; these are also sent when a round of messages have been executed. To handle temporary overload situations it is also possible to define a bigger send buffer.

If this parameter is set explicitly, then the memory is not dedicated to each transporter; instead, the value used denotes the hard limit for how much memory (out of the total available memory—that is, `TotalSendBufferMemory`) that may be used by a single transporter. For more information about configuring dynamic transporter send buffer memory allocation in MySQL Cluster, see Section 18.3.2.12, “Configuring MySQL Cluster Send Buffer Parameters”.

The default size of the send buffer in MySQL Cluster NDB 7.2 is 2MB, which is the size recommended in most situations. The minimum size is 64 KB; the theoretical maximum is 4 GB.

- **SendSignalId**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>boolean</td>
<td>[see text]</td>
<td>true, false</td>
</tr>
</tbody>
</table>
To be able to retrace a distributed message datagram, it is necessary to identify each message. When this parameter is set to \texttt{Y}, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in \texttt{-debug} builds.

- **Checksum**

  This parameter is a boolean parameter (enabled by setting it to \texttt{Y} or \texttt{1}, disabled by setting it to \texttt{N} or \texttt{0}). It is disabled by default. When it is enabled, checksums for all messages are calculated before they placed in the send buffer. This feature ensures that messages are not corrupted while waiting in the send buffer, or by the transport mechanism.

- **PortNumber (OBSOLETE)**

  This formerly specified the port number to be used for listening for connections from other nodes. This parameter should no longer be used; use the \texttt{ServerPort} data node configuration parameter for this purpose instead.

- **ReceiveBufferMemory**

  Specifies the size of the buffer used when receiving data from the TCP/IP socket.

  The default value of this parameter is 2MB. The minimum possible value is 16KB; the theoretical maximum is 4GB.

- **TCP_RCV_BUF_SIZE**

  (See Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”, for information about restart types.)
Determines the size of the receive buffer set during TCP transporter initialization. The default is recommended for most common usage cases.

- **TCP_SND_BUF_SIZE**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>unsigned</td>
<td>71540</td>
<td>1 - 2G</td>
</tr>
</tbody>
</table>

Restart Type: N

(See Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”, for information about restart types.)

Determines the size of the send buffer set during TCP transporter initialization. The default is recommended for most common usage cases.

- **TCP_MAXSEG_SIZE**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>unsigned</td>
<td>0</td>
<td>0 - 2G</td>
</tr>
</tbody>
</table>

Restart Type: N

(See Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”, for information about restart types.)

Determines the size of the memory set during TCP transporter initialization. The default is recommended for most common usage cases.

- **TcpBind_INADDR_ANY**

  Setting this parameter to TRUE or 1 binds IP_ADDR_ANY so that connections can be made from anywhere (for autogenerated connections). The default is FALSE (0).

### 18.3.2.9 MySQL Cluster TCP/IP Connections Using Direct Connections

Setting up a cluster using direct connections between data nodes requires specifying explicitly the crossover IP addresses of the data nodes so connected in the [tcp] section of the cluster config.ini file.

In the following example, we envision a cluster with at least four hosts, one each for a management server, an SQL node, and two data nodes. The cluster as a whole resides on the 172.23.72.* subnet of a LAN. In addition to the usual network connections, the two data nodes are connected directly using a standard crossover cable, and communicate with one another directly using IP addresses in the 1.1.0.* address range as shown:

```plaintext
# Management Server
[ndb_mgmd]
Id=1
HostName=172.23.72.20

# SQL Node
[mysqld]
Id=2
HostName=172.23.72.21
```
The `HostName1` and `HostName2` parameters are used only when specifying direct connections.

The use of direct TCP connections between data nodes can improve the cluster’s overall efficiency by enabling the data nodes to bypass an Ethernet device such as a switch, hub, or router, thus cutting down on the cluster’s latency. It is important to note that to take the best advantage of direct connections in this fashion with more than two data nodes, you must have a direct connection between each data node and every other data node in the same node group.

### 18.3.2.10 MySQL Cluster Shared-Memory Connections

MySQL Cluster attempts to use the shared memory transporter and configure it automatically where possible. `[shm]` sections in the `config.ini` file explicitly define shared-memory connections between nodes in the cluster. When explicitly defining shared memory as the connection method, it is necessary to define at least `NodeId1`, `NodeId2`, and `ShmKey`. All other parameters have default values that should work well in most cases.

---

**Important**

*SHM functionality is considered experimental only.* It is not officially supported in any current MySQL Cluster release, and testing results indicate that SHM performance is not appreciably greater than when using TCP/IP for the transporter.

For these reasons, you must determine for yourself or by using our free resources (forums, mailing lists) whether SHM can be made to work correctly in your specific case.

- **NodeId1**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>numeric</td>
<td>[none]</td>
<td>...</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”, for information about restart types.)

- **NodeId2**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>numeric</td>
<td>[none]</td>
<td>...</td>
</tr>
</tbody>
</table>

**Restart Type:** N
To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as **NodeId1** and **NodeId2**.

- **HostName1**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>name or IP address</td>
<td>[none]</td>
<td>...</td>
</tr>
</tbody>
</table>

**Restart Type: N**

(See Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”, for information about restart types.)

**HostName2**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>name or IP address</td>
<td>[none]</td>
<td>...</td>
</tr>
</tbody>
</table>

**Restart Type: N**

(See Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”, for information about restart types.)

The **HostName1** and **HostName2** parameters can be used to specify specific network interfaces to be used for a given SHM connection between two nodes. The values used for these parameters can be hostnames or IP addresses.

- **OverloadLimit**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>bytes</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type: N**

(See Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”, for information about restart types.)

When more than this many unsent bytes are in the send buffer, the connection is considered overloaded.

This parameter can be used to determine the amount of unsent data that must be present in the send buffer before the connection is considered overloaded. See Section 18.3.2.12, “Configuring MySQL Cluster Send Buffer Parameters”, for more information.

In some older releases, the effective value of this parameter was limited by the size of **SendBufferMemory**; in MySQL Cluster NDB 7.2, the actual value for **OverloadLimit** (up to the stated maximum of 4G) is used instead.

- **ShmKey**
### MySQL Cluster Configuration Files

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type: N**

(See [Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”](#), for information about restart types.)

When setting up shared memory segments, a node ID, expressed as an integer, is used to identify uniquely the shared memory segment to use for the communication. There is no default value.

- **ShmSize**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>bytes</td>
<td>1M</td>
<td>64K - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type: N**

(See [Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”](#), for information about restart types.)

Each SHM connection has a shared memory segment where messages between nodes are placed by the sender and read by the reader. The size of this segment is defined by `ShmSize`. The default value is 1MB.

- **SendSignalId**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>boolean</td>
<td>false</td>
<td>true, false</td>
</tr>
</tbody>
</table>

**Restart Type: N**

(See [Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”](#), for information about restart types.)

To retrace the path of a distributed message, it is necessary to provide each message with a unique identifier. Setting this parameter to `Y` causes these message IDs to be transported over the network as well. This feature is disabled by default in production builds, and enabled in `-debug` builds.

- **Checksum**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>boolean</td>
<td>true</td>
<td>true, false</td>
</tr>
</tbody>
</table>

**Restart Type: N**

(See [Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”](#), for information about restart types.)

This parameter is a boolean (`Y/N`) parameter which is disabled by default. When it is enabled, checksums for all messages are calculated before being placed in the send buffer.
This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

- **SigNum**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”, for information about restart types.)

When using the shared memory transporter, a process sends an operating system signal to the other process when there is new data available in the shared memory. Should that signal conflict with an existing signal, this parameter can be used to change it. This is a possibility when using SHM due to the fact that different operating systems use different signal numbers.

The default value of **SigNum** is 0; therefore, it must be set to avoid errors in the cluster log when using the shared memory transporter. Typically, this parameter is set to 10 in the [shm default] section of the config.ini file.

18.3.2.11 SCI Transport Connections in MySQL Cluster

[sci] sections in the config.ini file explicitly define SCI (Scalable Coherent Interface) connections between cluster nodes. Using SCI transporters in MySQL Cluster is supported only when the MySQL binaries are built using --with-ndb-sci=/your/path/to/SCI. The path should point to a directory that contains at a minimum lib and include directories containing SISCI libraries and header files. (See Section 18.3.5, “Using High-Speed Interconnects with MySQL Cluster” for more information about SCI.)

In addition, SCI requires specialized hardware.

It is strongly recommended to use SCI Transporters only for communication between ndbd processes. Note also that using SCI Transporters means that the ndbd processes never sleep. For this reason, SCI Transporters should be used only on machines having at least two CPUs dedicated for use by ndbd processes. There should be at least one CPU per ndbd process, with at least one CPU left in reserve to handle operating system activities.

- **NodeId1**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>numeric</td>
<td>[none]</td>
<td>...</td>
</tr>
</tbody>
</table>

**Restart Type:** N

(See Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”, for information about restart types.)

**NodeId2**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>numeric</td>
<td>[none]</td>
<td>...</td>
</tr>
</tbody>
</table>

**Restart Type:** N
To identify a connection between two nodes it is necessary to provide node identifiers for each of them, as `NodeId1` and `NodeId2`.

- **Host1SciId0**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>0 - 4294967039</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>(0xFFFFFEFF)</td>
</tr>
</tbody>
</table>
  
  **Restart Type: N**

(See Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”, for information about restart types.)

This identifies the SCI node ID on the first Cluster node (identified by `NodeId1`).

- **Host1SciId1**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>unsigned</td>
<td>0</td>
<td>0 - 4294967039</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>(0xFFFFFEFF)</td>
</tr>
</tbody>
</table>
  
  **Restart Type: N**

(See Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”, for information about restart types.)

It is possible to set up SCI Transporters for failover between two SCI cards which then should use separate networks between the nodes. This identifies the node ID and the second SCI card to be used on the first node.

- **Host2SciId0**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>unsigned</td>
<td>[none]</td>
<td>0 - 4294967039</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>(0xFFFFFEFF)</td>
</tr>
</tbody>
</table>
  
  **Restart Type: N**

(See Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”, for information about restart types.)

This identifies the SCI node ID on the second Cluster node (identified by `NodeId2 [239]`).

- **Host2SciId1**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>unsigned</td>
<td>0</td>
<td>0 - 4294967039</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>(0xFFFFFEFF)</td>
</tr>
</tbody>
</table>
  
  **Restart Type: N**
MySQL Cluster Configuration Files

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>(See Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”, for information about restart types.)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

When using two SCI cards to provide failover, this parameter identifies the second SCI card to be used on the second node.

- **HostName1**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>name or IP address</td>
<td>[none]</td>
<td>...</td>
</tr>
</tbody>
</table>

**Restart Type: N**

(See Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”, for information about restart types.)

**HostName2**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>name or IP address</td>
<td>[none]</td>
<td>...</td>
</tr>
</tbody>
</table>

**Restart Type: N**

(See Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”, for information about restart types.)

The **HostName1** and **HostName2** parameters can be used to specify specific network interfaces to be used for a given SCI connection between two nodes. The values used for these parameters can be hostnames or IP addresses.

- **SharedBufferSize**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>unsigned</td>
<td>10M</td>
<td>64K - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

**Restart Type: N**

(See Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”, for information about restart types.)

Each SCI transporter has a shared memory segment used for communication between the two nodes. Setting the size of this segment to the default value of 1MB should be sufficient for most applications. Using a smaller value can lead to problems when performing many parallel inserts; if the shared buffer is too small, this can also result in a crash of the **ndbd** process.

- **SendLimit**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>unsigned</td>
<td>8K</td>
<td>128 - 32K</td>
</tr>
</tbody>
</table>

**Restart Type: N**

(See Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”, for information about restart types.)
A small buffer in front of the SCI media stores messages before transmitting them over the SCI network. By default, this is set to 8KB. Our benchmarks show that performance is best at 64KB but 16KB reaches within a few percent of this, and there was little if any advantage to increasing it beyond 8KB.

- **SendSignalId**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>boolean</td>
<td>true</td>
<td>true, false</td>
</tr>
</tbody>
</table>

  **Restart Type: N**

  (See Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”, for information about restart types.)

  To trace a distributed message it is necessary to identify each message uniquely. When this parameter is set to Y, message IDs are transported over the network. This feature is disabled by default in production builds, and enabled in -debug builds.

- **Checksum**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>boolean</td>
<td>false</td>
<td>true, false</td>
</tr>
</tbody>
</table>

  **Restart Type: N**

  (See Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”, for information about restart types.)

  This parameter is a boolean value, and is disabled by default. When Checksum is enabled, checksums are calculated for all messages before they are placed in the send buffer. This feature prevents messages from being corrupted while waiting in the send buffer. It also serves as a check against data being corrupted during transport.

- **OverloadLimit**

<table>
<thead>
<tr>
<th>Effective Version</th>
<th>Type/Units</th>
<th>Default</th>
<th>Range/Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NDB 7.2.0</td>
<td>bytes</td>
<td>0</td>
<td>0 - 4294967039 (0xFFFFFEFF)</td>
</tr>
</tbody>
</table>

  **Restart Type: N**

  (See Section 18.3.3.4, “Other MySQL Cluster Configuration Parameters”, for information about restart types.)

  When more than this many unsent bytes are in the send buffer, the connection is considered overloaded. See Section 18.3.2.12, “Configuring MySQL Cluster Send Buffer Parameters”, for more information.

### 18.3.2.12 Configuring MySQL Cluster Send Buffer Parameters

Formerly, the NDB kernel employed a send buffer whose size was fixed at 2MB for each node in the cluster, this buffer being allocated when the node started. Because the size of this buffer could not
Overview of MySQL Cluster Configuration Parameters

be changed after the cluster was started, it was necessary to make it large enough in advance to accommodate the maximum possible load on any transporter socket. However, this was an inefficient use of memory, since much of it often went unused, and could result in large amounts of resources being wasted when scaling up to many API nodes.

This problem was eventually solved (in MySQL Cluster NDB 7.0) by employing a unified send buffer whose memory is allocated dynamically from a pool shared by all transporters. This means that the size of the send buffer can be adjusted as necessary. Configuration of the unified send buffer can accomplished by setting the following parameters:

- **TotalSendBufferMemory.** This parameter can be set for all types of MySQL Cluster nodes—that is, it can be set in the [ndbd], [mgm], and [api] (or [mysql]) sections of the config.ini file. It represents the total amount of memory (in bytes) to be allocated by each node for which it is set for use among all configured transporters. If set, its minimum is 256KB; the maximum is 4294967039.

To be backward-compatible with existing configurations, this parameter takes as its default value the sum of the maximum send buffer sizes of all configured transporters, plus an additional 32KB (one page) per transporter. The maximum depends on the type of transporter, as shown in the following table:

<table>
<thead>
<tr>
<th>Transporter</th>
<th>Maximum Send Buffer Size (bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>SendBufferMemory (default = 2M)</td>
</tr>
<tr>
<td>SCI</td>
<td>SendLimit (default = 8K) plus 16K</td>
</tr>
<tr>
<td>SHM</td>
<td>20K</td>
</tr>
</tbody>
</table>

This enables existing configurations to function in close to the same way as they did with MySQL Cluster NDB 6.3 and earlier, with the same amount of memory and send buffer space available to each transporter. However, memory that is unused by one transporter is not available to other transporters.

- **OverloadLimit.** This parameter is used in the config.ini file [tcp] section, and denotes the amount of unsent data (in bytes) that must be present in the send buffer before the connection is considered overloaded. When such an overload condition occurs, transactions that affect the overloaded connection fail with NDB API Error 1218 (Send Buffers overloaded in NDB kernel) until the overload status passes. The default value is 0, in which case the effective overload limit is calculated as SendBufferMemory * 0.8 for a given connection. The maximum value for this parameter is 4G.

- **SendBufferMemory.** This value denotes a hard limit for the amount of memory that may be used by a single transporter out of the entire pool specified by TotalSendBufferMemory. However, the sum of SendBufferMemory for all configured transporters may be greater than the TotalSendBufferMemory that is set for a given node. This is a way to save memory when many nodes are in use, as long as the maximum amount of memory is never required by all transporters at the same time.

18.3.3 Overview of MySQL Cluster Configuration Parameters

The next four sections provide summary tables of MySQL Cluster configuration parameters used in the config.ini file to govern the cluster's functioning. Each table lists the parameters for one of the Cluster node process types (ndbd, ndb_mgmd, and mysqld), and includes the parameter's type as well as its default, minimum, and maximum values as applicable.

These tables also indicate what type of restart is required (node restart or system restart)—and whether the restart must be done with --initial—to change the value of a given configuration parameter.

When performing a node restart or an initial node restart, all of the cluster's data nodes must be restarted in turn (also referred to as a rolling restart). It is possible to update cluster configuration parameters marked
Overview of MySQL Cluster Configuration Parameters

as node online—that is, without shutting down the cluster—in this fashion. An initial node restart requires restarting each ndbd process with the --initial option.

A system restart requires a complete shutdown and restart of the entire cluster. An initial system restart requires taking a backup of the cluster, wiping the cluster file system after shutdown, and then restoring from the backup following the restart.

In any cluster restart, all of the cluster’s management servers must be restarted for them to read the updated configuration parameter values.

**Important**

Values for numeric cluster parameters can generally be increased without any problems, although it is advisable to do so progressively, making such adjustments in relatively small increments. Many of these can be increased online, using a rolling restart.

However, decreasing the values of such parameters—whether this is done using a node restart, node initial restart, or even a complete system restart of the cluster—is not to be undertaken lightly; it is recommended that you do so only after careful planning and testing. This is especially true with regard to those parameters that relate to memory usage and disk space, such as MaxNoOfTables, MaxNoOfOrderedIndexes, and MaxNoOfUniqueHashIndexes. In addition, it is the generally the case that configuration parameters relating to memory and disk usage can be raised using a simple node restart, but they require an initial node restart to be lowered.

Because some of these parameters can be used for configuring more than one type of cluster node, they may appear in more than one of the tables.

**Note**

4294967039 often appears as a maximum value in these tables. This value is defined in the NDBCLUSTER sources as MAX_INT_RNIL and is equal to 0xFFFFFEFF, or $2^{32} - 2^8 - 1$.

### 18.3.3.1 MySQL Cluster Data Node Configuration Parameters

The summary table in this section provides information about parameters used in the [ndbd] or [ndbd default] sections of a config.ini file for configuring MySQL Cluster data nodes. For detailed descriptions and other additional information about each of these parameters, see Section 18.3.2.6, “Defining MySQL Cluster Data Nodes”.

These parameters also apply to ndbmtd, the multi-threaded version of ndbd. For more information, see Section 18.4.3, “ndbmtd — The MySQL Cluster Data Node Daemon (Multi-Threaded)”.

**Restart types.** Changes in MySQL Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary table as follows:

- **N**—Node restart: The parameter can be updated using a rolling restart (see Section 18.5.5, “Performing a Rolling Restart of a MySQL Cluster”).
- **S**—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.
- **I**—Initial restart: Data nodes must be restarted using the --initial option.
For more information about restart types, see Section 18.3.3, “Overview of MySQL Cluster Configuration Parameters”.

MySQL Cluster NDB 7.2 supports the addition of new data node groups online, to a running cluster. For more information, see Section 18.5.13, “Adding MySQL Cluster Data Nodes Online”.

#### 18.3.3.2 MySQL Cluster Management Node Configuration Parameters

The summary table in this section provides information about parameters used in the `[ndb_mgmd]` or `[mgm]` sections of a `config.ini` file for configuring MySQL Cluster management nodes. For detailed descriptions and other additional information about each of these parameters, see Section 18.3.2.5, “Defining a MySQL Cluster Management Server”.

**Restart types.** Changes in MySQL Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary table as follows:

- **N**—Node restart: The parameter can be updated using a rolling restart (see Section 18.5.5, “Performing a Rolling Restart of a MySQL Cluster”).
- **S**—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.
- **I**—Initial restart: Data nodes must be restarted using the `--initial` option.

For more information about restart types, see Section 18.3.3, “Overview of MySQL Cluster Configuration Parameters”.

**Note**

After making changes in a management node’s configuration, it is necessary to perform a rolling restart of the cluster for the new configuration to take effect. See Section 18.3.2.5, “Defining a MySQL Cluster Management Server”, for more information.

To add new management servers to a running MySQL Cluster, it is also necessary perform a rolling restart of all cluster nodes after modifying any existing `config.ini` files. For more information about issues arising when using multiple management nodes, see Section 18.1.6.10, “Limitations Relating to Multiple MySQL Cluster Nodes”.

#### 18.3.3.3 MySQL Cluster SQL Node and API Node Configuration Parameters

The summary table in this section provides information about parameters used in the `[mysqld]` and `[api]` sections of a `config.ini` file for configuring MySQL Cluster SQL nodes and API nodes. For detailed descriptions and other additional information about each of these parameters, see Section 18.3.2.7, “Defining SQL and Other API Nodes in a MySQL Cluster”.

**Note**

For a discussion of MySQL server options for MySQL Cluster, see Section 18.3.4.2, “MySQL Server Options for MySQL Cluster”; for information about MySQL server system variables relating to MySQL Cluster, see Section 18.3.4.3, “MySQL Cluster System Variables”.

---

2261
Restart types. Changes in MySQL Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary table as follows:

- **N**—Node restart: The parameter can be updated using a rolling restart (see Section 18.5.5, “Performing a Rolling Restart of a MySQL Cluster”).

- **S**—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.

- **I**—Initial restart: Data nodes must be restarted using the `--initial` option.

For more information about restart types, see Section 18.3.3, “Overview of MySQL Cluster Configuration Parameters”.

**Note**

To add new SQL or API nodes to the configuration of a running MySQL Cluster, it is necessary to perform a rolling restart of all cluster nodes after adding new [mysqld] or [api] sections to the config.ini file (or files, if you are using more than one management server). This must be done before the new SQL or API nodes can connect to the cluster.

It is not necessary to perform any restart of the cluster if new SQL or API nodes can employ previously unused API slots in the cluster configuration to connect to the cluster.

### 18.3.3.4 Other MySQL Cluster Configuration Parameters

The summary tables in this section provide information about parameters used in the [computer], [tcp], [shm], and [sci] sections of a config.ini file for configuring MySQL Cluster management nodes. For detailed descriptions and other additional information about individual parameters, see Section 18.3.2.8, “MySQL Cluster TCP/IP Connections”, Section 18.3.2.10, “MySQL Cluster Shared-Memory Connections”, or Section 18.3.2.11, “SCI Transport Connections in MySQL Cluster”, as appropriate.

**Restart types.** Changes in MySQL Cluster configuration parameters do not take effect until the cluster is restarted. The type of restart required to change a given parameter is indicated in the summary tables as follows:

- **N**—Node restart: The parameter can be updated using a rolling restart (see Section 18.5.5, “Performing a Rolling Restart of a MySQL Cluster”).

- **S**—System restart: The cluster must be shut down completely, then restarted, to effect a change in this parameter.

- **I**—Initial restart: Data nodes must be restarted using the --initial option.

For more information about restart types, see Section 18.3.3, “Overview of MySQL Cluster Configuration Parameters”.
